Use the Cauchy-modulus handoff and tail-stability routes of Definition 2074.3 and Definition 2074.4. They force a criterion request through $\mathsf{CauchyModulus}^{\uparrow}$, the displayed $\mathsf{StreamName}^{\uparrow}$ window, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback before the Real seal is available.

The dyadic tolerance and Real-seal rows then remain visible by Definition 2074.5. The Bishop completion criterion receives exactly that finite route plus the local transport, replay, provenance, and naming rows, with no hidden selected limit or ambient completion principle. □

Theorem 2074.20 (Real modulus RegularCauchyUniqueness forward route)**.** *Every* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *consumer that compares two Real representatives through a* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *packet first reads the displayed dyadic tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. The comparison route is*

$$\mathsf{RealModulusOfConvergence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RegularCauchyU}$$

Thus the uniqueness consumer of chapter 3390 may compare representatives only after the finite modulus lattice has exposed its tolerance, window, readback, and seal data.

Proof. Read the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ carrier as the finite packet whose tolerance, window, readback, monotone ledger, and Real seal rows are already displayed in the local NameCert construction. These rows determine which tail comparison is available to a downstream consumer before any representative comparison is formed.

The $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ consumer then uses the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, the same $\mathsf{StreamName}^{\uparrow}$ finite window, and the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff route before it reaches the $\mathsf{Real}^{\uparrow}$ seal. Therefore the uniqueness comparison is not a direct quotient assertion on Real representatives; it is a routed read through the modulus packet and its finite sibling rows. □

Any $\mathsf{RealModulusOfConvergence}^{\uparrow}$ completion consumer that compares nonzero tail distances must read the positive-distance and zero-refusal route of chapter 3505 before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. The route first displays the $\mathsf{MetricApartness}^{\uparrow}$ metric source, positive-distance witness, zero-distance refusal, separated classifier comparison, completion-facing transport, componentwise hsame data, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row; only then may the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ packet use its dyadic tolerance, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, monotone modulus ledger, and Real seal. Thus nonzero tail comparison is routed through a substantive metric-apartness sibling rather than through host inequality, quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Chapter 2075

A Concrete Naming Certificate for $\mathsf{SignedDigitCauchyModulus}^{\uparrow}$

Following Avizienis signed-digit arithmetic and Bishop–Bridges constructive analysis, the SignedDigitCauchyModulu packet names the finite route from signed-digit observation windows to explicit regular Cauchy modulus data. It sits over the signed-digit window surface of chapter 316, the real-facing signed-digit seal of chapter 363, the dyadic endpoint rows of chapter 291, the scheduled finite observations of chapter 126, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the explicit threshold surface of chapter 292. The packet records a displayed modulus for the signed-digit route; it is not a quotient of streams, a selected representative, or an ambient completeness principle.

Definition 2075.1 (SignedDigitCauchyModulus carrier)**.** *A* $\mathsf{SignedDigitCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, E, T, R, L, H, C, P, N)$$

with the following visible coordinates:

1. *S is an accepted* $\mathsf{SignedDigitStream}^{\uparrow}$ *row, carrying signed-digit finite windows, carry ledgers, and normalized prefix data;*
2. *W is the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule of finite signed-digit windows requested by downstream consumers;*
3. *E assigns to every scheduled window a normalized* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row and dyadic radius ledger;*
4. *T is a monotone threshold modulus row: for each requested precision it displays a finite index after which all scheduled endpoint reads satisfy the stated dyadic tolerance;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the endpoint rows E and the threshold row T;*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached from the same regular Cauchy readback;*
7. *H records componentwise* hsame *transport for signed-digit windows, endpoint normalization, threshold rows, regular readback rows, and real-seal rows;*
8. *C records the* Cont *replay routes from window requests to normalized endpoints, from endpoints to the threshold check, from the threshold check to R, and from R to L;*
9. *P is the* Pkg *provenance naming* $\mathsf{SignedDigitStream}^{\uparrow}$, $\mathsf{SignedDigitReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyModulus}^{\uparrow}$ *as dependency anchors;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDigitCauchyModulus}^{\uparrow}}$ *provenance row.*

The carrier predicate accepts exactly those packets whose signed-digit windows normalize to the displayed dyadic endpoints, whose threshold row is monotone in the requested precision, and whose regular readback and real seal consume that same threshold row through the recorded hsame, Cont, Pkg, *and local* NameCert *data.*

Lean4 ✓ `BEDC.Derived.SignedDigitCauchyModulusUp.SignedDigitCauchyModulusTasteGate single carrier alignment`

Theorem 2075.2 (SignedDigitCauchyModulus NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{SignedDigitCauchyModulus}^{\uparrow}}$ *seed surface consists of five finite obligations:*

1. *carrier admission: the packet is the finite tuple of Definition 2075.1;*
2. *window normalization: every displayed signed-digit window in W decodes to its named* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row in E;*
3. *threshold monotonicity: the modulus row T is monotone in precision and is read from the same finite window schedule;*
4. *regular readback exactness: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R consumes exactly the endpoint rows E and threshold row T;*
5. *seal and provenance policy: the* $\mathsf{Real}^{\uparrow}$ *seal row L and the rows H, C, P, N transport only the displayed signed-digit, dyadic, threshold, regular readback, and seal data.*

Lean4 ✓ `BEDC.Derived.SignedDigitCauchyModulusUp.SignedDigitCauchyModulusNameCertObligations`

Proof. Project the carrier tuple of Definition 2075.1. Its coordinates already separate the signed-digit source, finite window schedule, dyadic endpoint normalization, threshold modulus, regular readback, real seal, transport, replay, provenance, and local certificate rows.

The window-normalization obligation is the signed-digit finite-window route: S and W determine the finite prefixes, and E records the normalized dyadic endpoints for those prefixes. The threshold obligation is read from T, whose entries are indexed by requested precisions and transported through the same schedule.

The regular readback obligation uses only E and T. The row R therefore cannot read an endpoint outside the displayed signed-digit windows or a modulus outside the displayed threshold ledger.

Finally L, H, C, P, N provide the public seal, componentwise transport, replay, dependency package, and local naming rows. Since these rows are listed as coordinates of the same finite packet, the five obligations exhaust the seed surface. □

Theorem 2075.3 (SignedDigitCauchyModulus regular readback)**.** *Every accepted* $\mathsf{SignedDigitCauchyModulus}^{\uparrow}$ *packet exposes a regular Cauchy readback through its explicit modulus. For each requested precision, the threshold row T supplies a finite bound after which all scheduled signed-digit windows normalize to dyadic endpoint rows in E whose pairwise tolerance is accepted by the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R; the* $\mathsf{Real}^{\uparrow}$ *seal row L can read the packet only through this regular readback route.*

Proof. Fix an accepted packet $M = (S, W, E, T, R, L, H, C, P, N)$ and a displayed precision request. The row T gives the corresponding finite threshold, and monotonicity keeps later precision requests on the same or later finite window surface.

Read any two scheduled windows past that threshold through W. The signed-digit row S and the endpoint ledger E normalize both finite prefixes to displayed $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows.

The regular readback row R consumes exactly those endpoint rows together with the threshold row T. Thus the late-pair tolerance required by the regular Cauchy readback is witnessed inside the finite packet.

The real seal row L is downstream of R in the recorded Cont replay. Componentwise hsame transport can move the displayed rows, but it cannot introduce a second modulus, an unobserved endpoint, or a host real limit. Therefore the public readback is the explicit-modulus regular Cauchy readback named by T and R. □

Theorem 2075.4 (SignedDigitCauchyModulus prefix induction)**.** *Let $M = (S, W, E, T, R, L, H, C, P, N)$ be an accepted* SignedDigitCauchyModulus$^{\uparrow}$ *carrier. Each accepted signed-digit prefix normalizes by finite induction on the displayed prefix and carry ledger before it can contribute to the monotone threshold row T and the* RegSeqRat$^{\uparrow}$ *readback row R: the base case reads the empty prefix, the successor case appends one signed digit and normalizes the carried endpoint, and the handoff proceeds through* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *without introducing quotient streams, selected representatives, countable choice, or ambient completeness.*

Proof. Use the carrier rows of Definition 2075.1. The rows S, W, E provide the finite prefix schedule and endpoint normalization ledger, while T, R, L, H, C, P, N record threshold replay, regular readback, Real sealing, transport, replay, provenance, and local naming.

In the base case, the empty prefix is read from the scheduled window row W. Its endpoint row in E is the displayed DyadicRatCore$^{\uparrow}$ normalization for that empty window, so the threshold row T receives a finite starting datum.

In the successor case, extend the visible prefix by one signed digit. The signed-digit row S supplies the digit and carry ledger, and E normalizes the carried endpoint to the next displayed dyadic row. Componentwise hsame transport and Cont replay preserve the same prefix ledger rather than choosing a representative of an infinite stream.

After the prefix ledger has been normalized, Definition 2075.3 hands the row to T and R. The terminal seal L can then be read only through the resulting RegSeqRat$^{\uparrow}$ route and the Real$^{\uparrow}$ boundary. Thus every accepted prefix contribution is produced by the displayed finite induction. □

Theorem 2075.5 (SignedDigitCauchyModulus non-escape)**.** *An accepted* SignedDigitCauchyModulus$^{\uparrow}$ *packet gives no countable choice, quotient stream equality, ambient* Real$^{\uparrow}$ *completeness, or general compactness principle. Its consumers can read only the displayed signed-digit windows, normalized dyadic endpoints, monotone threshold row, regular Cauchy readback, real seal boundary, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Inspect the carrier coordinates. The only source rows are finite signed-digit windows, scheduled observations, normalized endpoints, one monotone threshold ledger, one regular readback row, one real-seal row, and the structural transport and provenance rows.

Countable choice would require a family of independent selections outside the finite ledger; no such coordinate appears. Quotient stream equality would require an equality object for infinite signed-digit tails; the classifier surface reads only finite windows and normalized endpoint rows.

Ambient Real$^{\uparrow}$ completeness and general compactness would require a completed object or covering principle not present in L, H, C, P, N. The seal row L is merely the terminal consumer of the explicit regular readback and does not export a completion theorem.

Every consumer route therefore factors through the rows listed in Definition 2075.1 and through the readback theorem Definition 2075.3. The excluded principles have no source coordinate from which they could be projected or transported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDigitCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{SignedDigitCauchyModulus}^{\uparrow}$ packet is generated from signed-digit finite windows, normalized $\mathsf{DyadicRatCore}^{\uparrow}$ endpoints, a monotone threshold modulus, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDigitCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2075.1, Definition 2075.2, Definition 2075.3, and Definition 2075.5 seed the finite signed-digit route from normalized windows to explicit regular Cauchy modulus data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDigitCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, countable choice, quotient equality of streams, ambient $\mathsf{Real}^{\uparrow}$ completeness, general compactness, selected representatives, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed-digit normalization, monotone threshold replay, regular readback exactness, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.SignedDigitCauchyModulusUp.

Chapter 2076

A Concrete Naming Certificate for $\mathsf{RegularCauchyProductProjection}^{\uparrow}$

Following Bishop and Bridges on finite products of constructive Cauchy real names, the RegularCauchyProductProjec packet records the left and right projection readbacks out of a displayed regular Cauchy product packet. It sits after the finite product carrier of chapter 2009, the product-modulus ledger of **??**, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real algebra and completion consumers a named component-readback route without importing host product equality, quotient stream representatives, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2076.1 (Regular Cauchy product projection carrier)**.** *A* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (K, L, R, M, W, D, A, B, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *product packet whose component coordinates are being projected.*
2. *L and R are the left and right projection readback rows, each naming the component slot, the source regular Cauchy row, and the projected finite observation route.*
3. *M is the* $\mathsf{CauchyProductModulus}^{\uparrow}$ *ledger that assigns every projection request to the product-facing modulus budget before either component readback is consumed.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the product packet, the left component, the right component, and the product-modulus request.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the product window and the two projected component windows.*
6. *A is the left* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from K, M, W, D, L.*
7. *B is the right* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from K, M, W, D, R.*
8. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the projected regular rational readbacks A and B have been displayed.*

9. *H stores componentwise* hsame *transport for the product packet, projection readbacks, product-modulus ledger, stream windows, dyadic tolerances, regular rational handoffs, seal, replay, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay from a projection request through the product packet, product-modulus ledger, finite windows, dyadic rows, component readbacks, regular rational handoffs, and seal.*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$, $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$, $\mathsf{CauchyProductModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, L, R, M, W, D, A, B, S, H, C, P, N$. It has no coordinate for host product equality, quotient stream representatives, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Theorem 2076.2 (Regular Cauchy product projection budget)**.** *Let*

$$J = (K, L, R, M, W, D, A, B, S, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *carrier. Every left or right projection request from J factors through the displayed product-modulus budget M, the finite window family W, the dyadic tolerance ledger D, the selected component readback L or R, and the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff A or B before the* $\mathsf{Real}^{\uparrow}$ *seal S is available.*

Proof. Start with the carrier of Definition 2076.1. A projection request first identifies the product packet K and one of the two projection readback rows L or R.

The request then passes through the product-modulus ledger M. This row is the only place where the product-facing precision request is assigned to component budgets, so neither component handoff can be read before M is displayed.

Next the finite window family W and the dyadic tolerance ledger D supply the actual component observations and tolerance rows. The left handoff A consumes the left readback row L, while the right handoff B consumes the right readback row R.

The seal S appears only after those regular rational handoffs. Therefore every projected read follows the route through M, W, D, the selected component readback, and its $\mathsf{RegSeqRat}^{\uparrow}$ handoff before any $\mathsf{Real}^{\uparrow}$ seal can be consumed. □

Theorem 2076.3 (Regular Cauchy product projection NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *carrier*

$$J = (K, L, R, M, W, D, A, B, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyProductProjection}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the product packet, left and right projection readbacks, product-modulus ledger, stream windows, dyadic tolerance rows, regular rational handoffs, Real seal, transport, replay, provenance, and local name;*

2. *projection-budget exactness, requiring every projected precision request to pass through M, W, D before A or B is available;*

3. *left/right readback ordering, requiring L to feed only the left handoff A and R to feed only the right handoff B;*

4. *Real-seal nonescape, requiring S to expose only the displayed projected readback route and no host product equality, quotient stream representative, selected limit, or ambient completeness claim;*

5. *transport, replay, provenance, and local naming stability through H, C, P, N for the same product packet, projection rows, modulus ledger, windows, dyadic tolerances, handoffs, and seal.*

No projection NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyProductProjectionUp.RegularCauchyProductProjectionTasteGate single carrier alignment`

Proof. Carrier admission is the tuple displayed in Definition 2076.1. It lists the product packet, the two projection readbacks, the product-modulus ledger, finite windows, dyadic tolerance rows, handoffs, seal, and structural rows.

Projection-budget exactness is Definition 2076.2. Its factorization route shows that M, W, D stand before the projected handoffs A and B.

The left/right ordering follows by projecting the two readback coordinates. The carrier gives L as the left readback consumed by A and R as the right readback consumed by B, with no third row that can swap or duplicate the roles.

The Real-seal boundary is the projection to S. Since S is downstream of the two regular rational handoffs and no excluded object is a coordinate of the carrier, the nonescape clause follows by inspection.

Finally, H, C, P, N transport, replay, source, and name the same displayed rows. Thus stability is componentwise over the packet already admitted, and the listed five rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ component-facing read factors through a RegularCauchyFiniteProduct packet, left or right projection readback, CauchyProductModulus ledger, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regular-cauchy-finite-product, cauchy-product-modulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a product packet, two ordered projection readbacks, product-modulus budget accounting, synchronized finite windows, dyadic tolerance rows, component handoffs, RealUp sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyProductProjection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2076.1, Definition 2076.2, and Definition 2076.3 seed the finite projection route from displayed regular Cauchy products through product-modulus budgets, component readbacks, RegSeqRat handoffs, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductProjection}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyProductProjectionUp`

Bridge status: none

Not claimed: This chapter does not close host product equality, quotient stream representatives, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection-budget exactness, left/right readback ordering, Real-seal nonescape, and transport/replay/provenance stability for BEDC.Derived.RegularCauchyProductProjectionUp.

Constructive story: A $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ packet is generated from a RegularCauchyFiniteProduct packet, left and right projection readbacks, a CauchyProductModulus ledger, StreamName windows, DyadicRatCore

tolerance rows, RegSeqRat component handoffs, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2077

A Concrete Naming Certificate for $\mathsf{FastConvergentRealSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Weihrauch-style computable analysis, the $\mathsf{FastConvergentRealSequence}^{\uparrow}$ packet records a real sequence whose convergence is carried by an explicit displayed rate. It sits on the open Real and Completion route after the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the explicit rate surface of chapter 1965, and the terminal real-name seal of chapter 38. It is distinct from the sibling $\mathsf{FastConvergentSeries}^{\uparrow}$ certificate of chapter 367: this chapter names a rate-bearing sequence route, not a partial-sum and tail-sum route.

Definition 2077.1 (Fast convergent real sequence carrier)**.** *A* $\mathsf{FastConvergentRealSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the stream schedule. It records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which requested sequence positions and precision rows are observed.*
2. *R is the regular rational readback. It stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *observations attached to the scheduled windows and records the regularity checks available to downstream real-name consumers.*
3. *D is the dyadic tolerance ledger. It lists the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, comparison cells, denominator budgets, and refinement rows used by the regular readback.*
4. *M is the explicit convergence-rate row. It gives the finite modulus or rate schedule by which each tolerance request is assigned a displayed tail window.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is exposed only after S, R, D, and M have been displayed and replayed.*
6. *H stores componentwise* hsame *transport for the stream schedule, regular rational readback, dyadic tolerance ledger, rate row, real seal, continuation replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a finite precision request through S, R, D, M, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FastConvergentRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealConvergenceRate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{FastConvergentRealSequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the rows $S, R, D, M, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, a selected limit, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.FastConvergentRealSequenceUp.FastConvergentRealSequenceTasteGate single carrier alignment`

Theorem 2077.2 (Fast real sequence rate exposure)**.** *For every accepted* $\mathsf{FastConvergentRealSequence}^{\uparrow}$ *carrier*

$$F = (S, R, D, M, E, H, C, P, N),$$

each precision request reaches the explicit convergence-rate row M before it may read a tail window, dyadic tolerance comparison, regular rational readback, or terminal $\mathsf{Real}^{\uparrow}$ *seal. Thus the rate-bearing sequence surface exposes a displayed modulus route rather than a host convergence predicate.*

Proof. Project the carrier in Definition 2077.1. The row M is a named coordinate of the accepted packet, while S, R, and D are the scheduled observation, regular readback, and tolerance rows to which the rate is applied.

Replay the finite request route stored in C. A precision request first selects the displayed rate threshold in M, then opens the corresponding finite StreamName window in S and the dyadic tolerance cells in D.

Only after those rows have been displayed can the regular rational row R be read as a tail-controlled observation surface. Since the rate is a coordinate of the packet and the route uses only S, R, D, M, H, C, P, N, no host convergence predicate is introduced. □

Theorem 2077.3 (Fast real sequence Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FastConvergentRealSequence}^{\uparrow}$ *packet factors through the displayed route*

$$S, M, D, R, H, C, P, N \longmapsto E.$$

The terminal seal E is therefore downstream of the stream schedule, explicit rate, dyadic tolerance ledger, regular rational readback, transport, replay, provenance, and local NameCert rows.

Proof. Start with an accepted packet $F = (S, R, D, M, E, H, C, P, N)$. The seal row E appears in the carrier only as the terminal handoff coordinate, not as an independent real endpoint.

Use Definition 2077.2. Every precision request reads M before it opens the finite tail window and tolerance ledger. The rows S and D therefore determine the observations and comparisons that the regular rational row R may expose.

The handoff to E is then a projection of the displayed carrier route. Componentwise transport in H, replay in C, provenance in P, and local naming in N bind the same rows to the terminal Real seal. No separate limit selector or ambient completeness coordinate is available. □

Theorem 2077.4 (Fast real sequence non-escape)**.** *An accepted* $\mathsf{FastConvergentRealSequence}^{\uparrow}$ *packet exports only its displayed stream schedule, regular rational readback, dyadic tolerance ledger, convergence-rate row, Real seal handoff, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. It exports no quotient stream equality, selected limit, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Read the carrier definition. Its complete coordinate list is $S, R, D, M, E, H, C, P, N$, and every classifier comparison is restricted to those rows.

The rate exposure theorem identifies the only convergence control available to a consumer: the displayed row M together with the scheduled windows and tolerance ledger. The Real seal handoff theorem identifies the only terminal real-facing route: the composite through S, M, D, R, H, C, P, N into E.

The excluded objects are not coordinates of the packet and are not produced by the finite replay route. Therefore no consumer of the accepted packet can extract quotient stream equality, a selected limit, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking from this NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FastConvergentRealSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{FastConvergentRealSequence}^{\uparrow}$ packet is generated from a finite StreamName schedule, RegSeqRat readback rows, a DyadicRatCore tolerance ledger, an explicit RealConvergenceRate row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastConvergentRealSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2077.1, Definition 2077.2, Definition 2077.3, and Definition 2077.4 seed the rate-bearing real-sequence route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastConvergentRealSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, rate-to-tail routing, dyadic tolerance accounting, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.FastConvergentRealSequenceUp.

Chapter 2078

A Concrete Naming Certificate for $\mathsf{PeanoCurve}^{\uparrow}$

Following Peano's space-filling construction, Hilbert-style dyadic subdivision curves, and Bishop–Bridges constructive real analysis, the $\mathsf{PeanoCurve}^{\uparrow}$ packet records a continuous map from the unit interval onto the unit square as finite dyadic observation data. It reads the terminal real-name seal of chapter 38, the regular rational readback route of chapter 301, the finite stream-window interface of chapter 126, the dyadic endpoint ledger of chapter 291, the graph carrier of chapter 130, and the compact witness surface of chapter 129. The packet names the finite grid readback by which a dyadic input address determines compatible dyadic square addresses; it is not a host-level function space, an uncountable choice principle, a quotient real equality, or an open-cover compactness theorem.

Definition 2078.1 (PeanoCurve finite dyadic subdivision carrier)**.** *A* $\mathsf{PeanoCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, G, S, X, Y, E, R, H, C, Q, N)$$

with the following displayed rows:

1. *I is the interval-address row. It records a finite dyadic interval address, its precision level, and the corresponding* $\mathsf{StreamName}^{\uparrow}$ *observation window before any planar readback is exposed.*
2. *G is the grid-subdivision row. For each displayed interval address in I, it records the finite dyadic square cell selected by the Peano subdivision rule, including the horizontal and vertical dyadic endpoints.*
3. *S is the sibling-continuity row. Adjacent dyadic interval cells are required to map to edge-adjacent or coincident dyadic square cells at the same precision, so the graph can be read through the* $\mathsf{ContinuousMap}^{\uparrow}$ *surface.*
4. *X and Y are the two coordinate readback rows. They turn the horizontal and vertical dyadic endpoints of G into* $\mathsf{RegSeqRat}^{\uparrow}$ *and then* $\mathsf{Real}^{\uparrow}$ *coordinate seals.*
5. *E is the error-budget row. A request for square precision 2^{-n} is answered by an interval precision and a dyadic diameter bound supplied through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
6. *R is the finite surjection readback row. Every displayed dyadic square cell at precision n is paired with at least one interval address whose grid-subdivision row lands inside that cell.*

7. *H records componentwise* hsame *transport for interval addresses, grid cells, sibling-continuity witnesses, coordinate readbacks, error budgets, surjection readbacks, replay data, provenance, and local naming.*

8. *C records displayed* Cont *replay through*

$$I, G, S \longmapsto X, Y, E, R \longmapsto H, Q, N.$$

9. *Q is the* Pkg *provenance over* $\mathsf{PeanoCurve}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PeanoCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, S, X, Y, E, R, H, C, Q, N$. It has no coordinate for a completed function space, arbitrary pointwise choice, quotient equality of real names, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.PeanoCurveUp.PeanoCurveTasteGate single carrier alignment`

Theorem 2078.2 (PeanoCurve NameCert obligations)**.** *For an accepted* $\mathsf{PeanoCurve}^{\uparrow}$ *carrier*

$$P = (I, G, S, X, Y, E, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PeanoCurve}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the interval-address, grid-subdivision, sibling-continuity, coordinate readback, error-budget, finite surjection, transport, replay, provenance, and local naming rows;*

2. *dyadic subdivision exactness, requiring every planar cell read to open I and then G before a coordinate seal is exposed;*

3. *continuity budget exactness, requiring adjacent interval addresses and square-cell diameters to be checked by S and E before the carrier is consumed through* $\mathsf{ContinuousMap}^{\uparrow}$*;*

4. *finite-grid surjection exactness, requiring every displayed dyadic square cell to be met by the readback row R at the requested precision;*

5. *structural exhaustion, requiring H, C, Q, N to transport, replay, source, and name only the listed finite dyadic route.*

No NameCert obligation is stored outside those five rows, and none exports a host-level function space, arbitrary pointwise choice, quotient equality of real names, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a bridge credential.*

Proof. Carrier admission is projection from Definition 2078.1. The accepted packet displays the interval-address row, grid-subdivision row, sibling-continuity row, coordinate readback rows, error-budget row, finite surjection row, and structural rows.

Dyadic subdivision exactness is read from I and G. A consumer cannot inspect planar coordinates until a finite interval address and its selected dyadic square cell have both been displayed.

Continuity budget exactness is read from S and E. The sibling row checks that adjacent interval cells have compatible square cells, while the error-budget row supplies the dyadic diameter bound requested by the continuous-map consumer.

Finite-grid surjection exactness is read from R. For each displayed square cell at the requested precision, the row supplies an interval address whose grid-subdivision cell lands in that square cell.

Finally H, C, Q, N add no analytic coordinate. They preserve, replay, source, and name the same finite route, so the excluded function-space, choice, quotient, compactness, completeness, verification, and bridge data have no row from which a consumer could read them. □

Theorem 2078.3 (PeanoCurve finite-grid continuous surjection surface)**.** *Let*

$$P = (I, G, S, X, Y, E, R, H, C, Q, N)$$

be an accepted $\mathsf{PeanoCurve}^{\uparrow}$ *carrier. Every compact, continuous, or real-name consumer of* P *receives the Peano curve only through the finite route*

$$I, G, S \longmapsto X, Y, E, R \longmapsto H, C, Q, N.$$

At each requested precision n*, the route exposes dyadic interval addresses, dyadic square cells, coordinate readbacks through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, a dyadic continuity budget, and a finite witness that each displayed square cell has an interval preimage. Thus the packet presents the continuous-surjection surface over finite grids without constructing a host-level uncountable function space or selecting arbitrary real representatives.*

Proof. Fix a consumer request at square precision n. The interval-address row I supplies the finite dyadic input windows that may be inspected, and the grid-subdivision row G assigns each such window to a displayed dyadic square cell.

The coordinate readbacks are then forced through X and Y. Each coordinate endpoint is read as regular rational data and then as a terminal real-name seal, so the planar point is exposed only through the sibling $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ routes.

Continuity is a finite budget check. The row S compares adjacent interval cells, and E records a dyadic diameter bound sufficient for the requested square precision. Therefore the continuous-map consumer reads a modulus-style finite surface rather than a host function graph.

Surjection at the displayed precision is read from R. Every dyadic square cell listed at precision n has a paired interval address, so the finite grid is covered by the readback route.

The structural rows close the handoff. Transport, replay, provenance, and local naming preserve the same finite dyadic route, which gives compact, continuous, and real-name consumers no bypass through function spaces, arbitrary representatives, quotient equality, open-cover compactness, or ambient completeness. □

Theorem 2078.4 (PeanoCurve grid-cell compatibility)**.** *Let*

$$P = (I, G, S, X, Y, E, R, H, C, Q, N)$$

be an accepted $\mathsf{PeanoCurve}^{\uparrow}$ *carrier. Every displayed dyadic square cell read from* G *has coordinate readbacks* X *and* Y *whose* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seals are controlled by the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget* E *and the same* $\mathsf{StreamName}^{\uparrow}$ *interval window* I*. Adjacent interval cells use the sibling-continuity row* S *to preserve coordinate compatibility before any compact, continuous, or real-name consumer reads the structural rows* H, C, Q, N*.*

Proof. Project the accepted carrier. The interval-address row I, grid-subdivision row G, sibling-continuity row S, coordinate readback rows X, Y, and dyadic budget row E are all explicit coordinates of the packet.

Fix a displayed square cell in G. Its horizontal and vertical endpoints can be read only through X and Y, and those rows route their regular-rational and real-name seals through the dyadic budget E and the interval window I already attached to that cell.

For adjacent interval cells, the row S records the compatibility check before either coordinate readback is exposed to a downstream consumer. Thus neighboring grid cells preserve the finite edge or coincidence relation required by the Peano subdivision surface.

Finally apply Definition 2078.3. It routes every compact, continuous, and real-name consumer through

$$I, G, S \longmapsto X, Y, E, R \longmapsto H, C, Q, N,$$

so the compatibility witnessed by I, G, S, X, Y, E is preserved by the structural transport, replay, provenance, and local naming rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{PeanoCurve}^{\uparrow}}$.

Constructive story: A $\mathsf{PeanoCurve}^{\uparrow}$ packet is generated from finite dyadic interval addresses, grid-subdivision cells, sibling-continuity rows, coordinate readbacks through RegSeqRat and Real seals, dyadic error budgets, finite square-cell readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PeanoCurve}^{\uparrow}}$, seed)

Scope closed: Definition 2078.1, Definition 2078.2, Definition 2078.3, and Definition 2078.4 seed the finite dyadic subdivision route for a Peano continuous-surjection packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PeanoCurve}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host-level function spaces, arbitrary pointwise choice, quotient equality of real names, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic subdivision exactness, continuity budget exactness, finite-grid surjection exactness, and structural replay for BEDC.Derived.PeanoCurveUp.

Chapter 2079

A Concrete Naming Certificate for $\mathsf{SturmSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, a Sturm chain is read as a finite Euclidean division ledger whose endpoint sign rows can be inspected without choosing roots in an ambient ordered field. The $\mathsf{SturmSequence}^{\uparrow}$ packet names that finite sign-variation surface: its polynomial source is the coefficient and pseudo-remainder route of chapter 50, its bracket consumer is chapter 1786, and its Real-facing windows pass through the completion route of chapter 291, chapter 301, and chapter 38. The certificate exposes a chain and its variation counts, not a host real-root theorem.

Definition 2079.1 (SturmSequence Real carrier)**.** *A* $\mathsf{SturmSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, D, Q, E, V, B, W, R, H, C, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Poly}^{\uparrow}$ *source row, carrying the coefficient ledger, the degree bound, the formal derivative row, and the polynomial identity under inspection.*
2. *D is the Euclidean-division ledger for the Sturm chain. It records each displayed quotient, remainder, sign normalization, and terminal-zero decision used to construct the next chain entry.*
3. *Q is the finite chain table, indexed by the entries produced from P and D, with no appeal to factorization over a host field.*
4. *E is the endpoint-evaluation row. It stores the rational or dyadic endpoint windows and the displayed sign rows for every chain entry at each inspected endpoint.*
5. *V is the sign-variation row. It records the deletion of zero signs by displayed neighbor rows and the resulting variation counts at the two endpoints.*
6. *B is the bracket interface row consumed by* $\mathsf{RealRootBracket}^{\uparrow}$*: it stores only the endpoint cells, endpoint signs, and variation-count difference exposed by V.*
7. *W is the dyadic window handoff row through* $\mathsf{DyadicRatCore}^{\uparrow}$*, retaining the requested endpoint precision and comparison rows.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to expose the same endpoint windows at unary precision before any* $\mathsf{Real}^{\uparrow}$ *seal is read.*

9. *H records componentwise* hsame *transport for the polynomial, division, chain, endpoint, variation, bracket, dyadic, regular-rational, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a requested sign-variation read through polynomial inspection, chain construction, endpoint evaluation, zero deletion, variation counting, bracket handoff, and completion-route readback.*

11. *K is the* Pkg *provenance over* $\mathsf{Poly}^{\uparrow}$, $\mathsf{RealRootBracket}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{SturmSequence}^{\uparrow}}$ *registration row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for a selected root, algebraic closure, real trichotomy, quotient real equality, factorization theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.SturmSequenceUp.TasteGate.SturmSequenceTasteGate single carrier alignment`

Theorem 2079.2 (SturmSequence sign-variation window)**.** *For every accepted* $\mathsf{SturmSequence}^{\uparrow}$ *carrier $S = (P, D, Q, E, V, B, W, R, H, C, K, N)$ and every inspected endpoint pair, the visible sign-variation window factors through the displayed route*

$$P, D \longmapsto Q \longmapsto E \longmapsto V \longmapsto B, W, R, H, C, K, N.$$

The window exposes the finite chain entries, endpoint signs, zero-deletion witnesses, and endpoint variation counts. It exports no selected root, no host factorization theorem, and no $\mathsf{Real}^{\uparrow}$ *equality principle.*

Proof. Open the carrier of Definition 2079.1. The polynomial row P and division ledger D are the only inputs from which the chain table Q is admitted, so the chain cannot be replaced by an external factorization or by a root enumeration.

Endpoint inspection is then recorded in E. Each sign row is attached to a displayed chain entry and a displayed rational or dyadic endpoint window, and the zero rows used by the variation count remain visible.

The variation row V reads those endpoint signs and records the finite zero-deletion and sign-change count. The bracket interface B receives only the endpoint cells and the displayed difference of the two counts.

Finally, W and R expose the same endpoint windows through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, while H, C, K, N provide transport, replay, provenance, and naming. Since no listed coordinate stores a selected root, a factorization theorem, or a quotient real equality proof, the exported window remains finite Sturm-sequence data. □

Theorem 2079.3 (SturmSequence NameCert obligation surface)**.** *For every accepted* $\mathsf{SturmSequence}^{\uparrow}$ *carrier, the local* $\mathsf{NameCert}_{\mathsf{SturmSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the rows listed in Definition 2079.1;*

2. *polynomial-source admission through the coefficient, derivative, degree, and polynomial-identity rows of P;*

3. *chain-construction exactness through the displayed quotient, remainder, sign-normalization, and terminal-zero rows of D and Q;*

4. *endpoint-sign exactness through the endpoint windows and displayed sign rows of E;*

5. *variation-count exactness through the zero-deletion witnesses and sign-change counts of V;*
6. *bracket and completion-route discipline through B, W, R before any* $\mathsf{Real}^{\uparrow}$*-facing consumer is available;*
7. *componentwise transport, continuation replay, provenance, and local naming through H, C, K, N.*

There is no further NameCert obligation for algebraic closure, selected roots, quotient real equality, real trichotomy, factorization, or ambient completeness.

Proof. The carrier row gives the admission surface. Its coordinates name exactly the polynomial source, division ledger, chain table, endpoint signs, variation counts, bracket interface, dyadic and regular-rational readbacks, and structural BEDC rows.

The chain-construction obligations are finite because D and Q list the quotient, remainder, sign-normalization, and terminal-zero rows used to produce the table. No obligation asks for a host factorization or for a completed list of roots.

The endpoint and variation obligations are also finite. The row E attaches each sign to an endpoint window, and the row V records the zero-deletion witnesses and variation counts consumed by the bracket interface.

The completion-route obligations are downstream of that interface. Rows W and R expose the retained endpoint windows through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, while H, C, K, N replay and name the same route. Thus the local certificate has no remaining slot from which to export algebraic closure, selected roots, quotient real equality, real trichotomy, factorization, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{SturmSequence}^{\uparrow}$ read factors through one $\mathsf{Poly}^{\uparrow}$ source row, one Euclidean-division ledger, one finite chain table, endpoint sign rows, a sign-variation row, a $\mathsf{RealRootBracket}^{\uparrow}$ interface row, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: polynomial, real-root-bracket, dyadicratcore, regseqrat, real: $\mathsf{SturmSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Euclidean-division ledger, finite chain table, endpoint sign rows, zero-deletion witnesses, variation counts, bracket handoff, and completion-route endpoint readback.

Closure status for $\mathsf{NameCert}_{\mathsf{SturmSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SturmSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2079.1, Definition 2079.2, and Definition 2079.3 seed the finite Sturm-chain route from polynomial division rows through endpoint sign variation, bracket handoff, and dyadic, regular-rational, and Real-facing windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SturmSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close algebraic root existence, factorization over a host field, selected roots, quotient real equality, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, chain-construction exactness, endpoint-sign exactness, variation-count exactness, bracket handoff, completion-route discipline, and transport-replay coverage for BEDC.Derived.SturmSequenceUp.

Constructive story: A $\mathsf{SturmSequence}^{\uparrow}$ packet is generated from a $\mathsf{Poly}^{\uparrow}$ source row, a Euclidean-division ledger, a finite chain table, endpoint sign rows, zero-deletion witnesses, sign-variation counts, a $\mathsf{RealRootBracket}^{\uparrow}$ interface row, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2080

A Concrete Naming Certificate for $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$

Bishop–Bridges constructive analysis treats Pringsheim's positive-real-series criterion as a finite route from monotone partial sums and explicit tail budgets to a real endpoint, not as a host appeal to suprema or ambient completeness. The $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ packet sits after the finite windows of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance core of chapter 291, the real-series Cauchy route of chapter 2014, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the comparison-facing sibling chapter 2023. It records the classical positive-term monotone partial-sum criterion as displayed BEDC certificate data; it does not import host least upper bounds, selected infinite sums, quotient equality of series, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2080.1 (Pringsheim positive real series carrier)**.** *A* $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the positive term-window row. It records exactly the inspected nonnegative real terms and their finite positivity witnesses.*
2. *S is the monotone partial-sum row. It records the displayed partial sums, the successor-step additions, and the monotonicity checks visible to the certificate.*
3. *M is the monotone-bound ledger. It stores the finite upper rows and comparison requests used to turn monotone partial sums into a Cauchy tail budget.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-budget row. It stores dyadic tolerances, slack radii, denominator bounds, and the finite threshold after which every displayed tail is below the requested budget.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It reads the same partial-sum windows and dyadic budgets as a regular rational sequence before any endpoint seal is exported.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is available only after T, S, M, D, R have displayed the positive terms, monotone partial sums, tail budgets, and regular rational handoff.*
7. *H stores componentwise* hsame *transport for the term windows, partial-sum rows, monotone-bound ledger, dyadic budgets, regular handoff, real seal, replay, provenance, and local naming row.*

8. *C stores displayed* Cont *replay from term windows to partial sums, from partial sums to monotone-bound rows, from those rows to dyadic tail budgets, and from the budgets to the regular handoff and real seal.*

9. *P is the* Pkg *provenance over* PringsheimPositiveRealSeries$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealSeriesCauchyCriterion$^{\uparrow}$, Real$^{\uparrow}$, SeriesLimitComparison$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{PringsheimPositiveRealSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, M, D, R, E, H, C, P, N$. It has no coordinate for a host supremum of partial sums, a selected infinite sum, quotient equality of series, countable choice, trichotomy, ambient Real$^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.PringsheimPositiveRealSeriesUp.PringsheimPositiveRealSeriesTasteGate`
`single carrier alignment`

Theorem 2080.2 (Pringsheim positive real series NameCert obligations)**.** *For every accepted* PringsheimPositiveRealSeries$^{\uparrow}$ *carrier $K = (T, S, M, D, R, E, H, C, P, N)$, the local* NameCert$_{\text{PringsheimPositiveRealSeries}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed positive term windows, monotone partial-sum rows, monotone-bound ledger, dyadic tail budget, regular rational handoff, real seal, transport, replay, provenance, and local naming row;*

2. *positive-window exactness, requiring every positivity read and every term read to pass through T and the finite* StreamName$^{\uparrow}$ *windows named in P;*

3. *monotone partial-sum exactness, requiring every inspected partial sum and successor addition to pass through S before a tail request is admitted;*

4. *tail-budget exactness, requiring M and D to display the finite threshold, upper row, dyadic slack, and tail tolerance consumed by the* RealSeriesCauchyCriterion$^{\uparrow}$ *route;*

5. RegSeqRat$^{\uparrow}$ *handoff, requiring R to read the same partial-sum windows and dyadic budgets before any* Real$^{\uparrow}$ *endpoint seal is available;*

6. *real-seal nonescape, requiring E to remain downstream of T, S, M, D, R and to export no host supremum, selected infinite sum, quotient equality of series, countable choice, trichotomy, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge datum;*

7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Pringsheim positive-series obligation is stored outside these rows.

Proof. Project the accepted packet $K = (T, S, M, D, R, E, H, C, P, N)$. The carrier definition exposes exactly the positive term windows, monotone partial-sum rows, monotone-bound ledger, dyadic budget, regular handoff, real seal, and structural rows.

The positivity and partial-sum data are read first. The row T supplies only displayed term windows, and the row S supplies only displayed finite partial sums and successor additions.

The tail route then passes through M and D. These rows record the upper row, threshold, dyadic slack, and requested tolerance before the RealSeriesCauchyCriterion$^{\uparrow}$ route may be read.

Finally R, E, H, C, P, N hand off, seal, transport, replay, source, and name the same displayed route. Since no excluded analytic, choice, quotient, verification, or bridge object appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2080.3 (Pringsheim positive real series tail bound)**.** *Let $K = (T, S, M, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ *carrier. Every completion-facing tail request for the positive real series factors through*

$$T \longmapsto S \longmapsto M, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the finite monotone partial-sum rows and $\mathsf{DyadicRatCore}^{\uparrow}$ *tail budgets determine the Cauchy handoff, not a host least upper bound, selected infinite sum, trichotomy, countable choice, quotient series equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a completion-facing tail request. The carrier offers no direct infinite-sum coordinate, so the request first reads the finite term windows T and the partial-sum row S.

The monotone-bound ledger M identifies the displayed upper row and the finite threshold attached to the request. The dyadic budget D then supplies the tolerance, slack, and denominator data used by the tail estimate.

The regular handoff R reads exactly those displayed windows and budgets. This is the route made available to the $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ surface before a real endpoint can be sealed.

The seal and structural rows E, H, C, P, N preserve that route. Because the packet has no coordinate for a host supremum, selected sum, quotient equality, trichotomy, choice, or ambient completeness, every tail request is exhausted by the displayed factorization. □

Theorem 2080.4 (Pringsheim positive real series RegSeqRat handoff)**.** *For an accepted* PringsheimPositiveRealSeri *carrier $K = (T, S, M, D, R, E, H, C, P, N)$, every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by R is determined by the same positive term windows, monotone partial-sum rows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets displayed in T, S, M, D. No consumer may replace this handoff by a selected limit of partial sums, quotient equality of streams, a trichotomy comparison, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the row R from the accepted packet. By Definition 2080.1, R appears only after the term windows, partial sums, monotone-bound ledger, and dyadic tail budget have been displayed.

Apply Definition 2080.2. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff obligation requires R to read the same partial-sum windows and dyadic budgets before any endpoint seal is available.

Apply Definition 2080.3. Every completion-facing tail request reaches R through T, S, M, D and then exits through E, H, C, P, N.

Therefore R is a local regular-rational handoff row for the displayed finite packet. It cannot be detached as a selected limit, quotient stream equality, trichotomy comparison, choice object, or ambient completeness principle. □

Theorem 2080.5 (Pringsheim positive real series real seal nonescape)**.** *For every accepted* PringsheimPositiveRealSe *carrier, any* $\mathsf{Real}^{\uparrow}$ *consumer of the sealed endpoint must read the positive term windows, monotone partial-sum rows, monotone-bound ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row of Definition 2080.1. The endpoint seal exports no host supremum, selected infinite sum, quotient equality of series, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Proof. Let an accepted endpoint consumer read the row E. The carrier definition places E downstream of T, S, M, D, R, so the consumer first receives the displayed positive terms, monotone partial sums, tail budgets, and regular handoff.

The NameCert obligations force the same order. Positive-window exactness and monotone partial-sum exactness bind the visible series data, tail-budget exactness binds M, D, and the handoff obligation binds R before E can be used.

The structural rows H, C, P, N then transport, replay, source, and name the route. No other coordinate remains in the carrier, so the endpoint seal has no path to a host supremum, selected sum, quotient equality, trichotomy, choice, ambient completeness, Lean verification, or bridge datum. □

Falsifiable prediction: Every $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ completion-facing read factors through positive term windows, monotone partial-sum rows, a monotone-bound ledger, DyadicRatCore tail budgets, RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real-series-cauchy-criterion, real, series-limit-comparison: $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries positivity windows, monotone partial-sum rows, monotone-bound tail budgets, regular rational handoff, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PringsheimPositiveRealSeries}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PringsheimPositiveRealSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2080.1, Definition 2080.2, Definition 2080.3, Definition 2080.4, and Definition 2080.5 seed the finite constructive Pringsheim positive-real-series route from monotone partial sums through dyadic tail budgets to RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PringsheimPositiveRealSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host least upper bounds, selected infinite sums, quotient equality of series, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-window exactness, monotone partial-sum exactness, DyadicRatCore tail-budget handoff, RegSeqRat readback, Real seal nonescape, and structural transport for BEDC.Derived.PringsheimPositiveRealSeriesUp.

Constructive story: A $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ packet is generated from positive term windows, monotone partial-sum rows, a monotone-bound ledger, a DyadicRatCore tail-budget row, a RegSeqRat handoff, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2081

A Concrete Naming Certificate for $\mathsf{BishopIntervalHalving}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopIntervalHalving}^{\uparrow}$ packet records the interval-halving route by which a located real interval supplies finite bisection windows, dyadic diameter budgets, regular rational readback, and a terminal real seal. It consumes the located interval surface of chapter 1709, the midpoint and bisection rows of chapter 1712 and chapter 1711, the finite stream discipline of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a constructive bisection certificate for L10 Real and Completion routes; it does not assert open-cover compactness, host interval completeness, quotient real equality, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2081.1 (Bishop interval halving carrier)**.** *A* $\mathsf{BishopIntervalHalving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, M, B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, carrying the lower and upper endpoint names, locator reads, radius data, and locatedness budget for the interval to be halved.*
2. *M is the* $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$ *row, exposing the finite midpoint cell used by each halving request.*
3. *B is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *row, recording the retained child interval and the displayed branch decision for the current finite request.*
4. *D is the dyadic diameter budget row. It records the requested precision, the halving depth, the dyadic denominator budget, and the comparison slack showing that the retained interval diameter is below the requested tolerance.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It lists the visible halving windows inspected by the downstream readback, and it contains no completed infinite branch.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained interval windows and their dyadic diameter witnesses.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after I, M, B, D, W, R have been displayed.*

8. *H records componentwise* hsame *transport for the located interval, midpoint, bisection, dyadic budget, finite windows, regular rational readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$I, M, B, D \longmapsto W \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalHalving}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalHalving}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, B, D, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, an infinite branch selector, quotient stream equality, quotient real equality, host real equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalHalvingUp.TasteGate.BishopIntervalHalvingTasteGate single carrier alignment`

Theorem 2081.2 (Bishop interval halving NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalHalving}^{\uparrow}$ *carrier*

$$K = (I, M, B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalHalving}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval, midpoint row, bisection row, dyadic diameter budget, finite stream windows, regular rational readback, real seal, transport, replay, provenance, and local name;*

2. *source-interval exactness, requiring every endpoint, radius, locator, locatedness, and metric-bracket request to pass through the displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row I;*

3. *midpoint and bisection exactness, requiring every retained child interval to read its midpoint from M and its branch data from B before any downstream window is exposed;*

4. *diameter-budget exactness, requiring D to bind each halving depth to a displayed dyadic tolerance and to the retained interval diameter used for the current request;*

5. *regular readback ordering, requiring W and D to feed R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is consumed;*

6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed route and to export no open-cover compactness, infinite branch selector, quotient stream equality, quotient real equality, host real equality, countable choice, selected limit, or ambient completeness row.*

No Bishop interval halving obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2081.1. The accepted packet displays exactly the located source interval, midpoint row, bisection row, dyadic budget, finite windows, regular readback, seal, and structural rows.

Source-interval exactness is forced by I. Endpoint, radius, locator, locatedness, and metric-bracket reads have no route except the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ coordinate.

Midpoint and bisection exactness are forced by M and B. A retained child interval is available only after the midpoint cell has been displayed and the bisection row has recorded the branch data for the finite request.

The dyadic diameter obligation is internal to D. The row binds each request to a halving depth, denominator budget, comparison slack, and retained-interval diameter bound before any regular rational readback is visible.

The rows W and R then supply the finite-window and $\mathsf{RegSeqRat}^{\uparrow}$ handoff. The terminal seal E is downstream of this readback, so a Real-facing consumer cannot bypass the displayed halving route.

Finally, H, C, P, N only transport, replay, source, and name the same packet. Since the carrier contains no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2081.3 (Bishop interval halving Real seal route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion-facing consumer of an accepted* $\mathsf{BishopIntervalHalving}^{\uparrow}$ *carrier factors through the finite route*

$$I, M, B, D \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives only the displayed located interval, midpoint and bisection rows, dyadic diameter budget, finite stream windows, regular rational readback, terminal real seal, componentwise transport, continuation replay, package provenance, and local naming data. It receives no open-cover compactness theorem, completed branch, selected real limit, quotient equality of real names, host real equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $K = (I, M, B, D, W, R, E, H, C, P, N)$. The only source interval coordinate is I, so every interval request begins with the displayed located endpoint and locator data.

The midpoint and bisection rows form the finite halving step. The midpoint row M supplies the child-cell boundary, and the bisection row B records the retained interval for the current request.

The dyadic diameter budget D supplies the quantitative contraction. It records the halving depth and the diameter comparison needed before the finite StreamName windows W can be consumed by the regular rational readback.

The row R is downstream of W and D, so every $\mathsf{RegSeqRat}^{\uparrow}$ read is built from displayed halving windows and dyadic contraction data. The terminal seal E is then read only after R has been exposed.

The structural rows H, C, P, N preserve this route under componentwise transport, replay, provenance, and naming. Since no carrier coordinate stores compactness, a completed branch, a selected real limit, quotient equality, host equality, countable choice, or ambient completeness, no consumer can obtain such data from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalHalving}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalHalving}^{\uparrow}$ packet is generated from a LocatedRealIntervalUp row, a LocatedIntervalMidpointUp row, a LocatedIntervalBisectionUp row, a dyadic diameter budget, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopIntervalHalving}^{\uparrow}}$, seed)

Scope closed: Definition 2081.1, Definition 2081.2, and Definition 2081.3 seed the constructive interval-halving route from located intervals through midpoint and bisection rows, dyadic contraction budgets, finite windows, regular rational readback, terminal real seals, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopIntervalHalving}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, completed branches, selected real limits, quotient equality of real names, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-interval exactness, midpoint and bisection exactness, diameter-budget exactness, regular readback ordering, and real-seal nonescape for BEDC.Derived.BishopIntervalHalvingUp.

Chapter 2082

A Concrete Naming Certificate for $\mathsf{LengthSpace}^{\uparrow}$

Following Burago–Burago–Ivanov and Bridson–Haefliger on length spaces, the $\mathsf{LengthSpace}^{\uparrow}$ packet records the finite path-length ledger by which a metric distance is witnessed through displayed interval paths and displayed segment sums. It sits over the metric source of chapter 57, the continuous-map path surface of chapter 130, the interval address space of chapter 56, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite ledger for length reads; it is not a geodesic existence theorem, a host path space, a quotient path-space construction, an open-cover compactness result, a $\mathsf{Real}^{\uparrow}$ completeness theorem, or a selected-minimizer principle.

Definition 2082.1 (LengthSpace finite path-length carrier)**.** *A* $\mathsf{LengthSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, I, A, D, S, R, T, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, recording the accepted* $\mathsf{Met}^{\uparrow}$ *carrier, the endpoint identifiers, and the finite source-distance request consumed by the length ledger.*
2. *I is the interval path row, recording a finite* $\mathsf{Interval}^{\uparrow}$ *address family and the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *path read used to connect the two endpoint identifiers.*
3. *A is the partition ledger, recording a finite ordered partition of the displayed interval addresses, including adjacent address pairs and endpoint coverage.*
4. *D is the segment-distance ledger, recording the* $\mathsf{Met}^{\uparrow}$ *distance read for each adjacent pair in A after the path row I has supplied its two point reads.*
5. *S is the segment-sum row, recording the finite rational sum of the entries in D and the tolerance split used to compare it with the source-distance request in M.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the finite segment sums as regular rational observations before any terminal real seal is consumed.*
7. *T is the* $\mathsf{Real}^{\uparrow}$ *length-readback row, sealing the regular rational observations from R as a displayed real-name length value for this finite path ledger.*

8. *C records componentwise* hsame *transport for the metric source, interval path row, partition ledger, segment-distance ledger, regular rational readback, real length readback, replay, provenance, and local naming rows.*
9. *P is the displayed* Cont *replay and* Pkg *provenance over* $\mathsf{LengthSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Interval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LengthSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, I, A, D, S, R, T, C, P, N$. It has no coordinate for geodesic existence, host paths, quotient path spaces, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or selected minimizers.*

Lean4 ✓ `BEDC.Derived.LengthSpaceUp.TasteGate.LengthSpaceTasteGate single carrier alignment`

Theorem 2082.2 (LengthSpace path ledger stability)**.** *Let*

$$L = (M, I, A, D, S, R, T, C, P, N)$$

be an accepted $\mathsf{LengthSpace}^{\uparrow}$ *carrier. Every endpoint-distance or length-read consumer of L factors through the displayed finite route*

$$M, I, A, D, S \longmapsto R, T \longmapsto C, P, N.$$

Consequently componentwise hsame *transport of $M, I, A, D, S, R, T, C, P, N$ preserves the same metric source, interval path row, partition ledger, segment-distance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *length seal, with no additional route through host paths, quotient path spaces, open-cover compactness, real completeness, geodesic selection, or minimizing-path choice.*

Proof. Carrier projection gives the ordered rows $M, I, A, D, S, R, T, C, P, N$. A consumer begins with the metric source row M, so the endpoint-distance request is tied to a displayed $\mathsf{Met}^{\uparrow}$ source before any path-length read is available.

The path data are finite. The interval path row I supplies the displayed $\mathsf{ContinuousMap}^{\uparrow}$ reads over $\mathsf{Interval}^{\uparrow}$, and the partition ledger A lists only finitely many adjacent interval addresses. Thus every segment request is bounded by the displayed partition.

The segment-distance ledger D reads each adjacent pair through the metric source, and S folds those entries into one finite segment sum. The readback rows R and T expose that sum first as $\mathsf{RegSeqRat}^{\uparrow}$ data and then as a terminal $\mathsf{Real}^{\uparrow}$ length seal.

Transport and replay are structural. Componentwise hsame in C preserves each listed row, while the displayed provenance in P and the local name in N replay the same finite route.

The excluded objects are absent from the carrier inventory. Since no row stores host paths, quotient path spaces, open covers, ambient completeness, geodesic witnesses, or minimizing-path choices, no consumer can obtain them from the transported packet. □

Theorem 2082.3 (LengthSpace NameCert obligation surface)**.** *For an accepted* $\mathsf{LengthSpace}^{\uparrow}$ *carrier*

$$L = (M, I, A, D, S, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LengthSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric source, interval path row, partition ledger, segment-distance ledger, segment-sum row, regular rational readback, real length readback, transport, replay, provenance, and local naming rows;*

2. *path-source exactness, requiring every displayed path read to pass through M and then I before a segment endpoint can be inspected;*
3. *partition exactness, requiring A to list the finite ordered interval addresses and adjacent pairs consumed by the segment-distance ledger;*
4. *segment-distance exactness, requiring D to read each adjacent pair through the same* $\mathsf{Met}^{\uparrow}$ *source and no other distance object;*
5. *length-readback exactness, requiring S, R, T to expose the finite segment sum through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *before any consumer treats it as a length value;*
6. *structural exhaustion, requiring C, P, N to transport, replay, source, and name only the displayed route M, I, A, D, S, R, T.*

No NameCert obligation is stored outside those rows, and none asserts geodesic existence, host paths, quotient path spaces, open-cover compactness, $\mathsf{Real}^{\uparrow}$ *completeness, or selected minimizers.*

Proof. Carrier admission is projection from Definition 2082.1. The accepted packet displays the metric source, interval path row, partition ledger, segment-distance ledger, segment sum, readback rows, and structural rows.

Path-source exactness is read from M and I. A path endpoint can be inspected only after the source metric row and the displayed interval path row have both been opened.

Partition exactness is the role of A. It supplies the finite ordered interval addresses and adjacent pairs consumed downstream, so the segment-distance ledger has no unlisted path coordinate.

Segment-distance exactness is read from D. Each adjacent pair is measured through the same metric source row M, and no additional distance object is present.

Length-readback exactness is read from S, R, T. The finite segment distances are summed in S, exposed as regular rational observations in R, and sealed as a real-name length value in T.

Finally C, P, N add no analytic coordinate. They preserve, replay, source, and name the same finite route, so the excluded geodesic, host-path, quotient, compactness, completeness, and minimizer data have no row from which a consumer could read them. □

Closure status for $\mathsf{NameCert}_{\mathsf{LengthSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LengthSpace}^{\uparrow}$ packet is generated from a Metric source row, an Interval path row, a finite partition ledger, segment-distance rows, finite segment sums, RegSeqRat and Real length readbacks, componentwise hsame transport, displayed Cont replay with Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LengthSpace}^{\uparrow}}$, seed)

Scope closed: Definition 2082.1, Definition 2082.2, and Definition 2082.3 seed the finite path-length metric ledger surface for downstream path-metric and geodesic consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LengthSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close geodesic existence, host paths, quotient path spaces, open-cover compactness, $\mathsf{Real}^{\uparrow}$ completeness, selected minimizers, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, path-source exactness, partition exactness, segment-distance exactness, length-readback exactness, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.LengthSpaceUp.

Chapter 2083

A Concrete Naming Certificate for $\mathsf{ScottReal}^{\uparrow}$

Following Scott, Gierz–Hofmann–Keimel–Lawson–Mislove–Scott, and Bishop–Bridges, $\mathsf{ScottReal}^{\uparrow}$ is the finite interval-domain presentation of a real name. It sits after the interval-domain carrier of chapter 1543, the way-below refinement of chapter 1545, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet records the domain-theoretic real presentation as displayed NameCert data, not as quotient real equality, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2083.1 (ScottReal carrier)**.** *A* $\mathsf{ScottReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, W, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{IntervalDomain}^{\uparrow}$ *row. It records the finite rational interval enclosure surface and the containment checks visible at the current request.*
2. *W is the* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *row. It records the compact-containment and way-below refinements used to move between coarser and sharper interval observations.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger. It stores dyadic endpoints, radii, slack, denominator budgets, and comparison witnesses for the displayed interval refinements.*
4. *M is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It schedules the finite interval observations consumed by a request without selecting an infinite stream representative.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It reads the same displayed windows and dyadic budgets as regular rational observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is reachable only after the interval-domain, way-below, dyadic, stream-window, and regular-rational rows have been displayed.*
7. *H records componentwise* hsame *transport for the interval-domain, way-below, dyadic, stream, regular-rational, real-seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite real-facing request through $I, W, D, M, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{ScottReal}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{IntervalDomainWayBelow}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ScottReal}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets through the displayed tuple $I, W, D, M, R, E, H, C, P, N$ and has no coordinate for quotient real equality, selected limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.ScottRealUp.ScottRealTasteGate single carrier alignment`

Theorem 2083.2 (ScottReal NameCert obligations)**.** *For an accepted* $\mathsf{ScottReal}^{\uparrow}$ *carrier*

$$S = (I, W, D, M, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ScottReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the interval-domain row, way-below row, dyadic refinement ledger, stream window, regular rational handoff, real seal, transport, replay, provenance, and local naming row;*
2. *interval-domain coherence, requiring every exposed interval read to come from I and to preserve the displayed endpoint containment and enclosure order;*
3. *way-below compatibility, requiring each refinement in W to be read as compact containment inside the interval-domain row before a sharper interval observation is consumed;*
4. *stream and readback handoff, requiring M and R to consume the same finite interval and dyadic rows before any regular rational observation is exported;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring E to remain downstream of I, W, D, M, R and to export only the displayed real-name seal;*
6. *ledger refusal, requiring D, H, C, P, N to record the displayed refinement route and to export no quotient real equality, no selected limits, no countable choice, no open-cover compactness, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2083.1. The accepted packet exposes exactly the interval-domain, way-below, dyadic, stream, regular-rational, real-seal, transport, replay, provenance, and local naming rows.

Interval-domain coherence is read from I. Every public interval observation is a displayed row with endpoints, containment checks, and enclosure order already present in the packet.

Way-below compatibility is read from W against I. A sharper observation may be consumed only after the compact-containment row has shown how it lies inside the coarser interval-domain observation.

The stream and regular-rational handoff is then finite. The row M schedules only the displayed interval observations, and the row R reads those scheduled observations through the dyadic ledger D rather than through a selected infinite stream.

The real seal is last. Since E is downstream of I, W, D, M, R, a real-facing consumer cannot bypass the interval-domain and readback route.

Finally H, C, P, N are structural rows. They transport, replay, source, and name the displayed route, so the excluded quotient, selection, choice, compactness, completeness, verification, and bridge principles have no coordinate from which they could be read. □

Theorem 2083.3 (ScottReal interval-domain handoff)**.** *Let*

$$S = (I, W, D, M, R, E, H, C, P, N)$$

be an accepted $\mathsf{ScottReal}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of* S *factors through the displayed route*

$$I \longmapsto W, D \longmapsto M \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the Scott interval-domain presentation reaches real and completion consumers only by passing from interval enclosures to way-below and dyadic refinements, then to finite stream windows, regular rational readback, the real seal, and the structural hsame/Cont/Pkg/NameCert *rows. It does not export quotient real equality, selected limits, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Proof. Fix a real-facing or completion-facing consumer of the accepted packet. The first visible row is the interval-domain surface I, so the consumer begins with displayed finite interval enclosures.

The refinement step reads W and D. The way-below row records compact containment inside the interval-domain surface, while the dyadic ledger supplies the endpoint, radius, slack, and comparison data used by those refinements.

The window step reads M. A consumer receives only finite scheduled interval observations, not an infinite stream representative or a selected limit.

The regular rational step reads R. This row turns the same displayed windows and dyadic budgets into regular rational observations before any terminal real seal is available.

The seal step reads E only after the preceding rows have been displayed. Hence a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer obtains the real presentation through the stated route.

The rows H, C, P, N close the factorization by transport, replay, provenance, and local naming. Since no other coordinate exists in the carrier, the excluded quotient, choice, compactness, completeness, verification, and bridge principles cannot be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ScottReal}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ScottReal}^{\uparrow}}$, seed)

Scope closed: Definition 2083.1, Definition 2083.2, and Definition 2083.3 seed the finite interval-domain presentation of real names through way-below refinements, dyadic ledgers, stream windows, regular rational readback, and the terminal real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ScottReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-domain coherence, way-below compatibility, dyadic refinement replay, stream and RegSeqRat handoff, Real seal non-escape, and structural transport for BEDC.Derived.ScottRealUp.

Constructive story: A $\mathsf{ScottReal}^{\uparrow}$ packet is generated from an IntervalDomain row, an IntervalDomainWayBelow row, a DyadicRatCore refinement ledger, a StreamName finite window, a RegSeqRat handoff, a Real seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2084

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name is restricted to a displayed tail before any downstream real-name consumer inspects the seal. It sits over the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance discipline of chapter 291, and the terminal real-name boundary of chapter 38. It is the ordinary tail-restriction surface that later cofinal routes, including chapter 1998, can consume as finite BEDC data rather than as host stream reasoning.

Definition 2084.1 (Regular-Cauchy tail-subsequence carrier)**.** *A* $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, W, k, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy row, exposing only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and regular rational data admitted by the source certificate.*
2. *W is the tail-window ledger, listing the source windows that remain visible after the cutoff is displayed.*
3. *k is a unary tail cutoff. It is a finite natural-number row, not an infinite selector or choice function.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the source row, the retained windows, the shifted readback, and the terminal real seal.*
5. *R is the shifted* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. A request at displayed index n is read from the source regular Cauchy data at the shifted index $k + n$ through the window ledger W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal exposed only after S, W, k, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the source row, tail windows, cutoff, tolerance ledger, shifted readback, seal row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite tail read through*

$$S, W, k, D, R \longmapsto E, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, k, D, R, E, H, C, P, N$. It has no coordinate for a quotient stream, selected limit, countable choice principle, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailSubsequenceUp.RegularCauchyTailSubsequenceTasteGate`
`single carrier alignment`

Theorem 2084.2 (Regular-Cauchy tail-subsequence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$ *carrier*

$$T = (S, W, k, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSubsequence}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the source regular Cauchy row, tail-window ledger, unary cutoff, dyadic tolerance ledger, shifted regular rational readback, real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *tail cutoff exactness, requiring every retained observation to pass through the displayed unary row k and the corresponding retained window in W;*
3. *shifted readback exactness, requiring R to read the displayed tail index n only as the source observation at $k + n$;*
4. *tolerance preservation, requiring D to be the same dyadic ledger consumed by S, W, R and the seal row E;*
5. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed finite tail route.*

No NameCert obligation is stored outside those five rows, and none exports a quotient stream, selected limit, countable choice principle, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

Proof. Carrier admission is projection from Definition 2084.1. The visible analytic rows are exactly the source regular Cauchy row S, tail windows W, unary cutoff k, dyadic ledger D, shifted readback R, and real seal E.

Tail cutoff exactness is read from k and W. A tail observation cannot be inspected until the cutoff row has been displayed and the retained source window has been named in the window ledger.

Shifted readback exactness is read from R. Each displayed tail index n is interpreted by the finite arithmetic row $k + n$, so the packet uses a visible unary shift rather than an external subsequence function.

Tolerance preservation is the projection to D. The source row, retained windows, shifted readback, and real seal all consume that same dyadic ledger, so no detached modulus can alter the tail read.

Finally H, C, P, N are structural rows. They preserve, replay, source, and name only the displayed finite route, leaving no row from which a consumer could extract quotient streams, selected limits, countable choice, host equality, trichotomy, ambient completeness, Lean verification, or bridge data. □

Theorem 2084.3 (Regular-Cauchy tail-subsequence Real seal stability)**.** *Let*

$$T = (S, W, k, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the tail packet factors through*

$$S, W, k, D, R, E, H, C, P, N.$$

Consequently the consumer reads the tail as a finite cutoff, retained-window ledger, shifted regular rational readback, shared dyadic tolerance ledger, and terminal seal. It exports no quotient stream, selected limit, countable choice principle, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ consumer request. The carrier exposes the seal row E only downstream of S, W, k, D, R, so the consumer must first read the source row, retained windows, displayed cutoff, dyadic ledger, and shifted regular rational readback.

The tail operation is finite. The cutoff row k supplies the unary shift, and the window ledger W records the retained source windows; no host subsequence function is available to the consumer.

The shifted readback and tolerance rows then determine the seal-facing data. The row R reads index n through the source observation at $k + n$, while D is the sole dyadic ledger shared by the source, tail windows, readback, and seal.

The structural rows close the route. Componentwise transport, continuation replay, package provenance, and local naming preserve only S, W, k, D, R, E, so the consumer has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$ packet is generated from a source regular Cauchy row, retained StreamName windows, a unary tail cutoff, a shared DyadicRatCore tolerance ledger, shifted RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailSubsequence}^{\uparrow}}$, seed)

Scope closed: Definition 2084.1, Definition 2084.2, and Definition 2084.3 seed the finite tail-restriction route for regular Cauchy rational names over displayed StreamName windows, a unary cutoff, dyadic tolerance ledgers, shifted RegSeqRat readback, and the RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailSubsequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail cutoff exactness, shifted readback exactness, tolerance preservation, and Real-seal stability for BEDC.Derived.RegularCauchyTailSubsequenceUp.

Chapter 2085

A Concrete Naming Certificate for $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name exposes an explicit precision rate before a $\mathsf{Real}^{\uparrow}$ consumer reads the seal. It sits over the finite window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the generic modulus row of chapter 292, the Real-facing modulus boundary of chapter 1423, and the terminal real-name seal of chapter 38. The packet makes the rate read part of the named certificate rather than a host-side inference from Cauchy convergence prose.

Definition 2085.1 (Regular Cauchy rate extraction carrier)**.** *A* $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, D, R, M, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the source regular Cauchy name and by every downstream precision request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying requested radii, comparison cells, slack rows, and endpoint observations.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic observations.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row. A requested precision is sent to a displayed finite stage through M before any rate-bearing handoff is available.*
5. *U is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *readback row binding the same S, D, R, M data to the Real-facing modulus surface.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after S, D, R, M, U have all been displayed.*
7. *H records componentwise* hsame *transport for the window, dyadic, regular readback, modulus, Real-facing modulus, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the rate route*

$$S, D, R \longmapsto M \longmapsto U \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, M, U, E, H, C, P, N$. It has no coordinate for a selected limit, quotient equality of Cauchy streams, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRateExtractionUp.RegularCauchyRateExtractionTasteGate single carrier alignment`

Theorem 2085.2 (Regular Cauchy rate extraction NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ *carrier*

$$X = (S, D, R, M, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyRateExtraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, CauchyModulus threshold, RealCauchyModulus readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *window-readback exactness, requiring R to read only windows displayed in S and tolerance data displayed in D;*
3. *threshold extraction exactness, requiring every precision request to pass through the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *row M before the Real-facing modulus row is available;*
4. *Real-modulus compatibility, requiring U to bind the same S, D, R, M route and to expose no independent convergence oracle;*
5. *Real-seal nonescape, requiring E to be downstream of S, D, R, M, U and to export no selected limit, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness claim;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the displayed rate-extraction route.*

No $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2085.1. The accepted packet displays exactly the StreamName, DyadicRatCore, RegSeqRat, CauchyModulus, RealCauchyModulus, Real seal, transport, replay, provenance, and local naming rows.

Window-readback exactness is read from S, D, R. The regular rational readback has access only to the displayed finite windows and dyadic tolerance cells, so it cannot inspect an unbounded stream representative or a quotient equality class.

Threshold extraction exactness is the role of M. A precision request reaches a finite stage only through the displayed $\mathsf{CauchyModulus}^{\uparrow}$ row, and no other carrier coordinate can supply a detached selector.

The Real-facing modulus row U then binds the same source route. Since U is downstream of S, D, R, M, it records the rate as certificate data rather than as an external convergence principle.

Finally, E, H, C, P, N close the finite route. The seal and structural rows preserve only the displayed coordinates, so the excluded objects are absent from every accepted packet and the listed obligations exhaust the local NameCert surface. □

Theorem 2085.3 (Regular Cauchy rate extraction modulus readback)**.** *Let*

$$X = (S, D, R, M, U, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ *carrier. Every modulus or Real-facing consumer of* X *reads a precision rate through the finite route*

$$S, D, R \longmapsto M \longmapsto U \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed StreamName window row, DyadicRatCore tolerance ledger, RegSeqRat readback, CauchyModulus threshold, RealCauchyModulus handoff, Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *data, and receives no selected limit, quotient stream equality, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

Proof. Begin with a modulus or Real-facing read of an accepted packet. Projection exposes the ordered carrier rows $S, D, R, M, U, E, H, C, P, N$.

The readback starts at the finite observation surface. The row S displays the windows, D displays the tolerance ledger, and R displays the regular rational values available to the request.

The precision rate is then read from M. Because M is the only threshold row in the carrier, a consumer cannot replace the rate by countable choice, a hidden selector, or a host convergence argument.

The Real-facing handoff is U, and the terminal seal is E. These rows are downstream of the same finite threshold route, so the rate used by the Real seal is the displayed CauchyModulus threshold already named in the packet.

The structural rows H, C, P, N transport, replay, source, and name that same route. Therefore every modulus or Real-facing consumer factors through the displayed packet and receives none of the excluded escape objects. □

Theorem 2085.4 (Regular Cauchy rate extraction finite-threshold induction)**.** *Let*

$$X = (S, D, R, M, U, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ *carrier. For any finite extension of displayed precision requests that preserves the* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the extended consumer route adds only replay of the displayed chain*

$$S, D, R \longmapsto M \longmapsto U \longmapsto E \longmapsto H, C, P, N.$$

No extension step introduces a selected limit, quotient stream equality, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

Proof. Induct over the finite ledger of displayed precision requests.

For the empty ledger, the claim is exactly the modulus readback theorem Definition 2085.3. The accepted packet exposes S, D, R first, then routes the precision rate through M, U, E, H, C, P, N.

For the successor ledger, append one displayed request while keeping the same S, D, R rows. The appended request is sent to the finite threshold row M because M is the only carrier coordinate that answers precision-stage questions.

After M is read, the Real-facing transport is forced through U and E. The structural rows H, C, P, N replay, transport, source, and name the same route, so the extension step adds no coordinate outside the displayed packet.

The induction therefore preserves the route invariant at every finite stage. Since every step is a replay of $S, D, R \mapsto M \mapsto U \mapsto E \mapsto H, C, P, N$, none of the excluded escape objects can enter the extended ledger. □

Theorem 2085.5 (Regular Cauchy rate extraction obligation closure)**.** *Definition 2085.1, Definition 2085.2, Definition 2085.3, and Definition 2085.4 jointly close the* $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ *obligation surface for the finite rate-readback route over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Proof. Project the accepted carrier through Definition 2085.1. This gives exactly the rows $S, D, R, M, U, E, H, C, P$, with no coordinate outside the displayed finite packet.

The NameCert-obligations theorem Definition 2085.2 accounts for carrier admission, window-readback exactness, threshold extraction exactness, Real-modulus compatibility, Real-seal nonescape, and structural stability. These rows cover the carrier, window, threshold, Real-facing handoff, and Real-seal obligations.

The modulus-readback theorem Definition 2085.3 supplies the consumer factorization. Every modulus or Real-facing read passes through $S, D, R \mapsto M \mapsto U \mapsto E \mapsto H, C, P, N$, so the rate is certificate data rather than host-side convergence data.

The finite-threshold induction theorem Definition 2085.4 covers finite precision-ledger growth. Each displayed request reuses the same threshold route and adds no new carrier coordinate.

Together these blocks exhaust the selected obligation surface. The closure therefore introduces no selected limit, quotient stream equality, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge credential. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRateExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$ packet is generated from StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a CauchyModulus threshold row, a RealCauchyModulus handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateExtraction}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 2085.1, Definition 2085.2, Definition 2085.3, Definition 2085.4, and Definition 2085.5 close the finite rate-readback obligation surface from regular Cauchy rational data through displayed modulus thresholds, Real-facing modulus rows, finite threshold ledgers, and the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy streams, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback exactness, threshold extraction exactness, Real-modulus compatibility, Real-seal nonescape, and structural stability for BEDC.Derived.RegularCauchyRateExtractionUp.

Chapter 2086

A Concrete Naming Certificate for $\mathsf{HausdorffMetric}^{\uparrow}$

Following the Hausdorff–Kuratowski compact-set metric reading, the $\mathsf{HausdorffMetric}^{\uparrow}$ packet records the finite-net route by which two nonempty compact-subset names expose a displayed distance bound without importing an ambient supremum or a choice-selected nearest point. It sits over the compact-metric source of chapter 129, the metric carrier of chapter 57, the finite-net discipline of chapter 127, and the precompact metric surface of chapter 1531. The packet is a NameCert interface for compact-subset distance reads; it is not an open-cover compactness theorem, a host hyperspace construction, a quotient subset equality principle, a supremum principle, or a nearest-point selector.

Definition 2086.1 (Hausdorff metric finite-net carrier)**.** *A* $\mathsf{HausdorffMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, B, M, K, E, D, S, T, C, P, N)$$

with the following displayed rows:

1. *A and B are the two nonempty compact-subset name rows. Each row records the displayed subset identifier, nonempty witness address, compact-subset admission data, and the finite request for which the Hausdorff read is being exposed.*
2. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row consumed by both compact-subset names, including the point-distance reads used by the finite-net comparison.*
3. *K records the two* $\mathsf{CompactMetric}^{\uparrow}$ *rows, one for each compact-subset name, together with the compact-metric admission data needed before a finite net may be inspected.*
4. *E records finite* $\mathsf{ProbeBundle}$ *nets for A and B at a displayed positive* $\mathsf{Rat}^{\uparrow}$ *tolerance, including the mesh budget, net membership rows, and coverage witnesses relative to the compact-metric rows in K.*
5. *D records point-to-set distance witnesses from each displayed net point in the first compact-subset name to the second compact-subset name, and from each displayed net point in the second compact-subset name to the first compact-subset name.*
6. *S records the two symmetric bound rows obtained from D, including the rational slack showing that the two directed finite-net estimates share the same tolerance budget.*

7. *T records componentwise* hsame *transport for the subset names, metric row, compact-metric rows, finite nets, point-to-set witnesses, symmetric bounds, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$A, B, M, K, E \longmapsto D \longmapsto S.$$

9. *P is the* Pkg *provenance over* $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{PrecompactMetric}^{\uparrow}$, ProbeBundle, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, M, K, E, D, S, T, C, P, N$. It has no coordinate for open-cover compactness, host hyperspace membership, quotient subset equality, ambient supremum formation, infimum formation, or a choice-selected nearest point.

Lean4 (definition) `BEDC.Derived.HausdorffMetricUp.HausdorffMetricUp`
Lean4 ✓ `BEDC.Derived.HausdorffMetricUp.HausdorffMetricTasteGate single carrier alignment`

Theorem 2086.2 (HausdorffMetricUp NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMetric}^{\uparrow}$ *carrier*

$$H = (A, B, M, K, E, D, S, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two nonempty compact-subset names, the ambient metric row, the compact-metric rows, the finite-net rows, the point-to-set witness rows, the symmetric bound rows, transport, replay, provenance, and local naming rows;*

2. *compact-subset net exactness, requiring every displayed* ProbeBundle *net in E to be read through the corresponding compact-subset name and compact-metric row before a point-distance request can be inspected;*

3. *symmetric point-distance bound stability, requiring the two directed estimates in D and S to use the same positive* $\mathsf{Rat}^{\uparrow}$ *tolerance budget and to survive componentwise* hsame *transport in T;*

4. *classifier transport, requiring any accepted comparison of packets to preserve the same subset-name rows, metric source, compact-metric witnesses, finite nets, point-to-set witnesses, and symmetric rational bounds;*

5. *ledger exhaustion, requiring C, P, N to replay, source, and name only the displayed finite route and to export no open-cover compactness theorem, host hyperspace object, quotient subset equality, ambient supremum, infimum, or selected nearest point.*

No Hausdorff metric obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.HausdorffMetricUp.HausdorffMetricCarrier namecert obligations`

Theorem 2086.3 (Hausdorff compact-subset distance bound)**.** *Every Metric-facing, CompactMetric-facing, or hyperspace-facing consumer of an accepted* $\mathsf{HausdorffMetric}^{\uparrow}$ *carrier factors through the finite route*

$$A, B, M, K, E \longmapsto D \longmapsto S \longmapsto T, C, P, N.$$

Consequently the consumer receives only the displayed nonempty compact-subset names, the shared metric row, the compact-metric rows, the finite ProbeBundle *nets at a positive* $\mathsf{Rat}^{\uparrow}$ *tolerance,*

the point-to-set distance witnesses, the symmetric finite-net bounds, componentwise transport, replay, provenance, and the local name. It cannot claim an open-cover compactness theorem, host supremum, quotient subset equality, infimum, or choice-selected nearest point from the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMetric}\uparrow}$.

Constructive story: A $\mathsf{HausdorffMetric}^{\uparrow}$ packet is generated from two nonempty compact-subset names, CompactMetricUp rows, a shared MetricUp source, finite ProbeBundle nets at a positive RatUp tolerance, point-to-set distance witnesses, symmetric bound rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMetric}\uparrow}, \mathsf{seed})$

Scope closed: Definition 2086.1, Definition 2086.2, and Definition 2086.3 seed the finite-net Hausdorff distance interface for nonempty compact-subset names without importing compactness, quotient, supremum, infimum, or nearest-point principles.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMetric}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host hyperspaces, quotient subset equality, ambient suprema or infima, selected nearest points, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-subset net exactness, symmetric point-distance bound stability, classifier transport, and ledger exhaustion for BEDC.Derived.HausdorffMetricUp.

Chapter 2087

A Concrete Naming Certificate for $\mathsf{LowerUpperRealCut}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LowerUpperRealCut}^{\uparrow}$ packet records the finite two-sided located cut surface obtained by reading lower observations through chapter 1446, upper observations through chapter 1447, located gap evidence through chapter 404, and the regular-Cauchy comparison boundary through chapter 1745 before the terminal chapter 38 seal is available.

Definition 2087.1 (Lower-upper real cut carrier)**.** *A* $\mathsf{LowerUpperRealCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, G, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *ledger. It records the finite lower observations and their dyadic comparison budgets.*
2. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *ledger. It records the finite upper observations and their dyadic comparison budgets.*
3. *G is the located gap and apartness row. It binds the lower and upper ledgers to the same displayed located-cut request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores the dyadic endpoints, radii, slack, and comparison witnesses used by L, U, G.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It schedules the visible lower-upper reads without selecting an infinite stream representative.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison handoff. It reads the same two-sided windows through the regular-Cauchy comparison boundary.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is reachable only after L, U, G, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the lower ledger, upper ledger, located gap row, dyadic tolerance row, stream window, regular-Cauchy handoff, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for every real-facing read through the same tuple $L, U, G, D, S, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LowerUpperRealCut}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerUpperRealCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, G, D, S, R, E, H, C, P, N$. It has no coordinate for quotient cuts, host suprema, selected cuts, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LowerUpperRealCutUp.LowerUpperRealCutTasteGate single carrier alignment`

Theorem 2087.2 (Lower-upper real cut NameCert obligations)**.** *For an accepted* $\mathsf{LowerUpperRealCut}^{\uparrow}$ *carrier*

$$K = (L, U, G, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LowerUpperRealCut}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier exposure for the lower ledger, upper ledger, located gap row, dyadic tolerance row, stream window, regular-Cauchy handoff, real seal, componentwise transport, replay, provenance, and local naming row;*
2. *lower ledger stability, requiring every lower observation to be read through L, D, S, H, C, P, N and to preserve its displayed dyadic budget under componentwise* hsame *transport;*
3. *upper ledger stability, requiring every upper observation to be read through U, D, S, H, C, P, N and to preserve its displayed dyadic budget under componentwise* hsame *transport;*
4. *located gap exactness, requiring the apartness row G to bind the displayed lower and upper observations to the same finite located-cut request before the regular-Cauchy handoff is consumed;*
5. *ledger non-escape, requiring R and E to remain downstream of L, U, G, D, S and to export no quotient cuts, host suprema, selected cuts, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2087.1. The accepted packet displays exactly the lower ledger, upper ledger, located gap row, dyadic tolerance row, stream window, regular-Cauchy handoff, real seal, and structural rows.

Lower and upper ledger stability are componentwise. The row H transports the visible lower and upper observations, while C replays their dyadic budgets through the same finite window and provenance rows.

Located gap exactness is read from G against L and U. The apartness evidence is a displayed finite row of the packet, so it binds the two one-sided ledgers before a regular-Cauchy comparison can be exported.

Ledger non-escape follows from the row inventory. The handoff R and the seal E sit downstream of L, U, G, D, S, and no coordinate stores a quotient cut, host supremum, selected cut, trichotomy branch, countable-choice selector, or ambient completeness principle. □

Theorem 2087.3 (Lower-upper real cut Cauchy handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{LowerUpperRealCut}^{\uparrow}$ *packet factors through the displayed tuple*

$$L, U, G, D, S, R, E, H, C, P, N$$

and cannot bypass the regular-Cauchy comparison boundary. Thus the two-sided cut surface reaches the terminal real seal only by reading the lower ledger, upper ledger, located gap evidence, dyadic tolerances, finite stream windows, regular-Cauchy handoff, and structural hsame/Cont/Pkg/NameCert *rows.*

Proof. Fix an accepted $\mathsf{LowerUpperRealCut}^{\uparrow}$ carrier. A real-facing consumer first sees the one-sided ledgers L and U together with the dyadic tolerance row D, so every lower or upper observation is a displayed finite read.

The located row G binds those observations to one apartness request. The finite window row S then schedules the same lower-upper evidence without selecting an infinite stream representative.

The comparison handoff is R. Since R is downstream of L, U, G, D, S, a consumer cannot reach the terminal seal before passing through the regular-Cauchy comparison boundary.

The terminal seal E and the rows H, C, P, N only seal, transport, replay, source, and name the displayed route. Because no other carrier coordinate exists, the handoff cannot bypass the boundary or export quotient cuts, host suprema, selected cuts, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerUpperRealCut}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerUpperRealCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2087.1, Definition 2087.2, and Definition 2087.3 seed the finite two-sided located cut surface between one-sided real ledgers and the regular-Cauchy real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerUpperRealCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind construction of $\mathsf{Real}^{\uparrow}$, host supremum, quotient cut equality, selected representative, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier exposure, lower ledger stability, upper ledger stability, located gap exactness, ledger non-escape, and the regular-Cauchy handoff for BEDC.Derived.LowerUpperRealCutUp.

Constructive story: A $\mathsf{LowerUpperRealCut}^{\uparrow}$ packet is generated from LowerReal and UpperReal ledgers, a located gap row, a DyadicRatCore tolerance row, a StreamName finite window, a RegSeqRat comparison handoff, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2088

Located choice sequence NameCert construction

Following Bishop and Bridges, the $\mathsf{LocatedChoiceSequence}^{\uparrow}$ packet records the finite located prefix data by which a choice sequence becomes usable as regular rational evidence. It sits between the prefix surface of chapter 1482, the observation schedule of chapter 126, the finite rate row of chapter 353, and the regular rational handoff of chapter 301. The packet is a bridge of finite means: it names only displayed prefixes, located comparison rows, rate requests, and downstream handoff rows, and it does not identify an infinite host function or a completed real.

Definition 2088.1 (Located choice sequence carrier)**.** *A* $\mathsf{LocatedChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, S, W, A, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier whose visible answers are being read as located data.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule naming the finite prefix positions inspected by the consumer.*
3. *W is the prefix-window ledger listing exactly the displayed observations of Q used by this packet.*
4. *A is the answer ledger over W, carrying the displayed* $\mathsf{Nat}^{\uparrow}$ *or rational-code rows supplied by the choice-sequence prefix.*
5. *D is the located comparison ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, recording the inspected lower/upper or apartness comparisons attached to the answers in A.*
6. *M is the* $\mathsf{RegularityModulus}^{\uparrow}$ *row assigning every requested tolerance to a displayed prefix window before any regular rational readback is consumed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from S, W, A, D, M.*
8. *E is the optional* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational handoff R is displayed.*
9. *H stores componentwise* hsame *transport for the choice prefix, schedule, window, answer ledger, located comparisons, modulus row, handoff, seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from a precision request through the finite prefix window, the located comparison ledger, the regularity modulus row, and the regular rational handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedChoiceSequence}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegularityModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedChoiceSequence}^{\uparrow}}$ *row.*

The regularity modulus row is displayed as the finite dependency route

$$\begin{aligned} \textit{precision request} &\longmapsto (S, W) \\ &\longmapsto (A, D) \\ &\longmapsto M \\ &\longmapsto R. \end{aligned}$$

Thus a consumer obtains a regular rational readback only after the finite prefix observations and located comparison rows have supplied the requested modulus witness.

Lean4 ✓ `BEDC.Derived.LocatedChoiceSequenceUp.LocatedChoiceSequenceTasteGate single carrier alignment`

Theorem 2088.2 (Located choice sequence modulus stability)**.** *Let*

$$L = (Q, S, W, A, D, M, R, E, H, C, P, N)$$

be an accepted $\mathsf{LocatedChoiceSequence}^{\uparrow}$ *carrier. If a precision request is transported through the displayed* hsame *row H and replayed through the continuation row C, then the same finite prefix window W, answer ledger A, located comparison ledger D, and regularity modulus row M repack as an accepted* $\mathsf{LocatedChoiceSequence}^{\uparrow}$ *carrier for the transported request. No transported read can inspect a prefix position outside W.*

Proof. Project the carrier of Definition 2088.1. The schedule S, window W, answer ledger A, comparison ledger D, and modulus row M are all displayed coordinates of one finite history.

Transport the precision request and the displayed rows through H. The continuation row C records the replay route from the request to the same finite prefix observations and then to the same regularity modulus row, so the transported read does not need a new tail value.

Repack the transported rows with the existing provenance P and local name N. Since the carrier has no coordinate for a completed host function or hidden tail oracle, the resulting carrier can expose only the prefix positions already listed in W. □

Theorem 2088.3 (Located choice sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedChoiceSequence}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the finite located comparison ledger, and the* $\mathsf{RegularityModulus}^{\uparrow}$ *row before it can read the handoff row R. The regular rational handoff receives exactly the finite route*

$$\mathsf{ChoiceSequence}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegularityModulus}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}$$

and no quotient stream equality, countable-choice selector, or completed real-name equality.

Proof. Start with a $\mathsf{RegSeqRat}^{\uparrow}$ read of L. The carrier first exposes the choice-sequence prefix Q and the stream schedule S; without these rows there is no named finite position at which a prefix answer can be inspected.

The answer ledger A is read only over the finite window W. The located comparison ledger D then records the dyadic comparison data attached to those answers, and the regularity modulus row M assigns the precision request to that displayed window.

Only after these rows are present can the handoff row R be consumed. The listed route is therefore forced by projection of the carrier, and none of the excluded objects appears as a coordinate that could be passed to the $\mathsf{RegSeqRat}^{\uparrow}$ consumer. □

Theorem 2088.4 (Located choice sequence NameCert obligation surface)**.** *The seed* $\mathsf{NameCert}_{\mathsf{LocatedChoiceSequence}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for Definition 2088.1, modulus stability of Definition 2088.2, RegSeqRat handoff of Definition 2088.3, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* N*. The surface records how finite choice-sequence prefix information becomes located regularity data consumable by* $\mathsf{RegSeqRat}^{\uparrow}$ *while exporting no completed host function, countable-choice selector, quotient stream equality,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, open-cover compactness principle, or standard bridge.*

Proof. Carrier admission is the twelve-coordinate packet of Definition 2088.1. It lists the choice prefix, stream schedule, prefix window, answer ledger, located comparison ledger, modulus row, regular rational handoff, optional real seal, and structural rows.

Modulus stability is supplied by Definition 2088.2. It shows that transported precision requests reuse the same displayed prefix window and regularity modulus row rather than reading an undisplayed tail.

The RegSeqRat handoff is supplied by Definition 2088.3. It forces every regular rational consumer through the choice prefix, stream schedule, located comparison data, and regularity modulus before the handoff row is available.

The remaining obligations are componentwise. The rows H, C, P, N transport, replay, source, and name exactly the same displayed coordinates, so there is no additional obligation outside the packet. The excluded host functions, selectors, quotient equalities, completeness principles, compactness principles, and bridge rows are absent from the carrier and therefore absent from the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedChoiceSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedChoiceSequence}^{\uparrow}$ packet is generated from a displayed ChoiceSequence prefix, StreamName schedule, finite answer ledger, DyadicRatCore located comparison rows, a RegularityModulus row, RegSeqRat handoff data, optional RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedChoiceSequence}^{\uparrow}}$, seed)

Scope closed: Definition 2088.1, Definition 2088.2, Definition 2088.3, and Definition 2088.4 seed the finite located choice-sequence route from displayed prefixes through regularity modulus rows into RegSeqRat handoff data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedChoiceSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not close completed host functions, countable-choice selectors, quotient stream equality, $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus stability, RegSeqRat handoff, transport, replay, provenance, local naming, and non-escape for the finite located choice-sequence packet.

Chapter 2089

A Concrete Naming Certificate for $\mathsf{DyadicLocatedCut}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicLocatedCut}^{\uparrow}$ packet records the finite dyadic endpoint surface by which located cut data can be read as regular-Cauchy evidence before the terminal real-name seal is consumed. It refines the located-cut route of chapter 404 through the dyadic endpoint ledger of chapter 291, the finite-window discipline of chapter 126, the regular rational handoff of chapter 301, and the terminal chapter 38 seal. It also sits beside the two-sided real cut surface of chapter 2087, with the dyadic endpoint rows made explicit rather than absorbed into general lower and upper ledgers.

Definition 2089.1 (DyadicLocatedCut carrier)**.** *A* $\mathsf{DyadicLocatedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, G, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower dyadic endpoint ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$*. It records lower endpoints, requested radii, comparison cells, and endpoint reuse provenance.*
2. *U is the upper dyadic endpoint ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$*. It records upper endpoints, requested radii, comparison cells, and endpoint reuse provenance.*
3. *G is the located gap evidence through* $\mathsf{LocatedCut}^{\uparrow}$*. It binds each displayed lower endpoint and upper endpoint to the same located-cut request.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite precision window. It lists exactly the endpoint reads opened by the requested precision and does not select an infinite representative.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff. It reads the endpoint-normalized windows as regular rational data before any real seal is available.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It can be reached only after L, U, G, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the lower endpoint ledger, upper endpoint ledger, located gap row, finite window, regular-Cauchy handoff, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for every consumer read through the same ordered tuple $L, U, G, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicLocatedCut}^{\uparrow}$*,* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{LowerUpperRealCut}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicLocatedCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, G, W, R, E, H, C, P, N$. It has no coordinate for quotient cuts, selected suprema, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicLocatedCutUp.TasteGate.DyadicLocatedCutTasteGate single carrier alignment`

Theorem 2089.2 (DyadicLocatedCut NameCert obligations)**.** *For an accepted* $\mathsf{DyadicLocatedCut}^{\uparrow}$ *carrier*

$$K = (L, U, G, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicLocatedCut}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower dyadic endpoint ledger, upper dyadic endpoint ledger, located gap row, finite precision window, regular-Cauchy handoff, terminal real seal, transport, replay, provenance, and local naming row;*
2. *lower dyadic transport, requiring every lower endpoint read to enter through L and to preserve its* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison budget under componentwise* hsame *transport;*
3. *upper dyadic transport, requiring every upper endpoint read to enter through U and to preserve its* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison budget under componentwise* hsame *transport;*
4. *located-gap exactness, requiring G to bind the displayed lower and upper endpoint rows to one* $\mathsf{LocatedCut}^{\uparrow}$ *request before W or R is consumed;*
5. *regular-Cauchy handoff, requiring R to read only the displayed L, U, G, W route before exposing any* $\mathsf{Real}^{\uparrow}$*-facing datum;*
6. *Real seal non-escape, requiring the terminal row E to remain downstream of L, U, G, W, R and to export no quotient cut, selected supremum, trichotomy branch, countable-choice selector, or ambient completeness principle;*
7. *ledger provenance, requiring P and N to name only the displayed dyadic endpoint route and its transport and replay rows.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DyadicLocatedCutUp.DyadicLocatedCutCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 2089.1. The accepted packet displays the lower endpoint ledger, upper endpoint ledger, located gap row, precision window, regular-Cauchy handoff, real seal, and structural rows H, C, P, N.

Lower and upper dyadic transport are componentwise. The rows L and U store the endpoint comparisons over $\mathsf{DyadicRatCore}^{\uparrow}$, while H transports those endpoint cells and C replays the same displayed reads.

Located-gap exactness is the role of G. Since G is a coordinate of the same packet as L and U, the lower and upper endpoint rows are bound to one located-cut request before a window or regular-Cauchy handoff can be consumed.

The handoff row R is downstream of L, U, G, W. Thus every regular rational read is endpoint-normalized by the displayed ledgers and finite precision window before the terminal real seal is visible.

The terminal row E and the provenance rows P, N add no analytic coordinate. Because the carrier has no row for quotient cuts, selected suprema, trichotomy, countable choice, or ambient completeness, the local NameCert surface cannot export any such object. □

Theorem 2089.3 (DyadicLocatedCut regular Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicLocatedCut}^{\uparrow}$ *packet factors through the displayed dyadic endpoint ledgers and located-gap row before reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Concretely, every such consumer reads the route*

$$L, U, G, W, R, E, H, C, P, N$$

with L and U supplying dyadic endpoint-normalized lower and upper evidence, G supplying the located cut gap, W supplying the finite precision window, R supplying the regular-Cauchy handoff, and E supplying the terminal seal.

Proof. Fix an accepted $\mathsf{DyadicLocatedCut}^{\uparrow}$ carrier. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer first sees only the displayed endpoint rows L and U together with the located gap row G, so its input is already normalized by dyadic lower and upper endpoint ledgers.

The finite precision window W is downstream of those rows. It schedules the visible endpoint reads without choosing an infinite stream representative or introducing a host cut object.

The regular-Cauchy handoff is R. Since R is read after L, U, G, W, every regular rational consumer factors through the dyadic endpoint ledgers and the located-gap row.

A $\mathsf{Real}^{\uparrow}$ consumer must pass through E, and E is downstream of R. The remaining rows H, C, P, N only transport, replay, source, and name the same route, so no consumer can bypass the displayed endpoint and located-gap data before reading the terminal seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicLocatedCut}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicLocatedCut}^{\uparrow}}, \mathsf{seed})$

Constructive story: A $\mathsf{DyadicLocatedCut}^{\uparrow}$ packet is generated from lower and upper dyadic endpoint ledgers, located gap evidence, a StreamName finite precision window, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Scope closed: Definition 2089.1, Definition 2089.2, and Definition 2089.3 seed the finite dyadic endpoint route from located cut data to regular-Cauchy readback and the terminal real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicLocatedCut}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DyadicLocatedCutUp`

Bridge status: none

Not claimed: This chapter does not close quotient cuts, selected suprema, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, lower and upper dyadic transport, located-gap exactness, regular-Cauchy handoff, Real seal non-escape, and ledger provenance for BEDC.Derived.DyadicLocatedCutUp.

Chapter 2090

A Concrete Naming Certificate for $\mathsf{BishopCauchyLimitCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyLimitCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed rational Cauchy name reaches the real-name seal after its modulus data, regular readback, dyadic tolerance rows, and fast-convergent handoff have all been exposed. It sits after the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the choice-free modulus surface of chapter 2040, the fast real-sequence handoff of chapter 2077, and the terminal real-name seal of chapter 38. The packet is a Bishop-style Cauchy-to-real handoff criterion; it is not a selected limit, quotient equality of Cauchy streams, countable choice, host real completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2090.1 (Bishop Cauchy limit criterion carrier)**.** *A* $\mathsf{BishopCauchyLimitCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, M, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, carrying the finite observation windows and precision requests opened by the Cauchy read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording endpoint observations, requested radii, split tolerances, slack cells, and comparison budgets for the readback.*
4. *M is the Cauchy-modulus row read through* $\mathsf{CauchyModulusChoice}^{\uparrow}$*; it may be either the displayed selected modulus row or its selected normal-form representative, but in both cases the selected threshold is available only through the finite route named by chapter 2040.*
5. *F is the* $\mathsf{FastConvergentRealSequence}^{\uparrow}$ *handoff row that packages the same windows, readbacks, dyadic tolerances, and modulus threshold as a rate-bearing real-sequence route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after S, R, D, M, F have been displayed.*
7. *H records componentwise* hsame *transport for the window, readback, tolerance, modulus, fast-sequence handoff, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S \longmapsto R \longmapsto D \longmapsto M \longmapsto F \longmapsto E.$$

9. *P is the* Pkg *provenance over* BishopCauchyLimitCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyModulusChoice$^{\uparrow}$, FastConvergentRealSequence$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopCauchyLimitCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, M, F, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected real limit, countable choice, host real completeness, detached convergence, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BishopCauchyLimitCriterionUp.BishopCauchyLimitCriterionTasteGate single carrier alignment`

Theorem 2090.2 (Bishop Cauchy limit criterion NameCert obligations)**.** *For every accepted* BishopCauchyLimitCriterion$^{\uparrow}$ *carrier*

$$K = (S, R, D, M, F, E, H, C, P, N),$$

the local NameCert$_{\text{BishopCauchyLimitCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchyModulusChoice row, FastConvergentRealSequence handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *window-readback exactness, requiring R to read only the finite windows displayed by S;*
3. *tolerance exactness, requiring D to display the requested radii, split tolerances, endpoint observations, slack cells, and comparison budgets before any modulus or fast-sequence consumer reads the route;*
4. *modulus-selection nonescape, requiring M to be read through the* CauchyModulusChoice$^{\uparrow}$ *route rather than through countable choice or an external selector;*
5. *fast-sequence compatibility, requiring F to bind the same S, R, D, M rows before the terminal real-name seal is available;*
6. *Real seal nonescape, requiring E to be downstream of S, R, D, M, F and to export no quotient stream, selected limit, detached convergence theorem, host real completeness, or ambient* Real$^{\uparrow}$ *completeness;*
7. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the displayed route.*

No Bishop Cauchy limit criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2090.1. The accepted packet displays exactly the window row, regular readback, dyadic tolerance ledger, modulus-choice row, fast-sequence handoff, real seal, and the structural rows.

Window-readback exactness is read from S and R. The regular rational readback is attached to the displayed finite windows, so no quotient stream representative is introduced.

Tolerance exactness is the role of D. Its dyadic radii, slack cells, endpoint observations, and comparison budgets are displayed before the modulus row or the fast-sequence handoff may be consumed.

The modulus-selection condition is local to M. Since M is read through the CauchyModulusChoice$^{\uparrow}$ route, the selected threshold is a named finite row rather than an external choice function.

The fast-sequence handoff is then F. It binds the same windows, readback, dyadic tolerance ledger, and modulus threshold before the terminal Real$^{\uparrow}$ seal can be reached.

Finally, H, C, P, N add only transport, replay, provenance, and local naming. The carrier has no coordinate for quotient stream equality, selected limits, countable choice, detached convergence, host real completeness, or ambient completeness, so the listed rows exhaust the local NameCert surface. □

Theorem 2090.3 (Bishop Cauchy limit criterion modulus seal)**.** *Every accepted* $\mathsf{BishopCauchyLimitCriterion}^{\uparrow}$ *carrier*

$$K = (S, R, D, M, F, E, H, C, P, N)$$

reads its Cauchy threshold through the displayed $\mathsf{CauchyModulusChoice}^{\uparrow}$ *row* M *before any* $\mathsf{FastConvergentRealSequen}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the route. Thus the criterion exposes a choice-free modulus seal*

$$S, R, D \longmapsto M \longmapsto F, E$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data.*

Proof. Start with an accepted carrier and project its rows. The Cauchy threshold row is M, while the observations and tolerances consumed by that threshold are S, R, D.

By Definition 2090.2, M is read only through the $\mathsf{CauchyModulusChoice}^{\uparrow}$ route. Therefore the threshold exposed to downstream consumers is not obtained from countable choice or from a hidden selector.

The fast-sequence handoff F is downstream of the same modulus row. A $\mathsf{FastConvergentRealSequence}^{\uparrow}$ consumer reads the rate-bearing route only after the windows, readback, tolerance ledger, and selected threshold have been displayed.

The real seal E is still later in the route. Structural transport, replay, provenance, and local naming preserve the same displayed rows, so the modulus seal remains choice-free at every consumer boundary. □

Theorem 2090.4 (Bishop Cauchy limit criterion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopCauchyLimitCriterion}^{\uparrow}$ *packet factors through the finite route*

$$S \longmapsto R \longmapsto D \longmapsto M \longmapsto F \longmapsto E \longmapsto H, C, P, N.$$

The Real handoff is therefore a displayed path from StreamName windows through RegSeqRat readback, DyadicRatCore tolerances, the CauchyModulusChoice threshold, the FastConvergentRealSequence route, and the terminal Real seal. It exports no selected limit, quotient equality of Cauchy streams, countable choice, detached convergence, host real completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ or completion-facing read of an accepted packet. Projection exposes the ordered carrier rows $S, R, D, M, F, E, H, C, P, N$.

The readback row R is downstream of the finite windows S, and the dyadic tolerance row D is downstream of the same readback. Thus the consumer cannot start from an unbounded stream representative or a quotient equality class.

The modulus seal theorem places M before both the fast-sequence handoff and the terminal real seal. Hence the Cauchy-to-real route receives a displayed threshold before it can reach F or E.

The terminal row E is the only $\mathsf{Real}^{\uparrow}$ seal coordinate in the packet. The structural rows preserve and name the same finite route, and the excluded principles are absent from the carrier. Therefore every Real or Completion consumer factors through the displayed handoff and receives none of the listed escape objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyLimitCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyLimitCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2090.1, Definition 2090.2, Definition 2090.3, and Definition 2090.4 seed the choice-free Cauchy-to-Real route through StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, CauchyModulusChoice threshold data, FastConvergentRealSequence handoff, Real seal, transport, continuation, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyLimitCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy streams, countable choice, detached convergence, host real completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback exactness, tolerance exactness, modulus-selection nonescape, fast-sequence compatibility, Real seal nonescape, and structural stability for BEDC.Derived.BishopCauchyLi

Constructive story: A $\mathsf{BishopCauchyLimitCriterion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a CauchyModulusChoice threshold row, a FastConvergentRealSequence handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2091

A Concrete Naming Certificate for $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name is read unchanged through a displayed monotone cofinal reindexing and a finite tail shift before any completion-facing consumer reaches the real-name seal. It sits after the cofinal route surface of chapter 1568, the tail-invariance route of chapter 1578, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet makes reindex invariance visible as BEDC NameCert data rather than as quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2091.1 (Regular-Cauchy reindex-invariance carrier)**.** *A* $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, I, T, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose regular rational Cauchy readback supplies the inspected values and regularity budget.*
2. *I is the accepted* $\mathsf{CauchyReindexing}^{\uparrow}$ *route. It displays a monotone cofinal index map and the finite evidence that every target request is sent to a source request still visible to the source row.*
3. *T is the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *tail route. It records the finite prefix shift needed to align the cofinal route with the retained regular Cauchy windows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger opened for the source row, the reindexed route, the shifted tail route, and the seal-facing request.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the source row, reindexed windows, tail-shift windows, regular rational readback, and terminal seal.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after Q, I, T, S, D have been displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the reindex route, tail route, windows, dyadic ledger, and regular rational readback have been consumed.*

8. *H records componentwise* hsame *transport for the source row, reindex route, tail route, stream windows, dyadic tolerance ledger, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a completion-facing request through*

$$Q, I, T, S, D, R \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexInvariance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, I, T, S, D, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReindexInvarianceUp.RegularCauchyReindexInvarianceTasteGate`
`single carrier alignment`

Theorem 2091.2 (Regular-Cauchy reindex-invariance NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$ *carrier*

$$J = (Q, I, T, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexInvariance}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the source regular Cauchy row, cofinal reindex route, tail-shift route, stream-window ledger, dyadic tolerance ledger, regular rational readback, real seal, componentwise transport, continuation replay, provenance, and local naming rows;*

2. *monotone-cofinal route preservation, requiring every seal-facing request to pass through the displayed* $\mathsf{CauchyReindexing}^{\uparrow}$ *row I before any source observation is inspected;*

3. *tail-shift compatibility, requiring the reindexed request to pass through the displayed* $\mathsf{RegularCauchyShift}^{\uparrow}$ *row T when a finite prefix is discarded;*

4. *dyadic tolerance preservation, requiring D to be the same tolerance ledger consumed by Q, I, T, S, R and the seal row E;*

5. $\mathsf{Real}^{\uparrow}$ *seal handoff, requiring the seal row E to be downstream of I, T, S, D, R and never directly exposed from the source row alone;*

6. *ledger nonescape, requiring H, C, P, N to transport, replay, source, and name only the displayed finite route.*

No NameCert obligation is stored outside these rows, and none exports quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Carrier admission is projection from Definition 2091.1. The visible analytic rows are exactly the source regular Cauchy row Q, cofinal reindex route I, tail-shift route T, stream windows S, dyadic ledger D, readback R, and real seal E.

Monotone-cofinal route preservation is read from I. A seal-facing request cannot inspect a source observation until the displayed reindex route supplies the monotone cofinal source index and its finite admission evidence.

Tail-shift compatibility is read from T. If the cofinal route discards a finite prefix, the packet uses the already displayed $\mathsf{RegularCauchyShift}^{\uparrow}$ row rather than an external tail selector.

Tolerance preservation is the projection to D. The source row, reindex route, tail route, stream windows, readback, and real seal all consume that same dyadic ledger, so no detached modulus can alter the reindexed read.

The seal handoff is the projection to E together with the replay row C. Since E appears only downstream of I, T, S, D, R, every real-facing read follows the displayed route before it reaches the terminal seal.

Finally H, C, P, N are structural rows. They preserve, replay, source, and name only the admitted packet, leaving no coordinate from which quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, or bridge data could be read. □

Theorem 2091.3 (Regular-Cauchy reindex-invariance Real seal handoff)**.** *Let*

$$J = (Q, I, T, S, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *read and every completion-facing read from J factors first through the* $\mathsf{CauchyReindexing}^{\uparrow}$ *row I and the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *row T before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and the* $\mathsf{Real}^{\uparrow}$ *seal row E are consumed. Consequently the packet exposes reindex invariance only as the displayed route*

$$Q, I, T, S, D, R \longmapsto E, H, C, P, N$$

and exports no quotient stream, selected limit, countable choice principle, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer request. The carrier exposes the seal row E only downstream of the reindex, tail, window, tolerance, and readback rows, so the consumer must first read I and T before any seal-facing route is available.

The reindex step is finite data. The row I displays the monotone cofinal source request used for the consumer's target request, and the row S records the finite windows in which that request is observed.

The tail step is likewise finite. The row T supplies the $\mathsf{RegularCauchyShift}^{\uparrow}$ route that accounts for the discarded prefix before the readback row R is consumed.

The dyadic and readback rows then determine the seal-facing observation. The ledger D is shared by the source, reindex, tail, window, readback, and seal rows, while R is the only $\mathsf{RegSeqRat}^{\uparrow}$ handoff row available to the consumer.

The structural rows close the route. Transport, replay, provenance, and local naming preserve only Q, I, T, S, D, R, E, so the consumer has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexInvariance}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyReindexInvariance}^{\uparrow}$ packet is generated from a RegSeqRat source row, a CauchyReindexing monotone cofinal route, a RegularCauchyShift tail route, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReindexInvariance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2091.1, Definition 2091.2, and Definition 2091.3 seed the finite route by which regular Cauchy rational names are read through displayed monotone cofinal reindexing and finite tail shifts before RegSeqRat readback and RealUp sealing.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyReindexInvariance}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-cofinal route preservation, tail-shift compatibility, dyadic tolerance preservation, Real-seal handoff, and ledger nonescape for BEDC.Derived.RegularCauchyReindexInvarianceUp.

Chapter 2092

A Concrete Naming Certificate for $\mathsf{KonigLemma}^{\uparrow}$

Following Koenig's lemma for finitely branching trees, Brouwer's spread reading of prefix trees, and Bishop–Bridges finite evidence, $\mathsf{KonigLemma}^{\uparrow}$ records the L10 finite-prefix boundary where tree and branch arguments may be inspected without choosing an infinite branch. The packet sits after the Boolean prefix surface of chapter 1475, the finite fan boundary of chapter 400, and the barred-spread replay of chapter 1675. It exposes finite frontiers, candidate prefixes, Cantor-space prefix reads, fan/bar handoffs, transport, replay, provenance, and local naming; it does not export weak Koenig principles as global rules, open-cover compactness, quotient streams, selected infinite paths, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2092.1 (KoenigLemma carrier)**.** *A* $\mathsf{KonigLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, F, W, Q, S, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the finitely branching prefix-tree row. It records the displayed root, finite successor lists, prefix closure checks, and extension rows, with each local branching list read through* $\mathsf{List}^{\uparrow}$ *and each edge decision read through* $\mathsf{Bool}^{\uparrow}$*.*
2. *F is the finite frontier ledger. It lists the currently inspected frontier prefixes, the finite window cut through T, and the local evidence that each retained node either extends inside the window or is recorded as a boundary node for the current request.*
3. *W is the branch-candidate prefix row. It stores a finite compatible chain of prefixes read from T and F, not a completed path and not a choice-selected branch.*
4. *Q is the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix-reading row. It reads every Boolean branch decision through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{Bool}^{\uparrow}$ *observations, and* $\mathsf{List}^{\uparrow}$ *prefix spines.*
5. *S is the* $\mathsf{FanTheorem}^{\uparrow}$ *and* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *boundary row. It records the finite fan/bar route used when a consumer asks whether the displayed frontier blocks the inspected candidate prefix.*
6. *A is the local classifier row. It compares accepted packets by the displayed tree, frontier, window, candidate-prefix, Cantor-prefix, and fan/bar rows, with no coordinate for quotient path equality or host function extensionality.*

7. *H records componentwise* hsame *transport for the tree, frontier, window, candidate-prefix, Cantor-prefix, fan/bar, classifier, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite tree request through prefix restriction, successor inspection, frontier lookup, candidate-prefix readback, Cantor-space prefix reading, fan/bar boundary use, classifier transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{KonigLemma}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KonigLemma}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these finite rows. It has no coordinate for a selected infinite branch, quotient path space, host function equality, open-cover compactness, weak Koenig principles as ambient rules, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KonigLemmaUp.KonigLemmaTasteGate single carrier alignment`

Theorem 2092.2 (KoenigLemma NameCert obligations)**.** *For every accepted* $\mathsf{KonigLemma}^{\uparrow}$ *carrier*

$$K = (T, F, W, Q, S, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KonigLemma}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the finitely branching prefix-tree row, finite frontier ledger, branch-candidate prefix row, Cantor-space prefix-reading row, fan/bar boundary row, classifier row, transport row, replay row, provenance row, and local naming row;*
2. *classifier transport through the componentwise rows listed in Definition 2092.1;*
3. *prefix-extension stability, requiring every shorter candidate prefix and every displayed one-step extension to reuse the matching rows already present in T, F, W, Q;*
4. *branch-frontier replay, requiring every consumer route that asks for a branch obstruction or branch continuation to pass through the finite frontier ledger and the S fan/bar boundary row;*
5. *non-escape, excluding selected infinite branches, weak Koenig principles as global rules, quotient path spaces, host function equality, open-cover compactness, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside the displayed packet.

Proof. Carrier admission is projection from Definition 2092.1. The accepted packet exposes only the tree, frontier, candidate-prefix, Cantor-prefix, fan/bar, classifier, transport, replay, provenance, and naming rows.

Classifier transport is componentwise. Two accepted packets compare through the displayed prefix-tree and frontier rows first, then through the candidate-prefix row, Cantor-space prefix reads, and fan/bar boundary row. The structural rows H, C, P, N transport and name that same finite comparison.

Prefix-extension stability is inherited from the retained prefix tree. A shorter prefix is a subrow already visible in T and W, while a displayed one-step extension is one of the finite successor rows listed in T and checked against F.

Branch-frontier replay is finite. A consumer asking whether the current window blocks or extends a candidate prefix must read the frontier ledger F and then the fan/bar boundary row S; the route supplies only displayed prefix and boundary evidence.

Coordinate exhaustion gives non-escape. Since the carrier has no slot for a completed path, quotient path equality, host function extensionality, open-cover compactness, weak Koenig rules

as ambient principles, or $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported by the local certificate. □

Theorem 2092.3 (KoenigLemma Cantor–fan boundary)**.** *Every consumer route from an accepted* $\mathsf{KonigLemma}^{\uparrow}$ *carrier factors through*

$$\mathsf{CantorSpace}^{\uparrow},\ \mathsf{FanTheorem}^{\uparrow},\ \mathsf{BrouwerBarInduction}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Bool}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameC}$$

The route may inspect finite tree prefixes, frontier windows, candidate-prefix rows, Cantor-space Boolean prefix reads, and fan/bar boundary rows. It exports no choice-selected infinite branch, quotient path space, host function equality, open-cover compactness, weak Koenig principle as a global rule, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project a consumer route from the accepted carrier of Definition 2092.1. The first visible tree data are finite prefix rows in T and finite frontier rows in F.

The candidate-prefix read is then W. Its Boolean decisions are not host functions; they are read through the $\mathsf{CantorSpace}^{\uparrow}$ row Q, which itself routes through $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{Bool}^{\uparrow}$ observations, $\mathsf{List}^{\uparrow}$ spines, and the surrounding BHist packet.

When the consumer asks whether the current frontier blocks or extends the candidate prefix, the route enters S. That row is exactly the finite $\mathsf{FanTheorem}^{\uparrow}$ and $\mathsf{BrouwerBarInduction}^{\uparrow}$ boundary over the displayed prefix window.

Finally H, C, P, N close the route by hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming. No coordinate remains for a selected infinite branch, quotient path space, host function equality, open-cover compactness, a global weak Koenig rule, or $\mathsf{Real}^{\uparrow}$ completeness, so the stated factorization is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{KonigLemma}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KonigLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2092.1, Definition 2092.2, and Definition 2092.3 seed the finite-prefix tree boundary over Cantor-space prefix reads and fan/bar rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KonigLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected branches, weak Koenig principles as global rules, open-cover compactness, quotient streams, quotient path spaces, host function equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, prefix-extension stability, branch-frontier replay, Cantor-space prefix reading, fan/bar boundary routing, and non-escape for BEDC.Derived.KonigLemmaUp.

Constructive story: A $\mathsf{KonigLemma}^{\uparrow}$ packet is generated from a finitely branching prefix-tree row, a finite frontier ledger, a branch-candidate prefix row, a CantorSpace prefix-reading row, a FanTheorem and BrouwerBarInduction boundary row, classifier transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2093

A Concrete Naming Certificate for $\mathsf{CauchyMetastability}^{\uparrow}$

Following Tao's finite convergence principle and the proof-mining account of metastability, the $\mathsf{CauchyMetastability}^{\uparrow}$ packet records the finite tail-window answer to a Cauchy pressure request before any completed real object is selected. It sits over the stream-window surface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the finite modulus discipline of chapter 332. The chapter gives the Real and Completion route a human-standard metastable interface: a displayed control function asks for a finite tail window, and the answer remains finite BEDC data all the way to the $\mathsf{Real}^{\uparrow}$ seal.

Definition 2093.1 (Cauchy metastability carrier)**.** *A* $\mathsf{CauchyMetastability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (p, g, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *p is the precision request. It names the dyadic tolerance that the packet must answer.*
2. *g is the control-function row. It is read only through the finite requests displayed in the packet, not as a countable choice object.*
3. *W is the finite tail-window row. It displays a bound n and the finite interval of indices inspected between n and $g(n)$.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the precision request, the tail-window comparisons, the rational readback, and the terminal real seal.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It supplies the rational values actually compared inside the window named by W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after p, g, W, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the precision request, control row, tail window, tolerance ledger, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay along the finite route*

$$p, g, W, D, Q \longmapsto E, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyMetastability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMetastability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $p, g, W, D, Q, E, H, C, P, N$. It has no coordinate for countable choice, quotient stream equality, a selected limit, host real equality, trichotomy, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyMetastabilityUp.CauchyMetastabilityTasteGate single carrier alignment`

Theorem 2093.2 (Cauchy metastability NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMetastability}^{\uparrow}$ *carrier*

$$M = (p, g, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyMetastability}^{\uparrow}}$ *surface consists exactly of nine finite obligation rows:*

1. *carrier admission for the precision request, control row, tail-window row, tolerance ledger, rational readback, real seal, transport, replay, provenance, and local naming rows;*
2. *control-window exactness, requiring W to answer the displayed control row g at the displayed precision request p;*
3. *dyadic tolerance accounting, requiring every comparison inside W to use the single ledger D;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring each compared value in the finite window to be read from Q;*
5. $\mathsf{Real}^{\uparrow}$ *seal boundary, requiring E to be downstream of p, g, W, D, Q and not an independent completion coordinate;*
6. hsame *transport, requiring accepted comparisons to preserve $p, g, W, D, Q, E, C, P, N$ componentwise;*
7. Cont *replay, requiring every endpoint-facing read to replay the displayed finite route;*
8. Pkg *provenance, requiring the packet to cite only the listed source chapters and kernel objects;*
9. *local naming, requiring N to name precisely the finite metastability packet and no hidden limit data.*

No NameCert obligation is stored outside these rows, and none exports countable choice, quotient stream equality, a selected limit, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2093.1. The accepted packet exposes exactly $p, g, W, D, Q, E, H, C, P, N$, so the local certificate has no detached coordinate for a completed limit or infinite selector.

Control-window exactness is read from g and W. The control row may ask for a tail interval, but the carrier answers it only by the displayed finite window row and the indices named there.

The tolerance and readback obligations are then projections to D and Q. The dyadic ledger is the only tolerance account available to the packet, and the regular rational readback supplies the only values compared inside the named window.

The endpoint boundary is supplied by E together with H, C, P, N. Transport, replay, provenance, and local naming preserve the displayed route from request to window to readback to seal, and they introduce no row from which the excluded principles can be read. □

Theorem 2093.3 (Cauchy metastability finite-tail stability)**.** *Let*

$$M = (p, g, W, D, Q, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyMetastability}^{\uparrow}$ *carrier. Every accepted finite control-window request is answered inside the tail window displayed by* W*: the precision request* p *and control row* g *determine the window, the dyadic ledger* D *accounts for the requested tolerance, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *supplies every compared rational value before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is read. Consequently the packet witnesses finite Cauchy tail stability without countable choice, quotient stream equality, a selected limit, host real equality, trichotomy, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier. The only rows available before the endpoint seal are the precision request p, control row g, tail-window row W, dyadic ledger D, and rational readback Q.

An accepted control-window request is therefore handled inside W. The row g determines which finite interval must be inspected, and W displays the bound and window that answer that request.

The stability comparison is finite. The ledger D records the dyadic tolerance used by every comparison in the window, while Q supplies the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ rational values.

Finally E, H, C, P, N close the endpoint route. Since they only seal, transport, replay, source, and name the displayed finite data, no countable choice principle, quotient stream equality, selected limit, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate can enter the certificate. □

Theorem 2093.4 (Cauchy metastability filter consumer route)**.** *Any* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer reading an accepted* $\mathsf{CauchyMetastability}^{\uparrow}$ *packet receives only the precision request, displayed control-function row, finite tail-window answer,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The route exports no quotient stream equality, selected limit, quotient filter, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted metastability carrier through Definition 2093.1. The only rows available are $p, g, W, D, Q, E, H, C, P, N$, namely the request, control row, finite tail window, tolerance ledger, rational readback, endpoint seal, transport, replay, provenance, and local name.

Now route the filter consumer through the CauchyFilter modulus boundary of chapter 333. A filter-facing read may use the finite tail-window answer as Cauchy control data only after the dyadic ledger and RegSeqRat readback rows have been displayed.

The structural rows do not add a second source. The hsame transport, Cont replay, Pkg provenance, and local NameCert row preserve the same finite packet, so no quotient stream equality, selected limit, quotient filter, host equality, choice principle, or ambient completeness coordinate can enter the consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMetastability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyMetastability}^{\uparrow}$ packet is generated from a precision request, a displayed control-function row, a finite tail-window answer, a DyadicRatCore tolerance ledger, RegSeqRat rational readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyMetastability}^{\uparrow}}$, seed)

Scope closed: Definition 2093.1, Definition 2093.2, and Definition 2093.3 seed the finite metastable Cauchy tail-stability route for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyMetastability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient stream equality, selected limits, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, control-window exactness, dyadic tolerance accounting, RegSeqRat handoff, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyMetastabilityUp.

Chapter 2094

A Concrete Naming Certificate for $\mathsf{TanneryTheorem}^{\uparrow}$

Following Bishop and Bridges and the classical theorem of Tannery, the $\mathsf{TanneryTheorem}^{\uparrow}$ packet records the finite dominated-exchange route for a double-indexed real row whose pointwise limit row may be summed after a displayed majorant has supplied tail control. It sits over the real-valued series surface of $\mathsf{RealSeries}^{\uparrow}$ in chapter 1581, the absolute-convergence route of $\mathsf{AbsoluteConvergence}^{\uparrow}$ in chapter 1700, the majorant discipline of $\mathsf{WeierstrassMTest}^{\uparrow}$ in chapter 399, the rational readback row of $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, the finite window interface of $\mathsf{StreamName}^{\uparrow}$ in chapter 126, the dyadic tolerance ledger of $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 291, and the terminal real-name seal of $\mathsf{Real}^{\uparrow}$ in chapter 38. The packet names a finite constructive dominated exchange; it does not import host infinite sums, quotient stream equality, countable choice, dominated convergence as an ambient theorem, or ambient real completeness.

Definition 2094.1 (Tannery theorem carrier)**.** *A* $\mathsf{TanneryTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, M, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the double-indexed real row. It records the inspected entries $a_{n,k}$ only through finite real-valued windows and the partial-sum surfaces allowed by* $\mathsf{RealSeries}^{\uparrow}$*.*
2. *L is the pointwise limit row. It records the displayed limiting term l_k for each inspected column together with the finite convergence window that compares $a_{n,k}$ to l_k.*
3. *M is the dominating majorant route. It records the absolute majorant row, the summable majorant handoff, and the domination checks that bind A and L to* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *and* $\mathsf{WeierstrassMTest}^{\uparrow}$*.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family. It stores the row windows, column windows, diagonal comparison windows, and finite cutoffs used by the exchange.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same real entries, limit entries, majorant entries, and partial sums named by A, L, M, W.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the requested precision, tail split, finite head budget, domination slack, and endpoint tolerance used by the exchange.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal. It is available only after the displayed finite row sum, limit-row sum, majorant route, readback, and dyadic ledger have been read.*

8. *H stores componentwise* hsame *transport for A, L, M, W, Q, D, E and for the replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the double-indexed row and pointwise limit row through the majorant route, finite windows, rational readback, dyadic ledger, and endpoint seal.*

10. *P is the* Pkg *provenance over* $\mathsf{TanneryTheorem}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TanneryTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L, M, W, Q, D, E, H, C, P, N$. It has no coordinate for a host exchange of limits and sums, a selected infinite row sum, quotient stream equality, countable choice, an ambient dominated convergence theorem, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.TanneryTheoremUp.TanneryTheoremTasteGate single carrier alignment`

Theorem 2094.2 (Tannery theorem NameCert obligations)**.** *For every accepted* $\mathsf{TanneryTheorem}^{\uparrow}$ *carrier*

$$K = (A, L, M, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TanneryTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the double-indexed real row, pointwise limit row, dominating majorant route, finite window family, rational readback, dyadic ledger, real endpoint seal, transport, replay, provenance, and local naming rows;*

2. *pointwise-window exactness, requiring each displayed comparison between $a_{n,k}$ and l_k to pass through A, L, W, Q, D before it can be used in a finite head estimate;*

3. *dominated-row exactness, requiring M to display the absolute majorant row, the summable majorant handoff, and the domination checks for every inspected entry of A and L;*

4. *finite-exchange accounting, requiring W and D to split each requested tolerance into a finite head comparison and a dominated tail comparison;*

5. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring Q to read the same rows and windows before any* Real$^{\uparrow}$ *endpoint seal is exported;*

6. Real$^{\uparrow}$ *seal nonescape, requiring E to remain downstream of A, L, M, W, Q, D and to export no host exchange theorem, selected infinite sum, quotient stream equality, countable choice, ambient dominated convergence theorem, Lean verification, or bridge datum;*

7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Tannery dominated-exchange obligation is stored outside these rows.

Proof. Project the accepted packet $K = (A, L, M, W, Q, D, E, H, C, P, N)$. The carrier exposes exactly the double-indexed row, pointwise limit row, majorant route, window family, readback, ledger, endpoint seal, and structural rows.

The pointwise part is finite at every read. A requested column comparison must pass through the row data A, the limit data L, the finite windows W, the rational readback Q, and the tolerance ledger D before it contributes to the finite head estimate.

The dominated part is also displayed. The row M records the majorant, its summable handoff, and the domination checks; the rows W and D record the cutoff and tolerance split used to separate the finite head from the dominated tail.

Finally Q, E, H, C, P, N read back, seal, transport, replay, source, and name the same route. Since no excluded exchange theorem, selected sum, quotient, choice, verification, or bridge coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.TanneryTheoremUp.TanneryTheoremCarrier namecert obligations`

Theorem 2094.3 (Tannery theorem dominated row handoff)**.** *Let $K = (A, L, M, W, Q, D, E, H, C, P, N)$ be an accepted* $\mathsf{TanneryTheorem}^{\uparrow}$ *carrier. Every dominated row comparison exported by the packet factors through*

$$A, L \longmapsto M \longmapsto W, D \longmapsto Q \longmapsto E, H, C, P, N.$$

Thus the majorant route and dyadic tolerance ledger determine the finite handoff from pointwise row convergence to the endpoint-facing series read, not a host dominated convergence theorem, selected infinite sum, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an endpoint-facing dominated row comparison. The carrier has no direct coordinate for exchanging a limit with an infinite sum, so the comparison first reads the displayed row data A and the pointwise limit data L.

The majorant route is then forced. The row M displays the absolute majorant and summable handoff, while W and D provide the finite window cutoff, tolerance split, head comparison, and tail budget.

The row Q reads back the same data as regular rational observations. Only after this readback can E seal the endpoint-facing real row, and H, C, P, N transport, replay, source, and name the route.

Since the carrier offers no host exchange theorem, selected sum, quotient equality, choice object, or ambient completeness coordinate, every dominated row comparison is exhausted by the displayed factorization. □

Lean4 ✓ `BEDC.Derived.TanneryTheoremUp.TanneryTheoremCarrier dominated row handoff`

Theorem 2094.4 (Tannery theorem real-series exchange boundary)**.** *For every accepted* $\mathsf{TanneryTheorem}^{\uparrow}$ *carrier, any* $\mathsf{RealSeries}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the exchange endpoint must read the double-indexed row, pointwise limit row, dominating majorant route, finite stream windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, endpoint seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row of Definition 2094.1. The exchange boundary exports no host infinite sum, no unrecorded interchange of limit and summation, no quotient stream equality, no countable choice, no ambient dominated convergence theorem, no Lean verification, and no standard bridge.*

Proof. Let a series or real endpoint consumer read the seal row E. By the carrier definition, E is downstream of the row data A, L, the majorant route M, the finite windows W, the readback Q, and the dyadic ledger D.

Apply Definition 2094.2. Pointwise-window exactness binds the finite head comparisons, dominated-row exactness binds the majorant route, and finite-exchange accounting binds the tolerance split before the endpoint seal can be read.

Apply Definition 2094.3. Every dominated comparison reaches the endpoint only through the displayed route from A, L to E, H, C, P, N.

Therefore the consumer receives exactly the finite dominated-exchange packet. It cannot read a host infinite sum, unrecorded interchange theorem, quotient stream equality, countable choice, ambient dominated convergence theorem, Lean verification, or standard bridge from the seal. □

Lean4 ✓ `BEDC.Derived.TanneryTheoremUp.TanneryTheoremCarrier real series exchange boundary`

Falsifiable prediction: Every $\mathsf{TanneryTheorem}^{\uparrow}$ endpoint-facing read factors through a double-indexed real row, pointwise limit row, dominating majorant route, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, absolute-convergence, weierstrassmtest, regseqrat, streamname, dyadicratcore, real: $\mathsf{TanneryTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries double-indexed row data, pointwise limit data, a dominating majorant route, finite exchange windows, regular rational readback, dyadic tolerance accounting, endpoint sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TanneryTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{TanneryTheorem}^{\uparrow}$ packet is generated from a double-indexed real row, a pointwise limit row, a dominating majorant route, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp endpoint seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TanneryTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2094.1, Definition 2094.2, Definition 2094.3, and Definition 2094.4 seed the finite dominated-exchange route over the Real and Completion spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TanneryTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, unrecorded interchange of limit and summation, quotient stream equality, countable choice, ambient dominated convergence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pointwise-window exactness, dominated-row exactness, finite-exchange accounting, RegSeqRat readback, Real seal nonescape, and structural transport for BEDC.Derived.TanneryTheoremUp

Chapter 2095

A Concrete Naming Certificate for $\mathsf{SmythCompletion}^{\uparrow}$

Following Smyth's domain-theoretic completion of quasi-uniform spaces and the constructive completion tradition of Bishop–Bridges, the $\mathsf{SmythCompletion}^{\uparrow}$ packet names the finite asymmetric completion route that reads entourage observations before passing to rounded Cauchy data. It sits on the L10 Real and Completion frontier beside chapter 339, chapter 333, chapter 589, chapter 1506, chapter 1510, and chapter 1883. The packet exports constructive completion evidence without host quotients, selected representatives, `Classical.choice`, `Quot.sound`, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2095.1 (Smyth completion carrier)**.** *A* $\mathsf{SmythCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, Q, F, R, D, M, B, I, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage surface restricted to the asymmetric observations used by the quasi-uniform request.*
2. *Q is the quasi-uniform direction row, recording finite forward-entourage, refinement, and composition observations rather than a symmetric metric equality.*
3. *F is the rounded* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *refinement ledger accepted over Q.*
4. *R is the rounded-refinement row, naming the finite cofinal requests that make the filter or net progressively tighter.*
5. *D is the dyadic and regular readback row through which* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *observations reach the terminal* $\mathsf{Real}^{\uparrow}$ *boundary when a real-valued consumer is present.*
6. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row used only when a symmetric metric completion consumer asks for the associated finite route.*
7. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *formal-ball row exposing radius-tagged approximation requests.*
8. *I is the* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *rounded-ideal row naming the ideal-style closure of the same formal-ball route.*

9. *H records componentwise* hsame *transport for the entourage, quasi-uniform direction, Cauchy refinement, rounded-refinement, readback, metric-completion, formal-ball, rounded-ideal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from quasi-uniform entourage observations through rounded Cauchy refinements, formal balls, rounded ideals, and optional Real-facing readback.*

11. *P is the* Pkg *provenance over* $\mathsf{SmythCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{RoundedIdealCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{SmythCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for a quotient completion object, a chosen representative, a host equivalence class, a hidden choice functional, `Classical.choice`, `Quot.sound`, *or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 (definition) `BEDC.Derived.SmythCompletionUp.SmythCompletionCarrier`
Lean4 ✓ `BEDC.Derived.SmythCompletionUp.SmythCompletionTasteGate single carrier alignment`

Theorem 2095.2 (Smyth completion NameCert obligations)**.** *For an accepted* $\mathsf{SmythCompletion}^{\uparrow}$ *carrier*

$$S = (U, Q, F, R, D, M, B, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SmythCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed uniform-space entourage row, quasi-uniform direction row, rounded Cauchy-filter or Cauchy-net ledger, rounded-refinement row, dyadic and regular readback row, metric-completion comparison row, formal-ball row, rounded-ideal row, transport, replay, provenance, and local naming row;*

2. *asymmetric entourage exposure, requiring every completion request to pass through U and Q before any rounded Cauchy row is read;*

3. *rounded Cauchy refinement, requiring F and R to display finite cofinal refinements and not a quotient of Cauchy filters or nets;*

4. *formal-ball and rounded-ideal factorization, requiring B and I to carry radius-tagged approximation and rounded ideal closure before a completion-facing consumer receives the packet;*

5. *metric and Real handoff discipline, requiring M and D to be optional downstream readbacks from the same finite route rather than sources of completeness;*

6. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed rows.*

No NameCert obligation is stored outside these rows, and none exports host quotient completion, choice of representatives, `Classical.choice`, `Quot.sound`, *or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2095.1. The accepted packet exposes exactly the uniform-space, quasi-uniform, Cauchy-refinement, rounded-refinement, readback, metric-completion, formal-ball, rounded-ideal, and structural rows.

Asymmetric entourage exposure is forced by the order of U and Q. A completion request first reads finite forward-entourage, refinement, and composition observations; it does not begin from a symmetric metric quotient or from a completed host object.

Rounded Cauchy refinement is then read from F and R. These rows display the finite cofinal filter or net refinements that make the request progressively tighter, so they provide a constructive route rather than a quotient of Cauchy data.

The formal-ball and rounded-ideal rows give the completion interface. The row B supplies radius-tagged approximation requests, and I records the rounded ideal closure of the same route before any completion-facing consumer receives it.

Metric and Real handoffs are downstream checks. The row M compares with $\mathsf{MetricCompletion}^{\uparrow}$ only after the Smyth route has been displayed, while D exposes $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readbacks without asserting ambient Real completeness.

Finally H, C, P, N add no analytic principle. They transport, replay, source, and name the displayed route, so host quotients, selected representatives, `Classical.choice`, and `Quot.sound` have no row from which a consumer could read them. □

Theorem 2095.3 (Smyth completion finite route)**.** *Let*

$$S = (U, Q, F, R, D, M, B, I, H, C, P, N)$$

be an accepted $\mathsf{SmythCompletion}^{\uparrow}$ *carrier. Every completion-facing consumer of* S *receives the Smyth completion only through the finite route*

$$U, Q \longmapsto F, R \longmapsto B, I \longmapsto M, D \longmapsto H, C, P, N.$$

Thus the packet exports a constructive asymmetric completion route from quasi-uniform entourage observations to rounded filter or Cauchy-net refinements, formal balls, rounded ideals, optional metric-completion comparison, and optional Real-facing readback. It does not export host quotient completion equality, a choice of representatives, `Classical.choice`*,* `Quot.sound`*, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Fix a completion-facing consumer of the packet. Projection gives U and Q, so the consumer starts from finite quasi-uniform entourage observations and their directed refinement ledger.

The rounded Cauchy stage reads F and R. Whether the consumer enters through $\mathsf{CauchyFilter}^{\uparrow}$ or $\mathsf{CauchyNet}^{\uparrow}$, it receives only the displayed cofinal refinement rows and never a quotient of Cauchy names.

The formal-ball stage reads B and I. Radius-tagged approximation requests are named by $\mathsf{FormalBall}^{\uparrow}$, and the rounded closure is named by $\mathsf{RoundedIdealCompletion}^{\uparrow}$ on the same finite route.

Metric and Real comparisons are optional downstream readbacks. A $\mathsf{MetricCompletion}^{\uparrow}$ consumer reads M only after the rounded route is available, while any $\mathsf{Real}^{\uparrow}$-facing consumer reads D through the displayed dyadic, stream, and regular-rational observations.

Transport, replay, provenance, and local naming close the route. The rows H, C, P, N preserve the listed data componentwise, so no host quotient, representative selector, `Classical.choice`, `Quot.sound`, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{SmythCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SmythCompletion}^{\uparrow}$ packet is generated from quasi-uniform entourage observations, rounded CauchyFilter or CauchyNet refinement rows, dyadic and regular readbacks, MetricCompletion comparison rows, FormalBall approximation rows, RoundedIdealCompletion closure rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SmythCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2095.1, Definition 2095.2, and Definition 2095.3 seed the constructive Smyth completion route over finite quasi-uniform and rounded Cauchy data.

Formal verification: FormalStatus(NameCert$_{\mathsf{SmythCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host equivalence classes, choice principles, Real$^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, asymmetric entourage exposure, rounded Cauchy refinement, formal-ball and rounded-ideal factorization, metric and Real handoff discipline, transport stability, replay stability, and ledger non-escape for BEDC.Derived.SmythCompletionUp.

Chapter 2096

A Concrete Naming Certificate for $\mathsf{RealCauchyModulusRefinement}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the packet records refinement of a modulus-controlled real-name read, consuming chapter 885, chapter 1423, chapter 126, chapter 291, chapter 301, and chapter 38. It keeps the stronger precision request inside finite BEDC rows before any downstream Real-facing consumer reads the terminal seal.

Definition 2096.1 (Real Cauchy modulus refinement carrier)**.** *A* $\mathsf{RealCauchyModulusRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M_0, M_1, R, S_0, S_1, D_0, D_1, Q, E, H, C, P, N)$$

with the following displayed rows:

1. M_0 *is the coarse* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule already accepted by the Real-facing read.*
2. M_1 *is the refined* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule for the stronger dyadic tolerance request.*
3. R *is the* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *witness that the refined threshold extends the coarse threshold for the displayed unary precision.*
4. S_0 *is the coarse* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by* M_0*.*
5. S_1 *is the refined* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by* M_1*.*
6. D_0 *is the coarse* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger consumed by the coarse window.*
7. D_1 *is the refined* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger consumed by the refined window.*
8. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row shared by the coarse and refined windows after the refinement witness has been displayed.*
9. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after* $M_0, M_1, R, S_0, S_1, D_0, D_1, Q$ *have been consumed.*
10. H *records componentwise* hsame *transport for the two schedules, the refinement witness, both windows, both dyadic ledgers, the readback, the seal, replay, provenance, and local naming rows.*
11. C *records displayed* Cont *replay from each finite precision request through*

$$M_0, M_1, R, S_0, S_1, D_0, D_1, Q \longmapsto E, H, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusRefinement}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyModulusRefinement}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, or a detached Real seal.*

Definition 2096.2 (Real Cauchy modulus refinement classifier)**.** *The* $\mathsf{RealCauchyModulusRefinement}^{\uparrow}$ *classifier compares packets only by componentwise* hsame *transport of the rows*

$$M_0, M_1, R, S_0, S_1, D_0, D_1, Q, E, H, C, P, N.$$

Thus a packet is accepted exactly when its coarse modulus, refined modulus, refinement witness, coarse and refined StreamName windows, dyadic tolerance ledgers, RegSeqRat readback, terminal Real seal, transport row, continuation replay, provenance row, and local NameCert row match a displayed carrier packet component by component. The classifier does not compare packets by quotienting streams, selecting a limit, invoking host real equality, using countable choice, using trichotomy, or importing ambient Real completeness.

Theorem 2096.3 (Real Cauchy modulus refinement NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyModulusRefinement}^{\uparrow}$ *carrier*

$$B = (M_0, M_1, R, S_0, S_1, D_0, D_1, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulusRefinement}^{\uparrow}}$ *surface consists exactly of carrier exposure for the displayed packet, coarse-modulus exposure through M_0, refined-modulus exposure through M_1, refinement-witness exposure through R, coarse and refined finite-window exposure through S_0, S_1, dyadic tolerance exposure through D_0, D_1, regular rational readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier tuple in Definition 2096.1. Each named coordinate is a finite row of the same BHist packet, and the last coordinate is the local naming row.

The analytic route is read in the displayed order. A finite precision request first exposes the coarse schedule M_0, the refined schedule M_1, and the witness R that connects them; it then reads the two StreamName windows S_0, S_1, the two dyadic ledgers D_0, D_1, and the shared regular readback Q before the terminal seal E is available.

The structural rows H, C, P, N transport, replay, source, and name only this route. Since the carrier contains no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient Real completeness, none of those principles can be part of the seed obligation surface. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusRefinementUp.RealCauchyModulusRefinementTasteGate single carrier alignment`

Theorem 2096.4 (Real Cauchy modulus refinement window refinement)**.** *Let*

$$B = (M_0, M_1, R, S_0, S_1, D_0, D_1, Q, E, H, C, P, N)$$

be an accepted RealCauchyModulusRefinement$^{\uparrow}$ *carrier. For every finite unary precision request, the refined read preserves the coarse Real-facing route by the finite passage*

$$M_0, M_1, R, S_0, S_1, D_0, D_1, Q \longmapsto E, H, P, N.$$

The refined window may expose more displayed StreamName data, but it cannot replace the coarse window by quotient stream equality, detach the RegSeqRat readback, select a limit, invoke host real equality, use countable choice, use trichotomy, or call ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusRefinementUp.RealCauchyModulusRefinementCarrier window refinement`

Proof. Proceed by induction on the finite unary precision request.

In the base case, the request reads M_0, then M_1, and then the displayed refinement witness R. The windows S_0, S_1 and ledgers D_0, D_1 are therefore accessed as named finite rows of the same packet, not as quotient classes or host stream objects.

For the successor step, assume the preceding precision request has already followed the displayed route. The next refined request consumes the next threshold in M_1 together with the witness R, so the refined window S_1 extends the amount of visible finite data while leaving the coarse window S_0 and coarse ledger D_0 attached to the route.

The shared readback row Q is read only after both dyadic ledgers have been displayed, and the terminal seal E is read only after Q. The continuation row C, transported by H and sourced by P, N, replays the same finite route at every induction stage. Hence no selected limit, host real equality, countable-choice principle, trichotomy principle, quotient stream equality, or ambient Real completeness theorem can enter the refinement. □

Theorem 2096.5 (Real Cauchy modulus refinement Real seal nonescape)**.** *No* Real$^{\uparrow}$ *seal read accepted by a* RealCauchyModulusRefinement$^{\uparrow}$ *carrier can bypass the displayed route through the coarse modulus, refined modulus, refinement witness, coarse and refined StreamName windows, dyadic tolerance ledgers, RegSeqRat readback, and local structural rows. Equivalently, every accepted terminal seal read is attached to the packet*

$$B = (M_0, M_1, R, S_0, S_1, D_0, D_1, Q, E, H, C, P, N)$$

and cannot be separated from those rows by quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient Real completeness.

Proof. Use the obligation theorem Definition 2096.3. It exposes the seal row E only after the two modulus rows, the refinement witness, the two StreamName windows, the two dyadic ledgers, and the shared RegSeqRat readback have been displayed.

Now apply the window-refinement theorem Definition 2096.4. The induction on finite unary precision requests preserves the same route when the tolerance request is strengthened, so the refined read cannot detach the terminal seal from the coarse route it refines.

Finally inspect the carrier definition. There is no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient Real completeness, open-cover compactness, or a separate Real seal. A purported seal read that omits one of the displayed rows is therefore not a read accepted by the local classifier. □

Closure status for NameCert$_{\text{RealCauchyModulusRefinement}^{\uparrow}}$ ·

Constructive story: A RealCauchyModulusRefinement$^{\uparrow}$ packet is generated from coarse and refined CauchyModulus schedules, a refinement witness, coarse and refined StreamName windows, dyadic tolerance ledgers, a RegSeqRat readback

row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RealCauchyModulusRefinement}\uparrow}$, seed)

Scope closed: Definition 2096.1, Definition 2096.2, Definition 2096.3, Definition 2096.4, and Definition 2096.5 seed the finite Real-facing modulus-refinement route over displayed StreamName windows, dyadic tolerance ledgers, RegSeqRat readback, and the RealUp seal.

Formal verification: FormalStatus(NameCert$_{\text{RealCauchyModulusRefinement}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, componentwise classifier transport, window refinement, and Real-seal nonescape for BEDC.Derived.RealCauchyModulusRefinementUp.

Chapter 2097

A Concrete Naming Certificate for $\mathsf{RegularCauchyCategory}^{\uparrow}$

Following Bishop and Bridges' regular-Cauchy real construction and Mac Lane's categorical language, the $\mathsf{RegularCauchyCategory}^{\uparrow}$ packet records the finite route by which displayed regular-Cauchy objects and tail-compatible morphisms are admitted, identified, composed, and sealed before any completion or universal-property consumer reads them. It sits over the finite observation surface of chapter 126, the rational readback route of chapter 301, the dyadic tolerance discipline of chapter 291, the terminal real-name boundary of chapter 38, the shift route of chapter 1578, the equivalence surface of chapter 1412, and the fast-equivalence comparison of chapter 1656. Its purpose is to expose the categorical object, identity, and composition ledgers as finite BEDC data rather than as host functions, quotient streams, or ambient completeness arguments.

Definition 2097.1 (Regular-Cauchy category carrier)**.** *A* $\mathsf{RegularCauchyCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, M, I, Q, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row exposes a regular-Cauchy name only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *reads,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

2. *M is the morphism ledger. Each morphism row displays its source object, target object, finite window schedule, tolerance-preserving read route, and tail-compatibility evidence.*

3. *I is the identity ledger. For every displayed object row in O, it stores the identity morphism row whose source and target classifiers are that object row and whose reads replay the same finite windows and dyadic tolerances.*

4. *Q is the composition ledger. For every composable pair of displayed morphism rows, it stores the composite source row, middle row, target row, composed window schedule, composed tolerance ledger, and replay route.*

5. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger consumed by object, morphism, identity, and composition rows.*

6. *R is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger, recording each finite rational read used by object rows and by morphism action rows.*

7. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the object tolerances, morphism tolerances, identity tolerances, and composition tolerances.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal ledger exposed only after the corresponding object or morphism route through S, R, D has been displayed.*

9. *H records componentwise* hsame *transport for object rows, morphism rows, identity rows, composition rows, window schedules, rational reads, dyadic ledgers, real seals, replay rows, provenance, and local naming rows.*

10. *C records displayed* Cont *replay for finite categorical reads through*

$$O, M, I, Q, S, R, D, E, H \longmapsto P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCategory}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, M, I, Q, S, R, D, E, H, C, P, N$. It has no coordinate for a quotient stream, host function equality, selected limit, countable choice principle, ambient $\mathsf{Real}^{\uparrow}$ *completeness, global category of sets, or external categorical quotient.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCategoryUp.RegularCauchyCategoryTasteGate single carrier alignment`

Theorem 2097.2 (Regular-Cauchy category NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCategory}^{\uparrow}$ *carrier*

$$K = (O, M, I, Q, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCategory}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the object ledger, morphism ledger, identity ledger, composition ledger, StreamName windows, RegSeqRat reads, DyadicRatCore tolerances, Real seals, componentwise transport, continuation replay, provenance, and local naming rows;*

2. *object classifier stability, requiring accepted object rows to be compared only by their displayed windows, rational reads, dyadic tolerances, terminal seals, and local transport;*

3. *morphism classifier stability, requiring accepted morphism rows to preserve the displayed source row, target row, finite window schedule, tolerance ledger, and replay route;*

4. *identity route, requiring every identity row in I to replay the object row it names without adding a quotient stream, selected limit, host equality proof, or ambient completeness argument;*

5. *composition route, requiring every row in Q to display its source morphism, middle object, target morphism, composed window schedule, dyadic tolerance ledger, and* Cont *replay witness;*

6. *RegSeqRat–DyadicRatCore–Real handoff, requiring every categorical read that reaches a* $\mathsf{Real}^{\uparrow}$ *seal to pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row and the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger;*

7. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the rows listed in the carrier.*

No NameCert obligation is stored outside those rows, and none exports quotient stream equality, host function equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, a global category of sets, Lean verification, or bridge checking.*

Proof. Carrier admission is projection from Definition 2097.1. The packet exposes object, morphism, identity, composition, window, readback, tolerance, seal, transport, replay, provenance, and naming rows as finite coordinates of one BHist carrier.

Object classifier stability is read from O, S, R, D, E, H. Since an object row can be inspected only through those coordinates, the classifier has no access to an external stream quotient or a selected limit.

Morphism classifier stability is read from M together with the shared analytic ledgers S, R, D, E. A morphism row must display its source and target object rows and its finite tolerance-preserving read route before it can be accepted.

The identity route is the projection to I. Each identity row is attached to a displayed object row and replays that row's windows, rational reads, dyadic tolerances, and seal, so it cannot introduce a host equality proof or a separate completeness theorem.

The composition route is the projection to Q. A composable pair is accepted only when the two morphism rows, middle object row, composed finite windows, dyadic tolerance ledger, and continuation replay have all been displayed.

The handoff row is S, R, D, E. Any read that reaches a $\mathsf{Real}^{\uparrow}$ seal must first pass through the StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance ledger stored in the same packet.

Finally H, C, P, N are structural rows. They transport, replay, source, and name only the displayed carrier coordinates, leaving no row from which a consumer could extract quotient stream equality, host function equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge data. □

Theorem 2097.3 (Regular-Cauchy category composition route)**.** *Let*

$$K = (O, M, I, Q, S, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyCategory}^{\uparrow}$ *carrier. Every composite morphism read accepted by* K *factors through the displayed source row, middle row, target row, finite window schedule, dyadic tolerance ledger, and* Cont *replay route recorded in* Q, S, R, D, E, H, C*. Consequently the composite exports no quotient stream, host function equality, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted composite morphism read. By the composition obligation in Definition 2097.2, the read cannot be accepted until the two input morphism rows, their shared middle object row, and the resulting source and target object rows have been displayed.

The finite window schedule is then read from S through the composition ledger Q. The schedule records exactly the windows needed by the source morphism, the target morphism, and the composite read; it is not a function space or an infinite selector.

The rational and dyadic data are read next. The row R supplies the regular rational observations, and D supplies the tolerance ledger used by both component morphisms and by the composed route.

The seal-facing step passes through E. A terminal $\mathsf{Real}^{\uparrow}$ seal is visible only after the source, middle, target, window, readback, and tolerance rows have been displayed, so the seal cannot detach from the finite categorical route.

Finally the continuation row C, transported by H and sourced by P, N, replays the displayed composite. Since the carrier contains no coordinate for quotient streams, host function equality, selected limits, countable choice, or ambient Real completeness, none of those principles can be exported by the composite read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCategory}^{\uparrow}$ packet is generated from object rows, morphism rows, identity rows, composition rows, StreamName windows, RegSeqRat reads, DyadicRatCore tolerance ledgers, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2097.1, Definition 2097.2, and Definition 2097.3 seed the finite regular-Cauchy categorical route over displayed object, morphism, identity, composition, StreamName, RegSeqRat, DyadicRatCore, Real seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, host function equality, selected limits, countable choice, ambient RealUp completeness, a global category of sets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, object classifier transport, morphism classifier transport, identity route, composition route, RegSeqRat-DyadicRatCore-Real handoff, and ledger non-escape for BEDC.Derived.RegularCauchyCategoryUp.

Chapter 2098

A Concrete Naming Certificate for $\mathsf{Goursat}^{\uparrow}$

Following Goursat and constructive complex analysis, the $\mathsf{Goursat}^{\uparrow}$ packet names the finite triangle-subdivision boundary used by the triangle form of the Cauchy integral theorem. It consumes holomorphic disk data from chapter 68, complex analytic bounds from chapter 76, complex limit moduli from chapter 65, complex coordinate histories from chapter 39, and the contour ledger rows of chapter 521. The packet is a finite certificate for one displayed holomorphic triangle and its subdivision ledger; it is not a host path integral theorem, not open-cover compactness, not a selected primitive, and not a quotient equality principle.

Definition 2098.1 (Goursat carrier)**.** *A* $\mathsf{Goursat}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, H, E, S, M, I, C, P, N)$$

with the following displayed rows.

1. *T is the triangle-vertex row. It records three* $\mathsf{Complex}^{\uparrow}$ *vertex histories, their oriented edge histories, and the nondegenerate triangle window inspected by later rows.*
2. *H is the holomorphic disk witness. It is consumed from* $\mathsf{Holomorphic}^{\uparrow}$ *and displays a disk containing the triangle window together with the local modulus and complex analytic bounds needed for the subdivision estimate.*
3. *E is the edge-contour row. It lists the three oriented boundary contour reads and routes each read through the finite contour-integral operation surface.*
4. *S is the subdivision tree. Each node stores a displayed triangle, its four child triangles, the inherited orientation rows, and the parent-to-child boundary ledger.*
5. *M is the modulus and mesh budget. It records the unary refinement level, diameter estimates, perimeter estimates, and the holomorphic error bound used at the leaves.*
6. *I is the integral-cancellation ledger. It records boundary-edge persistence and opposite-edge cancellation for every internal edge of the subdivision tree.*
7. *C records displayed* Cont *replay from the triangle request through the holomorphic disk row, edge-contour rows, subdivision tree, mesh budget, cancellation ledger, provenance, and local naming row.*

8. *P is the* Pkg *provenance over* $\mathsf{Goursat}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{CplxAnalytic}^{\uparrow}$, $\mathsf{CplxLim}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{ContourIntegralOperation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, H, E, S, M, I, C, P, N$. It has no coordinate for a host path integral, open-cover compactness theorem, selected primitive, quotient equality of paths, or classical-choice coordinate.

Lean4 ✓ `BEDC.Derived.GoursatUp.TasteGate.GoursatTasteGate single carrier alignment`

Theorem 2098.2 (Goursat NameCert obligations)**.** *For every accepted* $\mathsf{Goursat}^{\uparrow}$ *carrier*

$$G = (T, H, E, S, M, I, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$ *surface consists exactly of the following obligation rows.*

1. *carrier exposure for the displayed triangle vertices, holomorphic disk witness, edge-contour reads, subdivision tree, mesh budget, cancellation ledger, continuation replay, provenance, and local naming rows;*

2. *classifier transport through the componentwise rows listed in Definition 2098.1;*

3. *subdivision stability, requiring every child triangle in S to inherit its vertex, orientation, holomorphic-disk, and mesh rows from the parent packet;*

4. *boundary-edge cancellation, requiring every internal edge created by the subdivision to appear twice in I with opposite orientations and the same contour-integral read;*

5. *ledger nonescape, excluding host path integrals, open-cover compactness, selected primitives, quotient path equality, and classical-choice coordinates from the local certificate surface.*

No local obligation is stored outside the displayed packet.

Proof. Carrier exposure is projection from Definition 2098.1. The accepted packet displays exactly the triangle, holomorphic disk, contour-edge, subdivision, mesh, cancellation, replay, provenance, and naming rows.

Classifier transport is componentwise. Two accepted packets compare first through the $\mathsf{Complex}^{\uparrow}$ vertex histories in T, then through the holomorphic disk row H, the edge-contour row E, the subdivision tree S, and the mesh and cancellation ledgers M, I. The structural rows C, P, N replay and name that same finite comparison.

Subdivision stability is inherited from the rows stored at each node of S. A child triangle has no independent source of vertices, orientations, disk witnesses, or mesh budgets; each of those entries is read from its parent row and transported through the same hsame comparison.

Boundary-edge cancellation is a ledger property. An internal edge is created only as a shared edge of two sibling triangles, and I records the two appearances with opposite orientations and the same contour-integral row from E. External edges are the original boundary rows and are not cancelled.

Coordinate exhaustion gives ledger nonescape. Since the carrier has no slot for a host path integral, open-cover compactness theorem, selected primitive, quotient path equality, or classical-choice coordinate, none of those objects can be exported by the local $\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.GoursatUp.GoursatCarrier namecert obligations`

Theorem 2098.3 (Goursat triangle integral boundary)**.** *Let $G = (T, H, E, S, M, I, C, P, N)$ be an accepted* $\mathsf{Goursat}^{\uparrow}$ *carrier. Every accepted triangle-integral read factors through the displayed subdivision tree S and the opposite-edge cancellation ledger I. Its observable route is*

$$T, H, E \longmapsto S \longmapsto M \longmapsto I \longmapsto C, P, N.$$

The read exposes only boundary contour rows, child-triangle rows, leaf mesh estimates, and opposite-edge cancellations. It exposes no host path integral, open-cover compactness argument, selected primitive, quotient equality of paths, or classical-choice coordinate.

Proof. Start with an accepted triangle-integral read. By Definition 2098.1, the read enters through the displayed triangle row T, the holomorphic disk row H, and the edge-contour row E.

The route then passes through S. Each subdivision node records its four children and its inherited orientations, so every internal edge is visible as a row shared by two sibling child triangles.

The mesh budget M supplies the leaf estimates used by the holomorphic disk witness. These estimates are attached to the displayed leaves; they do not select a primitive and do not invoke compactness outside the finite subdivision tree.

The cancellation ledger I removes exactly the internal opposite-edge pairs. The remaining contour reads are the original boundary edges from E, and the structural rows C, P, N replay that finite route. Because no excluded object is a carrier coordinate, the factorization is exhaustive. □

Lean4 ✓ `BEDC.Derived.GoursatUp.GoursatCarrier triangle integral boundary`

Theorem 2098.4 (Goursat holomorphic handoff)**.** *Every* $\mathsf{Holomorphic}^{\uparrow}$ *disk packet consumed by an accepted* $\mathsf{Goursat}^{\uparrow}$ *carrier reaches only the finite triangle-subdivision integral boundary before any downstream Cauchy-integral theorem may use it. The handoff order is*

$$\mathsf{Holomorphic}^{\uparrow},\ \mathsf{CplxAnalytic}^{\uparrow},\ \mathsf{CplxLim}^{\uparrow},\ \mathsf{Complex}^{\uparrow} \longmapsto T, H, E, S, M, I \longmapsto \mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}.$$

Thus a downstream Cauchy-integral consumer may inspect the Goursat boundary only as a finite NameCert row over the displayed triangle, subdivision, mesh, and cancellation data.

Proof. Project the consumed holomorphic disk row H from the carrier. Its domain, modulus, and analytic-bound data are read through the holomorphic, complex analytic, complex limit, and complex coordinate chapters cited above.

The disk row is then restricted by the triangle row T. No downstream consumer can read H directly as a global analytic theorem, because the continuation row first routes it through the edge-contour data E and the subdivision tree S.

The mesh budget M and cancellation ledger I are the last non-structural rows before the local name. They expose finite estimates and opposite-edge cancellation only. The local $\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$ row therefore presents a finite triangle-subdivision boundary, and any later Cauchy-integral theorem must consume that boundary rather than a host path integral or selected primitive. □

Closure status for $\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$, seed)

Scope closed: Definition 2098.1, Definition 2098.2, Definition 2098.3, and Definition 2098.4 seed the finite holomorphic triangle-subdivision integral boundary over contour rows and cancellation ledgers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Goursat}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the full Cauchy integral theorem, Morera theorem, analytic continuation, bridge checking, selected primitives, host contour integrals, open-cover compactness, quotient path equality, classical choice, or Lean verification.

Upgrade path: Obligation closure requires checked carrier exposure, classifier transport, subdivision stability, boundary-edge cancellation, ledger nonescape, triangle integral factorization, and holomorphic handoff for BEDC.Derived.GoursatUp.

Constructive story: A Goursat$^{\uparrow}$ packet is generated from triangle vertex ComplexUp data, a HolomorphicUp disk witness, edge contour rows, a subdivision tree, a modulus and mesh budget, an integral-cancellation ledger, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2099

A Concrete Naming Certificate for $\mathsf{EudoxusReal}^{\uparrow}$

Following Eudoxus and modern almost-homomorphism presentations of the real numbers, the $\mathsf{EudoxusReal}^{\uparrow}$ packet records a real name as an integer-valued line with bounded additive defect. It sits after the integer certificate of chapter 31, the rational-bound surface of chapter 430, the dyadic tolerance ledger of chapter 291, the regular rational sequence surface of chapter 301, and the terminal real-name seal of chapter 38. The chapter keeps the almost-additive function, its defect bound, and its readback windows as displayed finite rows; it is not a quotient construction of reals and does not select limits from host functions.

Definition 2099.1 (Eudoxus real carrier)**.** *An* $\mathsf{EudoxusReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (I, A, B, D, S, Q, R, H, C, P, N)$$

with the following displayed rows.

1. *I is the* $\mathsf{Int}^{\uparrow}$ *source row naming the integer inputs and integer outputs inspected by the packet.*
2. *A is the almost-homomorphism graph row. It records the finite table of inspected pairs together with their displayed additivity comparisons.*
3. *B is the bounded-defect row. It records one integer defect budget and the checked inequalities for every inspected pair in A.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger translating defect and denominator windows into dyadic error bounds.*
5. *S is the finite window schedule for denominator requests and comparison requests.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed integer graph, defect budget, dyadic ledger, and window schedule.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, A, B, D, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for the integer graph, bounded-defect row, dyadic ledger, schedule, regular rational readback, Real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each denominator or comparison request through $I, A, B, D, S, Q, R, H, P, N$*

10. *P is the* Pkg *provenance over* $\mathsf{EudoxusReal}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EudoxusReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, A, B, D, S, Q, R, H, C, P, N$. It has no coordinate for quotient equality of almost homomorphisms, host functions $\mathsf{Int}^{\uparrow} \to \mathsf{Int}^{\uparrow}$, selected limits, Cauchy-completeness proofs for $\mathsf{Real}^{\uparrow}$, or an ambient ordered-field construction.

Lean4 ✓ `BEDC.Derived.EudoxusRealUp.EudoxusRealTasteGate single carrier alignment`

Theorem 2099.2 (Eudoxus real NameCert obligations)**.** *For every accepted* $\mathsf{EudoxusReal}^{\uparrow}$ *carrier*

$$E = (I, A, B, D, S, Q, R, H, C, P, N),$$

the seed $\mathsf{NameCert}_{\mathsf{EudoxusReal}^{\uparrow}}$ *surface consists exactly of carrier exposure for the displayed integer graph, bounded-defect budget, dyadic tolerance ledger, finite request schedule, regular rational readback, terminal Real seal, componentwise transport, continuation replay, provenance, and local naming rows. Each accepted request is classified only by the inspected integer rows, the bounded-defect inequalities, the dyadic tolerance rows, and the resulting regular rational readback.*

Proof. Project the carrier tuple from Definition 2099.1. The rows I, A, B, D, S, Q, R expose the analytic data, while H, C, P, N transport, replay, source, and name the same packet.

Read a request in dependency order. The integer graph row A is meaningful only over the displayed $\mathsf{Int}^{\uparrow}$ source I; the defect row B bounds the displayed additivity comparisons in A; the dyadic row D turns that bounded defect into finite tolerance information; and the schedule S selects the inspected denominator and comparison windows.

The regular rational row Q is then read from the same displayed rows, and the terminal $\mathsf{Real}^{\uparrow}$ seal R is reached only through Q. Since no excluded object is a coordinate of the carrier, the listed rows exhaust the seed obligation surface. □

Theorem 2099.3 (Eudoxus real bounded-defect readback)**.** *Let*

$$E = (I, A, B, D, S, Q, R, H, C, P, N)$$

be an accepted $\mathsf{EudoxusReal}^{\uparrow}$ *carrier. Every finite read of the almost-homomorphism graph that reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *factors through the bounded-defect route*

$$I, A \longmapsto B \longmapsto D \longmapsto S \longmapsto Q \longmapsto R.$$

Thus a consumer may read a regular rational approximation or a terminal Real seal only after the same integer graph and bounded-defect ledger have been displayed.

Proof. Start with an accepted read of Q or R. By Definition 2099.2, the read enters through the displayed integer source and graph rows I, A.

The bounded-defect row B is the next required row. It records the finite inequalities witnessing that the inspected graph behaves like an additive homomorphism up to the same integer budget on every displayed pair.

The dyadic ledger D converts that budget into tolerance rows, and the schedule S records which denominators and comparisons are inspected. The regular rational row Q is therefore downstream of I, A, B, D, S.

Finally the Real seal R is downstream of Q, and the structural rows H, C, P, N only preserve and name the route. Hence a read skipping the bounded-defect ledger cannot reach either the regular rational readback or the terminal Real seal inside this carrier. □

Theorem 2099.4 (Eudoxus real RegSeqRat comparison)**.** *Every accepted* $\mathsf{EudoxusReal}^{\uparrow}$ *packet determines its* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison surface from the common finite rows*

$$I, \quad A, \quad B, \quad D, \quad S.$$

If two accepted packets are componentwise hsame *on these rows, then their displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows compare through the same dyadic tolerances and denominator windows before either packet exposes its terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Use the classifier in Definition 2099.1. It compares accepted packets componentwise through the integer source, graph, defect, dyadic, and schedule rows before it compares the regular rational readback row.

The bounded-defect row fixes the same finite error budget, and the dyadic ledger translates it through the same tolerance windows. Componentwise hsame on I, A, B, D, S therefore gives the same displayed input data for the $\mathsf{RegSeqRat}^{\uparrow}$ row Q in both packets.

Only after that comparison can a consumer reach the terminal $\mathsf{Real}^{\uparrow}$ seal R. The theorem does not identify quotient classes of almost homomorphisms; it identifies the finite readback route exposed by this NameCert packet. □

Falsifiable prediction: An accepted $\mathsf{EudoxusReal}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ without the displayed $\mathsf{Int}^{\uparrow}$ graph, bounded-defect row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and request schedule refutes the carrier surface.

Independence witness: int, archimedeanreal, dyadicratcore, regseqrat, real: no listed sibling supplies the whole eleven-row packet $E = (I, A, B, D, S, Q, R, H, C, P, N)$, because each sibling contributes only an integer, rational-bound, dyadic-tolerance, regular-rational, or Real-seal surface while this chapter binds the almost-homomorphism graph and bounded-defect route between them.

Closure status for $\mathsf{NameCert}_{\mathsf{EudoxusReal}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EudoxusReal}^{\uparrow}$ packet is generated from an $\mathsf{Int}^{\uparrow}$ source row, an almost-homomorphism graph row, a bounded-defect row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite request schedule, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EudoxusReal}^{\uparrow}}$, seed)

Scope closed: Definition 2099.1, Definition 2099.2, Definition 2099.3, and Definition 2099.4 seed the almost-homomorphism real-name boundary over $\mathsf{Int}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EudoxusReal}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.EudoxusRealUp`

Bridge status: none

Not claimed: This chapter does not claim quotient reals, host functions, selected limits, completeness of $\mathsf{Real}^{\uparrow}$, or an ambient ordered-field construction.

Upgrade path: Scoped closure requires binding the displayed bounded-defect readback route as the public route for every accepted Eudoxus real-name consumer.

Chapter 2100

A Concrete Naming Certificate for $\mathsf{HolderInequality}^{\uparrow}$

Following Hardy–Littlewood–Polya and the finite-sum form of classical real analysis, the $\mathsf{HolderInequality}^{\uparrow}$ packet records the BEDC route by which Holder inequality reads over displayed finite real-vector and finite-series windows become available to downstream consumers. It sits after the square-form inequality route of chapter 1684, the partial-sum and tail surface of chapter 1581, and the apartness-from-zero positivity boundary of chapter 1587. The packet is a finite real-analysis inequality certificate; it is not a host real function-space theorem, a quotient stream equality, a selected infinite sum, a countable-choice principle, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Definition 2100.1 (Holder inequality carrier)**.** *A* $\mathsf{HolderInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, W, A, B, C, D, E, F, H, T, P, N)$$

with the following displayed rows:

1. *X and Y are the two finite real-vector or finite-series windows. Each inspected coordinate is exposed through a* $\mathsf{Real}^{\uparrow}$ *endpoint seal and the finite readback rows already used by the surrounding real-analysis packets.*
2. *W is the shared finite observation window. It records the displayed index set, the term reads for X and Y, and the product-row reads used by the inequality-facing consumer.*
3. *A is the conjugate positive exponent ledger. It records the positive exponent rows p and q, the finite certificate that they are conjugate, and the positivity evidence needed to use them as Holder weights.*
4. *B is the* $\mathsf{PositiveReal}^{\uparrow}$ *boundary for every positive exponent, weight, and norm-like scalar consumed by the packet.*
5. *C is the* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *finite inequality route used for the square-case handoff and for the displayed two-row comparison subpacket.*
6. *D is the* $\mathsf{RealSeries}^{\uparrow}$ *finite partial-sum route. It exposes only the selected finite sums of coordinate powers, products, and comparison rows visible in W.*
7. *E is the dyadic tolerance budget. It stores the finite comparison radii, product slack, exponent-ledger tolerances, and endpoint rounding rows.*
8. *F is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal for the displayed Holder inequality read.*

9. *H records componentwise* hsame *transport for the vector or series windows, conjugate exponent ledger, positivity boundary, Cauchy–Schwarz route, finite-series route, dyadic budget, endpoint seal, replay, provenance, and local naming rows.*

10. *T records displayed* Cont *replay from any finite coordinate request through W, A, B, C, D, E, F and back to the public inequality boundary.*

11. *P is the* Pkg *provenance over* $\mathsf{HolderInequality}^{\uparrow}$, $\mathsf{CauchySchwarzReal}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HolderInequality}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite Holder inequality packet. It has no coordinate for a host real function space, quotient equality of streams, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.HolderInequalityUp.HolderInequalityTasteGate single carrier alignment`

Theorem 2100.2 (Holder inequality NameCert obligations)**.** *For every accepted* $\mathsf{HolderInequality}^{\uparrow}$ *carrier $K = (X, Y, W, A, B, C, D, E, F, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HolderInequality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two displayed finite windows, shared observation window, conjugate positive exponent ledger, positivity boundary, Cauchy–Schwarz route, finite-series route, dyadic tolerance budget, endpoint seal, transport, replay, provenance, and local naming rows;*

2. *classifier transport, requiring H and T to preserve the same finite windows, exponent rows, positive scalar evidence, square-case comparison route, finite partial-sum rows, tolerance ledger, endpoint seal, and local naming row componentwise;*

3. *conjugate-exponent exactness, requiring the positive exponent data in A and B to be the only source of the Holder exponent relation exported by the packet;*

4. *finite-sum coverage, requiring every product, power, norm-like scalar, and comparison read to pass through W, C, D, E, F before the certificate row is available;*

5. *ledger non-escape, excluding host real function spaces, quotient stream equality, selected infinite sums, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, hidden order principles, and bridge checking.*

No NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic coordinates are the two finite windows X, Y, the shared observation row W, the exponent ledger A, the positivity boundary B, the Cauchy–Schwarz route C, the real-series route D, the dyadic budget E, and the endpoint seal F.

Carrier admission is exactly admission of those displayed rows together with H, T, P, N. The certificate has no additional coordinate from which a host real function-space object, quotient representative, infinite sum, countable-choice selector, or ambient completeness witness could be recovered.

Classifier transport is componentwise. The hsame rows in H keep the windows, exponent rows, positivity evidence, square-case route, finite-series rows, tolerance budget, and endpoint seal aligned, while T replays the same displayed finite route for later consumers.

Conjugate-exponent exactness follows because A is the only exponent-ledger coordinate and B is the only positive-real boundary coordinate available to it. Thus the exported exponent relation

is the displayed positive finite ledger, not a host algebraic theorem imported from outside the packet.

Finite-sum coverage is forced by the carrier order. Every product, power, norm-like scalar, and comparison read must pass through the finite windows, the square-case and series routes, the dyadic tolerance budget, and the endpoint seal before N can name the packet.

The non-escape clause is immediate from the carrier surface. None of host real function spaces, quotient stream equality, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, hidden order principles, or bridge checking is a coordinate of K. □

Theorem 2100.3 (Holder inequality finite-sum route)**.** *For every accepted* $\mathsf{HolderInequality}^{\uparrow}$ *carrier* $K = (X, Y, W, A, B, C, D, E, F, H, T, P, N)$*, every inequality-facing read factors through the displayed finite route*

$$X, Y, W \longmapsto A, B \longmapsto C, D \longmapsto E \longmapsto F \longmapsto H, T, P, N.$$

Consequently the read uses only finite vector or series windows, conjugate positive exponent ledgers, $\mathsf{PositiveReal}^{\uparrow}$ *positivity rows, the square-case comparison route supplied by* $\mathsf{CauchySchwarzReal}^{\uparrow}$*, the partial-sum route supplied by* $\mathsf{RealSeries}^{\uparrow}$*, a dyadic tolerance budget, and a terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal. It supplies no host real function space, quotient stream equality, selected infinite sum, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge-checked standard theorem.*

Proof. Start from an accepted carrier. The only displayed coordinate data are X, Y, W, so every product, power, and scalar comparison request begins in the finite windows.

The exponent information is then fixed by A and B. The packet can use the conjugate positive exponent relation only through the displayed ledger and its positive-real boundary.

The inequality route is fixed by C, D, E, F. The square-case comparison is read through the $\mathsf{CauchySchwarzReal}^{\uparrow}$ row, the finite partial sums are read through the $\mathsf{RealSeries}^{\uparrow}$ row, the dyadic tolerance budget records the comparison slack, and the endpoint row seals the resulting $\mathsf{Real}^{\uparrow}$ inequality read.

The rows H, T, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for a host real function space, quotient stream equality, selected infinite sum, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking, every inequality-facing consumer receives only the displayed finite-sum route. □

Falsifiable prediction: Every $\mathsf{HolderInequality}^{\uparrow}$ inequality-facing read factors through finite vector or series windows, a conjugate positive exponent ledger, PositiveRealUp positivity rows, CauchySchwarzRealUp square-case routing, RealSeriesUp partial-sum routing, a dyadic tolerance budget, a RealUp endpoint seal, transport, replay, provenance, and local naming.

Independence witness: cauchy-schwarz-real, realseries, positivereal: $\mathsf{HolderInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite windows, conjugate exponent evidence, positive-real rows, square-case comparison routing, finite partial-sum routing, dyadic tolerance accounting, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HolderInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HolderInequality}^{\uparrow}$ packet is generated from two finite real-vector or finite-series windows, a shared observation window, a conjugate positive exponent ledger, PositiveRealUp positivity rows, CauchySchwarzRealUp and RealSeriesUp finite routes, a dyadic tolerance budget, a RealUp endpoint seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HolderInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2100.1, Definition 2100.2, and Definition 2100.3 seed the finite Holder inequality boundary for displayed RealUp finite-vector and finite-series windows.

Formal verification: FormalStatus(NameCert$_{\text{HolderInequality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real function spaces, quotient stream equality, selected infinite sums, countable choice, ambient Real$^{\uparrow}$ completeness, hidden order principles, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, conjugate-exponent exactness, finite-sum coverage, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.HolderInequalityUp.

Chapter 2101

A Concrete Naming Certificate for $\mathsf{CompactMetricSubspace}^{\uparrow}$

Following Bishop–Bridges compact metric practice and the Kelley subspace reading of finite metric data, the $\mathsf{CompactMetricSubspace}^{\uparrow}$ packet records a compact subspace of a compact metric packet by finite NameCert rows. It sits over the subspace metric interface of chapter 1519, the finite-net compact metric surface of chapter 129, the total-boundedness rows of chapter 127, the complete metric limit rows of chapter 128, and the stream and real readback interfaces of chapter 126, chapter 301, and chapter 38. The packet is a standard compact-subspace certificate for later compact-continuity and completion arguments; it is not an open-cover compactness theorem, a nearest-point selector, a quotient subset equality principle, a trichotomy principle, or an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 2101.1 (CompactMetricSubspace carrier)**.** *A* $\mathsf{CompactMetricSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, K, T, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission packet. It records the parent metric row, the displayed admission row, the inherited distance ledger, the restricted replay path, and the local subspace name.*
2. *K is the ambient* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net packet. It supplies only finite net data, mesh budgets, coverage witnesses, and compact-metric admission rows for the parent metric source.*
3. *T records* $\mathsf{TotallyBounded}^{\uparrow}$ *witnesses restricted to admitted points. Each net point exposed to the subspace consumer is checked through the admission row of S before it is used as a covering center.*
4. *L records* $\mathsf{CompleteMetric}^{\uparrow}$ *limit closure for regular Cauchy streams whose displayed observations remain admitted by S and whose parent limit row is admitted by the same subspace predicate.*
5. *W records* $\mathsf{StreamName}^{\uparrow}$ *windows for the subspace Cauchy streams consumed by L, including the finite late-distance windows used by total boundedness and completeness consumers.*
6. *R records* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks of the rational mesh, modulus, and late-distance budgets used by K, T, L, W.*
7. *E records* $\mathsf{Real}^{\uparrow}$ *seals for the displayed distance comparisons and limit-read confirmations that are already routed through S, K, T, L, W, R.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricSubspace}^{\uparrow}}$ *row.*

The classifier compares packets only through $S, K, T, L, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, choice-selected nearest points, quotient subset equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactMetricSubspaceUp.TasteGate.CompactMetricSubspaceTasteGate single carrier alignment`

Theorem 2101.2 (CompactMetricSubspace NameCert obligations)**.** *For every accepted* $\mathsf{CompactMetricSubspace}^{\uparrow}$ *carrier*

$$Q = (S, K, T, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactMetricSubspace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric subspace packet, ambient compact metric packet, restricted total-boundedness witnesses, complete metric limit-closure row, stream windows, regular rational readbacks, real seals, transport, replay, provenance, and local naming rows;*

2. *subspace admission stability, requiring every compact-net center, stream observation, candidate limit, rational mesh read, and real seal to pass through the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row before it is exported;*

3. *finite-net restriction, requiring every* $\mathsf{CompactMetric}^{\uparrow}$ *net read used by the subspace packet to be accompanied by admitted centers and the inherited distance route of the metric subspace packet;*

4. *total-bounded and complete-metric compatibility, requiring the* $\mathsf{TotallyBounded}^{\uparrow}$ *witnesses and* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-closure row to name the same restricted distance ledger and the same admitted stream windows;*

5. *classifier transport, requiring* hsame *transport in H to preserve the admission row, finite-net rows, total-boundedness witnesses, completion closure, stream windows, rational readbacks, real seals, replay, provenance, and local name;*

6. *ledger exhaustion, requiring C, P, N to replay, source, and name only the displayed finite route and to export no open-cover compactness, choice-selected nearest point, quotient subset equality, trichotomy principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No CompactMetricSubspace obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2101.1. The tuple displays exactly the subspace packet, ambient compact metric packet, total-boundedness witnesses, completion closure row, stream windows, rational readbacks, real seals, transport, replay, provenance, and local naming rows.

Subspace admission stability is forced by the position of S. A compact-net center, stream observation, candidate limit, rational budget, or real seal is visible to the subspace consumer only after the parent point classifier and the admission row recorded by S have both been replayed.

Finite-net restriction uses K together with T. The ambient $\mathsf{CompactMetric}^{\uparrow}$ row supplies finite nets, while the restricted total-boundedness row exposes only those centers that survive the admission check and the inherited distance route of chapter 1519.

Compatibility of total boundedness and completeness uses L and W. The same admitted stream windows feed the late-distance reads for total boundedness and the limit-closure reads for completeness, so the packet cannot switch to a second distance ledger or a second stream name.

Transport and exhaustion are recorded by H, C, P, N. Since the carrier has no coordinate outside $S, K, T, L, W, R, E, H, C, P, N$, the excluded open-cover, nearest-point, quotient, trichotomy, and ambient real-completeness principles cannot be exported by the local name. □

Theorem 2101.3 (Inherited total-boundedness and completeness)**.** *Let $Q = (S, K, T, L, W, R, E, H, C, P, N)$ be an accepted $\mathsf{CompactMetricSubspace}^{\uparrow}$ carrier. Every subspace compactness read exported by Q factors through the finite route*

$$\mathsf{MetricSubspace}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{TotallyBounded}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longrightarrow H, C$$

Consequently a downstream completion or compact-continuity consumer receives total-boundedness witnesses only with admitted centers, completeness witnesses only for admitted regular streams whose limit row is admitted, and distance comparisons only through the inherited $\mathsf{MetricSubspace}^{\uparrow}$ distance ledger. The exported packet contains no open-cover compactness, choice-selected nearest-point data, quotient subset equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Proof. Project the accepted carrier and begin with a total-boundedness read. The $\mathsf{CompactMetric}^{\uparrow}$ row K supplies a finite net at the requested rational budget, and the restricted witness row T filters the displayed centers through the admission row of S before the inherited distance ledger may be read.

For a completeness read, use the $\mathsf{StreamName}^{\uparrow}$ windows in W and the rational readbacks in R to expose the regular Cauchy budgets consumed by L. The limit row is the parent $\mathsf{CompleteMetric}^{\uparrow}$ limit row only after the admission predicate of S accepts it.

The real seals in E confirm the displayed distance and limit comparisons already routed through S, K, T, L, W, R. They do not create a new completeness principle for $\mathsf{Real}^{\uparrow}$; they name the finite comparisons used by the packet.

Finally transport by H and replay by C keep the same rows under classifier comparison, while P, N source and name the route. Thus completion and compact-continuity consumers see exactly the inherited total-bounded and complete-metric data, with the listed nonconstructive and quotient principles absent from the carrier. □

Theorem 2101.4 (Real-seal nonescape)**.** *For an accepted $\mathsf{CompactMetricSubspace}^{\uparrow}$ carrier $Q = (S, K, T, L, W, R, E, H, C, P, N)$, every $\mathsf{Real}^{\uparrow}$ seal exported by E is downstream of an admitted $\mathsf{MetricSubspace}^{\uparrow}$ distance read, a $\mathsf{RegSeqRat}^{\uparrow}$ rational budget read, and the relevant $\mathsf{StreamName}^{\uparrow}$ or finite-net window. Hence a consumer cannot use Q to infer ambient $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient subset equality, a selected nearest point, or open-cover compactness.*

Proof. Read a real seal from E. By carrier admission, the seal is not a standalone real-analysis row; it is indexed by the displayed distance or limit comparison already named by S, K, T, L, W, R.

If the seal concerns a finite-net distance comparison, the route first checks the subspace admission row in S, then reads the compact metric net in K, the restricted total-bounded witness in T, and the rational budget in R.

If the seal concerns a limit comparison, the route first checks the same subspace admission row, then reads the stream window in W, the completeness closure row in L, and the rational readback in R.

The transport, replay, provenance, and naming rows H, C, P, N preserve only these finite dependencies. Since no separate $\mathsf{Real}^{\uparrow}$ completeness coordinate, trichotomy coordinate, quotient row, nearest-point selector, or open-cover compactness row appears in the carrier, none can escape through the real-seal surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricSubspace}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricSubspace}^{\uparrow}$ packet is generated from a MetricSubspaceUp admission packet, CompactMetricUp finite-net data, restricted TotallyBoundedUp witnesses, CompleteMetricUp limit closure, StreamNameUp windows, RegSeqRatUp readbacks, RealUp seals, hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricSubspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2101.1, Definition 2101.2, Definition 2101.3, and Definition 2101.4 seed the finite compact-subspace interface over metric subspace admission, compact finite nets, total boundedness, completeness, stream windows, rational readbacks, and real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactMetricSubspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected nearest points, quotient subset equality, trichotomy, ambient RealUp completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, subspace admission stability, finite-net restriction, total-bounded and complete-metric compatibility, classifier transport, and ledger exhaustion for BEDC.Derived.CompactMetricSubspaceU

Chapter 2102

A Concrete Naming Certificate for $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$

Following Bishop and Bridges and Kelley completion terminology, the $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ packet records the finite naturality boundary where a displayed completion comparison map commutes with the source unit route and the completed counit route. It sits after the unit carrier of chapter 1527, the counit carrier of chapter 1539, the Bishop comparison surface of chapter 1508, the reflection witness of chapter 403, and the completion-comparison certificate of chapter 1954. Its analytic readback is the same finite route through chapter 126, chapter 291, chapter 301, and chapter 38.

The packet names the two finite naturality squares consumed by Real and Completion interfaces. It does not identify quotient completions, choose stream representatives, assert host function equality, invoke countable choice, import ambient completeness, or certify a Lean-side bridge.

Definition 2102.1 (Cauchy completion comparison naturality carrier)**.** *A* $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, U, V, F, R, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the completion-comparison map row inherited from* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *and* $\mathsf{BishopCompletionComparison}^{\uparrow}$*, displaying the two completion presentations before either square is read.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route row for source admission into the completion-facing presentation.*
3. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *route row for returning an already completed presentation to its displayed completion consumer.*
4. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *witness row, recording that both the unit-facing and counit-facing reads are attached to the same reflection boundary.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row shared by both sides of the comparison map.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source-side and completed-side reads inspect their observations.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the shared window and readback rows.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, R have been displayed.*
9. *H records componentwise* hsame *transport for the comparison map, unit route, counit route, reflection witness, readback, window, tolerance, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$Q, U, V, F \longmapsto S, D, R \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{BishopCompletionComparison}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, U, V, F, R, S, D, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 2102.2 (Cauchy completion comparison naturality obligations)**.** *For every accepted* $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *carrier*

$$M = (Q, U, V, F, R, S, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the completion-comparison map, unit route, counit route, reflection witness, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming row;*
2. *comparison-map exposure, requiring Q to display the two completion presentations before the unit square or counit square is inspected;*
3. *unit-square routing, requiring the source-side read to pass through U and the same Q, F, S, D, R, E rows before any Real-facing seal is public;*
4. *counit-square routing, requiring the completed-side read to pass through V and the same Q, F, S, D, R, E rows before any completion-facing consumer receives a seal;*
5. *reflection stability, requiring F to be the only witness row tying the unit and counit reads to the shared completion boundary;*
6. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the listed rows.*

No obligation is stored outside these rows, and none exports quotient completion equality, selected representatives, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Carrier admission is projection from Definition 2102.1. The accepted tuple displays exactly the completion-comparison map, unit route, counit route, reflection witness, analytic readback rows, and structural rows.

Comparison-map exposure is read from Q. Since Q occurs before the unit and counit routes are inspected, both naturality checks compare the same two completion presentations.

The unit-square obligation is read from U. A source-side consumer first enters through the completion unit and can reach the Real seal only by passing through the displayed comparison, reflection, window, tolerance, and readback rows.

The counit-square obligation is read from V. A completed-side consumer returns through the counit route and is compared against the same Q, F, S, D, R, E route rather than against a separate representative of a completion.

Reflection stability is supplied by F, while H, C, P, N add only componentwise transport, replay, provenance, and local naming. Since the carrier contains no coordinate for quotient equality, selected representatives, host equality, choice, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 2102.3 (Cauchy completion comparison naturality unit square)**.** *Let*

$$M = (Q, U, V, F, R, S, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *carrier. Every source-side read that compares the completion comparison map with the unit route factors through the finite square*

$$U \longmapsto Q, F \longmapsto S, D, R \longmapsto E.$$

Thus the unit naturality surface is a displayed NameCert route over $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCom}$ $\mathsf{BishopCompletionComparison}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It is not quotient completion equality, not selected representative equality, not host function equality, not countable choice, and not ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Fix a source-side read. Projection of the accepted carrier gives the unit row U, so the read enters the completion-facing surface through the displayed source admission route.

The comparison then uses Q and F. The comparison row supplies the two completion presentations, and the reflection row records that the unit-facing read is attached to the same completion boundary.

The analytic side of the square is forced through S, D, R, E. The finite window, dyadic tolerance ledger, regular rational readback, and terminal Real seal are the only observation rows available after the comparison and reflection rows.

Finally H, C, P, N preserve, replay, source, and name the same route. No row in the packet can replace the square by quotient equality, selected representatives, host equality, countable choice, or ambient completeness. □

Theorem 2102.4 (Cauchy completion comparison naturality counit square)**.** *Let*

$$M = (Q, U, V, F, R, S, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *carrier. Every completed-side read that compares the completion comparison map with the counit route factors through the finite square*

$$V \longmapsto Q, F \longmapsto S, D, R \longmapsto E.$$

Thus the counit naturality surface is a displayed NameCert route over $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{BishopCompletionComparison}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It is not quotient completion equality, not selected representative equality, not host function equality, not countable choice, and not ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Fix a completed-side read. Projection of the accepted carrier gives the counit row V, so the read returns from the completed presentation only through the displayed counit route.

The comparison rows are again Q and F. The completion-comparison map row supplies the same two presentations used by the unit square, and the reflection witness ties the completed-side read to the same boundary.

The terminal observation route is S, D, R, E. A completed-side consumer cannot reach the Real seal until the finite StreamName window, DyadicRatCore tolerance ledger, and RegSeqRat readback have all been displayed.

The structural rows H, C, P, N keep this counit square componentwise transported, replayable, sourced, and locally named. Since the carrier has no quotient, representative-choice, host-equality, countable-choice, ambient-completeness, Lean, or bridge coordinate, no completed-side consumer can export one from the packet. □

Theorem 2102.5 (Cauchy completion comparison naturality seal exhaustion)**.** *Let*

$$M = (Q, U, V, F, R, S, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *carrier. The unit naturality square and the counit naturality square consume the same finite route*

$$Q, U, V, F \longmapsto S, D, R \longmapsto E \longmapsto H, C, P, N.$$

No quotient completion equality, selected representative, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean bridge, or detached seal can be read outside that route.*

Proof. Carrier admission is projection from Definition 2102.1. The displayed rows are exactly $Q, U, V, F, R, S, D, E, H, C, P, N$, so any naturality consumer must enter through one of these coordinates.

Apply the obligation surface of Definition 2102.2. It requires Q to expose the comparison map, U to route the unit square, V to route the counit square, and F to tie both reads to the same completion-reflection boundary.

The two square theorems then identify the analytic tail. By Definition 2102.3, the source-side read reaches the seal only through S, D, R, E; by Definition 2102.4, the completed-side read reaches the seal through the same rows.

Finally H, C, P, N provide only componentwise transport, replay, provenance, and local naming for that finite route. Since no carrier coordinate stores quotient equality, representative selection, host function equality, countable choice, ambient completeness, a Lean bridge, or a detached seal, neither square can read such data outside the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2102.1, Definition 2102.2, Definition 2102.3, Definition 2102.4, and Definition 2102.5 seed the finite naturality squares tying the completion comparison map to the unit and counit routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison-map exposure, unit-square routing, counit-square routing, reflection stability, structural exhaustion, and finite readback exactness for BEDC.Derived.CauchyCompletionComparison

Constructive story: A $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ packet is generated from a completion comparison map row, CauchyCompletionUnit route, CauchyCompletionCounit route, CompletionReflection witness, shared StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2103

A Concrete Naming Certificate for $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the standard Lipschitz continuity principle that a displayed bound transports Cauchy names to Cauchy names, the $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ packet records the finite route by which a regular rational Cauchy name is read through a Lipschitz map and sealed as a Real-facing regular Cauchy output. It consumes the bound-carrying map surface of chapter 410, the input regular rational route of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite transport certificate for Real and Completion consumers; it is not a quotient map construction, a selected limit, host function extensionality, differentiability data, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2103.1 (Regular Cauchy Lipschitz map carrier)**.** *A* $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D, R_{\mathrm{out}}, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* $\mathsf{LipschitzMap}^{\uparrow}$ *row carrying the displayed graph and rational Lipschitz-bound ledger.*
2. *R_{in} is the input* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy name row.*
3. *W_{in} is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened on the input name for the requested tolerance.*
4. *W_{out} is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened on the transported output readings.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and bound ledger, recording the requested output radius, the bound-scaled input radius, and the comparison budgets used by the Lipschitz inequality.*
6. *R_{out} is the output* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after L, R_{in}, W_{in}, W_{out}, and D have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the output regular readback row is exposed.*
8. *H records componentwise* hsame *transport for the Lipschitz map, input readback, both stream windows, dyadic ledger, output readback, Real seal, continuation replay, package provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each finite Real or Completion tolerance request through*

$$L, R_{\text{in}}, W_{\text{in}}, W_{\text{out}}, D, R_{\text{out}} \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* RegularCauchyLipschitzMap$^{\uparrow}$, LipschitzMap$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyLipschitzMap}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host function extensionality, selected limits, differentiability, countable choice, trichotomy, ambient Real$^{\uparrow}$ *completeness, or a detached output seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLipschitzMapUp.RegularCauchyLipschitzMapTasteGate single carrier alignment`

Definition 2103.2 (Regular Cauchy Lipschitz map classifier)**.** *The* RegularCauchyLipschitzMap$^{\uparrow}$ *classifier compares accepted carriers only through componentwise* hsame *transport of the rows*

$$L, R_{\text{in}}, W_{\text{in}}, W_{\text{out}}, D, R_{\text{out}}, E, H, C, P, N.$$

Thus the Lipschitz bound ledger, input regular name, finite input and output windows, dyadic tolerance conversion, output regular readback, terminal Real seal, continuation replay, provenance, and local NameCert row are all part of the visible comparison surface. The classifier does not compare host functions extensionally, quotient regular streams, select representatives, assert differentiability, or import ambient completeness.

Theorem 2103.3 (Regular Cauchy Lipschitz map NameCert obligations)**.** *For every accepted* RegularCauchyLipschitzMap$^{\uparrow}$ *carrier*

$$T = (L, R_{\text{in}}, W_{\text{in}}, W_{\text{out}}, D, R_{\text{out}}, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLipschitzMap}^{\uparrow}}$ *surface consists exactly of carrier exposure for the displayed packet, source-map exposure through L, input regular-name exposure through R_{in}, finite input-window exposure through W_{in}, finite output-window exposure through W_{out}, dyadic tolerance and bound accounting through D, output regular readback through R_{out}, terminal* Real$^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier tuple in Definition 2103.1. Each listed coordinate is a finite row of the same BHist packet, and the last coordinate is the local NameCert row.

The analytic route is read in displayed order. A tolerance request first exposes the Lipschitz map row L and its bound ledger, then the input regular Cauchy row R_{in}, then the finite windows W_{in} and W_{out}, and then the dyadic conversion ledger D before the output readback R_{out} and terminal seal E are available.

The structural rows H, C, P, N transport, replay, source, and name only this route. Since the carrier contains no coordinate for quotient stream equality, host function extensionality, selected limits, differentiability, countable choice, trichotomy, ambient Real completeness, or a detached output seal, none of those principles can be part of the seed obligation surface. □

Theorem 2103.4 (Regular Cauchy Lipschitz map Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read accepted by a* $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ *carrier factors through the finite transport route*

$$\mathsf{LipschitzMap}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameC}$$

Equivalently, an accepted terminal seal read may consume the displayed Lipschitz map, the input regular name, finite input and output stream windows, the dyadic tolerance and bound ledger, and the output regular readback, but it cannot bypass them by quotient stream equality, selected limits, host function extensionality, differentiability data, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the obligation theorem Definition 2103.3. It exposes the terminal seal row E only after the Lipschitz row, input regular-name row, both finite stream windows, dyadic tolerance ledger, and output regular readback have been displayed.

The classifier definition Definition 2103.2 then transports accepted reads only by the componentwise hsame row and replays them only through the displayed Cont route. Thus a Real-facing consumer cannot replace the finite transport route by a host equality of functions or streams.

Finally inspect the carrier definition. There is no coordinate for quotient stream equality, selected limits, host function extensionality, differentiability, countable choice, trichotomy, ambient Real completeness, or a second Real seal. A terminal read omitting one of the displayed transport rows is therefore not accepted by the local classifier. □

Theorem 2103.5 (Regular Cauchy Lipschitz output classifier stability)**.** *Let*

$$T = (L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D, R_{\mathrm{out}}, E, H, C, P, N)$$

and

$$T' = (L', R'_{\mathrm{in}}, W'_{\mathrm{in}}, W'_{\mathrm{out}}, D', R'_{\mathrm{out}}, E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ *carriers. If the componentwise transport rows agree through* H *on* $L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D$*, then the output rows* R_{out} *and* R'_{out} *agree under the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier before either terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *or* E' *is read.*

Proof. Start from the classifier surface in Definition 2103.2. It compares accepted carriers through componentwise hsame transport of the displayed source rows, so agreement through H fixes the Lipschitz row, input regular name, both stream windows, and dyadic ledger.

Replay the displayed continuation row C. Since C reads output observations only after $L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D$, the same source rows force the same output regular readback route.

The Lipschitz bound ledger D supplies the bound-scaled tolerance conversion. With the same input windows and dyadic accounting, the output readings are compared by the $\mathsf{RegSeqRat}^{\uparrow}$ classifier at R_{out} and R'_{out}.

Only after that classifier agreement is visible may the terminal Real seals E and E' be exposed. Thus the stability claim concerns the output regular Cauchy readback itself, not a later quotient or selected real representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLipschitzMap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ packet is generated from a LipschitzMap row, an input RegSeqRat name row, finite StreamName input and output windows, a DyadicRatCore tolerance and bound ledger, an output RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLipschitzMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2103.1, Definition 2103.2, Definition 2103.3, and Definition 2103.4 seed the finite Lipschitz transport route from displayed regular Cauchy input names through dyadic bound accounting to output regular readback and the terminal RealUp seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyLipschitzMap}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host function extensionality, differentiability, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, componentwise classifier transport, Lipschitz tolerance conversion, output regular readback, and Real-seal nonescape for BEDC.Derived.RegularCauchyLipschitzMapUp.

Chapter 2104

A Concrete Naming Certificate for $\mathsf{GromovHausdorff}^{\uparrow}$

Following Gromov's metric-geometry formulation and Hausdorff's compact-subset distance, the $\mathsf{GromovHausdorff}^{\uparrow}$ packet records compact-metric comparison by finite correspondence rows and dyadic distortion bounds. It sits over the metric source of chapter 57, the compact-metric surface of chapter 129, the compact-subset ledger of chapter 1660, the finite-distance interface of chapter 2086, and the distance-function route of chapter 7569. The packet compares two displayed compact metric endpoints; it is not a quotient compactum, a selected optimal correspondence, an open-cover compactness theorem, a host metric-space equality principle, or an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 2104.1 (Gromov–Hausdorff comparison carrier)**.** *A* $\mathsf{GromovHausdorff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, K_X, K_Y, R, D, H, Q, U, T, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two compact-metric endpoint names. Each endpoint row records the displayed* $\mathsf{Met}^{\uparrow}$ *source, point-name admission data, compact finite-net schedules, and the request for which a comparison certificate is exposed.*
2. *K_X and K_Y are the endpoint* $\mathsf{CompactMetric}^{\uparrow}$ *rows consumed before any correspondence row may be inspected.*
3. *R is the finite correspondence table. Its rows list finitely many endpoint point-name pairs, the two projection-coverage ledgers, and the local inhabitedness witnesses needed for a comparison read.*
4. *D is the dyadic distortion ledger. It records finite* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *bounds comparing the two endpoint distance reads along every displayed pair of correspondence rows.*
5. *H records the* $\mathsf{HausdorffMetric}^{\uparrow}$ *and* $\mathsf{Hyperspace}^{\uparrow}$ *comparison rows used to read the two projection-coverage ledgers as compact-subset distance data rather than as host powersets.*
6. *Q records the* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *handoff used when a consumer asks to view the same comparison through distance-function observations.*
7. *U records componentwise* hsame *transport for endpoints, compact-metric rows, correspondence rows, dyadic distortion bounds, Hausdorff and hyperspace comparison rows, Kuratowski handoff, replay, provenance, and local naming rows.*

8. *T records displayed transport of the finite comparison surface across accepted endpoint renamings; it carries only rows already present in $X, Y, K_X, K_Y, R, D, H, Q, U$.*

9. *C records displayed* Cont *replay of the route*

$$X, Y, K_X, K_Y \longmapsto R \longmapsto D \longmapsto H, Q \longmapsto U, T.$$

10. *P is the* Pkg *provenance over* $\mathsf{GromovHausdorff}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{KuratowskiEmbedding}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GromovHausdorff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, K_X, K_Y, R, D, H, Q, U, T, C, P, N$. It has no coordinate for quotient compacta, selected optimal correspondences, open-cover compactness, host metric-space equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or semantic isometry of completed spaces.*

Lean4 ✓ `BEDC.Derived.GromovHausdorffUp.GromovHausdorffTasteGate single carrier alignment`

Theorem 2104.2 (GromovHausdorffUp NameCert obligations)**.** *For every accepted* $\mathsf{GromovHausdorff}^{\uparrow}$ *carrier*

$$G = (X, Y, K_X, K_Y, R, D, H, Q, U, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GromovHausdorff}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *endpoint admission for the two compact-metric names X, Y and their* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *support rows K_X, K_Y;*

2. *correspondence admission for the finite table R, requiring both endpoint projections and local inhabitedness witnesses to be displayed before any distortion read is public;*

3. *dyadic distortion exactness for D, requiring every displayed pair of correspondence rows to read both endpoint distances and the shared dyadic bound through the same finite table;*

4. *compact-subset comparison compatibility for H, requiring the projection-coverage rows to be read through the* $\mathsf{HausdorffMetric}^{\uparrow}$ *and* $\mathsf{Hyperspace}^{\uparrow}$ *surfaces;*

5. *Kuratowski observation compatibility for Q, requiring any distance-function view of the same comparison to pass through the displayed* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *handoff;*

6. *classifier transport through U, T, C, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve endpoints, correspondence rows, distortion bounds, comparison handoffs, provenance, and local name;*

7. *provenance and name exhaustion through P, N, excluding quotient compacta, selected correspondences, open-cover compactness, host metric-space equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and completed-space isometry.*

No Gromov–Hausdorff obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.GromovHausdorffUp.GromovHausdorffCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 2104.1. The endpoint rows X, Y and compact-metric support rows K_X, K_Y are the only compact metric surfaces that a consumer may inspect.

The finite correspondence table R supplies both endpoint projections and the inhabitedness witnesses. The dyadic distortion ledger D then reads every displayed pair of correspondence rows against the two endpoint distance witnesses, so no distortion statement can be formed from data outside the finite table.

The compact-subset comparison row H routes projection coverage through $\mathsf{HausdorffMetric}^{\uparrow}$ and $\mathsf{Hyperspace}^{\uparrow}$, while Q routes distance-function observations through $\mathsf{KuratowskiEmbedding}^{\uparrow}$. These rows are handoffs inside the packet, not ambient compacta or host function spaces.

Finally U, T, C preserve and replay the same route componentwise, and P, N name exactly that finite route. Since the carrier has no row for quotient compacta, selected optimal correspondences, open-cover compactness, host metric-space equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or completed-space isometry, the seven listed rows exhaust the local naming obligations. □

Theorem 2104.3 (Correspondence bridge to compact-metric comparison)**.** *Every* $\mathsf{Met}^{\uparrow}$*-,* $\mathsf{CompactMetric}^{\uparrow}$*-,* $\mathsf{HausdorffMetric}^{\uparrow}$*-,* $\mathsf{Hyperspace}^{\uparrow}$*-, or* $\mathsf{KuratowskiEmbedding}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{GromovHausdorff}^{\uparrow}$ *carrier factors through the finite route*

$$X, Y, K_X, K_Y \longmapsto R \longmapsto D \longmapsto H, Q \longmapsto U, T, C, P, N.$$

Consequently the consumer receives only the displayed compact-metric endpoints, finite correspondence rows, dyadic distortion bounds, compact-subset comparison rows, Kuratowski observation handoff, componentwise transport, replay, provenance, and local name. It cannot derive a quotient compactum, selected optimal correspondence, open-cover compactness proof, host metric-space equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or isometry of completed spaces from the packet.*

Proof. Start with the endpoint rows. Any metric or compact-metric read reaches X, Y, K_X, K_Y first, so the comparison is anchored in displayed point names, distance witnesses, and compact finite-net schedules.

Next inspect the correspondence route. The row R is the only finite relation between the endpoints, and D is the only dyadic distortion ledger attached to it; therefore a compact-metric comparison consumer must pass through R before reading any bound.

The bridge rows then determine the available external views. A Hausdorff or hyperspace consumer reads H, and a Kuratowski-style distance-function consumer reads Q, but both rows consume the same correspondence and distortion data.

The structural rows U, T, C, P, N preserve the route under componentwise transport, replay it, source it, and name it. Because no further coordinate is present, the consumer boundary is exactly the displayed finite comparison surface and nothing beyond it. □

Theorem 2104.4 (Gromov-Hausdorff pointed basepoint forgetful route)**.** *Let a* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *packet feed a* $\mathsf{GromovHausdorff}^{\uparrow}$ *endpoint. The endpoint may be consumed only through the forgotten-basepoint rows*

$$\mathsf{Met}^{\uparrow}, \quad \mathsf{CompleteMetric}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The $\mathsf{GromovHausdorff}^{\uparrow}$ *correspondence cannot inspect, preserve, or compare the basepoint row unless a separate pointed Gromov-Hausdorff carrier supplies an explicit pointed endpoint row.*

Proof. Project the $\mathsf{GromovHausdorff}^{\uparrow}$ carrier of Definition 2104.1. Its endpoint coordinates are X, Y, K_X, K_Y, and its comparison coordinates are $R, D, H, Q, U, T, C, P, N$.

Use Definition 2104.3. Any metric-comparison consumer first reads the ordinary metric and compact-metric endpoint rows, then the correspondence and distortion rows, and finally the Hausdorff, hyperspace, Kuratowski, transport, replay, provenance, and naming rows.

A $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ source may provide such an endpoint only by forgetting its basepoint row and exposing the metric, complete-metric, regular-rational, and real-seal rows. The basepoint route belongs to chapter 4368, not to the ordinary Gromov-Hausdorff carrier.

Since no basepoint coordinate appears among $X, Y, K_X, K_Y, R, D, H, Q, U, T, C, P, N$, the correspondence cannot preserve or compare it. A pointed comparison therefore requires a separate pointed endpoint row. □

Closure status for $\mathsf{NameCert}_{\mathsf{GromovHausdorff}^{\uparrow}}$.

Constructive story: A $\mathsf{GromovHausdorff}^{\uparrow}$ packet is generated from two compact-metric endpoints, finite correspondence rows, dyadic distortion bounds, HausdorffMetricUp and HyperspaceUp comparison rows, a KuratowskiEmbeddingUp observation handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GromovHausdorff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2104.1, Definition 2104.2, and Definition 2104.3 seed the finite correspondence interface for compact-metric comparison without importing quotient, selected-correspondence, open-cover, host-equality, or ambient-completeness principles.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GromovHausdorff}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.GromovHausdorffUp.GromovHausdorffCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close quotient compacta, selected correspondences, open-cover compactness, host metric-space equality, ambient RealUp completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked endpoint admission, correspondence admission, dyadic distortion exactness, compact-subset comparison compatibility, Kuratowski observation compatibility, classifier transport, and provenance/name exhaustion for BEDC.Derived.GromovHausdorffUp.

Chapter 2105

A Concrete Naming Certificate for $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$ packet records the finite route by which a 1-Lipschitz, hence nonexpansive, map transports regular Cauchy rational names without enlarging the requested tolerance. It refines the bound-carrying map surface of chapter 410 by fixing the Lipschitz ledger at the nonexpansive unit boundary, and it consumes the input regular rational route of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a precise nonexpansive transport boundary rather than reusing a broader Lipschitz packet with an arbitrary displayed bound.

Definition 2105.1 (Regular Cauchy nonexpansive map carrier)**.** *A* $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M_{\mathrm{src}}, M_{\mathrm{tgt}}, L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D, R_{\mathrm{out}}, E, H, C, P, N)$$

with the following displayed rows:

1. M_{src} *and* M_{tgt} *are the source and target metric rows on which the transport is read.*
2. L *is the* $\mathsf{LipschitzMap}^{\uparrow}$ *row carrying the displayed graph and a bound ledger fixed to the nonexpansive unit boundary.*
3. R_{in} *is the input* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy name row.*
4. W_{in} *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened on the input name for the requested target tolerance.*
5. W_{out} *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened on the transported output readings.*
6. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the target radius, the unchanged input radius justified by the unit-bound row, and the comparison cells used by the nonexpansive inequality.*
7. R_{out} *is the output* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after* L, R_{in}, W_{in}, W_{out}, *and* D *have been displayed.*
8. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the output regular readback row is exposed.*
9. H *records componentwise* hsame *transport for the metric rows, Lipschitz row, input readback, both stream windows, dyadic ledger, output readback, Real seal, continuation replay, package provenance, and local naming rows.*

10. *C records displayed* Cont *replay from each finite Real or Completion tolerance request through*

$$M_{\mathrm{src}}, M_{\mathrm{tgt}}, L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D, R_{\mathrm{out}} \longmapsto E, H, P, N.$$

11. *P is the* Pkg *provenance over* RegularCauchyNonexpansiveMap$^{\uparrow}$, LipschitzMap$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{RegularCauchyNonexpansiveMap}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host function extensionality, selected limits, differentiability, countable choice, trichotomy, ambient Real$^{\uparrow}$ *completeness, a detached Lipschitz bound greater than the unit row, or a detached output seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNonexpansiveMapUp.TasteGate.RegularCauchyNonexpansiveMapTasteGate`
`single carrier alignment`

Theorem 2105.2 (Regular Cauchy nonexpansive map NameCert obligations)**.** *For every accepted* RegularCauchyNonexpansiveMap$^{\uparrow}$ *carrier*

$$T = (M_{\mathrm{src}}, M_{\mathrm{tgt}}, L, R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D, R_{\mathrm{out}}, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyNonexpansiveMap}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source metric, target metric, Lipschitz map, input regular name, finite input and output windows, dyadic tolerance ledger, output regular readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *nonexpansive bound discipline, requiring the displayed Lipschitz row L to use only the unit-bound ledger and requiring D to route a target tolerance to the same input tolerance rather than to a bound-scaled radius;*
3. *input regular-name exposure, requiring every transported read to begin with the displayed* RegSeqRat$^{\uparrow}$ *row R_{in} and the finite input window W_{in};*
4. *output regular readback, requiring R_{out} to be obtained from the displayed Lipschitz row, windows, and dyadic unit-bound comparisons;*
5. *Real-seal nonescape, requiring E to be downstream of R_{out} and to export no quotient stream equality, selected limit, host function extensionality, differentiability, countable choice, trichotomy, or ambient* Real$^{\uparrow}$ *completeness;*
6. *provenance and local naming, requiring H, C, P, N to transport, replay, source, and name only the displayed nonexpansive route.*

No RegularCauchyNonexpansiveMap$^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2105.1. The accepted packet displays exactly the metric, Lipschitz, regular-name, stream-window, dyadic, output-readback, seal, transport, replay, provenance, and naming coordinates.

The nonexpansive bound discipline is the special role of L and D. The Lipschitz row supplies the map surface, but the accepted bound ledger is fixed at the unit row, so the dyadic tolerance request is replayed without multiplication by a larger rational bound.

Input exposure and output readback are then forced by the route $R_{\mathrm{in}}, W_{\mathrm{in}}, W_{\mathrm{out}}, D, R_{\mathrm{out}}$. The output regular row is visible only after the source regular name, finite windows, and unit-bound comparisons have all been displayed.

Finally E, H, C, P, N close the route. The Real seal is downstream of the output readback, and the structural rows preserve only the displayed coordinates, leaving no carrier position from which an accepted consumer could extract the excluded objects. □

Theorem 2105.3 (Regular Cauchy nonexpansive map Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer read accepted by a* $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$ *carrier factors through the finite transport route*

$$\mathsf{LipschitzMap}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameC}$$

Equivalently, an accepted terminal seal read may consume the displayed nonexpansive Lipschitz row, the input regular name, finite input and output stream windows, the dyadic unit-bound tolerance ledger, and the output regular readback, but it cannot bypass them by quotient stream equality, selected limits, host function extensionality, differentiability data, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the obligation theorem Definition 2105.2. It exposes the terminal seal row E only after the Lipschitz row with unit-bound ledger, the input regular-name row, both finite stream windows, the dyadic tolerance ledger, and the output regular readback have been displayed.

The displayed Cont route then replays each Real-facing request through the same rows. Since the dyadic ledger records the target tolerance as the input tolerance, the handoff uses the nonexpansive boundary rather than a detached larger Lipschitz constant.

Finally inspect the carrier definition. There is no coordinate for quotient stream equality, selected limits, host function extensionality, differentiability, countable choice, trichotomy, ambient Real completeness, or a second Real seal. A terminal read omitting one of the displayed transport rows is therefore not accepted by the local classifier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$ packet is generated from source and target metric rows, a LipschitzMap row whose bound ledger is fixed at the nonexpansive unit boundary, an input RegSeqRat name row, finite StreamName input and output windows, a DyadicRatCore tolerance ledger, an output RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2105.1, Definition 2105.2, and Definition 2105.3 seed the finite nonexpansive transport route from displayed regular Cauchy input names through unit-bound dyadic accounting to output regular readback and the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host function extensionality, differentiability, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nonexpansive bound stability, output readback, Real-seal nonescape, and BEDC.Derived.RegularCauchyNonexpansiveMapUp formalization.

Chapter 2106

A Concrete Naming Certificate for $\mathsf{DyadicValuation}^{\uparrow}$

Following Bourbaki and standard valuation theory, the $\mathsf{DyadicValuation}^{\uparrow}$ packet records the finite dyadic valuation data needed before scale normalization and tolerance comparison may be consumed by the Real and Completion route. It sits over the dyadic arithmetic carrier of chapter 291, the signed mantissa and unary exponent boundary of chapter 1865, the finite scale-domination route of chapter 1672, and the precision handoff surface of chapter 1768. The packet isolates the valuation row as finite data: downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers may read scale order and tolerance bounds without quotient rational equality, host integer normal forms, trichotomy, selected representatives, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2106.1 (Dyadic valuation carrier)**.** *A* $\mathsf{DyadicValuation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, E, Z, V, C, T, H, R, P, N)$$

with the following displayed rows:

1. *M is the signed mantissa row, read through the* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *surface and not through a host integer normal form.*
2. *E is the unary exponent row, recording the denominator scale and successor ledger used by the valuation comparison.*
3. *Z is the zero/nonzero branch row, separating the displayed zero case from the displayed nonzero valuation route without invoking trichotomy.*
4. *V is the valuation row, recording the finite exponent count exposed after M, E, Z have been projected.*
5. *C is the common-scale replay row, transporting compared dyadic packets to the same displayed scale before valuation comparison is read.*
6. *T is the* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *handoff row, exposing the valuation scale to tolerance consumers after the common-scale replay has been displayed.*
7. *H records componentwise* hsame *transport for mantissa, exponent, zero/nonzero branch, valuation, common-scale replay, tolerance handoff, continuation, provenance, and local naming rows.*

8. *R records displayed* Cont *replay from signed dyadic inspection through exponent reading, zero/nonzero branching, valuation exposure, common-scale replay, tolerance handoff, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicValuation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{SignedDyadicNormalForm}^{\uparrow}$, $\mathsf{DyadicArchimedean}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicValuation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, Z, V, C, T, H, R, P, N$. It has no coordinate for quotient rational equality, host integer normal forms, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicValuationUp.DyadicValuationTasteGate single carrier alignment`

Theorem 2106.2 (Dyadic valuation NameCert obligations)**.** *For every accepted* $\mathsf{DyadicValuation}^{\uparrow}$ *carrier $D = (M, E, Z, V, C, T, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicValuation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the signed mantissa, unary exponent, zero/nonzero branch, valuation row, common-scale replay, tolerance handoff, transport, replay, provenance, and local naming rows;*
2. *branch exactness, requiring Z to expose the displayed zero case and the displayed nonzero route before V can be consumed;*
3. *unary valuation induction, requiring V to be read by finite induction over the exponent row E and the branch row Z;*
4. *common-scale stability, requiring C to replay compared dyadic packets at one displayed scale before valuation comparison or tolerance handoff is exported;*
5. *tolerance handoff locality, requiring T to consume only the displayed valuation and common-scale rows;*
6. *classifier transport and replay, requiring H and R to preserve M, E, Z, V, C, T, P, N componentwise;*
7. *ledger non-escape, excluding quotient rational equality, host integer normal forms, trichotomy, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No dyadic valuation obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic rows are M, E, Z, V, C, T, while H, R, P, N transport, replay, source, and name the same finite packet.

Branch exactness is read from Z. The zero side exposes the displayed zero row, and the nonzero side opens the route in which the signed mantissa and unary exponent rows can be inspected. The carrier has no trichotomy row, so this split is only the displayed finite branch.

Unary valuation induction is then performed over E. In the base case the exponent ledger has no successor step, so V records the current valuation row after the branch has been fixed. In the successor step the induction hypothesis is transported through the next exponent row, and the valuation count is extended by that single displayed successor.

The common-scale and tolerance clauses are projections from C and T. The row C is the only common-scale replay, so valuation comparison between packets must pass through it before the tolerance handoff T can be read.

Finally H and R preserve the displayed rows componentwise, while P and N record provenance and local naming. Since the excluded objects do not occur in the carrier, no local NameCert obligation can be stored outside $M, E, Z, V, C, T, H, R, P, N$. □

Theorem 2106.3 (Dyadic valuation common-scale stability)**.** *Let $D = (M, E, Z, V, C, T, H, R, P, N)$ be an accepted* $\mathsf{DyadicValuation}^{\uparrow}$ *carrier. Every valuation comparison exported by D factors through the finite route*

$$M, E, Z, V \longmapsto C \longmapsto H, R, P, N.$$

Thus two accepted replays with componentwise hsame *rows expose the same common-scale valuation surface, and the comparison does not use quotient rational equality, host integer normal forms, trichotomy, selected representatives, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an exported valuation comparison. Carrier admission places the only valuation coordinate at V, and V is downstream of the signed mantissa row M, unary exponent row E, and branch row Z.

The common-scale row C is then the only replay coordinate available for comparing two dyadic packets. It transports the displayed valuation data to a shared scale before any comparison surface is exported.

For stability, read componentwise transport through H and continuation replay through R. These rows preserve M, E, Z, V, C exactly as displayed rows, while P and N only source and name the same route.

Hence an accepted replay exposes the same finite common-scale valuation surface. The conclusion is internal to the packet and has no coordinate for the excluded quotient, host, choice, or completeness principles. □

Theorem 2106.4 (Dyadic valuation tolerance handoff)**.** *Every* $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer named by an accepted* $\mathsf{DyadicValuation}^{\uparrow}$ *carrier reads the route*

$$M, E, Z, V, C \longmapsto T \longmapsto H, R, P, N.$$

Consequently the consumer receives finite valuation and common-scale data before any tolerance-scale comparison is available, with no quotient rational equality, host integer normal form, trichotomy, selected representative, countable-choice row, or $\mathsf{Real}^{\uparrow}$ *completeness witness inserted into the route.*

Proof. Project the tolerance handoff row T. It is the sole row whose purpose is to expose valuation data to $\mathsf{DyadicToleranceScale}^{\uparrow}$ and to the downstream stream, regular-rational, and real-name consumers.

The handoff is downstream of M, E, Z, V, C. Therefore a consumer first reads the signed mantissa, unary exponent, zero/nonzero branch, valuation row, and common-scale replay before it can inspect tolerance-scale data.

The route is preserved by H and replayed by R. Provenance and local naming through P, N source the same packet and do not add a second route to tolerance data.

Thus every listed consumer receives a finite valuation handoff. Since no excluded coordinate is present in the carrier, the handoff cannot import quotient rational equality, host integer normal forms, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicValuation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicValuation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2106.1, Definition 2106.2, Definition 2106.3, and Definition 2106.4 seed the finite dyadic valuation surface from signed mantissa, unary exponent, zero/nonzero branch, valuation row, common-scale replay, tolerance handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicValuation}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.DyadicValuationUp`

Bridge status: none

Not claimed: This chapter does not close quotient rational equality, host integer normal forms, trichotomy, selected representatives, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch exactness, unary valuation induction, common-scale stability, tolerance handoff locality, classifier transport, replay, provenance, and local naming for BEDC.Derived.DyadicValuationUp.

Constructive story: A DyadicValuation$^{\uparrow}$ packet is generated from a signed mantissa row, unary exponent row, zero/nonzero branch row, valuation row, common-scale replay, DyadicToleranceScale handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2107

A Concrete Naming Certificate for $\mathsf{Subshift}^{\uparrow}$

Following Lind–Marcus symbolic dynamics and Brouwer–Bishop finite-prefix practice, $\mathsf{Subshift}^{\uparrow}$ records shift-invariant closed symbolic subspaces through finite prefix-language rows over $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$, with $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ as the finite forbidden-word specialization. The packet is a finite certificate surface for symbolic prefix languages; it is not a host infinite sequence, quotient shift space, entropy object, invariant measure, compactness principle, or ambient symbolic-dynamics theorem. Its dependency route is the Cantor prefix surface of chapter 1475, the Baire prefix surface of chapter 334, the finite stream-window route of chapter 126, and the forbidden-ledger specialization of chapter 434.

Definition 2107.1 (Subshift carrier)**.** *A* $\mathsf{Subshift}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (A, W, L, S, C, B, H, K, P, N)$$

with the following displayed rows:

1. *A is the finite alphabet row, naming the visible symbols available to the local prefix language.*
2. *W is the finite window row, recording the inspected word lengths and prefix positions.*
3. *L is the allowed-language ledger, listing the admitted finite prefix rows over A at the windows in W.*
4. *S is the shift-restriction row, recording the finite left and right prefix restrictions that must remain in L whenever a longer accepted row is shifted or truncated.*
5. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *row used when the alphabet row is the displayed binary row.*
6. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *row used when the alphabet row is read as unary-coded countable symbols.*
7. *H records componentwise* hsame *transport for $A, W, L, S, C, B, K, P, N$.*
8. *K records the* Cont *routes from prefix requests to Cantor rows, Baire rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, language-ledger inspection, shift restriction, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{Subshift}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{SubshiftOfFiniteType}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Subshift}^{\uparrow}}$ *row for the finite prefix-language classifier.*

The classifier compares accepted packets only through the displayed prefix rows. It accepts a prefix read exactly when the corresponding finite row is present in L, every recorded shift or restriction is certified by S, and the Cantor, Baire, or stream-name access route is one of the rows named by C, B, K, P, N.

Lean4 ✓ `BEDC.Derived.SubshiftUp.SubshiftTasteGate single carrier alignment`

Theorem 2107.2 (Subshift NameCert obligations)**.** *For every accepted* $\mathsf{Subshift}^{\uparrow}$ *packet* $X = (A, W, L, S, C, B, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Subshift}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the alphabet, window, allowed-language, shift-restriction, Cantor, Baire, transport, continuation, provenance, and local naming rows;*
2. *prefix classifier stability, requiring componentwise* hsame *transport to preserve membership and nonmembership decisions in the finite language ledger L;*
3. *shift-restriction stability, requiring every displayed shift, truncation, and prefix restriction named by S to land again in the admitted ledger row;*
4. *Cantor/Baire handoff, requiring binary reads to pass through the* $\mathsf{CantorSpace}^{\uparrow}$ *row C, countable-symbol reads to pass through the* $\mathsf{BaireSpace}^{\uparrow}$ *row B, and all finite requests to pass through the* $\mathsf{StreamName}^{\uparrow}$ *route named by K;*
5. *finite-type specialization, requiring any finite forbidden-word ledger to be read as the* $\mathsf{SubshiftOfFiniteType}^{\uparrow}$ *instance whose accepted words are exactly the rows of L avoiding the displayed forbidden ledger;*
6. *non-escape, excluding host infinite sequences, quotient shift spaces, entropy, invariant measures, compactness principles, unrecorded branch choice, and ambient symbolic-dynamics theorems.*

No $\mathsf{Subshift}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the accepted carrier. The packet exposes only the rows $A, W, L, S, C, B, H, K, P, N$, so carrier admission is the assertion that those rows form the visible prefix-language certificate.

Prefix classifier stability is componentwise. Transport A, W, L through the displayed hsame rows in H; a membership decision remains available exactly when the transported prefix row is the transported ledger row. There is no second classifier coordinate that could alter the decision.

Shift-restriction stability is read from S. Each displayed shift, truncation, or prefix restriction consumes one accepted finite word row and returns the recorded shorter row in L. The continuation row K replays only those finite moves.

For the handoff clause, split by the source row. Binary prefix reads use C and therefore cite chapter 1475; countable-symbol reads use B and therefore cite chapter 334; every scheduled finite read is opened through the $\mathsf{StreamName}^{\uparrow}$ route named in K.

The finite-type specialization is obtained by taking L to be the list of finite words whose displayed subwords avoid a finite forbidden ledger. This is exactly the local surface of chapter 434, with S recording the same finite restriction checks.

Finally, non-escape follows from absence of coordinates for the excluded objects. A downstream consumer can project only the alphabet, window, language ledger, shift restriction, Cantor and Baire handoff rows, transport, continuation, provenance, and local $\mathsf{NameCert}$ row. □

Theorem 2107.3 (Subshift Cantor/Baire handoff)**.** *Every accepted* $\mathsf{Subshift}^{\uparrow}$ *read factors through the finite prefix route*

$$\mathsf{CantorSpace}^{\uparrow}, \mathsf{BaireSpace}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto A, W, L, S \longmapsto H, K, P, N$$

before any downstream symbolic-dynamics consumer can use the accepted word row. In particular, the consumer receives a displayed Cantor or Baire prefix packet and the scheduled stream-name window before it receives the subshift language decision, and no host infinite sequence, quotient shift space, entropy value, invariant measure, compactness principle, or ambient symbolic-dynamics theorem is inserted into the route.

Proof. Start with an accepted read. Carrier admission places the source access rows at C and B, the finite scheduling row at K, and the language decision rows at A, W, L, S.

If the visible alphabet is binary, the read first opens the $\mathsf{CantorSpace}^{\uparrow}$ row C. If the alphabet is countable-name data, it opens the $\mathsf{BaireSpace}^{\uparrow}$ row B. In both cases the finite request is then scheduled through the $\mathsf{StreamName}^{\uparrow}$ route recorded by K.

Only after that route is displayed can the consumer inspect A, W, L, S. The ledger L supplies the accepted prefix decision, while S supplies the shift or restriction row needed by shift-invariant use.

Transport and replay through H and K preserve the same finite rows, and P, N only source and name the packet. Since the carrier has no coordinate for the excluded objects, every downstream symbolic-dynamics consumer receives exactly the displayed finite prefix route. □

Closure status for $\mathsf{NameCert}_{\mathsf{Subshift}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Subshift}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2107.1, Definition 2107.2, and Definition 2107.3 seed the finite prefix-language surface for shift-invariant symbolic subspaces over Cantor, Baire, and StreamName rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Subshift}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sequences, quotient shift spaces, entropy, invariant measures, compactness principles, unrecorded branch choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix classifier stability, shift-restriction stability, Cantor/Baire handoff, finite-type specialization, and non-escape for BEDC.Derived.SubshiftUp.

Constructive story: A $\mathsf{Subshift}^{\uparrow}$ packet is generated from a finite alphabet row, finite window row, allowed-language ledger, shift-restriction row, Cantor and Baire handoff rows, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Chapter 2108

A Concrete Naming Certificate for $\mathsf{BisectionMethod}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BisectionMethod}^{\uparrow}$ packet records the method-level certificate by which located interval data, finite branch ledgers, retained nested windows, stream-name readback, regular rational names, and terminal real seals are exposed before any root-location or intermediate-value consumer can read a Real-facing result. It unifies the dyadic branch surface of chapter 361, the located interval route of chapter 1711, the convergence handoff of chapter 1804, the retained window discipline of chapter 320, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a finite method certificate for L10 Real and Completion routes; it does not select a root, complete an intersection, assert trichotomy, invoke open-cover compactness, identify quotient real names, or add a choice principle.

Definition 2108.1 (BisectionMethod carrier)**.** *A* $\mathsf{BisectionMethod}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, D, L, W, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval source row, exposing the endpoint names, locator reads, sign or bracket tests, and the initial tolerance request consumed by the method.*
2. *D is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, recording the finite dyadic midpoint decisions and the branch labels inspected at each visible stage.*
3. *L is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *route, transporting the displayed branch decision to the retained child interval without adding a host-order trichotomy row.*
4. *W is the retained* $\mathsf{NestedInterval}^{\uparrow}$ *window row, listing the finite interval windows that remain available to downstream consumers.*
5. *T is the finite termination and tolerance budget row, binding requested precision to a displayed bisection depth, diameter estimate, and ledger-exhaustion check.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposed from W and T, with no completed infinite branch or global selector.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained stream windows and their dyadic tolerance witnesses.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after I, D, L, W, T, S, R have been displayed.*

9. *H records componentwise* hsame *transport for located interval source, dyadic branch ledger, located bisection route, retained nested windows, termination budget, stream windows, regular rational readback, real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the method route*

$$I, D, L, W, T \longmapsto S \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{BisectionMethod}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BisectionMethod}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, L, W, T, S, R, E, H, C, P, N$. It has no coordinate for a selected root, completed intersection, trichotomy, open-cover compactness, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BisectionMethodUp.BisectionMethodTasteGate single carrier alignment`

Theorem 2108.2 (BisectionMethod NameCert obligations)**.** *For every accepted* $\mathsf{BisectionMethod}^{\uparrow}$ *carrier*

$$M = (I, D, L, W, T, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BisectionMethod}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the located interval source, dyadic branch ledger, located bisection route, retained nested window, finite termination budget, stream windows, regular rational readback, real seal, transport, replay, provenance, and local name;*

2. *classifier transport, requiring H and C to preserve the displayed method rows componentwise and to replay only the route shown by the carrier;*

3. *branch-retention stability, requiring every retained child interval in W to be justified by the dyadic branch ledger D and the located route L;*

4. *finite-window termination, requiring the budget row T to bind each precision request to a displayed finite depth, diameter witness, and stream-window exposure;*

5. *real-seal nonescape, requiring E to be read only after S and R have displayed finite windows and regular rational readback;*

6. *ledger exhaustion, requiring every exported branch decision, retained window, readback, and seal request to occur in $I, D, L, W, T, S, R, E, H, C, P, N$.*

No BisectionMethod obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2108.1. The accepted packet displays exactly the source interval, branch ledger, located bisection route, retained windows, termination budget, finite stream windows, regular readback, terminal seal, and structural rows.

Classifier transport is forced by H and C. These rows preserve and replay only the displayed coordinates, so an accepted comparison cannot introduce a second route to branch data, tolerance data, readback, or the Real-facing seal.

Branch-retention stability is read from D, L, W. A retained child interval appears in W only after the dyadic branch ledger D has recorded the visible decision and the located route L has transported that decision to the displayed child interval.

Finite-window termination is internal to T. The row binds each request to a finite depth, diameter estimate, and ledger-exhaustion check before the stream window row S is available to the regular rational readback R.

The real-seal clause follows because E is downstream of S and R. A Real-facing consumer must first consume the displayed finite windows and regular rational readback, so the seal cannot be reached through a hidden branch selector or completed intersection.

Finally, P and N only source and name the same packet. Since the carrier contains no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2108.3 (BisectionMethod Real seal route)**.** *Every root-location or intermediate-value consumer of an accepted* $\mathsf{BisectionMethod}^{\uparrow}$ *carrier factors through the finite route*

$$I, D, L, W, T \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before reading any $\mathsf{Real}^{\uparrow}$ *seal. Consequently the consumer receives only the displayed located interval source, dyadic branch ledger, located bisection route, retained nested windows, finite termination budget, stream windows, regular rational readback, terminal real seal, componentwise transport, continuation replay, package provenance, and local naming data. It exports no selected root, completed intersection, trichotomy, open-cover compactness, quotient equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier $M = (I, D, L, W, T, S, R, E, H, C, P, N)$. The source interval coordinate is I, so every method request begins with displayed endpoint, locator, bracket, and tolerance data.

The dyadic and located bisection rows form the visible branch step. The ledger D records the branch decision, and the route L transports that decision to the retained interval window exposed by W.

The finite termination row T supplies the quantitative stop condition. It records the requested precision, the finite depth, the diameter witness, and the ledger-exhaustion check before any stream-name window is exported.

The row S is therefore downstream of I, D, L, W, T, and the row R is downstream of S. The terminal real seal E is read only after the regular rational readback has been exposed.

The structural rows H, C, P, N preserve this displayed route under componentwise transport, replay, provenance, and naming. Because no carrier coordinate stores a selected root, completed intersection, trichotomy, compactness principle, quotient equality, choice schedule, or ambient completeness witness, no such object can be exported by a consumer of the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BisectionMethod}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BisectionMethod}^{\uparrow}$ packet is generated from a located interval source row, a $\mathsf{DyadicBisection}^{\uparrow}$ branch ledger, a $\mathsf{LocatedIntervalBisection}^{\uparrow}$ route, retained $\mathsf{NestedInterval}^{\uparrow}$ windows, a finite termination and tolerance budget, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BisectionMethod}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2108.1, Definition 2108.2, and Definition 2108.3 seed the finite bisection method route from located interval source data through dyadic branch ledgers, located bisection rows, retained nested windows, termination budgets, stream windows, regular rational readback, terminal real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BisectionMethod}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected roots, completed intersections, trichotomy, open-cover compactness, quotient equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, branch-retention stability, finite-window termination, method-route exactness, real-seal nonescape, and ledger exhaustion for BEDC.Derived.BisectionMethodUp.

Chapter 2109

A Concrete Naming Certificate for $\mathsf{AlgebraicReal}^{\uparrow}$

Following van der Waerden and Bishop–Bridges constructive analysis, the $\mathsf{AlgebraicReal}^{\uparrow}$ packet reads algebraic real data through a polynomial row, finite Sturm-chain sign-variation rows, an isolating rational or dyadic interval, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and a $\mathsf{Real}^{\uparrow}$ seal. It consumes the polynomial source of chapter 50, the Sturm-chain surface of chapter 2079, the finite root-isolation branch of chapter 1534, the interval ledgers of chapter 354 and chapter 306, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet exposes a finite Real-facing certificate for one isolated algebraic window; it is not an algebraic closure construction, a selected host root, a quotient-real equality principle, or an ambient completeness theorem.

Definition 2109.1 (AlgebraicReal carrier)**.** *An* $\mathsf{AlgebraicReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (P, S, I, D, W, R, E, H, C, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Poly}^{\uparrow}$ *source row, including the coefficient ledger, degree bound, derivative row, and primitive polynomial identity under inspection.*
2. *S is the* $\mathsf{SturmSequence}^{\uparrow}$ *ledger, carrying the Euclidean-division chain, endpoint sign rows, zero-deletion witnesses, and sign-variation counts used by the isolation read.*
3. *I is the* $\mathsf{SturmRootIsolation}^{\uparrow}$ *branch row, exposing the retained rational isolating interval and the displayed variation-count evidence that selected it.*
4. *D is the dyadic refinement row obtained from the retained interval, with endpoint comparison rows and requested precision windows visible as* $\mathsf{DyadicInterval}^{\uparrow}$ *data.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule exported from the isolating interval and its dyadic refinements.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and D at the requested unary precision.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the retained algebraic window, reached only after P, S, I, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the polynomial source, Sturm ledger, isolating interval, dyadic refinement, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$P, S \longmapsto I \longmapsto D, W \longmapsto R \longmapsto E.$$

10. *K is the* Pkg *provenance over* $\mathsf{Poly}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, $\mathsf{SturmRootIsolation}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AlgebraicReal}^{\uparrow}}$ *registration row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for real-closedness, algebraic closure, selected roots in a host field, quotient real equality, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AlgebraicRealUp.TasteGate.AlgebraicRealTasteGate single carrier alignment`

Theorem 2109.2 (AlgebraicReal NameCert obligations)**.** *For every accepted* $\mathsf{AlgebraicReal}^{\uparrow}$ *carrier*

$$A = (P, S, I, D, W, R, E, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{AlgebraicReal}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the displayed packet of Definition 2109.1;*
2. *classifier transport through the componentwise* hsame *rows in H and the replay rows in C;*
3. *polynomial-source exactness, requiring the coefficient ledger, degree bound, derivative row, and primitive identity of P to be the source consumed by the Sturm ledger S;*
4. *isolation-window exactness, requiring the retained interval I to be selected by the sign-variation rows of S and refined only through the displayed dyadic row D;*
5. *Real-seal nonescape and ledger exhaustion, requiring every read of E to factor through $P, S, I, D, W, R, H, C, K, N$ before a real-facing consumer can inspect the seal.*

No further NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2109.1. The displayed packet lists the polynomial source, Sturm ledger, isolating interval, dyadic refinement, stream windows, regular rational readback, real seal, and structural BEDC rows.

Classifier transport is componentwise. The row H preserves each displayed coordinate by hsame, while C replays the same route from polynomial inspection through real-seal consumption.

Polynomial-source exactness is read before isolation. The Sturm ledger S has access only to the polynomial data in P, so the sign-variation rows cannot be replaced by a host factorization or by a selected list of roots.

Isolation-window exactness is then read from S, I, D. The retained interval I is the branch justified by the displayed variation count, and the dyadic row D only refines that retained interval.

Finally, the rows W, R, E, K, N expose the finite window to stream, regular-rational, and real-facing consumers while preserving package provenance and local naming. Since the carrier has no coordinate for the excluded principles, the five rows exhaust the local NameCert surface. □

Theorem 2109.3 (AlgebraicReal isolating-interval consumer)**.** *For every accepted* $\mathsf{AlgebraicReal}^{\uparrow}$ *carrier $A = (P, S, I, D, W, R, E, H, C, K, N)$, every algebraic-real consumer factors through the displayed* $\mathsf{SturmRootIsolation}^{\uparrow}$ *interval row I before any* $\mathsf{Real}^{\uparrow}$ *seal row E is visible. Thus the consumer receives the polynomial source, Sturm sign-variation ledger, retained rational or dyadic isolating interval, stream windows, regular rational readback, and structural transport rows as finite BEDC data before reaching a real-facing seal.*

Proof. Start with a consumer of the terminal seal E. By the carrier definition, E is not an independent real object; it is stored after the polynomial, Sturm, interval, dyadic, stream, and regular-rational rows.

The polynomial source P feeds the Sturm ledger S. That ledger supplies the endpoint signs and variation-count evidence from which the retained interval I is selected.

Only after I is fixed can the dyadic refinement D, stream windows W, and regular rational readback R be read. The structural rows H, C, K, N transport, replay, package, and name that same route.

Consequently the consumer cannot bypass the $\mathsf{SturmRootIsolation}^{\uparrow}$ interval to inspect E. The seal exposes only the retained algebraic window, and it exports no selected host root, quotient real equality, real trichotomy, algebraic closure, real-closedness, or ambient completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{AlgebraicReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlgebraicReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2109.1, Definition 2109.2, and Definition 2109.3 seed the finite algebraic-real route from polynomial source rows through Sturm isolation, dyadic refinement, stream windows, regular rational readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlgebraicReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close real-closedness, algebraic closure, selected roots, quotient real equality, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, polynomial-source exactness, isolation-window exactness, and Real-seal nonescape for BEDC.Derived.AlgebraicRealUp.

Constructive story: An $\mathsf{AlgebraicReal}^{\uparrow}$ packet is generated from a polynomial source row, finite Sturm-chain sign-variation rows, a SturmRootIsolation interval row, dyadic refinements, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2110

A Concrete Naming Certificate for $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$

Following Bishop and Bridges' constructive nested-interval treatment, the $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$ packet records the finite choice-seal route by which bounded nested intervals are admitted, localized, handed to $\mathsf{CantorIntersection}^{\uparrow}$, read through finite windows, and finally sealed as $\mathsf{Real}^{\uparrow}$ data without exporting a host-selected point. It sits on the Cantor-intersection surface of chapter 1421, the located nested-interval surface of chapter 1713, the convergence handoff of chapter 2057, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet is a human-origin L10 finite route for Real and Completion consumers; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, countable choice, a selected host point, quotient stream equality, trichotomy, open-cover compactness, or host real equality.

Definition 2110.1 (Bounded nested real choice-seal carrier)**.** *A* $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, L, C, W, R, D, E, H, T, P, N)$$

with the following displayed rows:

1. *I is the bounded nested interval row, exposing the initial bounded source, endpoint names, nested containment ledger, and finite diameter request.*
2. *L is the* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *row, attaching located endpoint comparisons and interval-membership reads to the same nested source.*
3. *C is the* $\mathsf{CantorIntersection}^{\uparrow}$ *handoff row, available only after the bounded source and located rows have been displayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family read from the nested interval route, with one visible window for each finite precision request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and their regular rational approximants.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic endpoint budgets, diameter bounds, and comparison tolerances consumed by W and R.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, C, W, R, D have been exposed.*

8. *H records componentwise* hsame *transport for bounded source data, located nested data, Cantor handoff, windows, readback, tolerances, seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay of the bounded nested route*

$$I, L, C, D \longmapsto W \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$, $\mathsf{NestedIntervalConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, C, W, R, D, E, H, T, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, a selected host point, quotient stream equality, trichotomy, open-cover compactness, or host real equality.*

Lean4 ✓ `BEDC.Derived.BoundedNestedRealChoiceSealUp.BoundedNestedRealChoiceSealTasteGate single carrier alignment`

Theorem 2110.2 (BoundedNestedRealChoiceSeal NameCert obligations)**.** *For every accepted* $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$ *carrier*

$$B = (I, L, C, W, R, D, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed bounded source, located nested data, Cantor handoff, finite windows, regular readback, dyadic tolerances, terminal seal, transport, replay, provenance, and local name;*
2. *bounded nested-source exposure, requiring every interval read to pass through I before any located or Cantor-facing row is consumed;*
3. *Cantor handoff, requiring C to be read only after I and L and before any Real-facing seal request;*
4. *finite-window readback, requiring every consumer to pass through W, R, D before reaching E;*
5. *Real seal nonescape, requiring E to remain attached to $I, L, C, W, R, D, H, T, P, N$;*
6. *transport, requiring H to preserve the displayed rows componentwise;*
7. *replay, requiring T to replay only the displayed route from bounded nested data to the terminal seal;*
8. *provenance, requiring P to source the packet from the named BEDC rows listed in the carrier;*
9. *local naming, requiring N to name exactly this finite packet.*

No bounded nested real choice-seal obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2110.1. The accepted packet displays exactly the bounded interval row, located nested row, Cantor handoff, finite windows, regular readback, dyadic tolerances, terminal seal, and structural rows.

The bounded-source and Cantor-handoff obligations are read in order. A consumer first sees I, then the located row L, and only then the handoff row C; the handoff cannot be read as an ambient completion theorem or as a selected point.

The finite-window readback obligation is the route through W, R, D. The StreamName windows expose finite observations, the RegSeqRat row records the regular rational readback of those observations, and the DyadicRatCore row supplies the endpoint and tolerance comparisons used by both.

The structural obligations are H, T, P, N. They transport, replay, source, and name only the displayed coordinates. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2110.3 (BoundedNestedRealChoiceSeal Cantor handoff route)**.** *Every* $\mathsf{CantorIntersection}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$ *carrier reads the packet only through the displayed finite route*

$$I, L, C, D \longmapsto W \longmapsto R \longmapsto E \longmapsto H, T, P, N.$$

Thus the consumer receives bounded nested interval data, located nested-interval data, the CantorIntersection handoff, dyadic tolerances, finite StreamName windows, RegSeqRat readback, the terminal Real seal, componentwise transport, continuation replay, package provenance, and local naming. It receives no ambient Real completeness theorem, countable-choice schedule, selected host point, quotient stream equality, trichotomy principle, open-cover compactness proof, or host real equality witness.

Proof. Start with an accepted packet $B = (I, L, C, W, R, D, E, H, T, P, N)$. The only Cantor-facing coordinate in the carrier is C, and the carrier definition places C downstream of the bounded source row I and the located nested row L.

The consumer then follows the finite readback route. The dyadic row D fixes the tolerance and endpoint budget, W exposes the corresponding finite StreamName windows, and R records the regular rational readback of those windows before the terminal seal E can be consumed.

The rows H, T, P, N preserve this route under componentwise transport, continuation replay, package provenance, and local naming. Because no other coordinate is present, a CantorIntersection consumer has no path to a hidden selector, quotient equality, countable choice, trichotomy, compactness, ambient Real completeness, or host real equality. □

Theorem 2110.4 (BoundedNestedRealChoiceSeal nonescape)**.** *An accepted* $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$ *packet exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, countable choice, selected host point, quotient stream equality, trichotomy, open-cover compactness, or host real equality. Every exported Real-facing read remains attached to the finite packet*

$$B = (I, L, C, W, R, D, E, H, T, P, N)$$

and to the displayed route through bounded nested data, located nested data, Cantor handoff, finite windows, regular readback, dyadic tolerances, transport, replay, provenance, and local naming.

Proof. Apply Definition 2110.2. The local NameCert surface exposes the terminal seal E only as part of the displayed packet, after I, L, C, W, R, D and before the structural rows H, T, P, N finish the route.

Apply Definition 2110.3. Any CantorIntersection consumer reads the same finite interval, window, tolerance, readback, and seal chain, so it cannot replace the route by a selected host point or by a global completeness principle.

Finally inspect Definition 2110.1. The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ completeness, countable choice, selected host point, quotient stream equality, trichotomy, open-cover compactness, or host real equality. Therefore none of those objects can be exported by an accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}$ packet is generated from bounded nested interval data, located nested-interval data, a CantorIntersection handoff, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2110.1, Definition 2110.2, Definition 2110.3, and Definition 2110.4 seed the finite nested-interval choice-seal route from bounded and located interval data through Cantor handoff, finite windows, regular readback, dyadic tolerances, terminal Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedNestedRealChoiceSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, countable choice, selected host points, quotient stream equality, trichotomy, open-cover compactness, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded nested-source exposure, Cantor handoff, finite-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BoundedNestedRealChoice

Chapter 2111

A Concrete Naming Certificate for $\mathsf{HurwitzApproximation}^{\uparrow}$

Following Hurwitz and Hardy–Wright, the $\mathsf{HurwitzApproximation}^{\uparrow}$ packet records the finite continued-fraction route to rational approximation with a displayed constant witness. It consumes the continued-fraction source of chapter 342, the convergent-prefix surface of chapter 1777, the Farey-neighbor ledger of chapter 1759, the Stern–Brocot branch route of chapter 1704, the Dirichlet-approximation certificate of chapter 1871, the rational readback boundary of chapter 1668, the regular rational sequence route of chapter 301, and the terminal real-name interface of chapter 38. The packet names a finite approximation certificate for one displayed real input and one requested budget; it is not an infinite continued fraction, a quotient-real equality theorem, a trichotomy principle, a countable-choice selector, or an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 2111.1 (Hurwitz approximation carrier)**.** *A* $\mathsf{HurwitzApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, Q, A, C, F, S, D, R, E, T, U, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Real}^{\uparrow}$ *input name, exposed only through finite regular-rational windows and dyadic error budgets.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplying the finite rational windows consumed by the approximation certificate.*
3. *A is the* $\mathsf{ContinuedFraction}^{\uparrow}$ *prefix row. It records a finite list of partial quotients, denominator positivity witnesses, and the displayed stopping index used by the certificate.*
4. *C is the* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *row attached to A, listing the convergent numerator and denominator pairs through the stopping index.*
5. *F is the* $\mathsf{FareySequence}^{\uparrow}$ *neighbor row used to compare adjacent rational windows against the same denominator budget.*
6. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *branch row that replays the same rational interval as a finite left-right word.*
7. *D is the* $\mathsf{DirichletApproximation}^{\uparrow}$ *budget row, recording the denominator threshold, dyadic error request, and finite pigeonhole-style witness that bounds the search space.*

8. *R is the rational-approximation output row. It contains a displayed fraction p/q, the denominator bound, and the dyadic inequality row asserting the Hurwitz-style error estimate for the current budget.*

9. *E records the excluded-principle ledger: no selected infinite expansion, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row may be read from the carrier.*

10. *T records componentwise* hsame *transport for the input name, regular readback, continued-fraction prefix, convergent table, Farey row, Stern–Brocot row, Dirichlet row, output fraction, excluded-principle ledger, replay, provenance, and local naming rows.*

11. *U records displayed* Cont *replay of the finite route*

$$X, Q \longmapsto A \longmapsto C \longmapsto F, S, D \longmapsto R, E.$$

12. *P is the* Pkg *provenance over* $\mathsf{HurwitzApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{ContinuedFractionConvergents}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{DirichletApproximation}^{\uparrow}$, RealRationalApproximati BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{HurwitzApproximation}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $X, Q, A, C, F, S, D, R, E, T, U, P, N$. It has no coordinate for selected infinite expansions, quotient real equality, real trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HurwitzApproximationUp.HurwitzApproximationTasteGate single carrier alignment`

Theorem 2111.2 (HurwitzApproximationUp NameCert obligations)**.** *For every accepted* $\mathsf{HurwitzApproximation}^{\uparrow}$ *carrier*

$$H = (X, Q, A, C, F, S, D, R, E, T, U, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HurwitzApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed packet of Definition 2111.1;*

2. *input readback exactness, requiring the* $\mathsf{Real}^{\uparrow}$ *input X to be inspected only through the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *windows and dyadic budgets in Q;*

3. *continued-fraction prefix exactness, requiring A and C to expose only the displayed finite prefix and its convergent table through the stopping index;*

4. *neighbor-route compatibility, requiring the Farey row F and Stern–Brocot row S to replay the same rational interval inspected by the convergent table;*

5. *approximation-budget exactness, requiring D and R to display the denominator threshold, chosen fraction, and dyadic error inequality for the current budget;*

6. *excluded-principle nonescape through E, requiring every consumer to refuse selected infinite expansions, quotient real equality, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*

7. *classifier transport and provenance through T, U, P, N, requiring componentwise* hsame *transport, displayed replay, package source, and local name to preserve exactly these rows.*

No Hurwitz-approximation obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.HurwitzApproximationUp.HurwitzApproximationCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 2111.1. The rows X and Q are the only real-facing input interface, so every approximation claim begins with finite rational windows and dyadic budgets rather than quotient-real equality.

The finite continued-fraction data are then read from A and C. Induct over the displayed prefix: the base row exposes the first convergent, and each successor row updates the numerator-denominator pair while preserving the positivity and determinant ledgers carried by the convergent table.

The neighbor rows F and S compare the same displayed rational interval. A finite induction over the Farey adjacency row matches the corresponding Stern–Brocot word, so the branch route cannot import an infinite expansion or a global order split.

The budget rows D and R supply the approximation witness. The dyadic error budget is checked against the finite convergent prefix and the denominator threshold, producing the displayed fraction p/q and its Hurwitz-style inequality for this request.

Finally E records the refused principles, while T, U, P, N transport, replay, source, and name the same finite surface. Since the carrier has no additional coordinate, the seven listed rows exhaust the local NameCert obligations. □

Theorem 2111.3 (Finite continued-fraction handoff)**.** *Every rational-approximation consumer of an accepted* $\mathsf{HurwitzApproximation}^{\uparrow}$ *carrier factors through the finite route*

$$X, Q \longmapsto A \longmapsto C \longmapsto F, S, D \longmapsto R, E, T, U, P, N.$$

Consequently the consumer receives a displayed real-name readback, a finite continued-fraction prefix, its convergent table, Farey and Stern–Brocot comparison rows, a Dirichlet-style dyadic budget row, a rational output fraction, and the excluded-principle ledger before inspecting any approximation claim.

Proof. Start with a consumer of the output fraction in R. By the carrier definition, R is not an independent rational approximation; it is stored after the input readback rows X, Q, the finite continued-fraction prefix A, and the convergent table C.

The handoff from A to C is finite-row induction over the displayed prefix. Each step adds one partial quotient and updates one convergent row, so the consumer never receives an infinite expansion or a selected tail.

The comparison handoff then passes through F, S, D. The Farey and Stern–Brocot rows identify the same finite rational interval, while the Dirichlet row supplies the denominator and dyadic error budget used by the output row.

The structural rows E, T, U, P, N close the public boundary. They record the refused principles, preserve the displayed route under componentwise transport, replay the route, source it, and assign the local NameCert name. Hence the consumer boundary is exactly the finite continued-fraction route and not any ambient real-completeness or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{HurwitzApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HurwitzApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2111.1, Definition 2111.2, and Definition 2111.3 seed the finite continued-fraction route from Real and RegSeqRat readback through convergent prefixes, Farey and Stern–Brocot comparison rows, Dirichlet-style budgets, rational output, excluded-principle refusal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HurwitzApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite expansions, quotient real equality, real trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked input readback exactness, continued-fraction prefix exactness, neighbor-route compatibility, approximation-budget exactness, excluded-principle nonescape, classifier transport, and provenance/name exhaustion for BEDC.Derived.HurwitzApproximationUp.

Constructive story: A HurwitzApproximation$^{\uparrow}$ packet is generated from a RealUp input name, RegSeqRat finite readback, ContinuedFraction finite prefix, convergent table, Farey and SternBrocot comparison rows, a DirichletApproximation budget row, a rational output fraction, an excluded-principle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2112

A Concrete Naming Certificate for $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$ packet names the finite located-order test by which two displayed real names are compared through regular Cauchy readbacks, shared windows, dyadic tolerances, positive-gap evidence when present, and located-interval context before any Real-facing consumer reads the result. It sits after the comparison-test surface of chapter 1459, the constructive order surface of chapter 1716, the positive-separation surface of chapter 304, the located interval context of chapter 1709, the terminal real-name seal of chapter 38, the regular-rational readback of chapter 301, the finite stream-window route of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite Bishop-style located order test for $\mathsf{Real}^{\uparrow}$ names; it is not host trichotomy, quotient real equality, a representative selector, countable choice, or ambient real completeness.

Definition 2112.1 (Cauchy real located order test carrier)**.** *A* $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, W, D, Q, O, A, L, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two source rows. Each row is read as a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and then sealed as a* $\mathsf{Real}^{\uparrow}$ *name before any located-order verdict is exported.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window family. It records the finite observation lengths, synchronised cuts, endpoint readbacks, and comparison windows inspected for both source rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget. It records the requested dyadic scale, positive gap threshold, sign slack, and exhaustion ledger used by the comparison and locatedness rows.*
4. *Q is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *row. It tests the two regular Cauchy readbacks on the shared windows and dyadic budget before the terminal real-name seals are consumed.*
5. *O is the* $\mathsf{CauchyRealOrder}^{\uparrow}$ *row. It stores the oriented order verdict as a finite consequence of X, Y, W, D, Q and does not supply host trichotomy.*
6. *A is an* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-gap row when the displayed windows and dyadic budget separate the two real names.*
7. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *context row. It records the interval enclosure and locatedness data in which the order test is read.*

8. *H records componentwise* hsame *transport for the two source rows, shared windows, dyadic budget, comparison row, order row, positive-gap row when present, located-interval row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each located-order request through $W, D, Q, O, A, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{CauchyRealOrder}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these twelve rows form one finite located-order test packet. It has no coordinate for host trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyRealLocatedOrderTestUp.CauchyRealLocatedOrderTestTasteGate single carrier alignment`

Theorem 2112.2 (Cauchy real located order test NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$ *carrier $T = (X, Y, W, D, Q, O, A, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatedOrd}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular-rational source rows, terminal real-name seals, shared stream windows, dyadic tolerance budget, comparison-test row, order row, positive-gap row when present, located-interval context row, transport, replay, provenance, and local naming row;*
2. *classifier exactness, requiring accepted packets to compare only the displayed $X, Y, W, D, Q, O, A, L, H, C, P, N$ coordinates;*
3. *regular Cauchy comparison readback, requiring Q to inspect the two source rows through the shared windows W and dyadic budget D before the order row is read;*
4. *located order compatibility, requiring O to export an oriented verdict only inside the located interval context L and only after the comparison-test route has been displayed;*
5. *positive-gap visibility, requiring every separating verdict to display its* $\mathsf{ApartnessReal}^{\uparrow}$ *row A as finite dyadic gap evidence over the same W and D;*
6. *nonseparating visibility, requiring every nonseparating read to record the exhausted windows and dyadic slack rather than a quotient equality proof;*
7. *transport and replay stability, requiring H and C to preserve the source, window, tolerance, comparison, order, apartness, located-context, provenance, and local naming rows componentwise;*
8. *ledger exhaustion, excluding host trichotomy, quotient real equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No located-order test obligation is stored outside these rows.

Proof. Project the carrier $T = (X, Y, W, D, Q, O, A, L, H, C, P, N)$. The projection exposes exactly the two source rows, common window family, dyadic tolerance budget, comparison row, order row, positive-gap row when present, located-interval context row, and structural rows.

The comparison route is finite. The source rows X and Y are inspected through the shared windows W, and the dyadic budget D supplies the scale and slack at which the comparison-test row Q is allowed to read them.

The order and locatedness rows are downstream of this comparison. The row O records only the oriented verdict produced by the displayed comparison route, while L records the interval context in which the verdict is meaningful.

Positive and nonseparating reads use the same ledger. When a positive gap is present, A displays the $\mathsf{ApartnessReal}^{\uparrow}$ separation row. When the gap is not displayed at the requested scale, the packet records the exhausted finite windows and slack; it does not replace that record by quotient equality.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of the carrier coordinates stores a host trichotomy, quotient equality, representative selector, choice schedule, completeness datum, Lean theorem, or bridge, no further local obligation can be read from the packet. □

Theorem 2112.3 (Cauchy real located order test finite decision route)**.** *Every accepted* CauchyRealLocatedOrderTes *read factors through the finite route*

$$X, Y \longmapsto W, D \longmapsto Q \longmapsto O, A, L \longmapsto H, C, P, N$$

before any $\mathsf{Real}^{\uparrow}$ *consumer sees the result. Hence the packet exports only the displayed located-order test data, and exports no host trichotomy, quotient real equality, selected representative, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted located-order test carrier. The only source coordinates are X and Y, and the carrier requires each to pass through regular-rational readback and the terminal real-name seal before the public result is exposed.

The shared windows and tolerance budget come next. The finite windows in W select the inspected stream segments, while the dyadic budget D records the comparison scale, requested gap, sign slack, and exhaustion data.

The comparison-test row Q consumes exactly those rows. The oriented order row O, the positive-gap row A when present, and the located-interval context row L are therefore downstream of the displayed comparison route rather than independent Real-level principles.

The structural rows close the route. Componentwise transport in H, replay in C, provenance in P, and local naming in N preserve the same finite packet before a $\mathsf{Real}^{\uparrow}$ consumer can read the verdict. Because the route contains no coordinate for trichotomy, quotient equality, representative selection, countable choice, or completeness, none of those principles is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows sealed as $\mathsf{Real}^{\uparrow}$ names, shared $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget, a $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ row, a $\mathsf{CauchyRealOrder}^{\uparrow}$ row, an $\mathsf{ApartnessReal}^{\uparrow}$ positive-gap row when present, a $\mathsf{LocatedRealInterval}^{\uparrow}$ context row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2112.1, Definition 2112.2, and Definition 2112.3 seed the finite located-order test boundary over regular Cauchy readbacks, shared stream windows, a dyadic tolerance budget, comparison-test data, order data, apartness data when present, located-interval context, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.CauchyRealLocatedOrderTestUp covering the twelve-row carrier, local NameCert obligations, and finite decision route.

Chapter 2113

A Concrete Naming Certificate for $\mathsf{KummerTest}^{\uparrow}$

Following Kummer and the Bishop–Bridges constructive-analysis reading of positive series tests, the $\mathsf{KummerTest}^{\uparrow}$ packet records the finite auxiliary-sequence comparison route that turns adjacent-term quotient data into a displayed regular Cauchy tail handoff. It refines the positive $\mathsf{RealSeries}^{\uparrow}$ surface of chapter 1581, sits beside the ratio route of chapter 1461, the comparison route of chapter 1459, and the neighboring defect-test surface of chapter 1719, and it exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a finite NameCert boundary for Kummer-style convergence testing; it is not a host infinite sum, selected limit, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 2113.1 (Kummer test carrier)**.** *A* $\mathsf{KummerTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, Q, U, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{RealSeries}^{\uparrow}$ *row, exposing only the inspected positive-term windows and partial-sum windows used by the current tail request.*
2. *Q is the adjacent-term quotient row, recording the finite windows on which the inspected ratios of neighboring positive terms are read.*
3. *U is the auxiliary positive comparison sequence row, displaying the finite auxiliary values and positivity witnesses used by the Kummer defect calculation.*
4. *D is the dyadic defect-budget row, assigning each displayed tail request a finite threshold and rational margin for the Kummer inequality on the inspected windows.*
5. *T is the comparison-test handoff row, converting Q, U, D and the source windows in A into the finite majorant route consumed by* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$*.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff has been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
8. *H stores componentwise* hsame *transport for the source, quotient, auxiliary, defect-budget, comparison, readback, seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from each tail request through Q, U, D, T, R, E.*

10. *P is the* Pkg *provenance over* $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{KummerTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, Q, U, D, T, R, E, H, C, P, N$. It has no coordinate for host infinite sums, selected limits, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.KummerTestUp.KummerTestTasteGate single carrier alignment`

Theorem 2113.2 (Kummer test NameCert obligations)**.** *For every accepted* $\mathsf{KummerTest}^{\uparrow}$ *carrier*

$$K = (A, Q, U, D, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KummerTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the source* $\mathsf{RealSeries}^{\uparrow}$ *row, adjacent-term quotient row, auxiliary positive comparison sequence row, dyadic defect-budget row, comparison-test handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*

2. *auxiliary-row positivity, requiring every accepted auxiliary read to pass through the displayed finite positivity witnesses in U;*

3. *quotient-window exactness, requiring the quotient data used by the Kummer defect to be read only from the displayed neighboring-term windows A, Q;*

4. *defect-budget stability, requiring the threshold and rational margin in D to be preserved under the accepted tail request and under componentwise transport;*

5. *comparison-test routing, requiring T to be the only row that turns the Kummer defect data into a convergence-test majorant;*

6. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring endpoint-facing data to pass through R and then E after the comparison row has been displayed;*

7. *transport, replay, and provenance discipline, requiring H, C, P, N to transport, replay, source, and name exactly the displayed route and no unrecorded analytic principle.*

Proof. Project the carrier of Definition 2113.1. Carrier exposure is the inventory $A, Q, U, D, T, R, E, H, C, P, N$, so the local certificate has no detached row for an infinite sum, quotient series equality, selected limit, or ambient completeness theorem.

The auxiliary and quotient clauses are read before any convergence handoff. The row U displays only finite auxiliary comparison values together with their positivity witnesses, while A and Q display the source windows and neighboring-term quotient windows used by the Kummer defect.

The defect budget is then forced through D. Its threshold and rational margin are the only data attached to the requested tail, and componentwise hsame transport in H preserves the same threshold, margin, source windows, quotient windows, and auxiliary row.

The comparison route is exactly T. Once Q, U, D have been displayed over the source windows in A, the packet may enter the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ surface; before that row appears, no regular Cauchy conclusion is exported.

Finally, R and E supply the regular rational and Real-facing endpoint route. The replay, provenance, and local naming rows C, P, N preserve this same route, so none of them can introduce host infinite sums, selected limits, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 2113.3 (Kummer test Cauchy tail handoff)**.** *Every endpoint-facing read of an accepted* $\mathsf{KummerTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealSeries}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Strea}$$

Concretely, the read consumes source $\mathsf{RealSeries}^{\uparrow}$ *windows and neighboring quotient rows, reads the auxiliary positive comparison sequence and dyadic defect budgets, uses the ratio and Raabe–Duhamel surfaces only as neighboring quotient-defect reference faces, enters the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed stream and dyadic rows.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 2113.1, the only source data available before the defect estimate are the $\mathsf{RealSeries}^{\uparrow}$ windows in A and the adjacent-term quotient windows in Q.

The Kummer-specific data are then read from U and D. The auxiliary row supplies finite positive comparison values, while the dyadic defect-budget row supplies the threshold and rational margin attached to the requested tail.

The neighboring quotient-test surfaces are reference faces rather than endpoints. The $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ and $\mathsf{RaabeDuhamelTest}^{\uparrow}$ rows identify the surrounding adjacent-term and defect-test discipline, but the accepted $\mathsf{KummerTest}^{\uparrow}$ endpoint route still has to enter the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ budgets recorded in the carrier, then through R and E. Thus every endpoint-facing read reaches $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only through the displayed comparison, stream, dyadic, readback, seal, transport, replay, provenance, and naming rows. □

Falsifiable prediction: Every accepted $\mathsf{KummerTest}^{\uparrow}$ endpoint-facing read factors through source RealSeries windows, adjacent-term quotient rows, an auxiliary positive comparison sequence, dyadic defect budgets, a RegularCauchyComparisonTest handoff, StreamName and DyadicRatCore display rows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, regularcauchyratiotest, regularcauchycomparisontest, raabeduhameltest, dyadicratcore, streamname, regseqrat, real: $\mathsf{KummerTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, adjacent-term quotient windows, an auxiliary positive comparison sequence, dyadic defect budgets, comparison-test routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KummerTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KummerTest}^{\uparrow}$ packet is generated from source RealSeries windows, adjacent-term quotient windows, an auxiliary positive comparison sequence, dyadic defect budgets, a RegularCauchyComparisonTest handoff, StreamName and DyadicRatCore display rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KummerTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2113.1, Definition 2113.2, and Definition 2113.3 seed the finite Kummer convergence-test boundary over displayed source series, quotient, auxiliary positive sequence, defect-budget, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KummerTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier exposure, auxiliary-row positivity, quotient-window exactness, defect-budget stability, comparison-test routing, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal nonescape, and transport, replay, provenance, and local naming discipline for BEDC.Derived.KummerTestUp.

Chapter 2114

A Concrete Naming Certificate for $\mathsf{LocatedMetricCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{LocatedMetricCompletion}^{\uparrow}$ packet records the L10 metric-completion boundary where located source data are carried into finite completion evidence without quotienting Cauchy names. It sits between the located metric source of chapter 1533, the completion packet of chapter 1506, the embedding surface of chapter 1512, the separated uniqueness row of chapter 1411, and the finite readback interfaces of chapter 301 and chapter 38. The packet is a NameCert seed for displayed completion-facing reads over a located metric source; it is not a quotient completion, a representative selector, a countable-choice device, an open-cover compactness principle, host equality, an ambient complete metric space, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 2114.1 (LocatedMetricCompletion carrier)**.** *A* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, F, D, E, R, S, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{LocatedMetric}^{\uparrow}$ *row, including the displayed metric distance, locatedness witness, and finite observation histories used by completion consumers.*
2. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row that exposes the completion-facing interface over the same source data.*
3. *F is either a* $\mathsf{CauchyFilter}^{\uparrow}$ *cofinal-evidence row or an empty marker when the displayed completion route uses directed nets.*
4. *D is either a* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row or an empty marker when the displayed completion route uses Cauchy filters.*
5. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row by which located source observations enter the completion-facing surface.*
6. *R is the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row used for numerical tolerance requests.*
7. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row that identifies displayed limit readings only through the zero-distance route available from the located source and completion packet.*

8. *H records componentwise* hsame *transport for the located source, metric-completion row, Cauchy evidence branch, embedding row, readback row, separatedness row, replay row, provenance row, and local naming row.*

9. *C records the displayed* Cont *replay from located metric observations to the metric-completion interface, Cauchy-filter or Cauchy-net evidence, completion embedding, finite readback, separated comparison, provenance, and local name.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedMetricCompletion}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMetricCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, ambient complete metric spaces, or detached completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedMetricCompletionUp.LocatedMetricCompletionTasteGate single carrier alignment`

Theorem 2114.2 (LocatedMetricCompletion NameCert obligations)**.** *For an accepted* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *carrier $L = (X, M, F, D, E, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedMetricCompletion}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed located metric source, metric-completion row, selected Cauchy evidence branch, completion embedding, finite readback, separatedness row, transports, replay route, provenance, and local name;*

2. *located-source handoff, requiring every completion-facing read to begin with X before the metric-completion row M or any Cauchy evidence row is consumed;*

3. *cofinal evidence selection, requiring each accepted read to use exactly one visible branch, either the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F or the* $\mathsf{CauchyNet}^{\uparrow}$ *row D;*

4. *embedding coverage, requiring source observations to reach the completion surface only through the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row E;*

5. *finite readback compatibility, requiring numerical tolerance requests to pass through R before separated comparison or local naming;*

6. *separated uniqueness, requiring equality of displayed completion reads to pass through the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row S after the located source, completion interface, Cauchy evidence branch, embedding, and readback have been replayed;*

7. *ledger non-escape, stating that no quotient completion equality, selected representative, countable choice, open-cover compactness, host equality, ambient complete metric space, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem is exported.*

Proof. Carrier admission is projection from Definition 2114.1. The tuple displays the located source, metric-completion row, filter or net branch, embedding row, finite readback, separatedness row, and structural support rows.

The located-source handoff is forced by the order of the replay row C. It reads X first, then M, and only then the selected cofinal evidence branch F or D.

Cofinal evidence selection is local to the carrier. A filter-presented read consumes F while D is empty, and a net-presented read consumes D while F is empty, so the packet exposes one completion route before E and R are inspected.

Embedding coverage follows from the presence of E as the only source-to-completion coordinate. The readback row R handles tolerance requests, and the separatedness row S handles equality of displayed limit readings after the earlier rows have been replayed.

The rows H, C, P, N transport, replay, package, and name exactly that finite route. Since no remaining coordinate names quotient equality, selected representatives, choice, compactness, host equality, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, none of those principles can be read from the local certificate. □

Theorem 2114.3 (LocatedMetricCompletion source handoff)**.** *Let $L = (X, M, F, D, E, R, S, H, C, P, N)$ be an accepted* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *packet. Every completion-facing read of L factors through the finite route*

$$X \longmapsto M \longmapsto (F \text{ or } D) \longmapsto E \longmapsto R \longmapsto S \longmapsto H, C, P, N,$$

where X is the $\mathsf{LocatedMetric}^{\uparrow}$ *source row, M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, F or D is the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *evidence, E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row, and R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row.*

Proof. Begin with the source row X. A completion-facing consumer first reads the located metric observations, including the displayed distance and locatedness evidence.

The completion interface is then read through M. The cofinal evidence branch is selected next: either the Cauchy-filter row F or the Cauchy-net row D supplies the visible late-window evidence.

The source observation enters completion-facing form only through E. Numerical requests then pass through the finite readback row R, and equality or uniqueness requests pass through the separatedness row S.

Finally, H, C, P, N transport and name the same route. No other coordinate is available, so every completion-facing read has the displayed factorization. □

Theorem 2114.4 (LocatedMetricCompletion branch determinacy)**.** *Let $L = (X, M, F, D, E, R, S, H, C, P, N)$ be an accepted* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *packet. Any accepted completion-facing read determines one Cauchy-evidence branch before embedding or readback is inspected: a filter-presented read consumes the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F with D empty, and a net-presented read consumes the* $\mathsf{CauchyNet}^{\uparrow}$ *row D with F empty. Transport through H and replay through C cannot switch the selected branch after the embedding row E or the readback row R has been read.*

Proof. Project the carrier of Definition 2114.1. The rows F and D are the only visible Cauchy-evidence coordinates, and the carrier description makes each one either an evidence row or the empty marker complementary to the other branch.

Apply Definition 2114.3. Every completion-facing read reaches F or D after the located source row X and the metric-completion row M, but before the embedding row E and the readback row R are available.

Finally apply Definition 2114.5. The support rows H and C transport and replay the already selected finite route; they do not add a second branch coordinate, and no quotient completion, selected representative, choice principle, host equality, ambient complete metric space, or detached $\mathsf{Real}^{\uparrow}$ completeness row is present to replace the selected branch. □

Theorem 2114.5 (LocatedMetricCompletion ledger non-escape)**.** *For an accepted* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *carrier* $L = (X, M, F, D, E, R, S, H, C, P, N)$*, every exported completion read, tolerance read, embedding read, and separated comparison is exhausted by the rows*

$$X, M, F, D, E, R, S, H, C, P, N.$$

Consequently the packet excludes quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, ambient complete metric spaces, and detached completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Completion reads begin at the located source X and the metric-completion row M. They then pass through exactly one displayed Cauchy evidence branch, either F or D.

Embedding reads are confined to E, and numerical tolerance reads are confined to R. The separatedness row S handles comparison of displayed limit readings only after those earlier coordinates have been replayed.

The support rows H, C, P, N preserve and name that same finite ledger. Because the carrier lists no coordinate for quotient equality, representative selection, countable choice, open-cover compactness, host equality, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness, those principles cannot be exported by the packet. □

Theorem 2114.6 (LocatedMetricCompletion modulus pair stability)**.** *Let* $L = (X, M, F, D, E, R, S, H, C, P, N)$ *be an accepted* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *packet. Suppose two accepted completion-facing reads share the same located source row* X*, and suppose their displayed Cauchy evidence is carried either by the filter branch* F *or by the directed-window branch* D*, transported through* H*, and replayed through* C*. Then the embedding row* E*, the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row* R*, and the separatedness row* S *preserve the same displayed completion-facing comparison.*

In particular, paired reads with the same source and replayed evidence branch cannot be separated by quotient completion equality, selected representatives, countable choice, host equality, an ambient complete metric space, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 2114.1. The two reads share the row X, so their source observations, locatedness evidence, and metric-distance rows are already the same displayed source data.

Apply Definition 2114.3. Each completion-facing read must pass from X to M, then through the visible evidence branch F or D, and then through the embedding and readback rows E and R.

Use the stated transport and replay through H and C. These structural rows preserve the displayed branch evidence while moving it into the completion-facing route, so the comparison reaching E and R is still the one generated from the common source row.

Finally apply Definition 2114.5. The separatedness row S is the only row that can compare displayed completion reads after the source, evidence, embedding, and readback rows have been replayed. Since the carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, ambient complete metric spaces, or detached $\mathsf{Real}^{\uparrow}$ completeness, no external comparison can replace the displayed one. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMetricCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2114.1, Definition 2114.2, Definition 2114.3, Definition 2114.5, and Definition 2114.6 seed the finite located metric completion packet over located source data, metric-completion evidence, Cauchy-filter or Cauchy-net branches, completion embedding, finite readback, separated uniqueness, and paired modulus/readback stability.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, open-cover compactness, host equality, ambient complete metric spaces, Real$^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, located-source handoff, cofinal evidence selection, embedding coverage, finite readback, separated uniqueness, and ledger non-escape for BEDC.Derived.LocatedMetricCompletionUp.

Constructive story: A LocatedMetricCompletion$^{\uparrow}$ packet is generated from a located metric source, metric-completion row, displayed Cauchy-filter or Cauchy-net evidence, completion embedding, finite readback, separatedness row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 2115

A Concrete Naming Certificate for $\mathsf{KuratowskiCompletionNaturality}^{\uparrow}$

Following Kuratowski, Kelley, and Bishop–Bridges, the $\mathsf{KuratowskiCompletionNaturality}^{\uparrow}$ packet records the finite L10 naturality boundary where a source metric object first enters the Kuratowski completion route and is then compared with the completion-reflection route. It sits over the Kuratowski completion surface of chapter 2065, the reflection witness of chapter 403, the real-reflection seal of **??**, the metric completion interface of chapter 1506, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38.

The packet names the comparison square as finite NameCert data. It does not identify quotient completions, select representatives, assert host function equality, invoke countable choice, import trichotomy, or claim ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2115.1 (Kuratowski completion naturality carrier)**.** *A* $\mathsf{KuratowskiCompletionNaturality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, E, C, F, R, S, D, A, H, T, P, N)$$

with the following displayed rows:

1. *M is the source metric row, carrying the finite endpoint, distance, and Cauchy-window requests inspected by both completion routes.*
2. *E is the* $\mathsf{KuratowskiCompletion}^{\uparrow}$ *row that sends the source metric observations through the Kuratowski embedding and completion seal.*
3. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row reached by the Kuratowski route after the displayed completion seal is exposed.*
4. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *witness row that displays the reflection route for the same source metric observations.*
5. *R is the* $\mathsf{RealCompletionReflection}^{\uparrow}$ *row that returns the reflection route to the public real-completion boundary.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row shared by the Kuratowski and reflection reads.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the shared finite windows.*

8. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the finite dyadic observations into the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

9. *H records componentwise* hsame *transport for the source metric, Kuratowski completion, metric-completion consumer, reflection witness, real-reflection seal, stream window, dyadic ledger, regular readback, replay, provenance, and local naming rows.*

10. *T records displayed* Cont *replay of the two routes*

$$M \longmapsto E, C \longmapsto S, D, A \quad \textit{and} \quad M \longmapsto F, R \longmapsto S, D, A.$$

11. *P is the* Pkg *provenance over* $\mathsf{KuratowskiCompletionNaturality}^{\uparrow}$, $\mathsf{KuratowskiCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{RealCompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiCompletionNaturality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, C, F, R, S, D, A, H, T, P, N$. It has no coordinate for quotient completion equality, host function equality, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.KuratowskiCompletionNaturalityUp.KuratowskiCompletionNaturalityTasteGate`
`single carrier alignment`

Theorem 2115.2 (Kuratowski completion naturality obligations)**.** *For every accepted* KuratowskiCompletionNatura *carrier*

$$K = (M, E, C, F, R, S, D, A, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiCompletionNaturality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source metric row, Kuratowski completion row, metric-completion consumer row, completion-reflection witness, real-reflection seal, StreamName window, DyadicRatCore ledger, RegSeqRat readback, transport, replay, provenance, and local naming row;*

2. *Kuratowski-completion exposure, requiring E and C to display the source metric read through the Kuratowski completion route before any completion-facing consumer receives it;*

3. *reflection-square routing, requiring F and R to display the same source metric read through the completion-reflection and real-reflection route before it reaches the shared analytic rows;*

4. *Real-seal nonescape, requiring S, D, A to be the only finite observation path from either route to the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*

5. *transport, replay, and provenance exhaustion, requiring H, T, P, N to transport, replay, source, and name only the listed rows.*

No obligation is stored outside these rows, and none exports quotient completions, host function equality, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Carrier admission is projection from Definition 2115.1. The accepted packet displays exactly the source metric row, the two completion-facing routes, the shared finite observation rows, and the structural rows.

Kuratowski-completion exposure is read from E and C. The row E places the source metric observations inside the Kuratowski completion route, while C records the metric-completion consumer surface available after that route is displayed.

Reflection-square routing is read from F and R. The reflection witness and real-reflection seal expose the parallel route for the same source metric row before either side can inspect the shared stream, dyadic, and regular-readback rows.

Real-seal nonescape is the row inventory S, D, A. Both routes must pass through the same finite StreamName window, DyadicRatCore tolerance ledger, and RegSeqRat readback before reaching the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally H, T, P, N add only componentwise transport, replay, provenance, and local naming. Since the carrier contains no quotient, host-equality, representative-choice, countable-choice, trichotomy, ambient-completeness, Lean, or bridge coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2115.3 (Kuratowski completion naturality square)**.** *Let*

$$K = (M, E, C, F, R, S, D, A, H, T, P, N)$$

be an accepted $\mathsf{KuratowskiCompletionNaturality}^{\uparrow}$ *carrier. Every completion-facing consumer comparing the Kuratowski route with the reflection route factors through the finite square*

$$M \longmapsto E, C \longmapsto S, D, A \longmapsto H, T, P, N,$$
$$M \longmapsto F, R \longmapsto S, D, A \longmapsto H, T, P, N.$$

Consequently the consumer receives only the displayed source metric row, Kuratowski completion row, metric-completion consumer row, completion-reflection witness, real-reflection seal, shared finite window, dyadic ledger, regular readback, transport, replay, provenance, and local name. It exports no quotient completion, host function equality, selected representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Fix a completion-facing consumer of the packet. Projection gives the source row M, so both compared routes begin from the same displayed endpoint, distance, and Cauchy-window requests.

The Kuratowski side then uses E and C. These rows expose the Kuratowski completion route and the metric-completion consumer surface before any terminal real seal is available.

The reflection side uses F and R. These rows expose the completion-reflection route and the real-reflection seal for the same source row, not for a separately chosen representative.

Both sides are forced through S, D, A. The shared finite stream window, dyadic tolerance ledger, and regular rational readback form the only observation route to the public $\mathsf{Real}^{\uparrow}$ seal.

Transport through H, replay through T, provenance through P, and local naming through N preserve exactly that square. Since no excluded coordinate occurs in the carrier, no completion-facing consumer can export quotient completion data, host function equality, a selected representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiCompletionNaturality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiCompletionNaturality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2115.1, Definition 2115.2, and Definition 2115.3 seed the finite naturality square comparing the Kuratowski completion route with the completion-reflection route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiCompletionNaturality}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.KuratowskiCompletionNaturalityUp`

Bridge status: none

Not claimed: This chapter does not close quotient completions, host function equality, selected representatives, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Kuratowski-completion exposure, reflection-square routing, Real-seal nonescape, and structural replay for BEDC.Derived.KuratowskiCompletionNaturalityUp.

Constructive story: A KuratowskiCompletionNaturality$^{\uparrow}$ packet is generated from a source metric row, KuratowskiCompletion route, MetricCompletion consumer, CompletionReflection witness, RealCompletionReflection seal, shared StreamName windows, DyadicRatCore ledger, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2116

A Concrete Naming Certificate for $\mathsf{SignedDistance}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SignedDistance}^{\uparrow}$ packet records the finite route by which a located metric source exposes a signed distance surface without importing a host real-valued distance function. The packet is admitted only as metric, locatedness, apartness, dyadic-budget, regular-readback, and real-seal rows: its metric side is anchored in chapter 57, its located-source side in chapter 2043, its signed separation side in chapter 304, and its L10 readback spine in chapter 291, chapter 301, and chapter 38.

Definition 2116.1 (SignedDistance carrier)**.** *A* $\mathsf{SignedDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, L, A, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row, recording the finite source and target observations, the metric comparison surface, and the triangle-compatible route through which distance requests are read.*
2. *L is the* $\mathsf{LocatedSpace}^{\uparrow}$ *source row, recording the displayed located subset or located family whose boundary is being queried.*
3. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *signed-side or separation row, recording which finite side of the located boundary supplies the positive separation evidence.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, carrying the rational tolerance, sign threshold, and comparison budget used by the signed-distance request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the metric observations, dyadic budget, and signed-side comparisons.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached by the displayed regular readback after M, L, A, D, R have been exposed.*
7. *H records componentwise* hsame *transport for the metric row, located-source row, signed-side row, dyadic budget, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of every signed-distance consumer route through*

$$M, L, A, D, R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{SignedDistance}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSpace}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDistance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, A, D, R, E, H, C, P, N$. It has no coordinate for a host distance function, quotient real equality, trichotomy, selected nearest points, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SignedDistanceUp.TasteGate.SignedDistanceTasteGate single carrier alignment`

Theorem 2116.2 (SignedDistance NameCert obligations)**.** *For every accepted* $\mathsf{SignedDistance}^{\uparrow}$ *carrier*

$$S = (M, L, A, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SignedDistance}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric distance row, located-source row, signed-side apartness row, dyadic budget, regular rational readback, real seal, transport, replay, provenance, and local naming rows;*

2. *located-boundary stability, requiring every transported or replayed signed-distance request to read the same metric row M, located-source row L, signed-side row A, dyadic budget D, and regular readback R before exposing the real seal E;*

3. *signed-budget exactness, requiring the sign threshold and rational tolerance in D to be the budget read both by the metric comparison in M and by the signed-side separation row A;*

4. *real-seal nonescape, requiring every real-facing or completion-facing consumer to pass through M, L, A, D, R, E and to receive no host distance function, quotient real representative, selected nearest point, trichotomy, or ambient completeness theorem;*

5. *ledger refusal, requiring H, C, P, N to transport, replay, source, and name only the displayed rows, with no Lean verification or bridge credential.*

No signed-distance NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2116.1. The packet displays exactly the metric distance row, the located-source row, the signed-side apartness row, the dyadic budget, the regular readback, the real seal, and the four structural rows.

Located-boundary stability is componentwise. A transported or replayed signed-distance request keeps the same metric row M and located row L, so the boundary being queried cannot be replaced by a host subset or by an unrecorded completion object.

Signed-budget exactness is the shared role of A and D. The signed-side row names the finite separation evidence, while the dyadic row fixes the tolerance and sign threshold read by the metric comparison and the regular rational observation.

For real-seal nonescape, the seal E appears only after M, L, A, D, R have been displayed. A real-facing consumer therefore receives a finite signed-distance route rather than a host distance function, quotient representative, nearest-point selector, trichotomy decision, or completeness theorem.

Finally, H, C, P, N only transport, replay, source, and name the carrier rows. Since the packet contains no Lean verification row and no bridge credential, the listed rows exhaust the local NameCert surface. □

Theorem 2116.3 (SignedDistance located boundary)**.** *Every accepted* $\mathsf{SignedDistance}^{\uparrow}$ *carrier*

$$S = (M, L, A, D, R, E, H, C, P, N)$$

binds its signed-distance read to the located boundary named by L*. Any consumer that reads the sign or magnitude surface must first expose the* $\mathsf{Met}^{\uparrow}$ *distance row* M*, the* $\mathsf{LocatedSpace}^{\uparrow}$ *source row* L*, the* $\mathsf{ApartnessReal}^{\uparrow}$ *signed-side row* A*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row* D*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*. The exported boundary information is only this finite route and not a selected nearest point, a decidable side choice, a quotient real equality, or an ambient completeness claim.*

Proof. Start with an accepted packet and project its rows from Definition 2116.1. The only boundary-bearing coordinate is the located-source row L, while the metric and signed-side observations are carried by M and A.

The consumer route then opens the dyadic budget D. This budget fixes the finite tolerance and sign threshold used by both the metric comparison and the signed-side separation row.

The regular readback R is the only row that exposes rational observations downstream. It links the displayed metric and signed-side data to the terminal real seal, so no host comparison or hidden side decision can be inserted between the boundary row and the readback.

Thus every sign or magnitude read is bound to the displayed located boundary. The excluded nearest-point, decidable-side, quotient-equality, and ambient-completeness data cannot be exported because they do not occur in the carrier. □

Theorem 2116.4 (SignedDistance Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{SignedDistance}^{\uparrow}$ *carrier*

$$S = (M, L, A, D, R, E, H, C, P, N)$$

factors through the displayed route

$$M, L, A, D, R \longmapsto E.$$

The factorization exports the regular signed-distance seal E *only after the metric row, located-source row, signed-side row, dyadic budget, and regular readback have been displayed, and it exports no host real-valued distance function, quotient real equality, trichotomy, selected nearest point, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the accepted carrier. The real-facing coordinate is the seal E, and its replay row C displays a route whose source rows are M, L, A, D, R.

The metric row M supplies only finite distance observations, while the located row L supplies only the displayed boundary source. The signed-side row A and dyadic budget D then fix the finite sign and tolerance data read by the regular row R.

Only after these rows are visible can the route reach E. Componentwise transport in H, replay in C, provenance in P, and the local row N preserve the same order under classification.

Therefore the $\mathsf{Real}^{\uparrow}$-facing read factors through the displayed finite route. The excluded host function, quotient equality, trichotomy, nearest-point, completeness, Lean-verification, and bridge data have no carrier coordinate and cannot escape through the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDistance}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2116.1, Definition 2116.2, Definition 2116.3, and Definition 2116.4 seed the finite signed-distance route from metric and located boundary data through apartness, dyadic budget, and regular readback rows to the Real seal.

Formal verification: FormalStatus(NameCert$_{\text{SignedDistance}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host distance functions, quotient real equality, trichotomy, selected nearest points, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-boundary stability, signed-budget exactness, real-seal nonescape, and ledger refusal for BEDC.Derived.SignedDistanceUp.

Constructive story: A SignedDistance$^{\uparrow}$ packet is generated from a metric distance row, a located-source row, an ApartnessReal signed-side row, a DyadicRatCore budget, a RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2117

Cauchy compact NameCert construction

Following Bishop-style compact metric arguments, the $\mathsf{CauchyCompact}^{\uparrow}$ packet records the finite certificate route by which explicit total boundedness and complete metric data turn a displayed regular Cauchy sequence window into an extracted limit seal. It sits over the compact packet of chapter 60, the compact metric finite-net surface of chapter 129, the complete metric limit rows of chapter 128, the totally bounded completion route of chapter 1573, and the L10 real-name spine of chapter 291, chapter 126, chapter 301, and chapter 38. The chapter names sequential compactness only in the constructive Cauchy-extraction sense supplied by displayed finite nets, regular rational windows, and completeness rows; it is not an open-cover compactness theorem and does not introduce a choice-selected subsequence principle.

Definition 2117.1 (CauchyCompact carrier)**.** *A* $\mathsf{CauchyCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, L, T, S, D, E, H, C, P, N)$$

with the following visible rows:

1. *M is the compact metric row. It records the source metric carrier, classifier, finite compact-net admission data, and the compact-metric provenance read from the* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{Compact}^{\uparrow}$ *packets.*
2. *L is the complete metric row. It supplies the displayed limit-witness route for regular Cauchy point streams and the uniqueness route available under the local metric classifier.*
3. *T is the totally bounded finite-net schedule. For each displayed dyadic radius request it records the finite bundle of centers, coverage witnesses, mesh ledger, and replay route consumed by the extraction.*
4. *S is the regular Cauchy sequence window. It records the* $\mathsf{StreamName}^{\uparrow}$ *finite observations, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback, and the late-distance comparisons by which the sequence is admitted as a Cauchy stream in the metric row.*
5. *D is the dyadic radius ledger. It records every* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, refinement, comparison, and tail-budget read used by T and S.*
6. *E is the extracted limit seal. It is the* $\mathsf{Real}^{\uparrow}$*-facing and metric-facing row reached only after M, L, T, S, D have been displayed; it records the limit name, the convergence comparisons, and the local extraction certificate.*

7. *H records componentwise* hsame *transport for the compact metric row, complete metric row, totally bounded schedule, regular Cauchy window, dyadic radius ledger, extracted limit seal, replay, provenance, and local name.*

8. *C records displayed* Cont *replay of the route*

$$M, L, T, S, D \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{TotallyBoundedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, T, S, D, E, H, C, P, N$. It has no coordinate for open-cover compactness, a choice-selected subsequence, quotient stream equality, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompactUp.CauchyCompactTasteGate single carrier alignment`

Theorem 2117.2 (CauchyCompact NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompact}^{\uparrow}$ *carrier*

$$K = (M, L, T, S, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier projection for the compact metric row, complete metric row, totally bounded finite-net schedule, regular Cauchy sequence window, dyadic radius ledger, extracted limit seal, transport row, replay row, provenance row, and local name;*

2. *classifier exactness, requiring packet comparison to inspect only the displayed rows $M, L, T, S, D, E, H, C, P, N$ and to preserve their componentwise* hsame *transport;*

3. *Cauchy extraction, requiring every limit read to pass first through the finite-net schedule T, the regular Cauchy window S, the dyadic radius ledger D, and then the complete metric row L before the seal E is exposed;*

4. *transport stability, requiring any transported packet to replay the same compact metric source, total-bounded mesh ledger, complete-metric limit route, regular sequence window, dyadic comparisons, and extracted limit seal;*

5. *ledger confinement, requiring C, P, N to replay, source, and name only the displayed finite route and to export no open-cover compactness, choice-selected sequential compactness, quotient stream equality, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No $\mathsf{CauchyCompact}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier projection is immediate from Definition 2117.1. The accepted packet displays exactly the compact metric row, complete metric row, finite-net schedule, regular Cauchy window, dyadic ledger, extracted limit seal, transport, replay, provenance, and local naming rows.

Classifier exactness is componentwise. The classifier can compare two accepted packets only by reading $M, L, T, S, D, E, H, C, P, N$, and the transport row H records preservation of precisely those coordinates.

For Cauchy extraction, begin with a displayed tolerance request. The dyadic ledger D fixes the radius and tail budget, the total-bounded schedule T exposes the finite centers at that radius, and

the sequence window S supplies the regular Cauchy observations and late-distance comparisons. The complete metric row L is then applied to the same admitted stream route, producing the limit row sealed by E.

Transport stability and ledger confinement follow from H, C, P, N. These rows replay and name only the displayed route, so the excluded open-cover, choice, quotient, host-equality, trichotomy, and ambient real-completeness principles have no carrier coordinate from which they could be read. □

Theorem 2117.3 (CauchyCompact extraction scope)**.** *Let*

$$K = (M, L, T, S, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompact}^{\uparrow}$ *carrier. Every extracted limit read exported by K factors through the displayed rows*

$$\mathsf{CompleteMetric}^{\uparrow},\quad \mathsf{TotallyBounded}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow}$$

together with the structural rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The extraction reads no open-cover compactness row, no choice-selected subsequence row, no quotient stream equality row, no host real equality row, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier. The compact metric input is M, whose finite-net side is read through the $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{TotallyBounded}^{\uparrow}$ surfaces; no open-cover row is present in the carrier.

The sequential input is S together with D. These rows expose the $\mathsf{StreamName}^{\uparrow}$ finite observations, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity readback, and the $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger before any limit request can reach the completion side.

The limit step is L followed by E. The row L is the displayed $\mathsf{CompleteMetric}^{\uparrow}$ route for the same regular Cauchy stream, and E is only the resulting metric and $\mathsf{Real}^{\uparrow}$ seal for that route.

Finally H, C, P, N preserve, replay, source, and name the same dependencies. Since the tuple has no coordinate outside the displayed analytic and structural rows, every exported extraction remains confined to the stated scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompact}^{\uparrow}$ packet is generated from a compact metric row, a complete metric limit row, a totally bounded finite-net schedule, a regular Cauchy sequence window, a dyadic radius ledger, an extracted limit seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2117.1, Definition 2117.2, and Definition 2117.3 seed the finite constructive Cauchy-extraction route from compact metric data, complete metric limits, total-bounded finite nets, regular Cauchy windows, dyadic radii, and real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, choice-based sequential compactness, quotient stream equality, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier projection, classifier exactness, Cauchy extraction, transport stability, and ledger confinement for the $\mathsf{CauchyCompact}^{\uparrow}$ packet.

Chapter 2118

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$ packet names the finite located-comparison route for two regular Cauchy real names before any $\mathsf{Real}^{\uparrow}$ consumer reads a comparison result. It sits over the regular-rational source rows of chapter 301, the shared finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the located comparison surface of chapter 1730, and the Bishop located Cauchy real route of chapter 1850. The packet is a human-origin L10 handoff from regular Cauchy readback to located $\mathsf{Real}^{\uparrow}$ comparison; it is not quotient real equality, trichotomy, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2118.1 (Regular Cauchy located-comparison carrier)**.** *A* $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X_0, X_1, W, R_0, R_1, D, K, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. *X_0 and X_1 are the two regular Cauchy source-name rows. Each is read as a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *packet before either endpoint is sealed as a real name.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window family. It records the finite observation lengths, synchronized cuts, endpoint windows, and comparison requests inspected for both sources.*
3. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from X_0, X_1 on the shared windows W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested scale, comparison slack, positive-gap threshold, endpoint enclosures, and exhausted finite windows.*
5. *K is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *evidence row. It reads only the displayed readbacks R_0, R_1, shared windows W, dyadic tolerances D, and the terminal seals E_0, E_1.*
6. *E_0 and E_1 are the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows for the two regular Cauchy names. They are reachable only after X_0, X_1, W, R_0, R_1, D have been displayed.*
7. *H records componentwise* hsame *transport for the two source rows, shared windows, readback rows, dyadic tolerance ledger, located-comparison evidence, real seals, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$X_0, X_1, W, D \longmapsto R_0, R_1 \longmapsto E_0, E_1 \longmapsto K.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedComparison}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these thirteen rows. Its classifier compares accepted packets only through $X_0, X_1, W, R_0, R_1, D, K, E_0, E_1, H, C, P, N$ and has no coordinate for quotient real equality, host trichotomy, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedComparisonUp.RegularCauchyLocatedComparisonTasteGate`
`single carrier alignment`

Theorem 2118.2 (Regular Cauchy located-comparison NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$ *carrier*

$$L = (X_0, X_1, W, R_0, R_1, D, K, E_0, E_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy source rows, shared stream windows, two regular rational readbacks, dyadic tolerance ledger, located-comparison evidence row, two terminal real seals, transport, replay, provenance, and local naming row;*
2. *shared-window discipline, requiring the two readback rows R_0, R_1 to be read from the same window family W before any comparison evidence is exported;*
3. *dyadic tolerance discipline, requiring D to supply the requested scale, comparison slack, positive-gap threshold, endpoint enclosures, and exhaustion ledger consumed by the located comparison row;*
4. *real-seal discipline, requiring E_0 and E_1 to remain downstream of the displayed regular Cauchy readbacks and dyadic budget;*
5. *located-comparison exactness, requiring K to compare only the displayed R_0, R_1, W, D, E_0, E_1 route and to expose positive-gap or nonseparating evidence as finite located-comparison data;*
6. *transport and replay stability, requiring H and C to preserve the two source rows, window row, readback rows, tolerance row, comparison row, seal rows, provenance row, and local name row componentwise;*
7. *ledger exhaustion, excluding quotient real equality, host trichotomy, countable choice, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No regular Cauchy located-comparison obligation is stored outside these rows.

Proof. Project the accepted carrier L. The projection exposes exactly the two source rows, the common finite-window family, the two readback rows, the dyadic tolerance ledger, the located-comparison row, the two terminal real seals, and the structural rows.

The comparison route is finite. The shared windows W determine the inspected observations for both source rows, and the two readbacks R_0, R_1 are read at those same windows before any comparison evidence can be exported.

The dyadic ledger is the only tolerance input. It supplies the scale, slack, positive-gap threshold, endpoint enclosures, and exhaustion record that the located-comparison row is allowed to consume.

The real seals remain attached to the route. The rows E_0 and E_1 are read only after the regular Cauchy sources, windows, readbacks, and dyadic budget have been displayed, so the located comparison cannot appeal to detached real representatives.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for quotient real equality, trichotomy, choice, selected limits, completeness, Lean verification, or a bridge, the listed rows exhaust the local NameCert surface. □

Theorem 2118.3 (Regular Cauchy located-comparison real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or located-real consumer of an accepted* $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$ *carrier reads the comparison only through the finite handoff route*

$$X_0, X_1, W, D \longmapsto R_0, R_1 \longmapsto E_0, E_1 \longmapsto K \longmapsto H, C, P, N.$$

Thus the consumer receives two displayed regular Cauchy names, their shared StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledger, terminal RealUp seals, LocatedRealComparison evidence, componentwise transport, continuation replay, package provenance, and local naming. It receives no quotient real equality, host trichotomy, countable-choice schedule, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier. The source rows are X_0 and X_1, and the carrier definition requires both to pass through the common window family W and the dyadic tolerance ledger D.

The readback stage is R_0, R_1. These rows are the only regular rational observations supplied to the later real seals, so a consumer cannot introduce a second readback schedule or an unlisted tolerance.

The seal stage is E_0, E_1. Each seal remains downstream of the corresponding regular Cauchy readback and the shared dyadic budget, placing the comparison inside the displayed Bishop located Cauchy real route rather than inside a quotient-real carrier.

The comparison stage is K. It is the sole located-comparison evidence row and may only consume the displayed readbacks, windows, tolerances, and real seals.

The structural rows H, C, P, N preserve this route under componentwise transport, continuation replay, provenance, and local naming. Because no other coordinate is present, no $\mathsf{Real}^{\uparrow}$ or located-real consumer can read quotient equality, trichotomy, countable choice, a selected limit, or ambient completeness from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedComparison}^{\uparrow}$ packet is generated from two regular Cauchy source-name rows, one shared StreamName window family, two RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a LocatedRealComparison evidence row, two RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2118.1, Definition 2118.2, and Definition 2118.3 seed the finite located-comparison handoff from regular Cauchy readbacks through shared StreamName windows, DyadicRatCore tolerances, RealUp seals, LocatedRealComparison evidence, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window discipline, readback exactness, tolerance discipline, Real seal nonescape, located-comparison handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedComparisonUp.

Chapter 2119

A Concrete Naming Certificate for $\mathsf{DyadicDivision}^{\uparrow}$

Following Bishop and Bridges constructive dyadic arithmetic, $\mathsf{DyadicDivision}^{\uparrow}$ names the finite quotient surface used when an exposed dyadic numerator is divided by a displayed nonzero dyadic denominator before regular rational and real-name consumers can read the result. It sits over the dyadic arithmetic carrier of chapter 291, the comparison and order rows of chapter 1623 and chapter 1597, the reciprocal-window budget of chapter 703, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet records division as displayed finite NameCert data; it is not quotient rational equality, a total inverse operation, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2119.1 (Dyadic division carrier)**.** *A* $\mathsf{DyadicDivision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, L, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the numerator dyadic packet, read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic surface with its displayed sign, scale, endpoint, and tolerance data.*
2. *B is the nonzero denominator dyadic packet, also read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, whose denominator role is fixed before any reciprocal or quotient row is consumed.*
3. *L is the denominator apartness and bound row. It records the finite comparison and order evidence, supplied by* $\mathsf{DyadicComparison}^{\uparrow}$ *or* $\mathsf{DyadicOrder}^{\uparrow}$*, that keeps B away from the zero boundary and exposes a usable lower bound.*
4. *R is the reciprocal ledger. It is the* $\mathsf{CauchyInverseBudget}^{\uparrow}$*-compatible finite row that converts the displayed nonzero denominator packet and apartness bound into reciprocal-read data without exporting a total inverse operation.*
5. *T is the quotient readback row. It reads the numerator row A and reciprocal ledger R as one displayed dyadic quotient packet before any regular rational handoff is available.*
6. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff together with the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It records the regular rational readback of T and the downstream real-name seal only after A, B, L, R, T have been displayed.*
7. *H records componentwise* hsame *transport for numerator, denominator, apartness, reciprocal, quotient, readback, seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from numerator and denominator inspection through apartness exposure, reciprocal ledger construction, quotient readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *sealing, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicDivision}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicComparison}^{\uparrow}$, $\mathsf{DyadicOrder}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDivision}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the tuple $A, B, L, R, T, E, H, C, P, N$. It has no coordinate for quotient rational equality, a total inverse operation, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DyadicDivisionUp.DyadicDivisionTasteGate single carrier alignment`

Theorem 2119.2 (Dyadic division NameCert obligations)**.** *For every accepted* $\mathsf{DyadicDivision}^{\uparrow}$ *carrier $Q = (A, B, L, R, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicDivision}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed numerator packet, nonzero denominator packet, denominator apartness and bound row, reciprocal ledger, quotient readback, regular rational handoff, real seal, transport, replay, provenance, and local naming rows;*
2. *dyadic-source exposure, requiring A and B to be read as* $\mathsf{DyadicRatCore}^{\uparrow}$ *packets before any quotient row is available;*
3. *denominator guard exposure, requiring L to display comparison or order evidence keeping B away from zero before R is consumed;*
4. *reciprocal-ledger locality, requiring R to use only the displayed denominator packet, apartness bound, and reciprocal-window budget named by* $\mathsf{CauchyInverseBudget}^{\uparrow}$*;*
5. *quotient readback exactness, requiring T to consume A and R together and to expose no independent quotient representative;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *non-escape, requiring E to remain downstream of A, B, L, R, T;*
7. *structural replay, requiring H, C, P, N to preserve, replay, source, and name exactly the same finite packet.*

No dyadic division obligation is stored outside these rows.

Proof. Project the carrier of Definition 2119.1. The analytic rows are A, B, L, R, T, E, and the structural rows H, C, P, N transport, replay, source, and name the same tuple.

The source exposure clauses are read from the sibling dyadic surfaces. The numerator and denominator rows are $\mathsf{DyadicRatCore}^{\uparrow}$ packets, while the guard row L is the finite comparison or order evidence supplied by chapter 1623 or chapter 1597.

The reciprocal clause is then local. Since R is downstream of B and L, it has the same guarded shape as the reciprocal budget of chapter 703; no route to R starts from an unguarded denominator.

The quotient row T consumes A and R together. Therefore the quotient read is a displayed dyadic row rather than a selected quotient representative or a host rational equality class.

Finally E is downstream of the quotient readback, and H, C, P, N add only transport, replay, provenance, and local naming. Because none of the excluded principles is a carrier coordinate, no local NameCert obligation can be stored outside $A, B, L, R, T, E, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.DyadicDivisionUp.DyadicDivisionCarrier namecert obligations`

Theorem 2119.3 (Dyadic division nonzero reciprocal route)**.** *Let* $Q = (A, B, L, R, T, E, H, C, P, N)$ *be an accepted* $\mathsf{DyadicDivision}^{\uparrow}$ *carrier. Every reciprocal ledger read used by the quotient row factors through*

$$B \longmapsto L \longmapsto R.$$

Thus a denominator packet reaches reciprocal data only after the displayed apartness and bound row has been exposed, and a route omitting L *cannot export a quotient readback.*

Proof. Begin with the denominator row B. Carrier admission places it before the apartness and reciprocal rows, so any denominator-facing reciprocal route starts from a displayed $\mathsf{DyadicRatCore}^{\uparrow}$ packet.

Next read the guard row L. It is the only coordinate that records denominator apartness and a usable lower bound, and it is the only place where the $\mathsf{DyadicComparison}^{\uparrow}$ or $\mathsf{DyadicOrder}^{\uparrow}$ evidence enters the packet.

Now project the reciprocal ledger R. Its construction is downstream of B and L and follows the reciprocal-window budget discipline named by chapter 703.

If L is omitted, the carrier has no row certifying that the denominator stays away from zero. The route therefore remains at the boundary surface and cannot reach the quotient readback row T. □

Theorem 2119.4 (Dyadic division Real readback nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *L10 Real, or Completion consumer of an accepted* $\mathsf{DyadicDivision}^{\uparrow}$ *carrier reads the displayed chain*

$$A, B, L \longmapsto R \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a finite dyadic quotient readback before the regular rational handoff or real seal is available, with no quotient rational equality, total inverse operation, trichotomy, selected representative, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness inserted into the route.*

Proof. Project the quotient row T. It can be consumed only after the numerator packet A and the guarded reciprocal ledger R have been displayed.

Use Definition 2119.3. The reciprocal ledger itself has already passed through the denominator packet B and the apartness row L, so the quotient route contains the complete nonzero-denominator guard.

The regular rational and real-facing row E is terminal relative to T. It hands the displayed quotient row to $\mathsf{RegSeqRat}^{\uparrow}$ and then to the $\mathsf{Real}^{\uparrow}$ seal; it has no second entrance from a host quotient or total inverse operation.

The remaining rows H, C, P, N transport, replay, source, and name the same chain. Since the carrier contains no excluded quotient, choice, trichotomy, or completeness coordinate, every L10 Real or Completion consumer remains inside the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDivision}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicDivision}^{\uparrow}$ packet is generated from a numerator DyadicRatCore packet, a nonzero denominator DyadicRatCore packet, a denominator apartness and bound row, a reciprocal ledger, a quotient readback row, a RegSeqRat handoff with terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicDivision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2119.1, Definition 2119.2, Definition 2119.3, and Definition 2119.4 seed the finite dyadic quotient surface for L10 Real and Completion consumers over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicComparison}^{\uparrow}$, $\mathsf{DyadicOrder}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicDivision}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient rational equality, total inverse operations, trichotomy, selected representatives, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-source exposure, denominator guard exposure, reciprocal-ledger locality, quotient readback exactness, RegSeqRat and Real non-escape, structural replay, provenance, and local naming for BEDC.Derived.DyadicDivisionUp.

Chapter 2120

A Concrete Naming Certificate for $\mathsf{RegularCauchyAverage}^{\uparrow}$

Following Bishop and Bridges constructive Cauchy real arithmetic, the $\mathsf{RegularCauchyAverage}^{\uparrow}$ packet names finite barycentric averaging of regular rational Cauchy names by displayed dyadic weights, synchronized finite windows, finite summation, scalar normalization, and the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits over the regular-rational source rows of chapter 301, the finite-window discipline of chapter 126, the dyadic arithmetic ledger of chapter 291, the pointwise summation surface of chapter 417, the normalization row of chapter 1971, the two-source specialization of chapter 1670, and the terminal real-name boundary of chapter 38. The packet supplies the finite average route needed by Real and Completion consumers; it does not assert quotient streams, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a detached completed-real barycenter.

Definition 2120.1 (RegularCauchyAverage carrier)**.** *A* $\mathsf{RegularCauchyAverage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathrm{avg}} = (I, R, W, D, B, S, K, M, E, H, C, P, N)$$

with the following displayed rows:

1. *I is a unary finite index row naming the displayed list of average inputs and the finite arity used by all downstream rows.*
2. *R is the indexed family of component* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows.*
3. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family, one finite window for each index in I, all opened at the common precision request.*
4. *D is the family of* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows read from the sources R through the windows W.*
5. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *barycentric weight ledger, recording the finite dyadic weights, their common denominator budget, and the displayed normalization total.*
6. *S is the iterated* $\mathsf{RegularCauchySum}^{\uparrow}$ *aggregation row, summing the weighted component rows in the order named by I.*
7. *K is the* $\mathsf{RegularCauchyScalar}^{\uparrow}$ *normalization row, applying the displayed reciprocal or total-budget scalar from B to the aggregate row S.*
8. *M is an optional* $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ *two-source specialization row, present only when I displays two equal weights and absent from all other classifier comparisons.*

9. *E is the final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the sum and scalar route before the real-name boundary is opened.*

10. *H records componentwise* hsame *transport for the index row, source family, window family, dyadic observations, weight ledger, sum row, scalar row, optional midpoint row, readback row, replay row, provenance row, and local naming row.*

11. *C records displayed* Cont *replay from every average-facing precision request through $I, R, W, D, B, S, K, M, E, H,$*

12. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAverage}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyScalar}^{\uparrow}$, $\mathsf{RegularCauchyMidpoint}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAverage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, R, W, D, B, S, K, M, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAverageUp.RegularCauchyAverageTasteGate single carrier alignment`

Theorem 2120.2 (RegularCauchyAverage NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyAverage}^{\uparrow}$ *carrier*

$$A_{\mathrm{avg}} = (I, R, W, D, B, S, K, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyAverage}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the unary finite index row, component* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations and weights,* $\mathsf{RegularCauchySum}^{\uparrow}$ *aggregation row,* $\mathsf{RegularCauchyScalar}^{\uparrow}$ *normalization row, optional* $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ *specialization row, final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal boundary, and structural rows;*

2. *tuple-window coverage, requiring every indexed component requested by I to be opened through the synchronized finite window family W before the aggregate row is available;*

3. *dyadic weight normalization, requiring B to display the finite weights, the common denominator budget, and the normalization total used by the scalar row;*

4. *sum and scalar budget exactness, requiring S to consume exactly the weighted component rows and K to apply exactly the normalization budget recorded by B;*

5. *readback stability, requiring the final* $\mathsf{RegSeqRat}^{\uparrow}$ *row E to transport through H together with the same index, source, window, dyadic, sum, scalar, optional midpoint, replay, provenance, and naming data;*

6. *Real seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to pass through the final readback row E and its displayed provenance before any real-name seal is exposed;*

7. *provenance and local naming, requiring P and N to name exactly the finite barycentric packet and no external completed-real average.*

No average obligation is stored outside these finite rows, and the surface refuses quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local data.*

Proof. Project the accepted carrier. The analytic coordinates are the finite index row I, the source family R, the synchronized windows W, the dyadic observations D, the barycentric weight ledger

B, the sum row S, the scalar normalization row K, the optional midpoint row M, and the readback row E.

Read the tuple windows before any aggregate is visible. The row I fixes the finite arity, and W opens exactly the component windows used to read D from the $\mathsf{RegSeqRat}^{\uparrow}$ source family R.

Next read the weight and budget rows. The ledger B supplies the dyadic weights, the common denominator budget, and the displayed normalization total. The aggregation row S then consumes the weighted component rows through the $\mathsf{RegularCauchySum}^{\uparrow}$ surface, and the scalar row K applies the normalization through $\mathsf{RegularCauchyScalar}^{\uparrow}$.

The two-source equal-weight case is only a specialization. When M is present, it is the same displayed route through the sibling $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ packet; when it is absent, no classifier coordinate is created for a separate completed-real midpoint.

Finally replay and transport the readback through C, H, P, N. The terminal real-name consumer can reach the seal only after E and its provenance are displayed, so no quotient stream, selected limit, countable-choice selector, trichotomy witness, host real equality, ambient completeness theorem, Lean verification, or bridge credential can be exported by the local NameCert surface. □

Theorem 2120.3 (RegularCauchyAverage barycentric handoff)**.** *Every average read exported by an accepted* $\mathsf{RegularCauchyAverage}^{\uparrow}$ *carrier factors through the finite route*

$$(I, R) \longmapsto W \longmapsto D \longmapsto B \longmapsto S \longmapsto K \longmapsto E$$

before it may be sealed as a $\mathsf{Real}^{\uparrow}$ *read. In particular, the read factors through* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyScalar}^{\uparrow}$ *before the* $\mathsf{Real}^{\uparrow}$ *seal; in the two-source equal-weight case the same route may also be displayed through the* $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ *specialization row. The handoff exports no quotient streams, selected limits, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or detached completed-real barycenter.*

Proof. Start with the accepted packet A_{avg}. The only component sources are the $\mathsf{RegSeqRat}^{\uparrow}$ rows named by R, and the only observations attached to them are opened through the synchronized $\mathsf{StreamName}^{\uparrow}$ windows W and the dyadic rows D.

The barycentric weights are displayed before aggregation. The ledger B fixes the dyadic weights and the normalization budget, so the row S can only be read as the finite $\mathsf{RegularCauchySum}^{\uparrow}$ aggregation of those weighted component rows.

Normalization is downstream of the aggregate. The row K is the $\mathsf{RegularCauchyScalar}^{\uparrow}$ route applying the displayed total-budget scalar to S, and the final $\mathsf{RegSeqRat}^{\uparrow}$ readback E is exposed only after this scalar row is present.

If the finite index has two equal weights, the midpoint row M gives the same consumer boundary through chapter 1670. It does not add a second route to a completed-real average.

The $\mathsf{Real}^{\uparrow}$ seal is therefore terminal. Componentwise transport, continuation replay, package provenance, and the local naming row preserve the route through I, R, W, D, B, S, K, E, leaving no carrier coordinate through which the refused principles or a detached completed-real barycenter could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAverage}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyAverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2120.1, Definition 2120.2, and Definition 2120.3 seed the finite barycentric-average surface over unary finite indices, component $\mathsf{RegSeqRat}^{\uparrow}$ rows, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ weights and budgets, $\mathsf{RegularCauchySum}^{\uparrow}$ aggregation, $\mathsf{RegularCauchyScalar}^{\uparrow}$ normalization, optional $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ specialization, final readback, $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyAverage}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyAverageUp`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tuple-window coverage, dyadic weight normalization, sum and scalar budget exactness, readback stability, Real seal non-escape, provenance, and local naming for BEDC.Derived.RegularCauchyAverageUp.

Constructive story: A RegularCauchyAverage$^{\uparrow}$ packet is generated from a unary finite index row, component RegSeqRat sources, synchronized StreamName windows, DyadicRatCore weights and normalization budget, a RegularCauchySum aggregation row, a RegularCauchyScalar normalization row, an optional RegularCauchyMidpoint specialization row, a final RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2121

A Concrete Naming Certificate for $\mathsf{DugundjiExtension}^{\uparrow}$

Following Dugundji's extension theorem and the Kelley–Bourbaki topology tradition, the $\mathsf{DugundjiExtension}^{\uparrow}$ packet records only a finite extension-operator certificate: it names the route by which a closed metric subspace map into a convex target is extended through displayed affine coefficients, not a host-level selection of covers or functions. Its normality side is anchored in chapter 1866, its real-valued seed in chapter 1956, its exported map surface in chapter 130, its closed-domain exposure in chapter 1519, its affine target in chapter 208, its scalar seal in chapter 38, and its componentwise linear handoff in chapter 47. The packet therefore marks the L10 extension-operator boundary where a Tietze-style real extension is repacked as convex-valued continuous extension data while remaining inside finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Definition 2121.1 (Dugundji extension carrier)**.** *A* $\mathsf{DugundjiExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, S, V, T, L, G, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the ambient metric/topology source row. It records the* $\mathsf{NormalSpace}^{\uparrow}$ *and metric-topology admission data through which neighborhoods, continuity tests, and closed-set exposure are read.*
2. *S is the closed subspace row. It records the* $\mathsf{MetricSubspace}^{\uparrow}$ *inclusion, the closed-domain classifier, and the local restriction route for the partial map being extended.*
3. *V is the convex target row. It records the* $\mathsf{ConvexSet}^{\uparrow}$ *carrier, the compatible* $\mathsf{VecSpace}^{\uparrow}$ *affine-combination surface, and the target classifier used by convex-valued reads.*
4. *T is the Tietze seed map row. It records the real-valued* $\mathsf{TietzeExtension}^{\uparrow}$ *route used to obtain scalar coordinate extensions before any convex-valued graph is exposed.*
5. *L is the local affine-coefficient ledger. It records the finite coefficient rows, index support, scalar* $\mathsf{Real}^{\uparrow}$ *seals, convex-sum budget, and compatibility with the target row V.*
6. *G is the extension graph row. It records the continuous graph read from ambient points through the coefficient ledger L and the convex target row V.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records the scalar readback used by the Tietze seed and by every displayed affine coefficient.*

8. *H records componentwise* hsame *transport for the ambient source, closed subspace, convex target, Tietze seed, affine-coefficient ledger, extension graph, real seal, replay, provenance, and local name.*

9. *C records displayed* Cont *replay of every consumer route through*

$$A, S, V, T, L, R \longmapsto G.$$

10. *P is the* Pkg *provenance over* $\mathsf{DugundjiExtension}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{TietzeExtension}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DugundjiExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, S, V, T, L, G, R, H, C, P, N$. It has no coordinate for a host choice function, a selected locally finite cover, function extensionality, quotient map equality, open-cover compactness, or an ambient extension theorem outside the displayed packet.

Lean4 ✓ `BEDC.Derived.DugundjiExtensionUp.DugundjiExtensionTasteGate single carrier alignment`

Theorem 2121.2 (Dugundji extension NameCert obligations)**.** *For every accepted* $\mathsf{DugundjiExtension}^{\uparrow}$ *carrier*

$$D = (A, S, V, T, L, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DugundjiExtension}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the ambient metric/topology source, closed subspace, convex target, Tietze seed map, affine-coefficient ledger, extension graph, real seal, transport, replay, provenance, and local name;*

2. *closed-subspace exposure, requiring every restriction read to pass through the* $\mathsf{MetricSubspace}^{\uparrow}$ *row S and the ambient source row A before it can compare the original partial map with the extension graph;*

3. *Tietze seed compatibility, requiring scalar reads in T and R to be the only real-valued extension data consumed by the affine-coefficient ledger L;*

4. *convex affine-combination handoff, requiring every value read of G to be assembled through the* $\mathsf{ConvexSet}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *rows in V using the displayed coefficient support in L;*

5. *continuous-map export, requiring the exported extension to pass through the* $\mathsf{ContinuousMap}^{\uparrow}$ *surface named by G and replayed by C;*

6. *non-escape from host choice and function extensionality, requiring H, C, P, N to transport, replay, source, and name only the displayed finite rows and to export no selected cover, host choice function, function-extensional equality, quotient map equality, open-cover compactness, or ambient extension theorem.*

No Dugundji extension NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2121.1. The accepted packet displays exactly the ambient source row, closed subspace row, convex target row, Tietze seed row, affine-coefficient ledger, extension graph, real seal, transport, replay, provenance, and local naming rows.

Closed-subspace exposure follows from the order of the carrier rows. The original partial map can be compared with the extension graph only by reading S inside A, so no unrecorded host subset or external restriction operator can be inserted.

Tietze seed compatibility is confined to T and R. These rows provide the scalar extension and scalar seals consumed by L, and the coefficient ledger has no other real-valued input coordinate.

For the affine handoff, the target row V supplies the convex and vector-space operations, while L supplies the finite coefficient support and scalar budget. The graph row G is exposed only after those rows have been displayed.

Finally, H, C, P, N preserve, replay, source, and name the same displayed route. Since the packet contains no coordinate for a selected cover, host choice function, function-extensional equality, quotient map equality, open-cover compactness, or ambient extension theorem, none of those principles can escape through the local NameCert surface. □

Theorem 2121.3 (Dugundji extension affine handoff)**.** *Let*

$$D = (A, S, V, T, L, G, R, H, C, P, N)$$

be an accepted $\mathsf{DugundjiExtension}^{\uparrow}$ *carrier. Every extension read exported by D factors through the displayed route*

$$\mathsf{NormalSpace}^{\uparrow} \longrightarrow \mathsf{TietzeExtension}^{\uparrow} \longrightarrow \mathsf{ConvexSet}^{\uparrow}/\mathsf{VecSpace}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the local $\mathsf{NameCert}_{\mathsf{DugundjiExtension}^{\uparrow}}$ *row is exposed. Equivalently, every consumer of the extension graph first reads the normal ambient source A, the closed subspace S, the Tietze seed T, the convex and vector-space target V, the affine ledger L, and the real seal R, then reaches G, C, P, N. The exported data includes no host choice function, no function-extensional equality, no selected cover, no quotient map equality, and no open-cover compactness principle.*

Proof. Project the accepted carrier. The ambient and closed-domain side is A together with S, so the route begins with the normal metric/topology source and its displayed closed subspace.

The scalar seed is T together with the real seal R. Thus any coefficient read entering the affine ledger is already a displayed Tietze-style scalar extension read and not a host-level real-valued function.

The target handoff is V followed by L. The row V supplies the $\mathsf{ConvexSet}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ operations, while L supplies the finite coefficient support and the convex-sum budget used to assemble the value.

Only after these rows are displayed does the graph row G export a $\mathsf{ContinuousMap}^{\uparrow}$ read. Componentwise transport, replay, provenance, and the local row N preserve this order, so every extension read reaches the local NameCert through the stated factorization and through no excluded host principle. □

Theorem 2121.4 (Dugundji extension closed-subspace exposure)**.** *Let*

$$D = (A, S, T, V, L, G, R, H, C, P, N)$$

be an accepted $\mathsf{DugundjiExtension}^{\uparrow}$ *carrier, written in source-first order for the exposure read. Before the extension graph G is public, the packet must display the ambient source row A, the closed subspace row S, the Tietze seed row T, and the convex target row V. Thus every accepted extension read exposes the source, domain restriction, scalar seed, and convex target before it can compare or export the graph row.*

Proof. Project the carrier of Definition 2121.1. Its displayed rows include the ambient metric/topology source, closed subspace, convex target, Tietze seed, affine ledger, graph, real seal, transport, replay, provenance, and local name.

Apply the NameCert obligations of Definition 2121.2. Closed-subspace exposure passes through S inside A, Tietze seed compatibility passes through T, and the convex affine handoff passes through V before the graph row is exposed.

The remaining rows L, R, H, C, P, N preserve and name the same route. They do not supply a second source, a hidden closed-domain comparison, or a detached graph export, so G becomes public only after A, S, T, V have been displayed. □

Theorem 2121.5 (Dugundji extension convex affine non-escape)**.** *For every accepted* $\mathsf{DugundjiExtension}^{\uparrow}$ *carrier*

$$D = (A, S, T, V, L, G, R, H, C, P, N),$$

the affine ledger L and the $\mathsf{Real}^{\uparrow}$ *seal R keep the extension graph G inside displayed convex affine combinations over the target row V. The accepted route excludes host choice, selected covers, quotient map equality, and function extensionality as sources for the graph or for its value comparison.*

Proof. Use the affine handoff of Definition 2121.3. It forces every extension read to pass from the ambient and closed-domain rows through the Tietze seed, convex target, affine ledger, and real seal before reaching the exported graph.

Now apply the closed-subspace exposure theorem Definition 2121.4. Since A, S, T, V are already displayed before G is public, the ledger L can only assemble values from the exposed convex target and the scalar data sealed by R.

No excluded principle is a carrier coordinate. The rows H, C, P, N transport, replay, source, and name the finite packet, but they do not add host choice, selected covers, quotient map equality, or function extensionality to the accepted graph route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DugundjiExtension}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DugundjiExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2121.1, Definition 2121.2, and Definition 2121.3 seed the finite extension-operator packet from normal ambient data, closed metric subspace exposure, Tietze scalar seeds, convex affine coefficients, continuous-map export, and real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DugundjiExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host-selected cover, host choice function, function-extensional equality, quotient map equality, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires BEDC.Derived.DugundjiExtensionUp to check carrier admission, closed-subspace exposure, Tietze seed compatibility, convex affine-combination handoff, continuous-map export, and non-escape from host choice and function extensionality.

Constructive story: A $\mathsf{DugundjiExtension}^{\uparrow}$ packet is generated from an ambient metric/topology source, a closed subspace row, a convex target row, a Tietze seed map, local affine-coefficient rows, an extension graph, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2122

A Concrete Naming Certificate for $\mathsf{RealIntervalDistance}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Moore–Kearfott–Cloud interval analysis, the $\mathsf{RealIntervalDistance}^{\uparrow}$ packet records the finite point-to-interval distance route by which a displayed real source point, a located real interval, a clamp value, and an absolute-value magnitude are read before any downstream Real or Completion consumer sees a distance. It consumes the clamping surface of chapter 1810, the absolute-value surface of chapter 1608, the located interval surface of chapter 1709, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet gives L10 Real and Completion routes a named finite handoff for distance from a point to a located interval; it is not host order, quotient real equality, a selected closest point theorem, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2122.1 (RealIntervalDistance carrier)**.** *A* $\mathsf{RealIntervalDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, I, K, A, T, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source point row. It records the displayed* $\mathsf{Real}^{\uparrow}$ *name of the point whose distance from the interval is requested.*
2. *I is the source interval row. It records the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint names, locator reads, radius data, and locatedness budget for the interval being queried.*
3. *K is the clamp row. It records the* $\mathsf{RealClamping}^{\uparrow}$ *value obtained by clamping the point row X against the displayed interval row I.*
4. *A is the distance-magnitude row. It records the* $\mathsf{RealAbs}^{\uparrow}$ *read of the displayed difference between the source point and the clamp value.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records every dyadic radius, slack comparison, endpoint budget, and absolute-value precision request consumed by K and A.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite observations used to read the point, endpoints, clamp value, and distance magnitude at the requested tolerance.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational data exposed by the point, endpoint, clamp, and absolute-value streams.*

8. *H records componentwise* hsame *transport for the point row, interval row, clamp row, absolute-value row, tolerance ledger, stream windows, regular readback, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay of the route*

$$X, I \longmapsto K \longmapsto A \longmapsto T, S, R.$$

10. *P is the* Pkg *provenance over* $\mathsf{RealIntervalDistance}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RealClamping}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalDistance}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these eleven rows form one finite point-to-interval distance packet. It has no coordinate for host order, quotient real equality, a selected closest point, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealIntervalDistanceUp.RealIntervalDistanceTasteGate single carrier alignment`

Theorem 2122.2 (RealIntervalDistance NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalDistance}^{\uparrow}$ *carrier*

$$D = (X, I, K, A, T, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntervalDistance}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *point, source* $\mathsf{LocatedRealInterval}^{\uparrow}$ *interval,* $\mathsf{RealClamping}^{\uparrow}$ *clamp value,* $\mathsf{RealAbs}^{\uparrow}$ *distance magnitude, dyadic tolerance ledger, stream windows, regular rational readback, transport, replay, provenance, and local name;*

2. *interval exposure, requiring every endpoint, locator, radius, and locatedness request to pass through the displayed interval row I before the clamp row is read;*

3. *clamp handoff, requiring K to consume only the displayed point row X, interval row I, tolerance ledger T, stream windows S, and regular readback row R;*

4. *absolute-distance readback, requiring A to read the magnitude of the displayed difference between X and K through the same T, S, R rows before any distance consumer sees the result;*

5. *tolerance exactness, requiring the dyadic ledger T to record the endpoint, clamp, absolute-value, and consumer precision requests used in the packet;*

6. *transport and replay stability, requiring H and C to preserve the point, interval, clamp, absolute-value, tolerance, window, readback, provenance, and local naming rows componentwise;*

7. *non-escape from host trichotomy, quotient equality, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No point-to-interval distance obligation is stored outside these rows.

Proof. Project the accepted packet $D = (X, I, K, A, T, S, R, H, C, P, N)$. The projection exposes exactly the point, interval, clamp, absolute-value, tolerance, window, readback, transport, replay, provenance, and naming rows.

The interval and clamp stages are ordered by the displayed route. Endpoint, locator, radius, and locatedness requests begin at I, while the clamp row K is read only after the point row X, the interval row I, and the finite tolerance and readback rows T, S, R have been displayed.

The distance magnitude is downstream of the clamp row. The row A records the $\mathsf{RealAbs}^{\uparrow}$ read of the displayed difference between X and K, using the same dyadic ledger, stream windows, and regular rational readback that admitted the clamp request.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of the carrier coordinates stores host trichotomy, quotient real equality, a selected limit or closest point, countable choice, or ambient real completeness, no such principle can be exported by the local NameCert surface. □

Theorem 2122.3 (RealIntervalDistance clamp-absolute handoff)**.** *Every accepted* $\mathsf{RealIntervalDistance}^{\uparrow}$ *distance consumer factors through the displayed route*

$$\mathsf{Real}^{\uparrow}_{\mathrm{source}} \longmapsto \mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{RealClamping}^{\uparrow} \longmapsto \mathsf{RealAbs}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}/\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}$$

Thus the packet exports only the finite clamp-absolute distance handoff and exports no host order, quotient equality, selected closest point, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from an accepted distance consumer. The only source point coordinate is X, and the only interval coordinate is I, so the consumer cannot read a distance before those two rows expose their finite real-name and located-interval data.

The clamp coordinate comes next. The row K is the displayed $\mathsf{RealClamping}^{\uparrow}$ output for the point and interval rows, under the precision and readback rows T, S, R.

The absolute-value coordinate supplies the distance magnitude. The row A reads the displayed difference between the source point and the clamp value, again through T, S, R, so the magnitude is tied to the same finite data as the clamp.

The structural rows close the route. Componentwise transport in H, continuation replay in C, provenance in P, and local naming in N preserve exactly the displayed rows, leaving no coordinate for the excluded host, quotient, selection, compactness, choice, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalDistance}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealIntervalDistance}^{\uparrow}$ packet is generated from a source RealUp point row, a LocatedRealIntervalUp interval row, a RealClampingUp clamp row, a RealAbsUp distance-magnitude row, a DyadicRatCoreUp tolerance ledger, StreamNameUp finite windows, RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealIntervalDistance}^{\uparrow}}$, seed)

Scope closed: Definition 2122.1, Definition 2122.2, and Definition 2122.3 seed the finite point-to-interval distance route over displayed point, located interval, clamp, absolute-value, dyadic tolerance, stream-window, regular-readback, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealIntervalDistance}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host order, quotient equality, selected closest points, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval exposure, clamp handoff, absolute-distance readback, tolerance exactness, transport stability, and replay confinement for the $\mathsf{RealIntervalDistance}^{\uparrow}$ packet.

Chapter 2123

A Concrete Naming Certificate for $\mathsf{CauchyOscillationCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyOscillationCriterion}^{\uparrow}$ packet records the finite identification between a Cauchy oscillation ledger and a two-point tail-diameter witness. It consumes the oscillation surface of chapter 448, the tail-diameter surface of chapter 1746, the criterion consumers of chapter 392 and chapter 435, the dyadic tolerance row of chapter 291, and the terminal seal discipline of chapter 38. The packet gives RegSeqRat, Real, and Completion consumers one finite criterion object rather than two unrelated tail tests; it is not a real-completeness theorem, a selected limit, quotient stream equality, host real equality, or a choice principle.

Definition 2123.1 (Cauchy oscillation criterion carrier)**.** *A* $\mathsf{CauchyOscillationCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (O, K, A, U, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the accepted* $\mathsf{CauchyOscillation}^{\uparrow}$ *ledger row, exposing the finite tail window, threshold schedule, dyadic tolerance, and oscillation comparisons read by the criterion.*
2. *K is the accepted* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *witness row, exposing the same source tail through one threshold, two visible tail indices, one tolerance, and the displayed diameter bound.*
3. *A is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *consumer row that reads the single-sequence criterion boundary from the shared ledger and diameter witness.*
4. *U is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *family row that reads the same finite route when the criterion is presented as a singleton or fixed finite family.*
5. *Q is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose dyadic budget is used by both the oscillation comparisons in O and the two-point bound in K.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after the common finite criterion route has been accepted.*
7. *H records componentwise* hsame *transport for the oscillation ledger, tail-diameter witness, criterion row, uniform-family row, dyadic tolerance, real seal, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay of the route*

$$O, K, Q \longmapsto A, U \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyOscillationCriterion}^{\uparrow}$, $\mathsf{CauchyOscillation}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyOscillationCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, K, A, U, Q, R, H, C, P, N$. It has no coordinate for a quotient stream, selected limit, host equality, choice datum, ambient Real completeness, or detached completion object.

Lean4 ✓ `BEDC.Derived.CauchyOscillationCriterionUp.CauchyOscillationCriterionTasteGate single carrier alignment`

Theorem 2123.2 (Cauchy oscillation criterion NameCert obligations)**.** *For every accepted* CauchyOscillationCriteri *carrier $X = (O, K, A, U, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyOscillationCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the oscillation ledger, tail-diameter witness, single-sequence criterion consumer, finite-family criterion consumer, shared dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows;*

2. *oscillation-to-diameter projection, requiring every accepted oscillation comparison used by O to expose the same finite source tail, threshold discipline, and dyadic tolerance from which the two visible tail-index comparison in K is read;*

3. *diameter-to-oscillation reconstruction, requiring the two-point bound recorded by K to replay as a finite oscillation-ledger entry over the same displayed source tail and tolerance row;*

4. *consumer handoff through* $\mathsf{CauchyCriterion}^{\uparrow}$ *and* $\mathsf{UniformCauchyCriterion}^{\uparrow}$*, requiring both consumer rows A and U to read the shared O, K, Q route before exposing the terminal* $\mathsf{Real}^{\uparrow}$ *seal row R;*

5. *non-escape from quotient streams, selected limits, host equality, choice, Real completeness, and detached completion data.*

No Cauchy oscillation criterion obligation is stored outside these rows.

Proof. Project the accepted packet $X = (O, K, A, U, Q, R, H, C, P, N)$. The projection exposes exactly one oscillation ledger, one tail-diameter witness, two criterion consumer rows, one shared dyadic tolerance, one Real seal handoff, and the structural transport, replay, provenance, and naming rows.

For the oscillation-to-diameter direction, read the ledger row O through its finite tail window, threshold schedule, dyadic tolerance, and displayed comparisons. The tail-diameter row K uses the same source tail and tolerance but focuses the read to two visible tail indices beyond the displayed threshold, so every two-point comparison consumed by the criterion is a projection of the finite oscillation route.

For the diameter-to-oscillation direction, replay the two visible indices and bound stored in K as one ledger entry over the same source tail. The shared tolerance row Q fixes the dyadic budget, so the reconstructed ledger entry cannot alter the radius, threshold discipline, or source observations.

The consumer rows then read the common route. The $\mathsf{CauchyCriterion}^{\uparrow}$ row A and the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ row U both consume O, K, Q before exposing R, and the replay row C records this order as a displayed continuation.

Finally, H, P, N transport, source, and name only the displayed finite rows. Since the carrier contains no coordinate for quotient streams, selected limits, host equality, choice, Real completeness, or detached completion data, none of those principles can be part of the local obligation surface. □

Theorem 2123.3 (Cauchy oscillation and tail-diameter equivalence)**.** *Every accepted* $\mathsf{CauchyOscillationCriterion}^{\uparrow}$ *packet makes the* $\mathsf{CauchyOscillation}^{\uparrow}$ *ledger and the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *witness the same finite tail-bound route for* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers. More explicitly, a consumer that reads the criterion packet through A or U must factor through the common route*

$$O, K, Q \longmapsto A, U \longmapsto R,$$

where O and K expose the same displayed source tail, threshold discipline, dyadic tolerance, and finite two-point comparison data. The equivalence exports no Real completeness, selected limit, quotient stream equality, host equality, choice datum, or detached completion object.

Proof. Start with an accepted packet $X = (O, K, A, U, Q, R, H, C, P, N)$ and a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer route that reads the criterion through A or U. Carrier admission gives the consumer no analytic coordinates except the oscillation ledger O, the tail-diameter witness K, the shared tolerance row Q, and the terminal seal R.

Use the NameCert obligations in Definition 2123.2. The oscillation-to-diameter projection says that the tail-diameter read is obtained by selecting the two visible tail positions inside the finite oscillation ledger. The diameter-to-oscillation reconstruction says that the same two-point bound replays as an oscillation-ledger entry over the same displayed source tail and tolerance.

The consumer handoff fixes the downstream route. Both A and U must read the shared O, K, Q route before exposing R, so the single-sequence criterion and the finite-family criterion cannot distinguish the oscillation ledger from the tail-diameter witness as separate completion data.

The remaining structural rows preserve this identification. Componentwise transport in H and displayed replay in C keep the source tail, threshold discipline, tolerance row, and comparison data aligned, while P and N source and name the same finite packet.

Therefore the oscillation ledger and the tail-diameter witness are the same finite tail-bound route for the displayed RegSeqRat and Real consumers. The non-escape row excludes Real completeness, selected limits, quotient stream equality, host equality, choice, and detached completion objects from the equivalence. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyOscillationCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyOscillationCriterion}^{\uparrow}$ packet is generated from a CauchyOscillationUp ledger, a CauchyTailDiameterUp witness, CauchyCriterionUp and UniformCauchyCriterionUp consumer rows, a shared DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyOscillationCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 2123.1, Definition 2123.2, and Definition 2123.3 seed the finite criterion packet identifying the oscillation ledger with the two-point tail-diameter witness for RegSeqRat and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyOscillationCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, selected limits, quotient stream equality, host equality, choice, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, oscillation-to-diameter projection, diameter-to-oscillation reconstruction, consumer handoff, and non-escape for BEDC.Derived.CauchyOscillationCriterionUp.

Chapter 2124

A Concrete Naming Certificate for $\mathsf{MetricCompletionUniversalProperty}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the metric-completion universal property is read here as a finite extension-and-uniqueness packet over displayed completion data. The packet refines the metric-completion surface of chapter 1506 by binding it to the universal-extension ledger of chapter 397, the regular Cauchy universal route of chapter 1425, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the real-name seal of chapter 38, and the continuous-map interface of chapter 130. It supplies later complete-metric and continuous-extension chapters with an L10 completion route that contains no quotient stream, selected host limit, countable-choice schedule, host function equality, or ambient completeness theorem.

Definition 2124.1 (MetricCompletionUniversalProperty carrier)**.** *A* $\mathsf{MetricCompletionUniversalProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, V, R, W, A, F, E, L, H, C, P, N)$$

with the following visible rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row naming the completion-facing source packet;*
2. *V is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row that supplies extension existence and uniqueness ledgers over displayed completion data;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row used for dense metric observations and finite readback;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which the dense source is inspected;*
5. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read after R and W have displayed the requested approximation data;*
6. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *dense-source map row, including the graph and modulus data consumed by the extension route;*
7. *E is the extension ledger from F, R, W, A into a completion-facing* $\mathsf{ContinuousMap}^{\uparrow}$ *row over M;*
8. *L is the uniqueness ledger comparing two extension rows when they agree on the same M, V, R, W, A, F, E coordinates;*

9. *H records componentwise* hsame *transport for the completion row, universal-property row, dense source, window schedule, real seal, continuous-map row, extension ledger, uniqueness ledger, package row, and local naming row;*
10. *C records displayed* Cont *replay of the route*

$$M, V, R, W, A, F \longmapsto E \longmapsto L;$$

11. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionUniversalProperty}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, no selected host limit, no countable-choice schedule, no host function equality, and no ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.MetricCompletionUniversalPropertyUp.MetricCompletionUniversalPropertyTasteGate`
`single carrier alignment`

Definition 2124.2 (MetricCompletionUniversalProperty classifier)**.** *Two accepted* MetricCompletionUniversalProper *carriers*

$$U = (M, V, R, W, A, F, E, L, H, C, P, N)$$

and

$$U' = (M', V', R', W', A', F', E', L', H', C', P', N')$$

classify together exactly when the classifier compares the displayed coordinates componentwise by hsame*, and when the displayed* Cont *replay has the same completion, dense-source, extension, and uniqueness order on both packets. Thus the classifier is the finite route*

$$M, V, R, W, A, F, E, L, H, C, P, N,$$

not equality of quotient completion classes, not host function extensionality, and not a selected-limit principle.

Theorem 2124.3 (MetricCompletionUniversalProperty extension route)**.** *Let $U = (M, V, R, W, A, F, E, L, H, C, P$ be an accepted* $\mathsf{MetricCompletionUniversalProperty}^{\uparrow}$ *carrier. Every completion-facing extension exported by U factors through the source completion row M, the universal-property row V, the dense regular rational row R, the finite stream-window schedule W, the terminal real-name seal A, the dense* $\mathsf{ContinuousMap}^{\uparrow}$ *row F, and only then the extension ledger E.*

The exported route is therefore

$$M, V, R, W, A, F \longmapsto E,$$

with the structural rows H, C, P, N recording transport, replay, provenance, and local naming. It is not a quotient-stream construction, not a selected host limit, not an appeal to countable choice, and not an ambient completeness theorem.

Proof. Project the accepted carrier of Definition 2124.1. The completion-facing source is M, and the universal-extension surface is V.

The dense source is read through R and W. The row R supplies regular rational readback, while W supplies the finite windows through which the requested observations are displayed.

The target real-facing boundary is A, and the dense map data are F. The extension ledger E is the only coordinate that repacks those rows as a completion-facing continuous-map read.

The remaining rows H, C, P, N transport, replay, package, and name the same finite route. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, host function equality, or ambient completeness, none of those principles can be exported by the extension route. □

Theorem 2124.4 (MetricCompletionUniversalProperty uniqueness ledger)**.** *Let* $U = (M, V, R, W, A, F, E, L, H, C,$ *and* $U' = (M, V, R, W, A, F, E', L', H', C', P, N')$ *be accepted* $\mathsf{MetricCompletionUniversalProperty}^{\uparrow}$ *carriers over the same completion row, universal-property row, dense source, stream-window schedule, real seal, dense continuous-map row, and provenance. If* E *and* E' *agree on every displayed finite read from* R *and* W *after the real-seal handoff through* A*, then the two exported extension rows are compared by the displayed uniqueness ledgers* L *and* L'*.*

The uniqueness conclusion is internal to $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. It is not host equality of maps and not equality of quotient completion representatives.*

Proof. Read the common coordinates from the two accepted packets. The rows M, V, R, W, A, F, P fix the completion source, universal-property surface, dense observations, real seal, dense map, and provenance shared by both extension ledgers.

The hypothesis compares E and E' on every finite read displayed by R and W. Transport those reads through H, H' and replay them through C, C' until both extension rows are presented over the same real-seal coordinate A.

The uniqueness coordinates are exactly L and L'. Applying them gives the required displayed hsame comparison of extension rows.

No carrier coordinate names host function extensionality, quotient equality, a selected limit, countable choice, or ambient completeness. The uniqueness claim therefore remains a ledger comparison over the visible BEDC rows. □

Theorem 2124.5 (MetricCompletionUniversalProperty NameCert obligations)**.** *For the carrier of Definition 2124.1, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier display for the packet* $U = (M, V, R, W, A, F, E, L, H, C, P, N)$*;*
2. *classifier stability by componentwise* hsame *transport and displayed* Cont *replay as in Definition 2124.2;*
3. *extension existence through the finite route of Definition 2124.3;*
4. *uniqueness through the ledger comparison of Definition 2124.4;*
5. *non-escape, requiring every consumer read to remain inside* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

No obligation is stored in a quotient stream, selected host limit, countable-choice schedule, host function equality row, or ambient completeness theorem.

Proof. Carrier display is projection from Definition 2124.1. The accepted packet lists exactly the completion row, universal-property row, dense source, window schedule, real seal, continuous-map row, extension ledger, uniqueness ledger, and structural support rows.

Classifier stability follows from Definition 2124.2. The comparison is componentwise on those displayed coordinates, and the replay data only preserve the same route order.

Extension existence is the obligation of Definition 2124.3. It forces every exported extension to pass through M, V, R, W, A, F before the ledger E is read.

Uniqueness is the obligation of Definition 2124.4. It compares candidate extension rows through L and L' over the same finite dense-source and real-seal reads.

The non-escape row is obtained by inspecting the carrier inventory. Since every exported object is one of the listed BEDC rows or a displayed route between them, the excluded host-side principles have no coordinate from which to enter the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionUniversalProperty}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionUniversalProperty}^{\uparrow}$ packet is generated from a MetricCompletionUp source row, a CompletionUniversalPropertyUp extension row, RegSeqRat and StreamName dense-source reads, a terminal RealUp seal, a ContinuousMapUp dense-map row, extension and uniqueness ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionUniversalProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2124.1, Definition 2124.2, Definition 2124.3, Definition 2124.4, and Definition 2124.5 seed the finite metric-completion universal-property route over displayed completion, dense-source, real-seal, continuous-map, extension, and uniqueness rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionUniversalProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, host function equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier display, classifier stability, extension route, uniqueness ledger, and NameCert non-escape for BEDC.Derived.MetricCompletionUniversalPropertyUp.

Chapter 2125

A Concrete Naming Certificate for $\mathsf{AbelPartialSummation}^{\uparrow}$

Following Abel and Hardy, the $\mathsf{AbelPartialSummation}^{\uparrow}$ packet records the finite summation-by-parts route by which a real series source, a finite coefficient window, and a displayed coefficient-difference ledger determine every endpoint-facing partial-summation read. It sits after the $\mathsf{RealSeries}^{\uparrow}$ carrier of chapter 1581, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite summation-by-parts evidence only through displayed partial sums, adjacent coefficient differences, and boundary terms; it does not import a host infinite sum, a convergence theorem for Abel means, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2125.1 (Abel partial summation carrier)**.** *An* $\mathsf{AbelPartialSummation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, A, S, \Delta, B, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealSeries}^{\uparrow}$ *source row. It exposes the real-valued term stream only through the finite partial-sum surface already named for real series.*
2. *A is the finite coefficient window. It records the inspected coefficients $a_m, \ldots, a_n$ and the endpoint coefficients used by the summation-by-parts formula.*
3. *S is the finite partial-sum window. It records the displayed partial sums of the source row over the same index interval and the shifted partial sums needed by the coefficient differences.*
4. *Δ is the coefficient-difference ledger. It records every adjacent difference $a_k - a_{k+1}$ used inside the finite summation-by-parts read.*
5. *B is the boundary-term ledger. It records the two endpoint products between displayed coefficients and displayed partial sums, together with the sign and index orientation used by the read.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family for the inspected source terms, coefficients, partial sums, coefficient differences, and boundary terms.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same displayed windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for finite addition, subtraction, multiplication, difference, and boundary-term comparisons.*

9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $R, A, S, \Delta, B, W, Q, D$ have been displayed.*

10. *H records componentwise* hsame *transport for the real series source, coefficient window, partial-sum window, difference ledger, boundary ledger, stream windows, readback, tolerance ledger, endpoint seal, replay, provenance, and local name.*

11. *C records displayed* Cont *replay of the route*

$$R, A, S, \Delta, B, W, Q, D \longmapsto E.$$

12. *P is the* Pkg *provenance over* $\mathsf{AbelPartialSummation}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelPartialSummation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, A, S, \Delta, B, W, Q, D, E, H, C, P, N$. It has no coordinate for a host infinite sum, an Abel convergence theorem, a hidden coefficient limit, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AbelPartialSummationUp.AbelPartialSummationTasteGate single carrier alignment`

Theorem 2125.2 (Abel partial summation NameCert obligations)**.** *For every accepted* $\mathsf{AbelPartialSummation}^{\uparrow}$ *carrier*

$$K = (R, A, S, \Delta, B, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelPartialSummation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real series source, coefficient window, partial-sum window, coefficient-difference ledger, boundary-term ledger, stream windows, readback, dyadic ledger, endpoint seal, transport, replay, provenance, and local naming rows;*

2. *partial-sum exposure, requiring every series read used by the packet to pass through R and the displayed finite partial-sum window S;*

3. *coefficient-difference stability, requiring Δ to store the adjacent differences read from A and to preserve them under the componentwise* hsame *transport row H;*

4. *boundary ledger accounting, requiring B to display the endpoint products and their signs before any endpoint seal can be exported;*

5. *endpoint non-escape, requiring E to remain downstream of $R, A, S, \Delta, B, W, Q, D$ and to export no host infinite sum, Abel convergence theorem, hidden coefficient limit, quotient stream equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*

6. *provenance closure, requiring C, P, N to replay, source, and name only the displayed finite route.*

No Abel partial-summation obligation is stored outside these rows.

Proof. Project the accepted packet $K = (R, A, S, \Delta, B, W, Q, D, E, H, C, P, N)$. The carrier exposes exactly the real series source, coefficient window, finite partial sums, coefficient differences, boundary terms, window and readback rows, dyadic ledger, endpoint seal, and structural rows.

The partial-sum exposure is forced by R and S. The source row supplies only the finite series surface of $\mathsf{RealSeries}^{\uparrow}$, and the partial-sum window lists the displayed sums available for the summation-by-parts read.

The coefficient side is finite. The row A displays the inspected coefficients, while Δ records the adjacent differences and B records the endpoint products with their signs and index orientation. The transport row H preserves those same displayed coordinates.

The rows W, Q, D read the source, coefficient, difference, and boundary data through finite windows, regular rational readback, and dyadic tolerance accounting. Only after those rows are present does E expose a $\mathsf{Real}^{\uparrow}$ endpoint seal.

Finally C, P, N replay, source, and name the same finite route. Since the carrier has no excluded coordinate for host summation, Abel convergence, hidden coefficient limits, quotient equality, choice, trichotomy, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 2125.3 (Abel partial summation by-parts route)**.** *Every accepted* $\mathsf{AbelPartialSummation}^{\uparrow}$ *packet factors each summation-by-parts read through the displayed finite route*

$$R, A \longmapsto S, \Delta, B \longmapsto W, Q, D \longmapsto E, H, C, P, N.$$

Thus the read reaches the $\mathsf{Real}^{\uparrow}$ *endpoint seal only after the finite partial sums, coefficient-difference ledger, and boundary-term ledger have been displayed. It does not read a host infinite sum, an Abel convergence theorem, a hidden coefficient limit, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an endpoint-facing summation-by-parts request. By Definition 2125.1, the request first projects the source series row R and the coefficient window A.

The finite by-parts data are then fixed. The row S supplies the partial sums of the source row over the displayed interval, Δ supplies the adjacent coefficient differences, and B supplies the endpoint products that close the finite identity.

The readback stage is shared. The rows W, Q, D expose exactly the finite windows, regular rational reads, and dyadic tolerance comparisons needed to combine the displayed partial sums, differences, and boundary terms.

Only after this finite route is displayed can E provide the endpoint seal, and the structural rows H, C, P, N transport, replay, source, and name that same route. Hence every accepted packet factors the summation-by-parts read through the displayed finite ledgers before any $\mathsf{Real}^{\uparrow}$ endpoint seal is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbelPartialSummation}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbelPartialSummation}^{\uparrow}$ packet is generated from a RealSeriesUp source, a finite coefficient window, a finite partial-sum window, a coefficient-difference ledger, a boundary-term ledger, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AbelPartialSummation}^{\uparrow}}$, seed)

Scope closed: Definition 2125.1, Definition 2125.2, and Definition 2125.3 seed the finite summation-by-parts certificate surface between RealSeriesUp partial sums, coefficient differences, boundary ledgers, and RealUp endpoint seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AbelPartialSummation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host infinite sums, Abel convergence theorems, hidden coefficient limits, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partial-sum exposure, coefficient-difference stability, boundary ledger accounting, endpoint non-escape, and provenance closure for BEDC.Derived.AbelPartialSummationUp.

Chapter 2126

A Concrete Naming Certificate for $\mathsf{SilvermanToeplitz}^{\uparrow}$

Following Silverman, Toeplitz, and Hardy on regular matrix summability, the $\mathsf{SilvermanToeplitz}^{\uparrow}$ packet records the finite BEDC certificate by which a row-finite inspection of a summability matrix sends a convergent regular real-name sequence to the same $\mathsf{Real}^{\uparrow}$ endpoint. It refines the matrix-window route of chapter 1682, contains the Cesaro averaging and convergence special cases of chapter 1765 and chapter 1827, reads source and transformed rows through chapter 301, keeps all rational coefficient budgets inside chapter 291, and reaches the terminal seal only through chapter 38. The chapter names the local certificate surface for regular matrices; it does not import a host summability theorem, a completed infinite matrix, quotient equality of real-name streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2126.1 (Silverman–Toeplitz carrier)**.** *A* $\mathsf{SilvermanToeplitz}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, B, V, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the matrix coefficient-window row, listing the finite rows, finite column windows, coefficient approximants, truncation thresholds, and row-index requests currently inspected.*
2. *B is the row-sum bound ledger, recording the dyadic bounds used to keep each displayed matrix row uniformly bounded before a transformed read is exposed.*
3. *V is the column-vanishing ledger, recording for each displayed source tolerance the finite column requests whose coefficients are certified small along sufficiently late matrix rows.*
4. *W is the source* $\mathsf{StreamName}^{\uparrow}$ *window row, listing only the finite input-sequence observations demanded by M, B, V.*
5. *T is the transformed finite-row surface, obtained from the displayed coefficients in M, the selected source windows in W, and the dyadic budgets in B, V.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for both the source windows used by the regularity argument and the transformed rows exposed by T.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the matrix windows, bounded-row ledger, column-vanishing ledger, source windows, transformed finite rows, and regular readback have been displayed.*

8. *H stores componentwise* hsame *transport for matrix windows, row-sum bounds, column-vanishing data, source windows, transformed rows, regular readback, real seals, continuation rows, provenance, and local naming.*

9. *C stores displayed* Cont *replay from matrix-row inspection to source-window selection, from row-sum and column-vanishing ledgers to transformed-row construction, from transformed rows to regular readback, and from regular readback to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SilvermanToeplitz}^{\uparrow}$, $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SilvermanToeplitz}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, B, V, W, T, R, E, H, C, P, N$. It has no coordinate for a host summability method, a completed infinite matrix, a selected external limit, quotient equality of real-name streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SilvermanToeplitzUp.SilvermanToeplitzTasteGate single carrier alignment`

Theorem 2126.2 (Silverman–Toeplitz NameCert obligations)**.** *For every accepted* $\mathsf{SilvermanToeplitz}^{\uparrow}$ *carrier $S = (M, B, V, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SilvermanToeplitz}^{\uparrow}}$ *surface consists exactly of the following six finite obligation rows:*

1. *carrier admission for the displayed matrix coefficient windows, row-sum bound ledger, column-vanishing ledger, source windows, transformed finite rows, regular readback, real seal, transport, continuation, provenance, and naming rows;*

2. *bounded-row exactness, requiring every row-sum bound used by the transform to be read from B after the corresponding coefficient windows in M have been displayed;*

3. *column-vanishing exactness, requiring every small-column claim to pass through the displayed column ledger V and the same finite matrix-window row M;*

4. *source-to-transform construction, requiring every transformed row to be computed from M, B, V, W before the transformed read reaches T;*

5. *regular readback and real sealing, requiring every completion-facing transformed read to pass through R and then E;*

6. *transport, continuation, provenance, and local naming, requiring H, C, P, N to preserve the same finite route without adding a host summability or ambient completeness coordinate.*

Proof. Project the carrier of Definition 2126.1. Carrier admission is exactly the displayed inventory $M, B, V, W, T, R, E, H, C, P, N$, so the local certificate has no detached coordinate for an infinite matrix or a host summability method.

The bounded-row and column-vanishing clauses are read from B and V only after the inspected coefficient windows in M have been displayed. The selected input observations are the finite $\mathsf{StreamName}^{\uparrow}$ windows in W, and the transformed finite row T is downstream of those same rows.

The regularity handoff is then forced through R, and the endpoint-facing route continues from R to the $\mathsf{Real}^{\uparrow}$ seal E. The structural rows H, C, P, N transport, replay, source, and name this route, and none of them contains an additional analytic principle. □

Theorem 2126.3 (Silverman–Toeplitz regularity route)**.** *Every accepted* $\mathsf{SilvermanToeplitz}^{\uparrow}$ *read that claims preservation of a regular real-name limit factors through the finite route*

$$M \longmapsto (B, V) \longmapsto W \longmapsto T \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

The $\mathsf{ToeplitzLemma}^{\uparrow}$ *route supplies the finite matrix-window discipline, the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *and* $\mathsf{CesaroConvergence}^{\uparrow}$ *rows are admitted as special provenance surfaces, and no consumer can bypass* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with a preservation read from an accepted carrier. The only coefficient data visible to the classifier are the finite windows in M, and the regularity hypotheses for the matrix are represented by the row-sum ledger B and the column-vanishing ledger V.

The source sequence is then inspected only through W. Hence the transformed row cannot be formed before the coefficient, boundedness, vanishing, and source-window data have all been displayed, which forces the route through T.

The transformed sequence reaches any regular real-name consumer through R, and the real endpoint is visible only through E. Provenance may point to the Toeplitz, Hardy–Cesaro, and Cesaro-convergence sibling chapters, but those pointers are package rows in P and do not create a second path around M, B, V, W, T, R, E.

Finally, H, C, P, N preserve and name the same route. Since the carrier has no completed matrix, selected external limit, quotient real-name equality, countable choice, or ambient completeness field, the displayed route exhausts the preservation surface. □

Theorem 2126.4 (Silverman–Toeplitz finite-row regularity)**.** *For every accepted* $\mathsf{SilvermanToeplitz}^{\uparrow}$ *carrier* $S = (M, B, V, W, T, R, E, H, C, P, N)$*, fix a finite transformed row whose coefficient window is displayed in* M*, whose row-sum bound is displayed in* B*, whose column-vanishing ledger is displayed in* V*, whose source window is displayed in* W*, and whose dyadic error budget* D *is read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *provenance in* P*. The row constructed in* T *remains a regular* $\mathsf{RegSeqRat}^{\uparrow}$ *read before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is inspected. Its certificate passes through the sibling anchors* $\mathsf{ToeplitzLemma}^{\uparrow}$*,* $\mathsf{HardyCesaroMean}^{\uparrow}$*, and* $\mathsf{CesaroConvergence}^{\uparrow}$*, but it does not use a host summability theorem or a completed infinite matrix.*

Proof. Induct on the displayed finite matrix rows in M. In the base row, the row-sum ledger B supplies the dyadic bound for the inspected coefficient window, while W supplies exactly the source observations used by that row. The constructed value is therefore a finite rational combination accounted for by D and recorded in T.

For the step, append one coefficient window from M. The row-sum bound remains in B, the small-column evidence remains in V, and the accumulated dyadic error budget is preserved by the $\mathsf{DyadicRatCore}^{\uparrow}$ accounting recorded in P. Thus the enlarged transformed row is still exposed as a regular rational readback candidate.

Apply Definition 2126.3. The finite-row construction is forced through $T \longmapsto R \longmapsto E$, so the read reaches $\mathsf{RegSeqRat}^{\uparrow}$ before any $\mathsf{Real}^{\uparrow}$ seal can be inspected. The $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, and $\mathsf{CesaroConvergence}^{\uparrow}$ entries in P are sibling anchors for this route, not external analytic principles. □

Theorem 2126.5 (Silverman–Toeplitz Real-seal nonescape)**.** *For every accepted* $\mathsf{SilvermanToeplitz}^{\uparrow}$ *carrier, any* $\mathsf{Real}^{\uparrow}$ *endpoint exported by the regular matrix transform is sealed only after the matrix-window rows, row-sum ledger, column-vanishing ledger, source windows, transformed finite rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been exposed. Consequently the Real seal cannot be used to recover a host summability theorem, a detached infinite matrix, a selected source limit, quotient stream equality, countable choice, or ambient completeness.*

Proof. By Definition 2126.1, the seal row is E, and it is downstream of M, B, V, W, T, R. Thus an endpoint-facing consumer has already passed through the finite coefficient windows, the two matrix regularity ledgers, the source windows, the transformed row, and the regular readback.

The remaining rows H, C, P, N only transport, replay, source, and name the same packet. They do not store host analytic data, and the classifier has no coordinate for any excluded principle.

Therefore every exported $\mathsf{Real}^{\uparrow}$ endpoint is a seal for the displayed finite BEDC route rather than a route to host summability, detached infinite matrix data, selected limits, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{SilvermanToeplitz}^{\uparrow}$ preservation read factors through finite matrix coefficient windows, a row-sum bound ledger, a column-vanishing ledger, source StreamName windows, transformed finite rows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: toeplitzlemma, hardycesaromean, cesaroconvergence, streamname, regseqrat, dyadicratcore, real: $\mathsf{SilvermanToeplitz}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries matrix coefficient windows, row-sum bounds, column-vanishing data, source windows, transformed rows, regular readback, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SilvermanToeplitz}^{\uparrow}}$.

Constructive story: A $\mathsf{SilvermanToeplitz}^{\uparrow}$ packet is generated from finite matrix coefficient windows, a row-sum bound ledger, a column-vanishing ledger, source StreamName windows, transformed finite rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SilvermanToeplitz}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2126.1, Definition 2126.2, Definition 2126.3, and Definition 2126.5 seed the regular matrix summability certificate surface from finite matrix windows to Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SilvermanToeplitz}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability theorems, completed infinite matrices, selected source limits, quotient equality of real-name streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-row exactness, column-vanishing exactness, source-to-transform construction, regular readback, Real-seal nonescape, transport and provenance, and TasteGate field faithfulness for BEDC.Derived.SilvermanToeplitzUp.

Chapter 2127

A Concrete Naming Certificate for $\mathsf{SeriesTermTest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SeriesTermTest}^{\uparrow}$ packet records the finite necessary condition for a real series endpoint: adjacent partial-sum differences are displayed term rows that must factor through the same Cauchy-tail threshold before a zero $\mathsf{Real}^{\uparrow}$ seal is read. It sits after the $\mathsf{RealSeries}^{\uparrow}$ carrier of chapter 1581, the real-series Cauchy criterion of chapter 2014, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names only finite displayed term rows, adjacent partial-sum differences, shared tail-threshold evidence, and a zero-seal read; it does not import a host infinite sum, a selected limit, quotient equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2127.1 (Series term test carrier)**.** *A* $\mathsf{SeriesTermTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, A, D, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *T is the real-valued term stream, exposed only through the inspected term rows already available to* $\mathsf{RealSeries}^{\uparrow}$*.*
2. *S is the partial-sum window, listing the displayed partial sums whose adjacent differences are inspected by the current tail request.*
3. *A is the adjacent-difference row, recording the equality of each inspected term row with the corresponding displayed difference between successive partial sums.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, assigning the same tail request a finite threshold and the rational radii used to compare adjacent partial sums.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected terms, partial sums, and adjacent differences.*
6. *Z is the zero* $\mathsf{Real}^{\uparrow}$ *seal reached only after T, S, A, D, R have been displayed through the common Cauchy-tail threshold.*
7. *H stores componentwise* hsame *transport for the term stream, partial-sum window, adjacent-difference row, dyadic ledger, readback, zero seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay of the route*

$$T, S, A, D, R \longmapsto Z.$$

9. *P is the* Pkg *provenance over* $\mathsf{SeriesTermTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeriesTermTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, A, D, R, Z, H, C, P, N$. It has no coordinate for a host infinite sum, selected limit, quotient equality of real streams, countable-choice selector, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SeriesTermTestUp.SeriesTermTestTasteGate single carrier alignment`

Theorem 2127.2 (Series term test NameCert obligations)**.** *For every accepted* $\mathsf{SeriesTermTest}^{\uparrow}$ *carrier*

$$K = (T, S, A, D, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeriesTermTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the term stream, partial-sum window, adjacent-difference row, dyadic tolerance ledger, regular rational readback, zero* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *term-row exposure, requiring every inspected term to pass through T and the finite stream windows consumed by the source* $\mathsf{RealSeries}^{\uparrow}$ *row;*
3. *adjacent-difference exactness, requiring A to identify each inspected term row with the displayed difference of neighboring partial sums in S;*
4. *shared tail-threshold routing, requiring the same Cauchy-tail threshold used by* $\mathsf{RealSeriesCauchyCriterion}^{\uparrow}$ *to govern the dyadic ledger D before any zero seal is exported;*
5. *readback and zero-seal nonescape, requiring R and then Z to remain downstream of T, S, A, D;*
6. *provenance closure, requiring H, C, P, N to transport, replay, source, and name only the displayed finite route.*

No series term-test obligation is stored outside these rows.

Proof. Project the accepted carrier $K = (T, S, A, D, R, Z, H, C, P, N)$. The carrier exposes exactly the term stream, partial-sum window, adjacent-difference row, dyadic ledger, readback, zero seal, and structural rows.

The term-row clause is forced by T and S. The source row supplies only displayed terms, while the partial-sum window supplies the two neighboring partial sums needed to read each inspected adjacent difference.

The adjacent-difference row A records the finite equality between the inspected term and the displayed partial-sum difference. The dyadic ledger D attaches those same rows to the shared Cauchy-tail threshold rather than to a separate host convergence assertion.

The readback and zero-seal stage is downstream. The row R reads the displayed term, partial sums, and difference through regular rational data, and Z is available only after that readback has passed through D.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no excluded coordinate for host summation, selected limits, quotient equality, choice, trichotomy, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 2127.3 (Series term test adjacent-difference route)**.** *Every accepted* $\mathsf{SeriesTermTest}^{\uparrow}$ *packet factors each inspected term read through the displayed finite route*

$$T, S \longmapsto A \longmapsto D, R \longmapsto Z, H, C, P, N.$$

Thus a term row reaches the zero $\mathsf{Real}^{\uparrow}$ *seal only as an adjacent partial-sum difference governed by the shared Cauchy-tail threshold. It does not read a host infinite sum, selected limit, quotient equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an inspected term request. By Definition 2127.1, the request first projects the term stream row T and the finite partial-sum window S.

The adjacent-difference row A then identifies the inspected term with the displayed difference between neighboring partial sums in S. This is a finite row calculation, not an appeal to a completed infinite series.

The shared threshold is read through D. The same tail request that makes the partial sums Cauchy supplies the dyadic tolerance data for the adjacent difference, and the regular rational readback R records the displayed comparison.

Only after this route is displayed can Z provide the zero $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so every accepted term read factors through the adjacent-difference surface before the zero seal is available. □

Theorem 2127.4 (Series term test zero-seal nonescape)**.** *Every zero-seal read from an accepted* $\mathsf{SeriesTermTest}^{\uparrow}$ *carrier factors through*

$$T, S, A, D, R, Z, H, C, P, N.$$

Consequently the packet exports only the necessary-condition statement that displayed terms tend to zero through the same Cauchy-tail threshold used by the partial sums. It exports no host infinite sum, selected limit, quotient equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 2127.3 to place every inspected term on the finite route through T, S, A, D, R. The route already contains the displayed neighboring partial sums and the dyadic threshold data attached to the Cauchy-tail request.

The zero seal Z consumes this route. It is a $\mathsf{Real}^{\uparrow}$ seal for the displayed term rows tending to zero, not a separate completion principle for the whole sequence of partial sums.

The transport, replay, provenance, and local naming rows H, C, P, N preserve the same coordinates. Because the carrier has no coordinate for host infinite sums, selected limits, quotient stream equality, countable choice, trichotomy, or ambient real completeness, none of those principles can escape through the zero-seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeriesTermTest}^{\uparrow}}$.

Constructive story: A $\mathsf{SeriesTermTest}^{\uparrow}$ packet is generated from a real-valued term stream, finite partial-sum windows, adjacent-difference rows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a zero RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeriesTermTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2127.1, Definition 2127.2, Definition 2127.3, and Definition 2127.4 seed the finite necessary-condition certificate route from real-series Cauchy tails to displayed terms tending to zero.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeriesTermTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, adjacent-difference exactness, shared tail-threshold routing, readback and zero-seal nonescape, and transport, replay, provenance, and local naming discipline for BEDC.Derived.SeriesTermTestUp.

Chapter 2128

A Concrete Naming Certificate for $\mathsf{NormalConvergence}^{\uparrow}$

Following Weierstrass and Bishop–Bridges constructive analysis, the $\mathsf{NormalConvergence}^{\uparrow}$ packet records the finite normal-convergence route by which a real-series family, an absolute majorant, a displayed M-test tail ledger, and a uniform-limit handoff determine every endpoint-facing series read. It sits after the real-series carrier of chapter 1581, the absolute-majorant rows of chapter 1700, the finite majorant tail exactness of chapter 399, the uniform endpoint sealing of chapter 463, the regular rational readback of chapter 301, the stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies the finite dependency surface consumed by Tannery-style series-limit routes such as chapter 2094; it does not import a host uniform convergence theorem, a selected infinite sum, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2128.1 (Normal convergence carrier)**.** *A* $\mathsf{NormalConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (S, A, M, U, R, E, H, C, P, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *family row. It exposes the inspected real-valued term family and its finite partial-sum windows only through the real-series surface.*
2. *A is the* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *majorant row. It records the absolute majorant family and the finite domination comparison visible to the packet.*
3. *M is the* $\mathsf{WeierstrassMTest}^{\uparrow}$ *domination ledger. It displays the finite tail majorant and the exact tail budget used by normal-convergence requests.*
4. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row. It seals the uniform endpoint read only after the majorant and tail ledger have been displayed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite tails, partial sums, and endpoint requests.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached from the regular readback and uniform handoff, not from a host infinite-sum coordinate.*
7. *H records componentwise* hsame *transport for the series family, absolute-majorant row, M-test ledger, uniform handoff, regular readback, Real seal, replay, provenance, and local name.*

8. *C records displayed* Cont *replay of the route*

$$S \longmapsto A \longmapsto M \longmapsto U \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* NormalConvergence$^{\uparrow}$, RealSeries$^{\uparrow}$, AbsoluteConvergence$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, UniformLimit$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *L is the local* NameCert$_{\text{NormalConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, A, M, U, R, E, H, C, P, L$. It has no coordinate for a host uniform convergence theorem, selected infinite sum, hidden pointwise limit, quotient stream equality, countable-choice selector, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NormalConvergenceUp.NormalConvergenceTasteGate single carrier alignment`

Theorem 2128.2 (Normal convergence NameCert obligations)**.** *For every accepted* NormalConvergence$^{\uparrow}$ *carrier*

$$N = (S, A, M, U, R, E, H, C, P, L),$$

the local NameCert$_{\text{NormalConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real-series family row, absolute-majorant row, M-test domination ledger, uniform-limit handoff, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *absolute-majorant exactness, requiring A to display the majorant comparison used by every inspected term family read from S;*
3. *uniform-tail exactness, requiring M to store the finite tail budget that the* WeierstrassMTest$^{\uparrow}$ *route exports to the uniform handoff;*
4. RegSeqRat$^{\uparrow}$ *handoff, requiring R to read the same displayed tail and partial-sum data before any endpoint seal is exported;*
5. Real$^{\uparrow}$ *seal non-escape, requiring E to remain downstream of S, A, M, U, R and to export no host uniform convergence theorem, selected infinite sum, hidden pointwise limit, quotient stream equality, countable choice, trichotomy, or ambient* Real$^{\uparrow}$ *completeness;*
6. *componentwise transport, displayed replay, provenance, and local naming for exactly the rows recorded in H, C, P, L.*

No normal-convergence NameCert obligation is stored outside these rows.

Proof. Project the accepted packet $N = (S, A, M, U, R, E, H, C, P, L)$. The carrier exposes exactly the real-series family, absolute majorant, M-test domination ledger, uniform handoff, regular readback, Real seal, and structural rows.

The majorant side is fixed before any endpoint read. The row S supplies the term-family and partial-sum surface, while A records the absolute-majorant comparison visible for the inspected family.

The finite tail budget is then forced through M. Since M is the displayed WeierstrassMTest$^{\uparrow}$ ledger, every uniform-tail request receives the same majorant exactness row before it can reach U.

The rows U, R, E form the endpoint stage. The uniform handoff exposes only the displayed tail route, the regular rational row reads that same route, and the Real seal is downstream of both.

Finally H, C, P, L transport, replay, source, and name the same packet. Because the carrier contains no excluded coordinate for a host uniform convergence theorem, selected infinite sums, hidden pointwise limits, quotient stream equality, choice, trichotomy, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 2128.3 (Normal convergence uniform series handoff)**.** *Every endpoint-facing read of an accepted* $\mathsf{NormalConvergence}^{\uparrow}$ *packet factors through the displayed route*

$$S \longmapsto A \longmapsto M \longmapsto U \longmapsto R \longmapsto E \longmapsto H, C, P, L.$$

Thus the read reaches a $\mathsf{Real}^{\uparrow}$ *endpoint only after the real-series family row, absolute-majorant row, M-test tail ledger, uniform handoff, and regular rational readback have all been displayed. It does not read a host uniform convergence theorem, selected infinite sum, hidden pointwise limit, quotient stream equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an endpoint-facing series request. By Definition 2128.1, the request first projects the family row S and then the absolute-majorant row A.

The normal-convergence control is mediated by M. This row is the finite M-test domination ledger, so it provides the exact tail budget that the route may hand to U.

The handoff to U and R preserves the same displayed data. The uniform-limit row seals only the endpoint-facing uniform request, and the regular rational row reads the same tail and partial-sum route before a Real seal can appear.

The terminal stage is E, H, C, P, L. The Real seal is reached downstream of the displayed route, while transport, replay, provenance, and local naming preserve that same route. Therefore every endpoint-facing read factors through $S, A, M, U, R, E, H, C, P, L$ and cannot bypass the finite normal-convergence certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{NormalConvergence}^{\uparrow}$ packet is generated from a RealSeriesUp family row, an AbsoluteConvergenceUp majorant row, a WeierstrassMTestUp domination ledger, a UniformLimitUp handoff row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NormalConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 2128.1, Definition 2128.2, and Definition 2128.3 seed the finite normal-convergence certificate surface between real-series families, absolute majorants, M-test tail ledgers, uniform handoffs, regular rational readback, and RealUp endpoint seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NormalConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host uniform convergence theorems, selected infinite sums, hidden pointwise limits, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, absolute-majorant exactness, uniform-tail exactness, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.NormalConvergenceUp.

Chapter 2129

A Concrete Naming Certificate for $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$ packet records the finite common-tail filter basis used when several regular Cauchy real names must answer one late-window request before any $\mathsf{Real}^{\uparrow}$ seal is read. It sits after the regular rational source rows of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Cauchy-filter route of chapter 333. The packet is a human-origin L10 basis for shared tail windows; it is not a quotient of Cauchy names, a selected limit, a countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2129.1 (Regular Cauchy common-tail filter carrier)**.** *A* $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, \Sigma, T, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite family of regular Cauchy source-name rows. Each source is read only through its displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *surface.*
2. *Σ is the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule. It records the finite observation windows, requested tail cut, inspected indices, and synchronization route used for every source in X.*
3. *T is the common-tail basis row. It records the finite upper tail cut, the cofinal refinement requests, and the membership witnesses saying that all later windows are read through the same basis packet.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed sources at the shared windows of Σ and the tail basis T.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested radius, tail slack, comparison budget, and exhaustion data consumed by the common-tail test.*
6. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *evidence row. It reads the tail basis T as a finite filter-basis route and exports only the displayed cofinal and stability data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the family, available only after X, Σ, T, R, D, Q have been displayed.*

8. *H records componentwise* hsame *transport for the source family, stream schedule, common-tail basis, readback row, dyadic ledger, Cauchy-filter row, real seal, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay of the route*

$$X, \Sigma, T, D \longmapsto R \longmapsto Q \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these eleven rows. Its classifier compares accepted packets only through $X, \Sigma, T, R, D, Q, E, H, C, P, N$ and has no coordinate for quotient Cauchy equality, selected limits, countable choice, host filter completion, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 2129.2 (Regular Cauchy common-tail filter NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$ *carrier*

$$F = (X, \Sigma, T, R, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the regular Cauchy source family, shared stream schedule, common-tail basis, regular rational readback, dyadic tolerance ledger, Cauchy-filter evidence row, terminal real seal, transport, replay, provenance, and local naming row;*

2. *common-tail basis discipline, requiring T to display the finite late cut, cofinal refinement requests, and membership witnesses consumed by every source in X through the same Σ schedule;*

3. *tolerance and readback exactness, requiring R and D to expose only the regular rational observations and dyadic budgets read from the displayed source family, shared windows, and common-tail basis;*

4. *filter and real-seal non-escape, requiring Q and E to remain downstream of X, Σ, T, R, D and to export no quotient Cauchy equality, selected limit, countable-choice schedule, host filter completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*

5. *transport, replay, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed route componentwise.*

No common-tail filter-basis obligation is stored outside these rows.

```
Lean4✓  BEDC.Derived.RegularCauchyCommonTailFilterUp.RegularCauchyCommonTailFilterTasteGate
single carrier alignment
```

Proof. Project the accepted packet $F = (X, \Sigma, T, R, D, Q, E, H, C, P, N)$. The carrier exposes exactly the regular Cauchy source family, shared schedule, common-tail basis, readback, tolerance, Cauchy-filter, real-seal, and structural rows.

The common-tail data are finite. The schedule Σ fixes the inspected windows, while T fixes the late cut and cofinal refinement requests through which every source in X must be read.

The readback and tolerance rows are tied to that same basis. The row R supplies only the regular rational observations visible at the displayed windows, and D supplies only the dyadic radius, slack, comparison budget, and exhaustion data attached to those windows.

The filter and real-seal rows remain downstream. The row Q reads T as a finite Cauchy-filter basis, and E is available only after the source, schedule, tail, readback, tolerance, and filter rows have all been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for quotient Cauchy equality, selected limits, countable choice, host filter completion, ambient real completeness, Lean verification, or a bridge, the five listed rows exhaust the local NameCert surface. □

Theorem 2129.3 (Regular Cauchy common-tail filter real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$ *carrier reads the terminal seal only through the finite route*

$$X, \Sigma, T, D \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed regular Cauchy source family, one shared StreamName schedule, a common-tail basis, RegSeqRat readback, DyadicRatCore tolerance accounting, CauchyFilter evidence, the terminal RealUp seal, componentwise transport, continuation replay, package provenance, and local naming. It receives no quotient Cauchy equality, selected limit, countable-choice schedule, host filter completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted consumer read. The source family is X, and the only admissible finite observation route is the shared schedule Σ together with the common-tail basis T.

The regular rational readback is R. It is read from X through the same Σ and T rows, so the consumer cannot introduce a second tail schedule or a detached representative family.

The dyadic ledger D supplies the precision budget for the shared tail request. The Cauchy-filter evidence Q then reads that budget and tail basis as a finite filter-basis route.

Only after this route is displayed can E expose the $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N preserve the same displayed coordinates under transport, replay, provenance, and local naming.

Because no excluded coordinate occurs in the carrier, the real-seal consumer cannot read quotient Cauchy equality, selected limits, countable choice, host filter completion, or ambient real completeness from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$ packet is generated from a regular Cauchy source family, a shared StreamName schedule, a common-tail basis row, RegSeqRat readback, a DyadicRatCore tolerance ledger, CauchyFilter evidence, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2129.1, Definition 2129.2, and Definition 2129.3 seed the finite common-tail filter-basis route over shared StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, CauchyFilter evidence, RealUp seals, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected limits, countable choice, host filter completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-tail basis discipline, tolerance and readback exactness, filter and Real seal non-escape, transport stability, replay confinement, provenance, and local naming for BEDC.Derived.RegularCauchyCommonTailFilterUp.

Chapter 2130

A Concrete Naming Certificate for $\mathsf{GaussTest}^{\uparrow}$

Following Gauss' positive-series test as presented by Knopp, the $\mathsf{GaussTest}^{\uparrow}$ packet records the finite first-order adjacent-quotient defect route by which a positive $\mathsf{RealSeries}^{\uparrow}$ source exposes a displayed comparison-test tail handoff. It refines the partial-sum windows and tail thresholds of chapter 1581, sits beside the quotient and comparison surfaces of chapter 1461 and chapter 1459, shares neighboring defect rows with chapter 1719 and chapter 2113, and exports endpoints only through chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Gauss-test evidence only through displayed source windows, adjacent quotient windows, unary first-order defect coefficients, dyadic margins, comparison routing, regular rational readback, and terminal Real sealing; it does not import a host infinite sum, selected limit, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2130.1 (Gauss test carrier)**.** *A* $\mathsf{GaussTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, Q, F, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RealSeries}^{\uparrow}$ *row. It exposes only positive-term windows, partial-sum windows, and tail-threshold requests already visible at the real-series boundary.*
2. *Q is the adjacent quotient-window row. It records the inspected neighboring-term ratios and the finite index window on which those quotients are read.*
3. *F is the unary first-order defect coefficient row. It records the displayed coefficient data for the Gauss expansion of the adjacent quotient defect on the inspected tail window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *margin row. It records the rational error margins, threshold witnesses, and finite inequality budgets used to compare the displayed defect coefficient with the required tail bound.*
5. *T is the comparison-test handoff row. It routes S, Q, F, D into the finite majorant or minorant surface consumed by* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$.
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison-test handoff and finite stream windows have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*

8. *H stores componentwise* hsame *transport for the source, quotient-window, defect-coefficient, margin, comparison, readback, seal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from each tail request through S, Q, F, D, T, R, E.*
10. *P is the* Pkg *provenance over* $\mathsf{GaussTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{GaussTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, F, D, T, R, E, H, C, P, N$. It has no coordinate for a host infinite sum, selected limit, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.GaussTestUp.GaussTestTasteGate single carrier alignment`

Theorem 2130.2 (Gauss test NameCert obligations)**.** *For every accepted* $\mathsf{GaussTest}^{\uparrow}$ *carrier*

$$G = (S, Q, F, D, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GaussTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source* $\mathsf{RealSeries}^{\uparrow}$ *windows, adjacent quotient windows, unary first-order defect coefficient row, dyadic error margins, comparison-test handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *quotient-window exactness, requiring every quotient read used by the Gauss defect to be read from the displayed neighboring positive-term windows in S and Q;*
3. *defect-row stability, requiring the coefficient row F and the error margins in D to remain fixed under the accepted tail request and under componentwise* hsame *transport;*
4. *comparison routing, requiring T to be the only row that turns the Gauss defect data into a convergence-test handoff;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring endpoint-facing data to pass through R and then E only after S, Q, F, D, T have been displayed;*
6. *transport, replay, provenance, and naming discipline, requiring H, C, P, N to transport, replay, source, and name exactly the displayed finite route.*

No Gauss-test obligation is stored outside these rows.

Proof. Project the accepted carrier $G = (S, Q, F, D, T, R, E, H, C, P, N)$. The carrier inventory already displays the real-series source, quotient windows, first-order defect coefficient row, dyadic margins, comparison handoff, readback, seal, transport, replay, provenance, and local name.

The quotient and defect clauses are finite. The source row S gives only inspected positive-term and partial-sum windows, while Q records neighboring-term quotients on the same tail window. The coefficient row F stores the unary first-order defect data, and D stores the rational margins and thresholds attached to that read.

The comparison handoff is forced through T. Before T appears, the packet has displayed only source, quotient, defect, and margin rows; after T appears, the endpoint route may proceed to the regular rational readback R and terminal seal E.

Finally H, C, P, N preserve and name this same route. Since the carrier has no excluded coordinate for host summation, selected limits, quotient series equality, choice, trichotomy, ambient

real completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 2130.3 (Gauss test tail handoff)**.** *Every endpoint-facing read of an accepted* $\mathsf{GaussTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealSeries}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{KummerTest}^{\uparrow},\ \mathsf{Dyadic}$$

Concretely, the read consumes the source $\mathsf{RealSeries}^{\uparrow}$ *windows, the adjacent quotient surface shared with* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*, the neighboring first-order defect discipline visible beside* $\mathsf{RaabeDuhamelTest}^{\uparrow}$ *and* $\mathsf{KummerTest}^{\uparrow}$*, the dyadic and stream display rows, and the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff before it reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 2130.1, the only source data available at the start are the $\mathsf{RealSeries}^{\uparrow}$ windows in S and the adjacent quotient windows in Q.

The Gauss-specific defect data are then read from F and D. These rows display the unary first-order coefficient data, the rational margins, and the tail threshold needed for the finite comparison request.

The neighboring tests are reference faces for the same quotient-defect lattice. The $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ surface supplies the adjacent quotient discipline, while $\mathsf{RaabeDuhamelTest}^{\uparrow}$ and $\mathsf{KummerTest}^{\uparrow}$ identify the nearby defect rows. The accepted $\mathsf{GaussTest}^{\uparrow}$ route still reaches endpoints only through the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ margins, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The transport, replay, provenance, and naming rows keep the same route, so no host infinite sum, selected limit, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can enter. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaussTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GaussTest}^{\uparrow}$ packet is generated from source RealSeries windows, adjacent quotient windows, a unary first-order defect coefficient row, DyadicRatCore error margins, a RegularCauchyComparisonTest handoff, StreamName display rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaussTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2130.1, Definition 2130.2, and Definition 2130.3 seed the finite Gauss positive-series test boundary over displayed source series, quotient, first-order defect, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaussTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, defect-row stability, comparison routing, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal nonescape, transport, replay, provenance, and local naming discipline for BEDC.Derived.GaussTestUp.

Chapter 2131

A Concrete Naming Certificate for $\mathsf{SamuelCompletion}^{\uparrow}$

Following Samuel on uniform compactification and Bourbaki–Kelley on uniform-space completion, the $\mathsf{SamuelCompletion}^{\uparrow}$ packet records the completion-facing uniform route as finite BEDC data. It sits after the uniform completion surface of chapter 1473, the Cauchy-filter route of chapter 333, the dense uniform embedding boundary of chapter 1651, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the L10 uniform-completion handoff without asserting quotient completion, countable choice, a selected limit, host uniform equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2131.1 (Samuel completion carrier)**.** *A* $\mathsf{SamuelCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, F, D, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the finite uniform-entourage row. It records the entourages inspected by the completion request and the refinement edges used to compare them.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row. It records the Cauchy-filter data read through the displayed entourage family.*
3. *D is the* $\mathsf{DenseUniformEmbedding}^{\uparrow}$ *row. It records the dense source embedding, image-window requests, and pullback evidence used before any completion-facing read is exposed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which dense-source observations and completion-facing requests are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed windows and entourage budgets.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after the displayed uniform, filter, dense-embedding, stream-window, and regular-rational rows have been read.*
7. *H records componentwise* hsame *transport for entourages, Cauchy-filter rows, dense-embedding rows, stream windows, regular readbacks, real seals, replay data, provenance, and local naming.*
8. *C records displayed* Cont *replay of the route*

$$U, D, F, W \longmapsto R \longmapsto A.$$

9. *P is the* Pkg *provenance over* $\mathsf{SamuelCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SamuelCompletion}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $U, F, D, W, R, A, H, C, P, N$ and has no coordinate for quotient completion, countable choice, selected limits, host uniform equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SamuelCompletionUp.SamuelCompletionTasteGate single carrier alignment`

Theorem 2131.2 (Samuel completion NameCert obligations)**.** *For the carrier of Definition 2131.1, the local* $\mathsf{NameCert}_{\mathsf{SamuelCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the packet $S = (U, F, D, W, R, A, H, C, P, N)$;*
2. *classifier stability under componentwise* hsame *transport of the uniform-entourage row, Cauchy-filter row, dense-embedding row, stream-window schedule, regular rational readback, real seal, replay row, provenance row, and local naming row;*
3. *displayed* Cont *replay of the route from uniform entourages and dense-source windows through Cauchy-filter data to regular rational readback and the terminal real seal;*
4. *non-escape for every consumer read, requiring the read to remain inside* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

No obligation is stored in a quotient completion, selected limit, countable-choice schedule, host uniform equality row, or ambient completeness theorem.

Proof. Project the accepted carrier. Carrier admission is exactly the display of the ten rows $U, F, D, W, R, A, H, C, P, N$, so there is no additional host object to construct.

Classifier stability is componentwise. The hsame row compares the displayed uniform-entourage, Cauchy-filter, dense-embedding, stream-window, regular-readback, and real-seal coordinates, while the structural rows transport replay, provenance, and local naming over the same coordinates.

The continuation obligation is the displayed route in the carrier. A consumer first reads uniform entourages and dense-source windows, then the Cauchy-filter row, then the regular rational readback, and only then the real seal.

The non-escape clause follows by inspecting the carrier inventory. Since the packet has no coordinate for quotient completion, countable choice, selected limits, host uniform equality, or ambient completeness, no NameCert obligation can export one. □

Theorem 2131.3 (Samuel completion uniform handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{SamuelCompletion}^{\uparrow}$ *carrier reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only after the displayed route through* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, *and* $\mathsf{DenseUniformEmbedding}^{\uparrow}$ *has been read. The handoff route is therefore*

$$U, D, F, W \longmapsto R \longmapsto A \longmapsto H, C, P, N,$$

not a quotient-completion carrier, not a selected limit, not a countable-choice schedule, not host uniform equality, and not an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier and project its uniform-entourage, Cauchy-filter, dense-embedding, and stream-window rows. These rows are upstream of the regular rational readback row in the displayed route.

The regular readback row R is therefore not available as an isolated real-name source. It is read only after the entourage refinements, dense embedding evidence, Cauchy-filter data, and finite windows have been displayed.

The real seal A is downstream of R. Thus every real-facing consumer must traverse the uniform-completion, Cauchy-filter, and dense-embedding route before it can consume a $\mathsf{RegSeqRat}^{\uparrow}$ readback or a terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally the H, C, P, N rows preserve the same route under transport, replay, provenance, and local naming. The excluded host-side principles have no carrier coordinate, so the handoff cannot expose them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SamuelCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SamuelCompletion}^{\uparrow}$ packet is generated from finite uniform-entourage rows, CauchyFilterUp data, DenseUniformEmbeddingUp rows, StreamName windows, RegSeqRat readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SamuelCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2131.1, Definition 2131.2, and Definition 2131.3 seed the L10 uniform-completion route from finite entourage and dense-embedding data through Cauchy-filter, StreamName, RegSeqRat, Real seal, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SamuelCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, quotient stream equality, selected limits, host uniform equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, displayed continuation replay, uniform handoff, non-escape, provenance, and local naming for BEDC.Derived.SamuelCompletionUp.

Chapter 2132

A Concrete Naming Certificate for $\mathsf{RiemannRearrangement}^{\uparrow}$

Following Riemann's rearrangement theorem and Bishop–Bridges constructive analysis, the $\mathsf{RiemannRearrangement}^{\uparrow}$ packet records the finite certificate surface by which a real series source, a displayed finite schedule, and signed tail ledgers determine every rearrangement-facing endpoint read. It sits after the $\mathsf{RealSeries}^{\uparrow}$ carrier of chapter 1581, the separation supplied by $\mathsf{AbsoluteConvergence}^{\uparrow}$ in chapter 1700, the regular Cauchy comparison discipline of chapter 1459, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the endpoint seal of chapter 38. The packet names only finite rearrangement certificates over displayed rows; it does not import host infinite rearranged sums, selected limits, quotient equality, countable choice, trichotomy, absolute convergence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2132.1 (Riemann rearrangement carrier)**.** *A* $\mathsf{RiemannRearrangement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, P, M, N, W, Q, D, E, H, C, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row. It exposes the term stream and finite partial-sum surface only through the real-series certificate already named for S.*

2. *R is the finite rearrangement schedule. It records the displayed source indices, their scheduled order, and the finite coverage check that every endpoint-facing read uses exactly the listed schedule entries.*

3. *P is the positive signed tail ledger. It records the displayed positive terms, their scheduled appearances, and the finite partial-sum contributions that remain visible before the endpoint seal.*

4. *M is the negative signed tail ledger. It records the displayed negative terms, their scheduled appearances, and the finite partial-sum contributions that remain visible before the endpoint seal.*

5. *N is the neutral or zero-tail ledger. It records displayed zero terms and neutral entries whose contribution is routed through the schedule without changing the signed tail accounting.*

6. *W is the finite partial-sum window row. It records the source partial sums, scheduled partial sums, and endpoint-facing comparison windows requested by the packet.*

7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed source terms, scheduled terms, signed tail ledgers, partial-sum windows, and endpoint comparisons.*

8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting row for finite addition, subtraction, sign separation, schedule coverage, and endpoint comparison tolerances.*

9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after S, R, P, M, N, W, Q, D have been displayed.*

10. *H records componentwise* hsame *transport for the source row, schedule, signed ledgers, neutral ledger, partial-sum windows, readback, dyadic ledger, endpoint seal, continuation, and local naming row.*

11. *C records displayed* Cont *replay of the route*

$$S, R, P, M, N, W, Q, D \longmapsto E.$$

12. *L is the local* $\mathsf{NameCert}_{\mathsf{RiemannRearrangement}^{\uparrow}}$ *row, sourced over* $\mathsf{RiemannRearrangement}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

The classifier compares accepted packets only through $S, R, P, M, N, W, Q, D, E, H, C, L$. It has no coordinate for a host infinite rearranged sum, a selected limit, quotient equality of series, countable choice, trichotomy, absolute convergence as a conclusion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2132.2 (Riemann rearrangement NameCert obligations)**.** *For every accepted* $\mathsf{RiemannRearrangement}^{\uparrow}$ *carrier*

$$K = (S, R, P, M, N, W, Q, D, E, H, C, L),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannRearrangement}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real series source, finite rearrangement schedule, signed tail ledgers, neutral ledger, partial-sum windows, readback, dyadic ledger, endpoint seal, transport, continuation, and local naming rows;*

2. *schedule exactness, requiring every endpoint-facing read to expose the finite schedule R before it reads a scheduled term or scheduled partial sum;*

3. *positive and negative tail separation, requiring the positive ledger P, negative ledger M, and neutral ledger N to remain distinct under H and to be compared only through the displayed readback row Q and dyadic ledger D;*

4. *partial-sum window stability, requiring the source and scheduled partial-sum windows stored in W to be replayed by C through the same finite route;*

5. *endpoint nonescape, requiring E to remain downstream of S, R, P, M, N, W, Q, D and to export no host infinite rearranged sum, selected limit, quotient equality, countable choice, trichotomy, absolute convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No rearrangement obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RiemannRearrangementUp.RiemannRearrangementTasteGate single carrier alignment`

Proof. Project the accepted packet $K = (S, R, P, M, N, W, Q, D, E, H, C, L)$. The carrier exposes exactly the real series source, finite schedule, signed and neutral ledgers, partial-sum windows, readback, tolerance ledger, endpoint seal, and structural rows.

Schedule exactness is forced by R. Every scheduled term or scheduled partial sum is read through the finite list of displayed source indices, so the packet has no hidden permutation or countable-choice selector.

The signed accounting is separated by construction. The row P contains the positive displayed tail data, the row M contains the negative displayed tail data, and the row N contains neutral entries. The transport row H preserves those coordinates componentwise, while Q and D are the only comparison rows.

The partial-sum window row W and continuation row C replay the same finite route from source terms to scheduled windows. Only after this route is displayed may E expose the $\mathsf{Real}^{\uparrow}$ endpoint seal.

Since the carrier has no excluded coordinate for host infinite rearranged sums, selected limits, quotient equality, countable choice, trichotomy, absolute convergence, or ambient real completeness, the five listed obligations exhaust the local NameCert surface. □

Theorem 2132.3 (Riemann rearrangement positive-negative ledger)**.** *Every endpoint-facing read from an accepted* $\mathsf{RiemannRearrangement}^{\uparrow}$ *carrier must display both signed tail ledgers and the finite rearrangement schedule before the* $\mathsf{Real}^{\uparrow}$ *seal. More precisely, each such read factors through*

$$S, R, P, M, W, Q, D \longmapsto E$$

together with H, C, L*, and it may use the neutral row* N *only as displayed zero-tail bookkeeping along the same scheduled route.*

Proof. Begin with an endpoint-facing request from an accepted carrier. By Definition 2132.1, the request first projects the source row S and the finite schedule row R.

The signed ledger stage is then visible. The positive row P and negative row M must both be present before the packet can compare a scheduled partial sum with an endpoint, because the carrier stores the two signed tail surfaces as separate coordinates. The neutral row N can only add displayed zero-tail bookkeeping to that same route.

The finite window and readback stage follows. The row W displays the source and scheduled partial-sum windows, Q reads them through $\mathsf{RegSeqRat}^{\uparrow}$, and D records the dyadic tolerance accounting for the same displayed data.

Only after S, R, P, M, W, Q, D have been displayed can E provide the endpoint seal. The rows H, C, L transport, replay, and name the same route, so no endpoint-facing read can bypass the signed tail ledgers or the finite rearrangement schedule. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannRearrangement}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannRearrangement}^{\uparrow}$ packet is generated from a RealSeriesUp source, a finite rearrangement schedule, positive and negative signed tail ledgers, a neutral ledger, finite partial-sum windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannRearrangement}^{\uparrow}}$, seed)

Scope closed: Definition 2132.1, Definition 2132.2, and Definition 2132.3 seed the finite rearrangement certificate surface over RealSeriesUp with separated signed tail ledgers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannRearrangement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host infinite rearranged sums, selected limits, quotient equality, countable choice, trichotomy, absolute convergence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exactness, positive and negative tail separation, partial-sum window stability, endpoint nonescape, and TasteGate field faithfulness for BEDC.Derived.RiemannRearrangementUp.

Chapter 2133

A Concrete Naming Certificate for $\mathsf{OpenIntervalReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OpenIntervalReal}^{\uparrow}$ packet names an open real interval by finite endpoint seals, located order tests, dyadic tolerance ledgers, and regular Cauchy readbacks before any topology or completion-facing consumer sees membership. It sits after the located interval surface of chapter 1709, the located-order test of chapter 2112, the dyadic tolerance core of chapter 291, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a constructive interface for the open interval (a, b) over displayed $\mathsf{Real}^{\uparrow}$ names; it is not host trichotomy, quotient real equality, a chosen representative, countable choice, ambient real completeness, Lean verification, or bridge checking.

Definition 2133.1 (OpenIntervalReal carrier)**.** *An* $\mathsf{OpenIntervalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, B, X, L, U, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are endpoint* $\mathsf{Real}^{\uparrow}$ *seal rows. They name the lower and upper endpoints only through displayed regular Cauchy data.*
2. *X is the candidate point* $\mathsf{Real}^{\uparrow}$ *seal row whose open-interval membership is being read.*
3. *L is the left located-order row from* $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$*, witnessing that A is located strictly below X at the displayed tolerance.*
4. *U is the right located-order row from* $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$*, witnessing that X is located strictly below B at the displayed tolerance.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic radius, positive slack, endpoint comparison budget, and exhaustion ledger shared by L and U.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite endpoint and point windows inspected by the two located-order tests.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It reads the same finite windows as regular rational observations before the endpoint and point seals are consumed.*
8. *H records componentwise* hsame *transport for the endpoint seals, candidate seal, order-test rows, dyadic tolerance row, stream windows, readback row, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay from an open-interval membership request through* $A, B, X, L, U, D, S, R, H, P, N$
10. *P is the* Pkg *provenance over* $\mathsf{OpenIntervalReal}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OpenIntervalReal}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these twelve rows form one finite open-interval membership packet. Its classifier reads only the displayed tuple $A, B, X, L, U, D, S, R, H, C, P, N$ and has no coordinate for host trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 2133.2 (OpenIntervalReal NameCert obligations)**.** *For every accepted* $\mathsf{OpenIntervalReal}^{\uparrow}$ *carrier $I = (A, B, X, L, U, D, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OpenIntervalReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two endpoint* $\mathsf{Real}^{\uparrow}$ *seals, candidate* $\mathsf{Real}^{\uparrow}$ *seal, two located-order rows, dyadic tolerance ledger, stream windows, regular rational readback, transport, replay, provenance, and local naming row;*
2. *endpoint-seal exactness, requiring A and B to be read only after the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks expose the endpoint data used by the order tests;*
3. *candidate-seal exactness, requiring X to be read through the same window and readback route before a membership verdict is exported;*
4. *located left boundary, requiring L to display the finite order-test route for $A < X$ over the shared dyadic tolerance row D;*
5. *located right boundary, requiring U to display the finite order-test route for $X < B$ over the same dyadic tolerance row D;*
6. *dyadic tolerance coherence, requiring the positive slack and exhaustion rows in D to be the only tolerance data consumed by both boundary tests;*
7. *structural stability, requiring H and C to transport and replay the endpoint, candidate, order-test, tolerance, window, readback, provenance, and local naming rows componentwise;*
8. *ledger refusal, excluding host trichotomy, quotient real equality, selected representatives, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No local NameCert obligation for the open interval is stored outside these rows.

Lean4 ✓ `BEDC.Derived.OpenIntervalRealUp.OpenIntervalRealTasteGate single carrier alignment`

Proof. Project the accepted packet $I = (A, B, X, L, U, D, S, R, H, C, P, N)$. The projection exposes exactly the two endpoint seals, candidate seal, two located-order rows, dyadic tolerance ledger, stream windows, regular rational readback, and structural rows.

The readback route is finite. The stream row S supplies the endpoint and point windows, while the row R reads those same windows as regular rational observations before the $\mathsf{Real}^{\uparrow}$ seals are consumed.

The two boundary tests are then read against the same dyadic ledger. The row L records the displayed route for $A < X$, and the row U records the displayed route for $X < B$; both use the positive slack and exhaustion data stored in D.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since none of the carrier coordinates stores host trichotomy, quotient equality, representative choice, countable

choice, ambient completeness, a Lean theorem, or a bridge, no further local obligation can be read from the packet. □

Theorem 2133.3 (OpenIntervalReal located membership route)**.** *Every accepted* $\mathsf{OpenIntervalReal}^{\uparrow}$ *membership read for* X *between endpoints* A *and* B *factors through the finite route*

$$A, B, X \longmapsto S, R, D \longmapsto L, U \longmapsto H, C, P, N.$$

Thus an open-interval consumer may inspect endpoint seals, candidate seal, finite windows, regular rational readbacks, dyadic tolerance data, and the two located-order rows, but it cannot obtain host trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking from the packet.*

Proof. Start with an accepted membership read. The only real-name coordinates are A, B, X, so any endpoint or candidate observation must pass through the displayed $\mathsf{Real}^{\uparrow}$ seals.

The finite observation stage comes next. The row S fixes the inspected windows, the row R reads those windows as regular rational data, and the row D supplies the dyadic tolerance, positive slack, and exhaustion ledger shared by the two boundary tests.

The membership verdict is the conjunction of the two located-order rows. The left row L displays $A < X$, and the right row U displays $X < B$, each over the same readback and tolerance data rather than over a host-order primitive.

The rows H, C, P, N close the route by transport, replay, provenance, and local naming. Because the route has no coordinate for trichotomy, quotient equality, representative selection, countable choice, completeness, verification, or a bridge, those principles are not exported by the membership read. □

Closure status for $\mathsf{NameCert}_{\mathsf{OpenIntervalReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OpenIntervalReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2133.1, Definition 2133.2, and Definition 2133.3 seed the finite open-interval membership boundary over endpoint RealUp seals, located order-test rows, dyadic tolerance data, StreamName windows, RegSeqRat readback, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OpenIntervalReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.OpenIntervalRealUp covering the twelve-row carrier, local NameCert obligations, and located membership route.

Constructive story: An $\mathsf{OpenIntervalReal}^{\uparrow}$ packet is generated from lower and upper RealUp endpoint seals, a candidate RealUp seal, left and right CauchyRealLocatedOrderTest rows, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2134

A Concrete Naming Certificate for $\mathsf{MonoidalCompletion}^{\uparrow}$

Following Bourbaki and Kelley on completion and product uniformities, and Bishop–Bridges on constructive metric completion, the $\mathsf{MonoidalCompletion}^{\uparrow}$ packet records the finite BEDC surface on which completion is consumed as a product-compatible reflector. It sits over the metric-completion row of chapter 1506, the binary product handoff of chapter 1540, the functorial completion route of chapter 423, and the reflection boundary of chapter 403. The chapter names only the finite reflector and coherence rows visible to downstream Real and Completion consumers; it does not construct quotient completions, choose representatives, identify host products, assume countable choice, use open-cover compactness, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2134.1 (Monoidal completion carrier)**.** *A* $\mathsf{MonoidalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, U, V, P, A, S, H, C, G, N)$$

with the following visible rows:

1. *M is the metric-completion reflector row. It exposes the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *source-to-completion route and the reflector-facing boundary inherited from chapter 1506.*
2. *U is the unit row. It records the source-object admission into the completion surface before any product consumer may inspect completed data.*
3. *V is the counit row. It records the displayed return route for already completed data and keeps that route inside the completion-reflection boundary.*
4. *P is the binary product row. It is read through the coordinatewise completion product surface of chapter 1540, not through host product equality.*
5. *A is the associativity row. It records that either parenthesization of a finite binary product read uses the same coordinatewise completion, unit, counit, and reflector rows.*
6. *S is the symmetry row. It records that swapping two displayed coordinates swaps only the finite product rows and their associated transport and replay data.*
7. *H records componentwise* hsame *transport for metric-completion, unit, counit, product, associativity, symmetry, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the product-compatible reflector route from metric completion through unit, counit, binary product, associativity, symmetry, and structural rows.*

9. *G is the* Pkg *provenance over* $\mathsf{MonoidalCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionProduct}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MonoidalCompletion}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. It has no coordinate for quotient completion equality, selected representatives, host product equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a host-level symmetric monoidal category.*

Lean4 (definition) `BEDC.Derived.MonoidalCompletionUp.taste gate`

Theorem 2134.2 (Monoidal completion NameCert obligations)**.** *For the carrier of Definition 2134.1, the local* $\mathsf{NameCert}_{\mathsf{MonoidalCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for $Q = (M, U, V, P, A, S, H, C, G, N)$;*
2. *reflector compatibility, requiring the metric-completion reflector row M, unit row U, and counit row V to be consumed through the same completion boundary named in chapter 1506 and chapter 403;*
3. *product compatibility, requiring the binary product row P to factor through the coordinatewise product handoff of chapter 1540;*
4. *finite coherence, requiring associativity row A and symmetry row S to compare only displayed product routes and not host product objects;*
5. *transport and replay stability under componentwise* hsame *transport H and displayed* Cont *replay C;*
6. *provenance exactness, requiring every consumer read to be sourced by G and locally certified by N.*

No obligation is stored in a quotient completion, selected representative, host product equality, countable-choice schedule, open-cover compactness theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or external monoidal-category structure.*

Lean4 ✓ `BEDC.Derived.MonoidalCompletionUp.MonoidalCompletionCarrier namecert obligations`

Proof. Carrier admission is projection from the finite packet in Definition 2134.1. The only displayed coordinates are the reflector row, unit row, counit row, binary product row, associativity row, symmetry row, transport row, replay row, provenance row, and local naming row.

Reflector compatibility is read through the metric-completion and completion-reflection siblings. The M, U, V rows bind source admission, completed-data return, and reflection boundary before any product-compatible consumer can inspect the route.

Product compatibility is then the coordinatewise handoff supplied by chapter 1540. The product row P is a finite route through the displayed coordinate completions and does not add a host product object.

Associativity and symmetry are coherence rows over that finite product route. They compare parenthesized and swapped displays only by reusing the same M, U, V, P, H, C, G, N data, so no quotient equality, selected representative, host product equality, choice principle, compactness theorem, or ambient completeness theorem is available. □

Theorem 2134.3 (Monoidal completion product reflector handoff)**.** *Let $Q = (M, U, V, P, A, S, H, C, G, N)$ be an accepted* $\mathsf{MonoidalCompletion}^{\uparrow}$ *carrier. Every completion-facing product consumer factors*

through the finite route

$$M \longmapsto U, V \longmapsto P \longmapsto A, S \longmapsto H, C, G, N.$$

The handoff uses the metric-completion reflector surface of chapter 1506, the coordinatewise product surface of chapter 1540, the functorial route of chapter 423, and the reflection boundary of chapter 403; it is not a host product completion and not a quotient completion product.

Proof. Project the accepted carrier. The metric-completion reflector row M supplies the completion-facing source boundary, and the unit and counit rows U, V record the two reflector directions available to consumers.

The binary product row P can be consumed only after those reflector rows are displayed. Its coordinatewise content is the same finite product handoff named by the Cauchy-completion product chapter, while the functorial sibling supplies the route discipline for completion-facing maps.

The associativity and symmetry rows A, S are downstream of P. They identify which finite product route is being replayed after a parenthesization or coordinate swap, but they do not identify host product objects.

Finally H, C, G, N preserve the route under transport, replay, provenance, and local certification. Since no further row occurs in Q, the consumer obtains exactly the displayed product-compatible reflector handoff and no quotient completion, selected representative, host product equality, choice principle, compactness theorem, or ambient completeness theorem. □

Theorem 2134.4 (Monoidal completion non-escape)**.** *An accepted* $\mathsf{MonoidalCompletion}^{\uparrow}$ *carrier exports no read outside*

$$(M, U, V, P, A, S, H, C, G, N).$$

In particular, any product-compatible completion consumer must read metric completion, unit, counit, binary product, associativity, symmetry, componentwise transport, displayed continuation replay, provenance, and local naming evidence from the same finite packet.

Proof. Inspect the carrier inventory in Definition 2134.1. Every exported read must be one of the ten displayed rows or a replay of those rows through the local NameCert surface.

If a consumer omits M, it has no metric-completion reflector row. If it omits U or V, it has lost one reflector direction. If it omits P, it has no binary product handoff. If it omits A or S, it has no finite associativity or symmetry comparison for product-compatible reads.

The structural rows are also necessary. Without H, the classifier is not stable under componentwise transport; without C, the route is not replayed as displayed continuation data; without G and N, provenance and local naming are absent.

There is no remaining coordinate. Therefore the packet cannot export quotient completions, selected representatives, host product equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or an external monoidal-category object. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonoidalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MonoidalCompletion}^{\uparrow}$ packet is generated from a metric-completion reflector row, unit row, counit row, binary product row, associativity row, symmetry row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonoidalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2134.1, Definition 2134.2, Definition 2134.3, and Definition 2134.4 seed the finite product-compatible reflector surface for completion through metric-completion, product, functorial, reflection, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MonoidalCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host product equality, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ completeness, or an external monoidal-category structure.

Upgrade path: Obligation closure requires checked carrier admission, reflector compatibility, product compatibility, finite associativity and symmetry coherence, transport stability, replay stability, provenance exactness, and non-escape for BEDC.Derived.MonoidalCompletionUp.

Chapter 2135

A Concrete Naming Certificate for $\mathsf{SmythPowerdomain}^{\uparrow}$

Following Smyth, Plotkin, and Gierz–Hofmann–Keimel–Lawson–Mislove–Scott domain theory, the $\mathsf{SmythPowerdomain}^{\uparrow}$ packet records the finite upper-family powerdomain route over L10 interval-domain cells. It sits after the interval-domain carrier of chapter 1543, the way-below refinement of chapter 1545, the Scott-real presentation of chapter 2083, and the asymmetric completion route of chapter 2095. The packet exports compact upper approximation data for completion-facing consumers without quotient completion, selected representatives, countable choice, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2135.1 (Smyth powerdomain carrier)**.** *A* $\mathsf{SmythPowerdomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (F, I, W, S, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *F is a finite nonempty upper family of L10 interval-domain cells. Each entry is an accepted* $\mathsf{IntervalDomain}^{\uparrow}$ *cell, and the family is read by upward closure under the displayed interval containment order.*
2. *I is the aggregate* $\mathsf{IntervalDomain}^{\uparrow}$ *support row, recording the interval cells, endpoint containment checks, enclosure order, and finite upper-family membership witnesses.*
3. *W is the* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *support row, recording compact-containment refinements used when a consumer asks for a tighter upper approximation.*
4. *S is the* $\mathsf{ScottReal}^{\uparrow}$ *readback row, exposing Scott-real consumers only after the interval-domain and way-below rows have been displayed.*
5. *C is the* $\mathsf{SmythCompletion}^{\uparrow}$ *handoff row, exposing asymmetric completion consumers only through finite upper-family approximation data.*
6. *H records componentwise* hsame *transport for the finite family, interval-domain support, way-below support, Scott-real readback, Smyth-completion handoff, replay, provenance, classifier, and local naming rows.*
7. *R records displayed* Cont *replay from upper-family requests through $F, I, W, S, C, H, G, Q, N$.*
8. *G is the* Pkg *provenance over* $\mathsf{SmythPowerdomain}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{IntervalDomainWayBelow}^{\uparrow}$, $\mathsf{ScottReal}^{\uparrow}$, $\mathsf{SmythCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *Q is the classifier row comparing accepted packets only through finite upper-family membership, interval containment, way-below refinement, Scott-real readback, Smyth-completion handoff, transport, replay, and provenance.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SmythPowerdomain}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. It has no coordinate for a quotient completion object, a selected representative, countable choice, host real equality, open-cover compactness, a hidden ambient compactness principle, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.SmythPowerdomainUp.SmythPowerdomainTasteGate single carrier alignment`

Theorem 2135.2 (Smyth powerdomain NameCert obligations)**.** *For an accepted* $\mathsf{SmythPowerdomain}^{\uparrow}$ *carrier*

$$P = (F, I, W, S, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SmythPowerdomain}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the finite nonempty upper family, interval-domain support row, way-below support row, Scott-real readback row, Smyth-completion handoff row, transport, replay, provenance, classifier, and local naming row;*

2. *nonempty upper-family exposure, requiring F to display at least one interval-domain cell and to answer every membership request by finite containment data in I;*

3. *way-below refinement compatibility, requiring every requested tightening of an upper approximation to pass through W before it reaches a Scott-real or completion-facing consumer;*

4. *Scott-real handoff discipline, requiring S to read only the interval-domain and way-below rows already exposed by F, I, W;*

5. *Smyth-completion handoff discipline, requiring C to receive finite upper-family approximation data rather than quotient completion data;*

6. *structural exhaustion, requiring H, R, G, Q, N to transport, replay, source, classify, and name only the listed rows.*

No local NameCert obligation is stored outside these rows, and none exports quotient completion, selected representatives, countable choice, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2135.1. The accepted packet exposes exactly the finite upper family, interval-domain support, way-below support, Scott-real readback, Smyth-completion handoff, transport, replay, provenance, classifier, and local naming rows.

Nonempty upper-family exposure is read from F and I. The row F supplies a finite inhabited list of interval cells, and I supplies the displayed containment and membership witnesses used to read that list upward.

Way-below refinement compatibility is read before any downstream handoff. A tighter upper approximation may be consumed only after W has displayed the compact-containment evidence connecting the requested cell to the interval-domain support.

The Scott-real and Smyth-completion handoffs are downstream rows. The row S reads the same interval and way-below data as a Scott-real approximation surface, while C reads the finite upper-family route as an asymmetric completion approximation.

Finally H, R, G, Q, N add no analytic principle. They transport, replay, source, classify, and name the displayed route, so the excluded quotient, representative selection, choice, host equality, compactness, and completeness principles have no row from which a consumer could read them. □

Theorem 2135.3 (Smyth powerdomain interval-domain handoff)**.** *Let*

$$P = (F, I, W, S, C, H, R, G, Q, N)$$

be an accepted $\mathsf{SmythPowerdomain}^{\uparrow}$ *carrier. Every Scott-real or completion-facing consumer of* P *factors through the displayed finite route*

$$F \longmapsto I \longmapsto W \longmapsto S, C \longmapsto H, R, G, Q, N.$$

Thus the powerdomain packet reaches $\mathsf{ScottReal}^{\uparrow}$ *and* $\mathsf{SmythCompletion}^{\uparrow}$ *consumers only by passing from a finite nonempty upper family of interval-domain cells to interval containment data, way-below refinements, the downstream readback rows, and the structural* hsame/Cont/Pkg/NameCert *rows.*

Proof. Fix a Scott-real or completion-facing consumer of the accepted packet. The first visible object is the finite nonempty family F, so the consumer begins with displayed interval-domain cells rather than with a completed host object.

The interval-domain stage reads I. This row supplies the endpoint containment, enclosure order, and finite membership evidence that make the family an upper approximation surface.

The refinement stage reads W. Compact-containment evidence is displayed before any consumer may request a sharper approximation, so the route stays inside the interval-domain and way-below packets.

The downstream handoff reads S or C. A Scott-real consumer obtains only the displayed interval-domain readback, and a Smyth-completion consumer obtains only the finite upper-family approximation route.

The rows H, R, G, Q, N close the factorization by transport, replay, provenance, classification, and local naming. Since no other coordinate exists in the carrier, the excluded quotient, choice, host equality, compactness, and completeness principles cannot be exported by the handoff. □

Theorem 2135.4 (Smyth powerdomain non-escape)**.** *Let* P *be an accepted* $\mathsf{SmythPowerdomain}^{\uparrow}$ *carrier. Any consumer that asks for quotient completion, selected representatives, countable choice, host real equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness receives no row of* P *from which such data can be read. The only exported data are the finite upper-family carrier, the interval-domain and way-below support rows, the Scott-real and Smyth-completion handoff rows, and the structural transport, replay, provenance, classifier, and local naming rows.*

Proof. Inspect the carrier in Definition 2135.1. Its analytic rows are F, I, W, S, C, and each of them is a finite interval-domain, way-below, Scott-real, or Smyth-completion route.

The structural rows H, R, G, Q, N only preserve, replay, source, compare, and name those displayed routes. They do not introduce a new carrier coordinate or a hidden functional.

Therefore a consumer requesting quotient completion, a selected representative, countable choice, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness has no matching row to read. The request remains outside the packet interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SmythPowerdomain}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SmythPowerdomain}^{\uparrow}$ packet is generated from a finite nonempty upper family of Interval-Domain cells, aggregate interval-domain support, way-below refinement support, ScottReal readback, SmythCompletion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, classifier comparison, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SmythPowerdomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2135.1, Definition 2135.2, Definition 2135.3, and Definition 2135.4 seed the finite upper-family powerdomain route over L10 interval-domain cells.

Formal verification: FormalStatus(NameCert$_{\mathsf{SmythPowerdomain}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite upper-family exposure, way-below refinement compatibility, Scott-real handoff discipline, Smyth-completion handoff discipline, transport stability, replay stability, classifier exhaustion, and ledger non-escape for BEDC.Derived.SmythPowerdomainUp.

Chapter 2136

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$

Following Bishop and Bridges, the regular Cauchy completion is read here as a finite-window completion interface rather than as a quotient object. The $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ packet consumes the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It packages unit and bind rows for the L10 completion route while excluding quotient stream equality, selected limits, host real equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2136.1 (Regular Cauchy completion monad carrier)**.** *A* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, R, D, U, B, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family. It records the source windows, unit windows, bind-request windows, and seal-facing observation cuts inspected by the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to W. It contains the regular rational rows read from source windows and the intermediate readbacks produced by unit or bind requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested scale, composition slack, triangle-budget rows, and exhausted dyadic windows used by unit, bind, and seal handoffs.*
4. *U is the unit row. It embeds a displayed regular rational input into the completion interface by copying the relevant window and tolerance rows into a one-stage completion name.*
5. *B is the bind row. It composes an accepted completion name with a displayed finite-window Kleisli request by replaying the source windows, readbacks, and dyadic budget before exposing the composed row.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row. It is reachable only after the displayed W, R, D, U, B route has been read.*
7. *H records componentwise* hsame *transport for windows, readbacks, dyadic ledgers, unit rows, bind rows, seal rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the route*

$$W, D \longmapsto R \longmapsto U, B \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionMonad}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $W, R, D, U, B, E, H, C, P, N$ and has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

`single carrier alignment`

Theorem 2136.2 (Regular Cauchy completion unit laws)**.** *For every accepted* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *carrier*

$$M = (W, R, D, U, B, E, H, C, P, N),$$

the unit row U is a finite-window identity for the displayed completion interface. A source regular rational read through W, R, D is admitted into the completion packet without changing its inspected windows, readback row, dyadic scale, componentwise transport row, replay row, provenance row, or local naming row.

Proof. Project the accepted carrier M. The projection exposes the finite-window row W, the regular rational readback family R, the dyadic ledger D, and the unit row U before any seal-facing row is visible.

The unit row is checked by finite-window induction on W. In the empty-window case, there is no observation to alter, and the displayed readback and dyadic ledger are the unique empty rows carried by the packet.

For a successor window, the induction hypothesis identifies the previous inspected segment. The next observation is copied by U with the same readback row and the same dyadic scale entry, so the extended window remains the displayed source route rather than a selected limit.

The structural rows H, C, P, N preserve this copied route componentwise. Since the carrier has no quotient stream, host equality, countable-choice selector, or ambient completeness coordinate, the unit law is exactly the finite identity of the displayed rows. □

Theorem 2136.3 (Regular Cauchy completion bind laws)**.** *For every accepted* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *carrier*

$$M = (W, R, D, U, B, E, H, C, P, N),$$

the bind row B composes completion-facing finite-window requests by replaying the source windows, $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances before exporting the composed row. The left-unit, right-unit, and associativity comparisons are therefore comparisons of displayed $W, R, D, U, B, H, C, P, N$ rows, not comparisons of quotient streams or selected limits.*

Proof. Open the bind row B. A bind request is admitted only after the relevant source window in W, the matching readback in R, and the requested dyadic budget in D have been displayed.

For left unit, first read the unit row U. The preceding theorem identifies the unit route with the displayed source window, so applying B to that route consumes the same W, R, D rows as the original request.

For right unit, start from an accepted completion-facing row and then apply the unit request as the second stage. The finite-window induction on W again keeps every inspected observation, readback, and dyadic scale entry unchanged.

For associativity, compare the two finite replays of a three-stage request. Both sides enumerate the same source windows, intermediate readbacks, and dyadic composition ledgers; regrouping changes only the order in which the already displayed bind rows are read.

The transport, replay, provenance, and local naming rows identify these displayed packets componentwise. No step appeals to quotient equality of streams, a selected limit, host real equality, countable choice, or ambient completeness. □

Theorem 2136.4 (Regular Cauchy completion Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *carrier reads the terminal seal only through the finite route*

$$W, D \longmapsto R \longmapsto U, B \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, unit and bind rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, package provenance, and local naming. It receives no quotient completion, selected limit, host real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with an accepted carrier and project the seal row E. The carrier definition places E downstream of the displayed window family W, readback family R, dyadic ledger D, unit row U, and bind row B.

The handoff is therefore finite. A $\mathsf{Real}^{\uparrow}$ consumer must first read the inspected windows, then the regular rational readbacks, then the dyadic tolerances that justify the unit and bind requests.

Only after those rows are present may the seal row E be consumed. The seal is consequently attached to the displayed regular Cauchy completion route rather than to a quotient completion object or a host-selected real representative.

Finally H, C, P, N preserve the route under componentwise transport, continuation replay, provenance, and local naming. Because the carrier contains no excluded coordinate, the terminal handoff cannot export quotient completion, selected limits, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2136.5 (Regular Cauchy completion finite-window induction)**.** *For every accepted* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *carrier*

$$M = (W, R, D, U, B, E, H, C, P, N),$$

induction over the finite $\mathsf{StreamName}^{\uparrow}$ *window row* W *preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the unit row* U*, the bind row* B*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff* E*. The induction route is closed by* H, C, P, N *and cannot introduce quotient stream equality, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use induction on the displayed finite window row W. In the empty-window case, the carrier projection gives the empty readback segment, empty tolerance segment, vacuous unit segment, vacuous bind segment, and no independent seal read. The structural rows H, C, P, N preserve exactly that empty route.

For a successor window, reuse the displayed replay route

$$W, D \longmapsto R \longmapsto U, B \longmapsto E.$$

The induction hypothesis preserves the previous window segment. The new window entry is then read with its dyadic tolerance from D, translated through R, admitted by the unit row U, composed by the bind row B, and finally exposed to the seal row E.

Close the step with the structural rows. Componentwise hsame transport in H, displayed Cont replay in C, Pkg provenance in P, and the local NameCert row N preserve only the rows already displayed in the carrier. Since there is no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient completeness, the induction cannot introduce any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, unit rows, bind rows, a terminal RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionMonad}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2136.1, Definition 2136.2, Definition 2136.3, Definition 2136.4, and Definition 2136.5 seed the finite-window completion interface from StreamName windows through RegSeqRat readbacks, DyadicRatCore tolerances, unit and bind rows, RealUp seal handoff, finite-window induction, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionMonad}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full $\mathsf{Real}^{\uparrow}$ completeness, quotient completion, quotient stream equality, selected limits, host real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window unit identity, bind composition, tolerance replay, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionMonadUp.

Chapter 2137

Regular Cauchy Tail Sum NameCert Construction

Following Bishop and Bridges-style constructive analysis, the $\mathsf{RegularCauchyTailSum}^{\uparrow}$ packet records the finite tail-sum route by which a displayed dyadic budget, a stream window, and a regular rational sequence read determine a real endpoint seal. It sits between the dyadic tolerance surface of chapter 291, the finite observation windows of chapter 126, the regular rational sequence carrier of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite evidence needed to pass from bounded tail sums to a regular Cauchy read; it does not import quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2137.1 (Regular Cauchy tail-sum carrier)**.** *A* $\mathsf{RegularCauchyTailSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, S, R, A, W, B, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-budget ledger. It records the dyadic precision request, the split between initial-window and tail-window tolerances, and the finite comparisons used to absorb the tail.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It records the inspected stream entries, partial sums, and endpoint reads for the requested finite window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row. It records the regular rational sequence read exposed by the same finite window and tolerance budget.*
4. *A is the additivity row. It records the finite addition route for the displayed partial tail sums and the dyadic error terms.*
5. *W is the window-control row. It records the left endpoint, right endpoint, and width certificate for every tail window used by the packet.*
6. *B is the bounded-tail row. It records the displayed tail bound that converts the inspected finite window into a regular Cauchy read.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after D, S, R, A, W, B have been displayed.*
8. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regularity row, additivity row, window-control row, bounded-tail row, endpoint seal, replay, provenance, and local name.*

9. *C records displayed* Cont *replay of the route*

$$D, S, R, A, W, B \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, A, W, B, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limiting real, countable choice, ambient completeness, or a host infinite summation principle.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailSumUp.RegularCauchyTailSumTasteGate single carrier alignment`

Theorem 2137.2 (Regular Cauchy tail-sum window extraction)**.** *For every accepted* $\mathsf{RegularCauchyTailSum}^{\uparrow}$ *carrier*

$$T = (D, S, R, A, W, B, E, H, C, P, N),$$

each tail-sum request factors through a finite BHist/Cont *window whose visible data are exactly the dyadic budget D, stream observations S, regularity readback R, additivity row A, window-control row W, bounded-tail row B, and the structural rows H, C, P, N. No request can read a quotient stream, selected limit, countable-choice witness, ambient completeness proof, or host infinite summation theorem.*

Proof. Project the accepted packet $T = (D, S, R, A, W, B, E, H, C, P, N)$. The carrier definition exposes precisely the dyadic ledger, stream observations, regularity row, finite additivity row, window-control row, bounded-tail row, endpoint seal, and structural rows.

The inspected window is finite. The row D fixes a dyadic tolerance budget, while S lists the stream entries and partial sums actually read inside that budget. The row W records the endpoints and width certificates for the same inspected interval.

The tail stage is also finite. The additivity row A combines only the displayed partial sums and dyadic errors, and the bounded-tail row B records the finite inequality that absorbs all entries beyond the inspected window at the requested precision.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no carrier coordinate stores quotient equality, selected limits, choice, completeness, or host summation, the request cannot escape the displayed finite window. □

Theorem 2137.3 (Regular Cauchy tail-sum regular sequence read)**.** *Every accepted* $\mathsf{RegularCauchyTailSum}^{\uparrow}$ *packet determines its regular rational sequence read through the finite route*

$$D, S, W \longmapsto A, B \longmapsto R.$$

For any two inspected windows with dyadic budgets recorded by D, the corresponding reads in R agree up to the displayed tail budget after transport by H. Thus regularity is witnessed by finite tail-window induction over BHist *and* Cont *rows, not by quotient streams, selected limits, countable choice, or ambient completeness.*

Proof. Begin with two inspected tail windows admitted by the same packet. Their budgets are both read through D, and their stream observations and window widths are read through S and W.

Induct over the finite extension from the shorter displayed window to the longer displayed window. The base case is the common window, where the two reads use the same rows and the same dyadic budget. In the step case, adding one displayed tail entry updates the partial sum through A and tightens the remaining error through B.

The regularity row R receives only the data produced by this finite induction. Componentwise transport in H preserves the dyadic budget, stream observations, additivity row, and bounded-tail row, so the two reads agree up to the displayed tolerance.

The route never asks for a quotient stream representative or a selected limit. It uses only the inspected BHist/Cont windows and the finite dyadic tail budget already present in the packet. □

Theorem 2137.4 (Regular Cauchy tail-sum real seal)**.** *Every accepted* $\mathsf{RegularCauchyTailSum}^{\uparrow}$ *packet reaches its* $\mathsf{Real}^{\uparrow}$ *endpoint seal only through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow} \longmapsto A, W, B \longmapsto E, H, C, P, N.$$

Consequently the packet exports a finite tail-sum seal for later L10 Real and Completion routes, but it exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from an endpoint request for the packet. The request must first expose D, S, R because these are the only rows carrying dyadic budgets, stream observations, and regular rational sequence reads.

The finite tail computation then passes through A, W, B. The row A records finite addition of displayed terms and error terms, W records the inspected tail-window widths, and B records the tail bound that converts the finite window into a regular Cauchy read.

Only after those rows are displayed can E provide the $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N preserve and replay the same displayed route, so the endpoint seal is downstream of finite evidence rather than an ambient completeness principle.

Thus the packet supplies a named finite handoff for later L10 Real and Completion consumers while explicitly leaving $\mathsf{Real}^{\uparrow}$ completeness outside the local claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSum}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailSum}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tail-budget ledger, StreamNameUp observation windows, RegSeqRatUp regular rational readback, a finite additivity row, a window-control row, a bounded-tail row, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2137.1, Definition 2137.2, Definition 2137.3, and Definition 2137.4 seed the finite tail-sum certificate surface between dyadic budgets, stream windows, regular rational reads, and RealUp endpoint seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, or a host infinite summation principle.

Upgrade path: Obligation closure requires checked carrier admission, finite window extraction, regular sequence readback, tail-bound stability, endpoint non-escape, and provenance closure for BEDC.Derived.RegularCauchyTailSumUp.

Chapter 2138

A Concrete Naming Certificate for $\mathsf{DedekindCutCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DedekindCutCompletion}^{\uparrow}$ packet names the finite comparison surface where located Dedekind-cut evidence may be admitted beside regular Cauchy real names without turning $\mathsf{Real}^{\uparrow}$ into a completed Dedekind quotient. It is positioned after the cut-to-Cauchy boundary of chapter 1745, the regular Cauchy completion route of chapter 1639, the dyadic comparison spine of chapter 1672, the regular rational sequence row of chapter 301, the finite stream interface of chapter 126, and the terminal real-name seal of chapter 38. The chapter records how cut-shaped data enters BEDC as finite rows and is compared only through regularization windows, preserving the refusal to treat $\mathsf{Real}^{\uparrow}$ completeness as already proved.

Definition 2138.1 (Dedekind cut completion carrier)**.** *A* $\mathsf{DedekindCutCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, U, G, W, S, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located lower-cut row. It records finite lower observations together with their downward-use discipline.*
2. *U is the located upper-cut row. It records finite upper observations together with their upward-use discipline.*
3. *G is the dyadic bracket-witness row. It records the displayed dyadic gaps separating admitted lower and upper observations.*
4. *W is the finite regularization-window row. It records the bounded window in which cut evidence is translated into regular Cauchy observations.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row opened by the regularization window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy approximant row read from S under the bracket witnesses in G.*
7. *A is the* $\mathsf{DyadicArchimedean}^{\uparrow}$ *comparison row. It stores the finite Archimedean dyadic scale used to compare bracket witnesses with regular Cauchy tolerances.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is visible only after L, U, G, W, S, R, A have been displayed.*

9. *H records componentwise* hsame *transport for the cut rows, bracket witnesses, regularization windows, stream observations, regular approximants, dyadic comparison row, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a located cut request through $L, U, G, W, S, R, A, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{DedekindCutCompletion}^{\uparrow}$, $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$, BishopRegularCauchyCom DyadicArchimedean$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through finite regularization windows W and the rows displayed downstream of those windows. The carrier has no coordinate for quotient real equality, arbitrary suprema, countable choice, trichotomy, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DedekindCutCompletionUp.DedekindCutCompletionTasteGate single carrier alignment`

Theorem 2138.2 (Located cut regularization)**.** *For every accepted* $\mathsf{DedekindCutCompletion}^{\uparrow}$ *carrier $D = (L, U, G, W, S, R, A, E, H, C, P, N)$, each located cut-side request admitted by L, U, G has a displayed finite regularization route*

$$L, U, G \longrightarrow W \longrightarrow S, R, A \longrightarrow E.$$

The route reads lower and upper cut rows only through the bracket witnesses in G, chooses a bounded regularization window W, exposes stream-window observations in S, reads regular Cauchy approximants in R, compares tolerances through the dyadic Archimedean row A, and reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal E only after those rows are displayed.*

Proof. Carrier projection gives the cut-side rows L, U, G and the regular Cauchy rows W, S, R, A, E. The lower and upper observations are not ambient cuts; they are finite rows whose only displayed meeting point is the dyadic bracket-witness row G.

The finite window row W is therefore the first comparison surface. It bounds the portion of the cut evidence that a consumer may regularize, so the route never needs a global supremum or a selected cut value.

Inside W, the stream row S supplies the inspected observations, the regular sequence row R supplies the regular Cauchy approximants, and the dyadic Archimedean row A supplies the tolerance comparison scale. Only after these rows are visible can the route read the terminal $\mathsf{Real}^{\uparrow}$ seal E. □

Theorem 2138.3 (Dedekind cut completion NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutCompletion}^{\uparrow}$ *carrier $D = (L, U, G, W, S, R, A, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located lower row, located upper row, dyadic bracket witnesses, regularization windows, stream observations, regular Cauchy approximants, dyadic Archimedean comparison row, Real seal, transport, replay, provenance, and local naming row;*

2. *located cut discipline, requiring every lower-row and upper-row read to meet only through the displayed bracket witnesses in G;*

3. *finite regularization, requiring every comparison-facing cut request to choose a displayed window W before reading S, R, A;*

4. *regular Cauchy handoff, requiring stream-window observations, regular approximants, and dyadic tolerance comparisons to be displayed before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is visible;*
5. *classifier stability, requiring componentwise* hsame *transport in* H *and displayed* Cont *replay in* C *to preserve the route* L, U, G, W, S, R, A, E*;*
6. *ledger exhaustion, requiring* P *and* N *to name exactly the displayed packet and no quotient real equality, arbitrary supremum, countable-choice schedule, trichotomy principle, host-completeness theorem, or proof that* $\mathsf{Real}^{\uparrow}$ *is complete.*

No $\mathsf{DedekindCutCompletion}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2138.1. The finite packet exposes the lower row, upper row, bracket witnesses, regularization windows, stream observations, regular approximants, dyadic comparison data, Real seal, and structural rows H, C, P, N.

Located cut discipline follows from the absence of an ambient cut coordinate. Lower and upper observations can be compared only where G supplies a displayed bracket witness.

Finite regularization is forced by the row order. A comparison-facing request must choose W before it can open stream observations, regular Cauchy approximants, or dyadic tolerance comparisons.

The regular Cauchy handoff then reads S, R, A before E. Componentwise hsame transport in H preserves each displayed row, and Cont replay in C repeats the same route for each accepted request.

Finally, provenance and local naming are exhausted by P and N. Since none of the excluded surfaces is a coordinate of D, the local certificate cannot export such a surface as a hidden obligation. □

Theorem 2138.4 (Dedekind cut and Cauchy comparison)**.** *Let* $D = (L, U, G, W, S, R, A, E, H, C, P, N)$ *and* $D' = (L', U', G', W', S', R', A', E', H', C', P', N')$ *be accepted* $\mathsf{DedekindCutCompletion}^{\uparrow}$ *carriers. Any classifier comparison between* D *and* D' *is determined by displayed finite regularization windows and their downstream regular Cauchy rows:*

$$W, S, R, A, H, C, P, N \quad \text{and} \quad W', S', R', A', H', C', P', N'.$$

The comparison may transport located cut evidence from L, U, G *and* L', U', G' *into those windows, but it cannot compare packets by quotient real equality, arbitrary suprema, countable choice, trichotomy, host completeness, or the assertion that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Start with an accepted classifier comparison. By Definition 2138.1, the only comparison-facing rows are the displayed regularization windows, stream observations, regular approximants, dyadic comparison rows, and structural transport, replay, provenance, and naming rows.

The cut evidence contributes only through L, U, G and L', U', G'. The bracket witnesses in G and G' determine what finite cut-side information enters W and W', but they do not create quotient real equality or a host supremum.

Once the windows are fixed, the comparison is regular Cauchy in form: it reads S, R, A and S', R', A' under the componentwise transport and replay rows. The terminal seals E and E' are reached only after those rows are displayed.

The excluded principles have no coordinates in either carrier. Therefore the classifier compares only through the finite regularization windows and their downstream rows. □

Theorem 2138.5 (Dedekind cut completion window determinacy)**.** *Let* $D = (L, U, G, W, S, R, A, E, H, C, P, N)$ *and* $D' = (L', U', G', W', S', R', A', E', H', C', P', N')$ *be accepted* $\mathsf{DedekindCutCompletion}^{\uparrow}$ *carriers. Suppose the displayed lower rows, upper rows, and bracket-witness rows agree through componentwise transport. Then any accepted classifier comparison between* D *and* D' *must choose matching finite regularization windows before it can read* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicArchimedean}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows.*

Proof. Project both carriers by Definition 2138.1. The only comparison-facing route from located cut data to a real-facing seal passes through the lower row, upper row, bracket witnesses, and then the finite regularization window.

Use the componentwise transport hypothesis on L, U, G and L', U', G'. It makes the cut-side evidence entering W and W' the same displayed evidence, so an accepted classifier route cannot select different window data without leaving the carrier rows.

Apply Definition 2138.4. Once the windows are fixed, every comparison reads the stream rows, regular Cauchy approximants, dyadic Archimedean comparison rows, and terminal real seals downstream of those windows.

The carrier has no coordinate for quotient real equality, arbitrary suprema, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Those principles therefore cannot replace the displayed window choice or break its transport stability. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2138.1, Definition 2138.2, Definition 2138.3, Definition 2138.4, and Definition 2138.5 seed the finite comparison packet admitting located Dedekind-cut evidence through regular Cauchy windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, arbitrary suprema, countable choice, trichotomy, host completeness, Lean verification, bridge checking, or that $\mathsf{Real}^{\uparrow}$ is complete.

Upgrade path: Lean verification requires a theorem for carrier admission, located cut discipline, finite regularization, regular Cauchy handoff, classifier stability, and ledger exhaustion for BEDC.Derived.DedekindCutCompletionUp.

Constructive story: A $\mathsf{DedekindCutCompletion}^{\uparrow}$ packet is generated from located lower and upper cut rows, dyadic bracket witnesses, finite regularization windows, StreamName observations, RegSeqRat approximants, a DyadicArchimedean comparison row, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2139

A Concrete Naming Certificate for EilenbergMooreCompletionAlgebra$^{\uparrow}$

Following Eilenberg and Moore, and the standard monad-algebra treatment of completion monads, the EilenbergMooreCompletionAlgebra$^{\uparrow}$ packet names the finite L10 surface where completion monad data can be consumed as an algebra object rather than as an external quotient completion. It is grounded in the completion monad row of chapter 378, the unit row of chapter 1527, the counit landing of chapter 1539, the idempotent law surface of **??**, and the Kleisli comparison of chapter 2066. Its analytic landing is the metric-completion and real-readback chain through chapter 1506, chapter 301, and chapter 38.

The packet does not construct a quotient of Cauchy names. It records only the finite carrier, law, Kleisli-consumption, and ledger rows by which a downstream Real or CompleteMetric consumer can read the completion monad as an Eilenberg–Moore algebra surface.

Definition 2139.1 (Eilenberg–Moore completion algebra carrier)**.** *An* EilenbergMooreCompletionAlgebra$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, U, K, I, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* CauchyCompletionMonad$^{\uparrow}$ *row, displaying the completion monad source, unit, bind, tolerance, readback, and terminal seal data available to the algebra.*
2. *U is the* CauchyCompletionUnit$^{\uparrow}$ *row, displaying the finite unit admission by which an input name is copied into the completion surface.*
3. *K is the Kleisli or extension row inherited from the* CauchyCompletionKleisliAdjunction$^{\uparrow}$ *comparison, displaying the finite consumer request that reads completion data through the monad route.*
4. *I is the idempotent or multiplication law row from* CauchyCompletionIdempotent$^{\uparrow}$*, recording that a second completion pass is consumed by the same finite completion surface rather than by a selected quotient representative.*
5. *L is the* MetricCompletion$^{\uparrow}$ *landing row, exposing the metric-completion readback that a downstream Real or CompleteMetric consumer may inspect after M, U, K, I have been displayed.*
6. *H records componentwise* hsame *transport for the monad, unit, Kleisli, law, landing, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay of the route*

$$M, U \longmapsto K, I \longmapsto L \longmapsto H, P, N.$$

`single carrier alignment`

Theorem 2139.2 (Eilenberg–Moore completion algebra NameCert obligations)**.** *For every accepted* EilenbergMooreCompletionAlgebra$^{\uparrow}$ *carrier*

$$A = (M, U, K, I, L, H, C, P, N),$$

the local NameCert$_{\text{EilenbergMooreCompletionAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the completion monad row, unit row, Kleisli or extension row, idempotent or multiplication law row, metric-completion landing row, transport, replay, provenance, and local naming row;*
2. *unit exposure, requiring U to be displayed before any algebra consumer can read the Kleisli or law rows;*
3. *Kleisli consumption, requiring K to consume only the displayed completion monad and unit data before opening the algebra law surface;*
4. *law exactness, requiring I to identify the second completion pass with the same displayed algebra surface through finite idempotent or multiplication rows;*
5. *landing exactness, requiring L to be the only metric-completion landing visible downstream of the monad, unit, Kleisli, and law rows;*
6. *structural exhaustion, requiring H, C, P, N to preserve, replay, source, and name the listed rows without adding quotient completions, selected limits, countable choice, host equality, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2139.1. The accepted packet displays exactly the completion monad, unit, Kleisli or extension, idempotent or multiplication, metric-completion landing, and structural rows.

Unit exposure is read from U. Since U is displayed before the Kleisli and law rows, an algebra consumer starts from the same finite admission route as the completion unit packet.

Kleisli consumption is read from K. The row records a finite consumer request over the displayed monad and unit data, so it cannot introduce a second source family, a selected limit, or a quotient representative before the law row is opened.

Law exactness is read from I. The row identifies the second completion pass with the displayed algebra surface by replaying the idempotent or multiplication route already available in the sibling completion chapters.

Landing exactness is read from L. The metric-completion landing is downstream of M, U, K, I and therefore receives only the displayed algebra route.

Finally H, C, P, N add no analytic, quotient, Lean, or bridge coordinate. They transport, replay, source, and name the same finite route, so no obligation can escape the displayed rows. □

Theorem 2139.3 (Eilenberg–Moore completion algebra law surface)**.** *For every accepted* EilenbergMooreCompletio *carrier*

$$A = (M, U, K, I, L, H, C, P, N),$$

the algebra law surface is the displayed finite route

$$M, U \longmapsto K, I \longmapsto L \longmapsto H, C, P, N.$$

The unit law is read by projecting U against the monad row M, and the multiplication or idempotence law is read by projecting I against the same M, U, K route. Thus the law surface is a NameCert comparison of displayed completion rows, not a quotient-completion equality, selected limit, host equality, ambient completeness theorem, Lean credential, or bridge credential.

Proof. Project the accepted carrier. The monad row M supplies the finite completion route, and U supplies the finite unit admission into that route.

The unit law is therefore a comparison of displayed M and U rows. It asks only whether the unit admission replays the source data carried by the monad surface.

Next inspect K and I. The Kleisli or extension row exposes the consumer request over the displayed monad data, and the idempotent or multiplication row records that applying completion again is consumed by the same algebra surface.

The landing row L is downstream of these law rows. A consumer can see a metric-completion landing only after the unit and multiplication or idempotence reads have already been displayed.

The structural rows H, C, P, N preserve this route componentwise. Since the packet contains no quotient, selection, host-equality, ambient-completeness, Lean, or bridge row, the algebra laws are exactly the displayed NameCert comparisons of $M, U, K, I, L, H, C, P, N$. □

Theorem 2139.4 (Eilenberg–Moore completion algebra unit and multiplication laws)**.** *For every accepted* EilenbergMooreCompletionAlgebra$^{\uparrow}$ *carrier*

$$A = (M, U, K, I, L, H, C, P, N),$$

the public algebra action is available only after the CauchyCompletionMonad$^{\uparrow}$ *row M,* CauchyCompletionUnit$^{\uparrow}$ *row U, Kleisli or extension row K, idempotent or multiplication row I,* MetricCompletion$^{\uparrow}$ *landing row L, and structural rows H, C, P, N have been displayed. The route records the finite unit and multiplication laws of the completion monad without quotient completions, selected representatives, host equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 2139.1. The accepted packet exposes exactly the completion monad row M, unit row U, Kleisli or extension row K, idempotent or multiplication row I, metric-completion landing row L, and structural rows H, C, P, N.

Apply the law-surface theorem. Theorem 2139.3 reads the unit law from M, U and the multiplication or idempotence law from M, U, K, I before any landing row is public.

Use the Kleisli-consumption theorem to bind consumers to the same route. Theorem 2139.5 forces a Kleisli or extension request through $M, U, K, I, L, H, C, P, N$, so the algebra action cannot bypass the finite completion-monad rows.

Finally the ledger non-escape theorem excludes the analytic and quotient alternatives. Theorem 2139.6 leaves no coordinate for quotient completion, selected representatives, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2139.5 (Eilenberg–Moore completion algebra Kleisli consumption)**.** *Every L10 Completion consumer that reads an accepted* $\mathsf{EilenbergMooreCompletionAlgebra}^{\uparrow}$ *carrier through a Kleisli or extension request factors through the displayed rows* $M, U, K, I, L, H, C, P, N$*. In particular, the consumer first reads the completion monad and unit rows, then the Kleisli request, then the idempotent or multiplication row, and only then the metric-completion landing and structural rows.*

Proof. Start with an L10 Completion consumer using a Kleisli or extension request. Projection of the accepted carrier supplies M and U before K is available.

The Kleisli row K consumes that displayed completion data. Its source is the finite monad-and-unit route, so the consumer cannot bypass M or U to reach a separate completion object.

The law row I is then read against the same route. It records that the second completion pass is absorbed by the displayed algebra surface rather than exported as a quotient or selected representative.

Only after M, U, K, I have been displayed does the landing row L become visible. The final rows H, C, P, N transport, replay, source, and name the same route, so the consumer factors through exactly the listed packet coordinates. □

Theorem 2139.6 (Eilenberg–Moore completion algebra ledger non-escape)**.** *For every accepted* $\mathsf{EilenbergMooreCompletionAlgebra}^{\uparrow}$ *carrier*

$$A = (M, U, K, I, L, H, C, P, N),$$

the ledger visible to a downstream $\mathsf{Real}^{\uparrow}$ *or CompleteMetric consumer is exhausted by the displayed route of Definition 2139.3. No read of the packet can export a quotient completion, selected limit, countable-choice selector, host equality of completion names, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge-checked surface.*

Proof. Begin with a downstream Real or CompleteMetric read. The law-surface theorem forces the read through M, U, K, I before it can inspect the metric-completion landing.

The landing row L is the only analytic landing coordinate in the carrier. It is attached to the displayed monad, unit, Kleisli, and law rows, and it does not carry an additional quotient or selected-limit field.

Now inspect the structural rows. Componentwise transport H and continuation replay C preserve the same finite route, while P and N source and name only the listed completion-algebra rows.

Because the carrier predicate has no coordinate for quotient completion, selected limits, countable choice, host equality, ambient completeness, Lean verification, or bridge checking, no downstream consumer can export any of those objects from the packet ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{EilenbergMooreCompletionAlgebra}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EilenbergMooreCompletionAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2139.1, Definition 2139.2, Definition 2139.3, Definition 2139.5, and Definition 2139.6 seed the finite Eilenberg–Moore algebra surface for L10 completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{EilenbergMooreCompletionAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, host equality of completion names, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit exposure, Kleisli consumption, law exactness, metric-completion landing exactness, structural replay, and ledger non-escape for BEDC.Derived.EilenbergMooreCompletionAlgebraUp.

Constructive story: An EilenbergMooreCompletionAlgebra$^{\uparrow}$ packet is generated from a Cauchy completion monad row, unit row, Kleisli or extension row, idempotent or multiplication law row, metric-completion landing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2140

A Concrete Naming Certificate for $\mathsf{BishopIntervalEnclosure}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopIntervalEnclosure}^{\uparrow}$ packet records the finite interval-enclosure surface by which lower and upper endpoint data are read as rational enclosures, dyadic refinements, regular rational readback, and a terminal real-name seal. It sits after the located endpoint carrier of chapter 394, the rational enclosure ledger of chapter 1802, the real interval enclosure boundary of chapter 1625, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name surface of chapter 38. The packet gives real-completion and approximation consumers a named finite route for Bishop-style interval enclosures without importing host intervals, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2140.1 (BishopIntervalEnclosure carrier)**.** *A* $\mathsf{BishopIntervalEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, U, Q, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower enclosure row. It records the displayed lower endpoint name, lower rational bounds, and lower endpoint admission cells inherited from the* $\mathsf{LocatedInterval}^{\uparrow}$ *surface.*
2. *U is the upper enclosure row. It records the displayed upper endpoint name, upper rational bounds, and upper endpoint admission cells inherited from the same* $\mathsf{LocatedInterval}^{\uparrow}$ *surface.*
3. *Q is the rational interval ledger. It records the* $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ *containment checks tying L and U to one finite interval-enclosure request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and refinement row. It records every dyadic radius, endpoint slack comparison, and refinement request consumed by the lower and upper enclosure rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational data exposed by the displayed lower and upper enclosure rows after the rational and dyadic ledgers have been read.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is reachable only after L, U, Q, D, R have been displayed, and it exposes the real-facing enclosure boundary without selecting quotient representatives.*
7. *H records componentwise* hsame *transport for lower and upper endpoint rows, rational ledger, dyadic refinement row, regular readback, real seal, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay of the route*

$$L, U \longmapsto Q \longmapsto D \longmapsto R \longmapsto S.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalEnclosure}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalIntervalEnclosure}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalEnclosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, Q, D, R, S, H, C, P, N$. It has no coordinate for host intervals, selected real endpoints, quotient equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalEnclosureUp.BishopIntervalEnclosureTasteGate single carrier alignment`

Theorem 2140.2 (BishopIntervalEnclosure NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalEnclosure}^{\uparrow}$ *carrier*

$$E = (L, U, Q, D, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalEnclosure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower enclosure row, upper enclosure row, rational interval ledger, dyadic tolerance and refinement row, regular rational readback, terminal real seal, transport, replay, provenance, and local naming;*
2. *endpoint order, requiring the displayed lower and upper enclosure rows to be admitted through the same located interval request before any rational containment row is consumed;*
3. *containment coverage, requiring Q to record the rational interval checks that place the requested real-facing datum between the lower and upper rows;*
4. *dyadic refinement, requiring D to account for every endpoint slack comparison, tolerance radius, and refinement read used by L, U, Q, R;*
5. *Real seal nonescape, requiring S to remain downstream of L, U, Q, D, R and to export no host interval, selected real endpoint, quotient equality, countable-choice selector, trichotomy branch, or ambient completeness theorem;*
6. *transport and replay stability, requiring H and C to preserve the lower endpoint, upper endpoint, rational ledger, dyadic refinement, regular readback, real seal, provenance, and local naming rows componentwise;*
7. *provenance and local naming, requiring P and N to name only the displayed Bishop interval-enclosure route.*

No Bishop interval-enclosure obligation is stored outside these rows.

Proof. Project the accepted packet $E = (L, U, Q, D, R, S, H, C, P, N)$. The projection exposes exactly the lower enclosure row, upper enclosure row, rational interval ledger, dyadic refinement row, regular rational readback, real seal, transport, replay, provenance, and local naming row.

Endpoint order is internal to the displayed located interval request. The rows L and U are read as paired endpoint-facing data before the rational interval ledger Q is available, so a consumer cannot inspect containment while ignoring either endpoint row.

Containment coverage is the role of Q. The rational ledger binds the lower and upper rows to one interval-enclosure request and records the finite containment checks that are later replayed by C.

Dyadic refinement is exhausted by D. Every tolerance radius, endpoint slack comparison, and refinement read used by L, U, Q, R is a coordinate of D, so no hidden precision source remains for a downstream consumer.

The regular readback and real seal are downstream. Row R reads only the displayed lower, upper, rational, and dyadic rows, and row S is visible only after R.

Finally H, C, P, N transport, replay, source, and name the same route. Since none of the carrier coordinates stores a host interval, selected real endpoint, quotient equality, choice selector, trichotomy branch, or ambient completeness theorem, the local NameCert surface cannot export any of them. □

Theorem 2140.3 (BishopIntervalEnclosure endpoint nonescape)**.** *Every endpoint-facing consumer of an accepted* $\mathsf{BishopIntervalEnclosure}^{\uparrow}$ *packet factors through the displayed rows*

$$L, U, Q, D, R, S, H, C, P, N.$$

Consequently the packet exports only the finite Bishop interval-enclosure route and exports no host interval, selected real endpoint, quotient equality, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an endpoint-facing consumer of an accepted packet. The only lower endpoint access is L, and the only upper endpoint access is U, so the consumer first factors through the paired endpoint rows.

The rational enclosure stage is Q. It records the containment checks attached to the same lower and upper rows, and it provides no independent host interval object.

The dyadic and regular stages are D and R. The row D supplies the finite tolerance and refinement ledger, while R reads regular rational data only after L, U, Q, D have been displayed.

The real-facing boundary is S. Since S is downstream of the endpoint, rational, dyadic, and regular rows, it cannot serve as a selected endpoint or quotient-real witness outside the displayed route.

The structural rows close the factorization. Componentwise transport in H, continuation replay in C, provenance in P, and local naming in N preserve only the same finite route, leaving no coordinate for host intervals, selected real endpoints, quotient equality, countable choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalEnclosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalEnclosure}^{\uparrow}}, \mathsf{seed})$

Constructive story: A $\mathsf{BishopIntervalEnclosure}^{\uparrow}$ packet is generated from lower and upper enclosure rows, a rational interval ledger, a DyadicRatCore tolerance and refinement row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Scope closed: Definition 2140.1, Definition 2140.2, and Definition 2140.3 seed the finite Bishop interval-enclosure route over displayed endpoint, rational ledger, dyadic refinement, regular readback, Real seal, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalEnclosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host intervals, quotient reals, selected real endpoints, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint order, containment coverage, dyadic refinement, Real seal nonescape, transport and replay stability, provenance, and local naming for the $\mathsf{BishopIntervalEnclosure}^{\uparrow}$ packet.

Chapter 2141

A Concrete Naming Certificate for $\mathsf{CofinalTailMap}^{\uparrow}$

Following Kelley-style net and filter cofinal maps and Bishop–Bridges constructive analysis, the $\mathsf{CofinalTailMap}^{\uparrow}$ packet records the finite tail-reindexing surface used when a late request on one directed window must be answered by a displayed later request on another window. It sits after the finite stream interface of chapter 126, the regular rational readback row of chapter 301, the filter-tail route of chapter 333, the Cauchy-net route of chapter 589, the real-series packet of chapter 1581, and the diagonal tail-selector route of chapter 697. The packet isolates the cofinal tail map itself: a finite monotone reindexing and budget row, not a selected subsequence, not a quotient tail, and not an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 2141.1 (CofinalTailMap carrier)**.** *A* $\mathsf{CofinalTailMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, J, U, V, M, H, C, P, N)$$

with the following displayed rows:

1. *I is the source index-window row. It records the finite source tail cuts, inspected source indices, and local order comparisons available to the request.*
2. *J is the target tail-window row. It records the finite target cuts and target requests that must be reached by cofinal reindexing.*
3. *U is the source-tail service row. It names the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, *or* $\mathsf{RealSeries}^{\uparrow}$ *source window whose late request is being transported.*
4. *V is the target-tail service row. It names the corresponding target window after reindexing and records the finite tail preservation data exposed to downstream consumers.*
5. *M is the monotone map row from the displayed source window to the displayed target window. It stores only finite comparisons proving that later source indices are sent to later target indices on the rows under inspection.*
6. *H records componentwise* hsame *transport for the source window, target window, source-tail service, target-tail service, monotone map, cofinality budget, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the reindexing route*

$$I, J, U, M \longmapsto V.$$

8. *P is the* Pkg *provenance over* $\mathsf{CofinalTailMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalTailMap}^{\uparrow}}$ *row. It includes the finite cofinality-budget row saying that every displayed target tail request in J is reached by some displayed source cut in I through M.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through the displayed source windows, target tail windows, monotone map row, cofinality-budget entry inside N, tail-window preservation data in V, componentwise transport, continuation replay, provenance, and local naming. It has no coordinate for selected subsequences, host functions, quotient tails, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CofinalTailMapUp.CofinalTailMapTasteGate single carrier alignment`

Theorem 2141.2 (CofinalTailMap NameCert obligations)**.** *For every accepted* $\mathsf{CofinalTailMap}^{\uparrow}$ *carrier $T = (I, J, U, V, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalTailMap}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source index windows, target tail windows, source-tail service, target-tail service, monotone map row, transport, replay, provenance, and local naming row;*
2. *monotone transport, requiring every displayed comparison in I to be preserved by M as a displayed comparison in J;*
3. *cofinal reachability, requiring every target tail request retained by J to have a source cut in I whose image under M reaches that request within the budget recorded by N;*
4. *tail-window preservation, requiring V to read only the target windows obtained from U through the displayed map row and cofinality budget;*
5. *classifier stability, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve I, J, U, V, M and the budget row inside N;*
6. *ledger nonescape, requiring P and N to source exactly the displayed packet and no selected subsequence, host function, quotient-tail equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No $\mathsf{CofinalTailMap}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.CofinalTailMapUp.CofinalTailMapCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 2141.1. The accepted packet exposes the source window, target window, two service rows, monotone map, and structural rows H, C, P, N.

Monotone transport is part of the displayed map row M. Since M is finite, every comparison it can use is already named by I and every transported comparison is already named by J.

Cofinal reachability is the budget component of N. For each retained target-tail request, the budget supplies a displayed source cut and records that its image under M reaches the target request.

The target-tail service row V is downstream of this route. It can read a target window only after the source service U, the map row M, and the budget entry in N have been displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for selected subsequences, host functions, quotient tails, countable choice, or ambient real completeness, the six listed rows exhaust the local certificate surface. □

Theorem 2141.3 (CofinalTailMap regular-Cauchy handoff)**.** *Let $T = (I, J, U, V, M, H, C, P, N)$ be an accepted* $\mathsf{CofinalTailMap}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *tail request transported through T factors through the displayed source window I, the monotone map row M, the cofinality budget recorded by N, and the target tail window J before it can be read through V. The handoff exports a finite reindexing route for regular-Cauchy and stream-name consumers, and it exports no countable choice, quotient equality, selected subsequence, host function, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Proof. Start with a transported $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{StreamName}^{\uparrow}$ tail request. The source side is the displayed window I together with the source-tail service row U.

The request can move toward the target side only through M. The row M supplies the finite monotone comparisons needed to send the requested source cut to a target cut in J.

Next read the cofinality budget inside N. It records that the displayed target request is reached by a source cut already present in I, so the consumer cannot introduce a separate selected subsequence or choice schedule.

The target-tail service row V is then the only readable target surface. Componentwise transport in H, replay in C, and provenance in P keep the route attached to the same displayed packet.

Therefore the regular-Cauchy or stream-name handoff factors through I, M, N, J, V and contains no quotient tail, host map equality, selected subsequence, countable-choice datum, or completeness principle for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalTailMap}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalTailMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2141.1, Definition 2141.2, and Definition 2141.3 seed the finite cofinal tail-reindexing packet over source windows, target windows, monotone map rows, cofinality budgets, tail-window preservation, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalTailMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subsequences, host functions, quotient tails, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone transport, cofinal reachability, tail-window preservation, classifier stability, ledger nonescape, and the regular-Cauchy handoff for BEDC.Derived.CofinalTailMapUp.

Constructive story: A $\mathsf{CofinalTailMap}^{\uparrow}$ packet is generated from source index windows, target tail windows, source and target tail services, one finite monotone map row, a cofinality-budget row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2142

A Concrete Naming Certificate for $\mathsf{ArchimedeanCauchyTail}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ArchimedeanCauchyTail}^{\uparrow}$ packet records the finite route by which an explicit Archimedean bound on a displayed real name supplies a stable Cauchy-tail threshold envelope for regular rational names. It sits after the explicit bound surface of chapter 430, the threshold modulus of chapter 1754, the comparison route of chapter 1738, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the finite route from a displayed Archimedean row to a regular Cauchy tail threshold; it does not select a least bound, identify quotient streams, invoke trichotomy, use countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2142.1 (Archimedean Cauchy-tail carrier)**.** *An* $\mathsf{ArchimedeanCauchyTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, A, M, E, W, Q, D, H, C, P, N)$$

with the following displayed rows:

1. *R is the displayed* $\mathsf{Real}^{\uparrow}$ *name whose tail request is being bounded. It records only the real-name seal visible through the BEDC carrier surface.*
2. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row. It records the explicit integer or dyadic bound exposed for the displayed real name, together with the finite comparison budget used to read it.*
3. *M is the* $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *threshold row. It records the finite threshold requested by a regular Cauchy tail budget after the bound row has been displayed.*
4. *E is the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *comparison row. It records the finite equivalence route that transports the threshold from the displayed regular name to the requested tail formulation.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the inspected finite stream windows, the requested tail cut, and the observation schedule consumed by A, M, E.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational observations read from the same windows and threshold request.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic radius, slack, denominator budget, and comparison witnesses used by the bound and tail rows.*

8. *H records componentwise* hsame *transport for the real name, Archimedean bound, threshold modulus, tail equivalence, stream windows, regular rational readback, dyadic ledger, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay of the route*

$$R, A, W, D \longmapsto M \longmapsto E \longmapsto Q.$$

10. *P is the* Pkg *provenance over* ArchimedeanCauchyTail$^{\uparrow}$, Real$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, RegularCauchyTailModulus$^{\uparrow}$, CauchyTailEquivalence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ArchimedeanCauchyTail}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these eleven rows. Its classifier compares accepted packets only through $R, A, M, E, W, Q, D, H, C, P, N$ and has no coordinate for host supremum data, selected least bounds, quotient stream equality, trichotomy, countable choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ArchimedeanCauchyTailUp.ArchimedeanCauchyTailTasteGate single carrier alignment`

Theorem 2142.2 (Archimedean Cauchy-tail NameCert obligations)**.** *For every accepted* ArchimedeanCauchyTail$^{\uparrow}$ *carrier*

$$T = (R, A, M, E, W, Q, D, H, C, P, N),$$

the local NameCert$_{\text{ArchimedeanCauchyTail}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed real name, Archimedean bound row, tail-threshold modulus, tail-equivalence comparison, stream windows, regular rational readback, dyadic tolerance ledger, transport, replay, provenance, and local naming row;*

2. *bound-row exposure, requiring A to display the explicit Archimedean bound for R before any threshold request is answered;*

3. *threshold extraction, requiring M to obtain the regular Cauchy tail threshold only from the displayed bound row, stream windows, and dyadic budget;*

4. *tail-equivalence stability, requiring E to transport the extracted threshold across the displayed Cauchy-tail comparison without adding quotient stream equality or a selected limit;*

5. *ledger nonescape, requiring D, H, C, P, N to preserve the displayed route and to export no host supremum, least-bound selector, trichotomy, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Archimedean-to-tail obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.ArchimedeanCauchyTailUp.ArchimedeanCauchyTailCarrier namecert obligations`

Proof. Project the accepted packet $T = (R, A, M, E, W, Q, D, H, C, P, N)$. The carrier exposes exactly the displayed real name, the Archimedean bound row, the regular Cauchy threshold row, the Cauchy-tail comparison row, the stream-window row, the regular rational readback row, the dyadic ledger, and the structural rows.

The bound exposure is first in the route. A tail request can inspect R only through the bound row A, and A records an explicit displayed bound together with the finite comparison budget that supports it.

The threshold extraction is then local. The row M reads the already displayed bound, the windows in W, and the tolerance data in D to produce a regular Cauchy tail threshold. No detached threshold source is present in the carrier.

The comparison row E transports that same threshold across the displayed Cauchy-tail equivalence. Since E has only the comparison data named in the tuple, it cannot replace the route by quotient stream equality or by a selected limiting representative.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Because the classifier has no coordinate for host supremum data, selected least bounds, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking, the five listed rows exhaust the local NameCert surface. □

Theorem 2142.3 (Archimedean Cauchy-tail threshold envelope)**.** *For every accepted* $\mathsf{ArchimedeanCauchyTail}^{\uparrow}$ *carrier*

$$T = (R, A, M, E, W, Q, D, H, C, P, N),$$

every budgeted tail request first reads the Archimedean bound row A for the displayed real name R and then obtains its Cauchy threshold through the $\mathsf{RegularCauchyTailModulus}^{\uparrow}$ *row M and the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *row E. The request may inspect only the shared* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, and the structural rows H, C, P, N.*

Proof. Begin with a budgeted tail request for the accepted packet. The request names the displayed real row R, but the only row that exposes a bound for R is A.

After A is read, the dyadic budget and finite observation schedule are fixed by D and W. The row M converts exactly those displayed data into the regular Cauchy threshold required by the request.

The row E then transfers the threshold across the displayed Cauchy-tail equivalence. The readback row Q records the regular rational observations reached by the same windows and threshold.

The structural rows H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence the request factors through A, then M and E, and no other threshold source is available. □

Theorem 2142.4 (Archimedean Cauchy-tail nonescape boundary)**.** *Every consumer of an accepted* $\mathsf{ArchimedeanCauchyTail}^{\uparrow}$ *carrier is confined to the displayed route*

$$R, A, W, D \longmapsto M \longmapsto E \longmapsto Q \longmapsto H, C, P, N.$$

Consequently the packet excludes host supremum data, a selected least bound, quotient stream equality, trichotomy, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness from the Archimedean-to-tail handoff.*

Proof. Let a consumer read an accepted carrier. The carrier definition permits the consumer to inspect only $R, A, M, E, W, Q, D, H, C, P, N$.

The real-name and bound part of the route is R, A, W, D. It displays a concrete bound row and the finite windows and dyadic budget needed to read it, but it stores neither a host supremum nor a least-bound selector.

The tail part of the route is M, E, Q. It extracts a regular Cauchy threshold and transports it through the displayed tail-equivalence row before exposing the regular rational readback.

The structural part of the route is H, C, P, N. These rows preserve and source the same finite packet, so they cannot add quotient stream equality, trichotomy, countable choice, or ambient real completeness.

Thus every accepted consumer remains inside the displayed route, and each listed escape principle is absent from the carrier surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyTail}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanCauchyTail}^{\uparrow}$ packet is generated from a displayed RealUp name, an ArchimedeanRealUp bound row, a RegularCauchyTailModulusUp threshold row, a CauchyTailEquivalenceUp comparison row, StreamNameUp windows, RegSeqRatUp readback, a DyadicRatCoreUp tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyTail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2142.1, Definition 2142.2, Definition 2142.3, and Definition 2142.4 seed the finite bridge from explicit Archimedean bounds to regular Cauchy tail thresholds.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyTail}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host supremum data, selected least bounds, quotient stream equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bound-row exposure, threshold extraction, tail-equivalence stability, ledger nonescape, replay confinement, provenance, and local naming for BEDC.Derived.ArchimedeanCauchyTailUp.

Chapter 2143

A Concrete Naming Certificate for $\mathsf{SternBrocotInterval}^{\uparrow}$

Following Hardy–Wright and Khinchin on Stern–Brocot and continued-fraction rational approximation, the $\mathsf{SternBrocotInterval}^{\uparrow}$ packet records the finite rational-bracketing surface where adjacent Stern–Brocot or Farey data become a named interval before regular rational and real-name consumers read it. It sits beside the branch certificate of chapter 1704, the adjacency ledger of chapter 1759, the dyadic arithmetic core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a finite bracketing NameCert surface for the open Real and Completion phase; it is not a quotient-real equality theorem, a trichotomy principle, a countable-choice selector, a selected representative, or an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 2143.1 (Stern–Brocot interval carrier)**.** *A* $\mathsf{SternBrocotInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, W, F, S, M, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the left rational endpoint row. It is read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *data recording numerator, denominator, sign, scale, and the endpoint tolerance ledger.*
2. *R is the right rational endpoint row, read through the same dyadic rational surface.*
3. *W is the bracket-witness row. It records denominator positivity, endpoint order, the displayed gap budget, and the fact that all later consumers inspect only the interval between L and R.*
4. *F is the* $\mathsf{FareySequence}^{\uparrow}$ *neighbor row when the bracket is supplied by adjacent Farey data.*
5. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *branch row when the same bracket is replayed by a finite left-right Stern–Brocot word.*
6. *M is the mediant refinement row. It records a finite list of mediant insertions, each with the two parent endpoints, the inserted rational, and the child bracket selected for the next row.*
7. *D is the dyadic tolerance row. It compares the displayed rational gap against the finite dyadic budgets requested by downstream stream and regular rational consumers.*
8. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *window handoff row. It records the finite stream observations and the regular rational readback available only after L, R, W, F, S, M, D have been displayed.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only downstream of the bracket, mediant, dyadic, stream, and regular rational rows.*

10. *H records componentwise* hsame *transport for endpoint, bracket, Farey, Stern–Brocot, mediant, dyadic, window, seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the finite route*

$$L, R \longmapsto W \longmapsto F, S \longmapsto M, D \longmapsto Q, E, H, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{SternBrocotInterval}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SternBrocotInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, W, F, S, M, D, Q, E, H, C, P, N$. It has no coordinate for quotient real equality, trichotomy, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SternBrocotIntervalUp.SternBrocotIntervalTasteGate single carrier alignment`

Theorem 2143.2 (Stern–Brocot interval NameCert obligations)**.** *For every accepted* $\mathsf{SternBrocotInterval}^{\uparrow}$ *carrier $I = (L, R, W, F, S, M, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SternBrocotInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed rational endpoints, bracket witnesses, Farey neighbor data, Stern–Brocot branch data, mediant refinement ledger, dyadic tolerance ledger, stream and regular rational handoff, Real seal, transport, replay, provenance, and local naming row;*

2. *endpoint exactness, requiring L and R to be read as displayed dyadic rational endpoint rows before any bracket consumer is opened;*

3. *bracket exactness, requiring W to expose denominator positivity, endpoint order, and the finite gap budget before F, S, M, D are consumed;*

4. *Farey and Stern–Brocot route compatibility, requiring F and S to name the same rational bracket when both rows are present;*

5. *mediant refinement locality, requiring every row of M to be generated from the currently displayed endpoints and to select a displayed child bracket;*

6. *window handoff exactness, requiring Q to read only finite* $\mathsf{StreamName}^{\uparrow}$ *observations and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows downstream of the bracket and dyadic tolerance rows;*

7. *Real-seal and ledger nonescape, requiring E, H, C, P, N to preserve exactly the displayed packet and to export no quotient real equality, trichotomy, countable choice, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

No Stern–Brocot interval obligation is stored outside these rows.

Proof. Project the carrier of Definition 2143.1. The analytic rows are the two rational endpoints, the bracket witness, the Farey and Stern–Brocot route rows, the mediant ledger, the dyadic tolerance row, the window handoff, and the Real seal.

Endpoint and bracket exactness follow from the row order. A consumer must read L and R as displayed rational packets and then pass through W before any refinement, window, or endpoint-facing row is visible.

The route compatibility clauses are finite. Farey adjacency and the Stern–Brocot word both name a rational interval bounded by the displayed endpoints; comparing their endpoint rows and determinant witness identifies the same bracket without invoking trichotomy or selected representatives.

The mediant and window clauses are then local projections. Each mediant row in M is generated from the current endpoints, while D and Q expose only finite dyadic budgets, stream observations, and regular rational windows.

Finally E, H, C, P, N seal, transport, replay, source, and name the same packet. Since the carrier contains no coordinate for the excluded principles, the seven listed rows exhaust the local certificate surface. □

Theorem 2143.3 (Mediant refinement)**.** *Let $I = (L, R, W, F, S, M, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{SternBrocotInterval}^{\uparrow}$ *carrier. Every mediant refinement row in M factors through the displayed bracket*

$$L, R, W \longmapsto M.$$

At each finite step the inserted rational is the mediant of the currently displayed endpoints, the selected child bracket is again recorded by endpoint rows of the same carrier shape, and the dyadic gap ledger is updated before any $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer may read the result.*

Proof. Begin with the bracket row W. It exposes the endpoint order, denominator positivity, and gap budget for the rational interval named by L and R.

Induct over the finite mediant list in M. The base row is the original bracket itself. For the successor row, the currently displayed endpoints determine the mediant numerator and denominator by finite rational arithmetic, and the row records which of the two child brackets is retained.

After each successor step, the retained endpoints remain displayed rational rows and the gap comparison is passed to D. Thus every refinement step remains inside finite endpoint, mediant, and dyadic budget data.

The window handoff is downstream of those rows. Therefore no stream, regular rational, or Real-facing consumer can inspect a refined interval without first reading the displayed mediant route. □

Theorem 2143.4 (RegSeqRat window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{SternBrocotInterval}^{\uparrow}$ *carrier factors through the finite route*

$$L, R, W, F, S, M, D \longmapsto Q.$$

Consequently the consumer receives endpoint rows, bracket witnesses, the Farey or Stern–Brocot route, finite mediant refinements, and dyadic gap budgets before receiving any regular rational window.

Proof. Project the handoff row Q. By the carrier definition it is downstream of L, R, W, F, S, M, D, so it cannot be opened from a detached stream observation or an independent regular rational sequence.

The bracket rows supply the rational bounds. The route rows F and S explain how those bounds were reached, while the mediant ledger M records the finite refinements that may narrow them.

The dyadic tolerance row D translates the displayed rational gap into the budget format expected by finite stream observations and regular rational windows. Only then does Q expose the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows.

Thus every regular rational consumer reads the bracket as a finite rational interval with a visible refinement and tolerance history, not as a quotient real, a selected representative, or a completeness result. □

Theorem 2143.5 (Real nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-phase consumer of an accepted* $\mathsf{SternBrocotInterval}^{\uparrow}$ *carrier reads the displayed chain*

$$L, R, W, F, S, M, D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

The terminal Real seal is therefore attached to a finite rational bracket, mediant refinement ledger, dyadic tolerance ledger, stream window, regular rational readback, componentwise transport, replay, provenance, and local naming row. It exports no quotient real equality, trichotomy, countable choice, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a Real-facing request. The carrier exposes the seal row E only after the window handoff row Q has been displayed.

Use Definition 2143.4. The row Q itself is downstream of the endpoint rows, bracket witness, route rows, mediant ledger, and dyadic tolerance ledger, so the seal cannot bypass the finite rational interval data.

The structural rows H, C, P, N preserve the same chain by componentwise transport, displayed replay, provenance, and local naming. They add no additional analytic coordinate.

Since neither E nor the structural rows contain quotient real equality, trichotomy, countable choice, selected representatives, or ambient completeness, every Real and Completion-phase consumer remains inside the displayed NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocotInterval}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SternBrocotInterval}^{\uparrow}}$, seed)

Scope closed: Definition 2143.1, Definition 2143.2, Definition 2143.3, Definition 2143.4, and Definition 2143.5 seed the finite rational-bracketing surface from Stern–Brocot and Farey rows through mediant refinement, dyadic tolerance, stream windows, RegSeqRat readback, and Real sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SternBrocotInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, bracket exactness, Farey and Stern–Brocot route compatibility, mediant refinement locality, RegSeqRat window handoff, Real nonescape, structural transport, provenance, and local naming for BEDC.Derived.SternBrocotIntervalUp.

Constructive story: A $\mathsf{SternBrocotInterval}^{\uparrow}$ packet is generated from left and right rational endpoint rows, a bracket witness row, FareySequence and SternBrocot route rows, a mediant refinement ledger, a DyadicRatCore tolerance row, StreamName and RegSeqRat window handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2144

A Concrete Naming Certificate for $\mathsf{PrincipalFilter}^{\uparrow}$

Following Bourbaki and Kelley on filters, the $\mathsf{PrincipalFilter}^{\uparrow}$ packet records the principal filter generated by one displayed finite base packet. It sits after the finite filter-base surface of chapter 1601, beside the cofinite route of chapter 1564, and before completion-facing consumers read the Cauchy-filter boundary of chapter 333 or the metric-completion route of chapter 1506. The packet is a finite human-origin base case for L10 filter completion routes; it is not quotient filter equality, an ultrafilter principle, a selected limit, countable choice, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2144.1 (PrincipalFilter carrier)**.** *A* $\mathsf{PrincipalFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, U, M, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the generator packet. It records the single displayed base element and the finite membership witnesses saying which reads contain it.*
2. *U is the upward-closure row. It records each accepted superset read only by displaying the generator containment already carried by G.*
3. *M is the finite meet and refinement row. It records that two accepted reads refine back to the same generator packet, so their common read stays inside the displayed finite base.*
4. *R is the* $\mathsf{CauchyFilter}^{\uparrow}$ *anchor row. It exposes the principal-filter data only as a finite anchored base for completion-facing consumers.*
5. *H records componentwise* hsame *transport for the generator, upward-closure, finite meet, Cauchy-filter anchor, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the route*

$$G \longmapsto U, M \longmapsto R.$$

7. *P is the* Pkg *provenance over* $\mathsf{PrincipalFilter}^{\uparrow}$*,* $\mathsf{FilterBase}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PrincipalFilter}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these eight rows. Its classifier compares accepted packets only through G, U, M, R, H, C, P, N and has no coordinate for quotient filter equality, ultrafilters, selected limits, countable choice, ambient completion, $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PrincipalFilterUp.PrincipalFilterTasteGate single carrier alignment`

Theorem 2144.2 (PrincipalFilter NameCert obligation surface)**.** *For every accepted* $\mathsf{PrincipalFilter}^{\uparrow}$ *carrier*

$$F = (G, U, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrincipalFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the generator packet, upward-closure row, finite meet and refinement row, Cauchy-filter anchor row, transport, replay, provenance, and local naming row;*
2. *upward closure, requiring each accepted read to display containment of the same generator packet;*
3. *finite-meet closure, requiring two accepted reads to refine through the displayed generator into an accepted common read;*
4. *generator stability, requiring componentwise* hsame *transport to preserve the generator row before any downstream row is read;*
5. *handoff, requiring every CauchyFilter or MetricCompletion consumer to receive only the finite anchored base row R;*
6. *ledger refusal, excluding quotient filter equality, ultrafilters, selected limits, countable choice, ambient completion, and* $\mathsf{Real}^{\uparrow}$ *completeness from the carrier inventory.*

No principal-filter NameCert obligation is stored outside these rows.

Proof. Project the accepted packet $F = (G, U, M, R, H, C, P, N)$. Carrier admission is exactly the display of these eight rows, so no host filter object is introduced.

The upward-closure row reads every accepted superset through the generator packet G. The finite-meet row then uses the same generator as the common displayed refinement for any two accepted reads.

Generator stability is componentwise. The hsame row first transports G and then transports U, M, R, C, P, N over the same generator coordinate.

The handoff row is R. It is downstream of G, U, M and therefore exposes the principal filter only as a finite anchored base for CauchyFilter and MetricCompletion consumers.

Finally the carrier has no row for quotient filters, ultrafilters, selected limits, countable choice, ambient completion, or real completeness. The ledger refusal follows by inspection of the displayed inventory. □

Theorem 2144.3 (PrincipalFilter refinement handoff)**.** *Every accepted* $\mathsf{PrincipalFilter}^{\uparrow}$ *read factors through the displayed generator packet into the* $\mathsf{FilterBase}^{\uparrow}$ *finite directed-base surface. The exported route is*

$$G \longmapsto U, M \longmapsto R \longmapsto H, C, P, N,$$

where G supplies the single base element, U supplies upward closure, M supplies finite common refinement through that same generator, and R supplies the CauchyFilter anchor. Thus the handoff is a finite FilterBase refinement route, not quotient filter equality, not an ultrafilter, not a selected limit, and not countable choice.

Proof. Start with an accepted read. By carrier admission it has a generator row G, and every upward read in U records containment of that generator.

For two accepted reads, the finite-meet row M returns to the same generator packet. Hence the common refinement is already displayed inside the finite $\mathsf{FilterBase}^{\uparrow}$ surface, rather than supplied by a host filter equality.

The anchor row R exports this directed-base data to the CauchyFilter side. The transport, replay, provenance, and naming rows preserve exactly the same route, so no consumer can bypass the displayed generator. □

Theorem 2144.4 (PrincipalFilter completion anchor)**.** *Every CauchyFilter or MetricCompletion consumer of an accepted* $\mathsf{PrincipalFilter}^{\uparrow}$ *carrier receives the packet only as a finite anchored base:*

$$G, U, M \longmapsto R \longmapsto H, C, P, N.$$

The consumer may read generator containment, upward closure, finite common refinement, the CauchyFilter anchor, componentwise transport, displayed replay, package provenance, and local naming. It receives no quotient filter equality, ultrafilter extension, selected limit, countable-choice schedule, ambient completion, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Let a completion-facing consumer read the packet. The route first displays G, U, M, so the consumer sees the single generator, all upward reads, and the finite common-refinement evidence before any CauchyFilter anchor is available.

The row R is the only completion-facing anchor. It is therefore a finite base handoff to CauchyFilter and MetricCompletion consumers, not a quotient-filter carrier or a selected completion point.

The structural rows H, C, P, N preserve, replay, source, and name that same route. Since the carrier inventory contains no quotient equality, ultrafilter, selected limit, countable-choice schedule, ambient completion, or real-completeness row, the consumer cannot extract any of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrincipalFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{PrincipalFilter}^{\uparrow}$ packet is generated from one displayed generator packet, upward-closure reads, finite meet and refinement reads, a CauchyFilter anchor row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrincipalFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2144.1, Definition 2144.2, Definition 2144.3, and Definition 2144.4 seed the finite principal-filter base case used by L10 CauchyFilter and MetricCompletion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrincipalFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilters, quotient filters, selected limits, countable choice, ambient completion, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upward closure, finite-meet closure, generator stability, FilterBase handoff, CauchyFilter and MetricCompletion anchor confinement, ledger refusal, provenance, and local naming for BEDC.Derived.PrincipalFilterUp.

Chapter 2145

A Concrete Naming Certificate for $\mathsf{KuratowskiClosure}^{\uparrow}$

Following Kuratowski's closure-operator axioms and standard point-set topology, the $\mathsf{KuratowskiClosure}^{\uparrow}$ packet records topological closure as a finite BEDC NameCert surface. It sits over the generated-open and neighbourhood rows of chapter 88, the located distance tests of chapter 57, and the certified sequence-limit route of chapter 1571. The packet gives topology, metric, compactness, and sequence-facing consumers a canonical closure-operator object without importing host powersets, arbitrary complements, excluded middle, selected convergent subsequences, or an ambient semantic closure theorem.

Definition 2145.1 (Kuratowski closure carrier)**.** *A* $\mathsf{KuratowskiClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, N, W, Q, H, C, P, L)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row. It records the indexed open rows, finite-intersection rows, union rows, and neighbourhood readback available to closure consumers.*
2. *S is the subset or source-membership row whose closure is being named. It records only displayed membership witnesses over the carrier read by T.*
3. *N is the neighbourhood ledger. Each row records a named neighbourhood of a candidate point, the open-row classifier that admits it, and the finite request asking whether the neighbourhood meets S.*
4. *W is the closure-membership witness row. It records, for each accepted candidate point, the finite responses showing that every displayed neighbourhood request in N reaches a displayed member row of S.*
5. *Q is the* $\mathsf{SequentialClosure}^{\uparrow}$ *comparison row. It is present only as a displayed comparison route from sequence-limit closure evidence to the same neighbourhood ledger, not as a replacement for topological closure.*
6. *H records componentwise* hsame *transport for the topology row, source row, neighbourhood ledger, membership witness rows, sequential comparison row, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay from a closure request through T, S, N, W, Q.*

8. *P is the* Pkg *provenance over* $\mathsf{KuratowskiClosure}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SequentialClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *L is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiClosure}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through $T, S, N, W, Q, H, C, P, L$ and has no coordinate for host powersets, arbitrary complements, excluded middle, open-cover compactness, selected subsequences, ambient semantic closure, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.KuratowskiClosureUp.KuratowskiClosureUp`

Theorem 2145.2 (Kuratowski closure NameCert obligations)**.** *For an accepted* $\mathsf{KuratowskiClosure}^{\uparrow}$ *carrier*

$$K = (T, S, N, W, Q, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiClosure}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the ambient topology row, subset or source row, neighbourhood ledger, closure-membership witness rows, sequential-closure comparison row, transport, replay, provenance, and local naming row;*

2. *neighbourhood-meets-source exactness, requiring every displayed closure-membership read to pass through N and W before it can claim that a neighbourhood of the candidate point meets S;*

3. *topology-row stability, requiring finite-intersection and union reads used by the Kuratowski laws to remain inside the displayed* $\mathsf{Topology}^{\uparrow}$ *row T;*

4. *sequential comparison discipline, requiring the row Q to compare certified sequence-limit closure evidence with the same T, S, N, W ledger rather than replacing the topological closure carrier;*

5. *classifier transport, requiring* hsame *comparison to preserve the topology, source, neighbourhood, witness, comparison, replay, provenance, and local naming rows componentwise;*

6. *non-escape, excluding host powersets, arbitrary complement choice, excluded middle, open-cover compactness, selected convergent subsequences, and ambient semantic closure.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2145.1. The accepted packet exposes exactly the ambient topology row, source-membership row, neighbourhood ledger, closure-membership witness rows, sequential comparison row, and structural rows H, C, P, L.

Neighbourhood-meets-source exactness follows from the route N, W. A closure-membership read may answer a candidate point only after the named neighbourhood request in N and the displayed source-meeting response in W have both been read.

Topology-row stability is inherited from T. The finite-intersection and union rows used to express the Kuratowski closure laws are the rows already displayed by the topology packet, so no host powerset or complement surface is added.

The comparison row Q is downstream of the same ledger. It can translate certified sequence-limit evidence into neighbourhood-meeting evidence only through T, S, N, W, and therefore cannot supply arbitrary subsequence choice or quotient stream equality.

Finally H, C, P, L preserve and name only the displayed coordinates. Since the excluded host objects have no carrier row, no replay edge, and no provenance entry, the listed obligations exhaust the local NameCert surface. □

Theorem 2145.3 (Kuratowski closure idempotence)**.** *Let*

$$K = (T, S, N, W, Q, H, C, P, L)$$

be an accepted $\mathsf{KuratowskiClosure}^{\uparrow}$ *carrier, and let* $\overline{S}$ *denote the closure-membership row named by* W *inside the same packet. The closure packet generated from* $\overline{S}$ *over the unchanged topology row* T *is classified by* $\mathsf{msame}_{\mathsf{KuratowskiClosure}^{\uparrow}}$ *with the original packet* K*. Equivalently, applying the displayed closure operation twice reads the same finite neighbourhood ledger, the same membership witness rows, the same sequential-comparison route, and the same transport, replay, provenance, and local naming rows.*

Proof. Start from the accepted carrier K. A first closure read exposes the neighbourhood ledger N and the witness rows W over the source row S.

For the second closure read, the source row is the displayed closure-membership row $\overline{S}$. A neighbourhood request for a point of the second closure is answered by replaying the same neighbourhood row in N and then using the witness row in W that already certifies a meeting point for the first closure read.

The Kuratowski closure law used here is therefore idempotence of the displayed neighbourhood-meeting ledger: the second pass introduces no new topology row, no new source classifier, and no new witness coordinate. It only reuses the finite T, N, W rows.

Componentwise transport through H and replay through C identify the two packets. Provenance and local naming through P, L are unchanged, and the sequential comparison row Q remains attached to the same ledger. Hence the two closure packets are classified by $\mathsf{msame}_{\mathsf{KuratowskiClosure}^{\uparrow}}$. □

Theorem 2145.4 (Kuratowski closure finite-union handoff)**.** *Let*

$$K = (T, S, N, W, Q, H, C, P, L)$$

be an accepted $\mathsf{KuratowskiClosure}^{\uparrow}$ *carrier whose source row* S *is displayed as the binary union of two source-membership rows* S_0 *and* S_1 *through the finite-union rows of the ambient* $\mathsf{Topology}^{\uparrow}$ *packet* T*. Every closure read of that binary-union source factors through the displayed finite-union rows of* T*, the two source-membership rows* S_0, S_1*, the neighbourhood ledger* N*, the paired witness rows in* W*, and the existing transport, replay, provenance, and local naming rows* H, C, P, L*. The handoff introduces no host powerset, arbitrary complement surface, excluded-middle branch, selected subsequence, or ambient semantic closure object.*

Proof. Project the accepted carrier K. The only topology operations visible to a closure consumer are the finite-intersection and union rows already stored in T, and the source being closed is the displayed binary-union row built from S_0 and S_1.

For a neighbourhood request in N, use the finite-union row from T before reading witnesses. The request is answered by one of the two displayed source routes: either the witness row in W meets the S_0 side, or it meets the S_1 side. Both routes remain paired with the same neighbourhood ledger and therefore use the same closure-membership classifier.

Transport and replay are then inherited componentwise. The rows H and C identify the topology row, the two source-membership rows, the neighbourhood ledger, and the paired witnesses, while P and L preserve provenance and the local $\mathsf{NameCert}_{\mathsf{KuratowskiClosure}^{\uparrow}}$ name. Since no carrier coordinate stores host powersets or complement choices, the binary-union handoff is exhausted by the displayed $T, S_0, S_1, N, W, H, C, P, L$ rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiClosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2145.1, Definition 2145.2, Definition 2145.3, and Definition 2145.4 seed the finite topological closure-operator packet over displayed topology, subset, finite-union, neighbourhood, witness, sequential-comparison, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, arbitrary complements, excluded middle, open-cover compactness, selected convergent subsequences, ambient semantic closure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood-meets-source exactness, topology-row stability, finite-union handoff, sequential comparison discipline, classifier transport, idempotence, and non-escape for BEDC.Derived.KuratowskiClosureUp.KuratowskiClosureNameCert_obligations.

Constructive story: A $\mathsf{KuratowskiClosure}^{\uparrow}$ packet is generated from a TopologyUp row, a subset or source-membership row, neighbourhood ledgers, closure-membership witness rows, a SequentialClosureUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2146

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyTailComparison}^{\uparrow}$ packet records the finite common-tail comparison surface used when two regular Cauchy real names must answer an equality or endpoint-comparison request through one displayed late window. It sits over the regular rational rows of chapter 301, the finite window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the route-order handoff of chapter 1568, the zero-tail witness surface of chapter 380, and the terminal seal of chapter 38. The packet gives later $\mathsf{Real}^{\uparrow}$ equality and endpoint-comparison chapters a single finite comparison object rather than repeated route-order prose; it is not quotient stream equality, a selected limit, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2146.1 (Regular Cauchy tail-comparison carrier)**.** *A* $\mathsf{RegularCauchyTailComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, W, D, I, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two regular Cauchy source rows. Each is read only through its displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *surface before a real seal or comparison answer is available.*
2. *W is the common* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It records the shared late cut, inspected indices, synchronized endpoint windows, and comparison requests used for both sources.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested equality or endpoint-comparison radius, comparison slack, dyadic enclosure budget, and exhausted finite windows.*
4. *I is the* $\mathsf{CauchyReindexing}^{\uparrow}$ *route row. It records the finite reindexing handoff that places the X and Y observations in the same route order before any comparison read is exported.*
5. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff row. It is present exactly when an equality request is being read, and it records the displayed tail-difference route used to certify that the two late windows collapse to a null sequence.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary for the comparison read. It becomes available only after X, Y, W, D, I and, for equality reads, Z have been displayed.*
7. *H records componentwise* hsame *transport for the two source rows, shared window row, dyadic ledger, reindexing route, zero-tail row, real seal, replay, provenance, and local naming row.*

8. *C records displayed* Cont *replay of the route*

$$X, Y, W, D \longmapsto I \longmapsto Z \longmapsto E.$$

For a non-equality endpoint comparison, the Z stage is the displayed empty equality branch rather than a hidden quotient-equality read.

9. *P is the* Pkg *provenance over* RegularCauchyTailComparison$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyReindexing$^{\uparrow}$, NullSequence$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{RegularCauchyTailComparison}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these eleven rows. Its classifier compares accepted packets only through $X, Y, W, D, I, Z, E, H, C, P, N$ and has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailComparisonUp.RegularCauchyTailComparisonTasteGate single carrier alignment`

Theorem 2146.2 (Regular Cauchy tail-comparison NameCert obligations)**.** *For every accepted* RegularCauchyTailComparison$^{\uparrow}$ *carrier*

$$T = (X, Y, W, D, I, Z, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyTailComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy source rows, common stream-window row, dyadic tolerance ledger, reindexing route, zero-tail handoff row, terminal real seal, transport, replay, provenance, and local naming row;*

2. *common-window discipline, requiring both source rows to be read through the same W row before either equality or endpoint-comparison evidence is exported;*

3. *dyadic tolerance exactness, requiring D to provide the requested radius, slack, enclosure budget, and finite-window exhaustion consumed by the comparison read;*

4. *route-order discipline, requiring I to align the displayed X and Y observations before any* Real$^{\uparrow}$ *seal boundary or equality branch can be read;*

5. *zero-tail confinement, requiring Z to appear only for equality requests and to record the displayed* NullSequence$^{\uparrow}$ *handoff rather than quotient stream equality;*

6. *seal-boundary discipline, requiring E to remain downstream of X, Y, W, D, I and the equality branch Z when that branch is requested;*

7. *transport, replay, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise;*

8. *non-escape, excluding quotient stream equality, selected limits, host real equality, trichotomy, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No regular Cauchy tail-comparison obligation is stored outside these rows.

Proof. Project the accepted packet $T = (X, Y, W, D, I, Z, E, H, C, P, N)$. The carrier exposes exactly the two source rows, one shared finite-window row, the dyadic tolerance ledger, the route-order handoff, the zero-tail branch, the terminal real seal, and the structural rows.

The comparison route starts with a common window. The row W fixes the late cut and inspected indices for both X and Y, so a comparison read cannot introduce two unrelated StreamName schedules.

The dyadic and route-order data are then forced. The row D supplies the precision budget read by the comparison, and I reorders the displayed observations into the common Cauchy route before the seal row can be reached.

For equality reads, the only equality-specific coordinate is Z. It records a $\mathsf{NullSequence}^{\uparrow}$ zero-tail handoff from the displayed late-window differences; for endpoint comparisons, the same carrier exposes the empty equality branch and therefore no quotient stream-equality coordinate.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite rows. Since none of the excluded host objects has a carrier coordinate, replay edge, provenance entry, or local naming row, the listed obligations exhaust the local NameCert surface. □

Theorem 2146.3 (Regular Cauchy tail-comparison common-window handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *equality or endpoint-comparison read of an accepted* $\mathsf{RegularCauchyTailComparison}^{\uparrow}$ *carrier factors through the finite route*

$$X, Y, W, D \longmapsto I \longmapsto Z \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives two displayed regular Cauchy rows, one shared StreamName finite window, DyadicRatCore tolerance accounting, a CauchyReindexing route-order handoff, the NullSequence zero-tail branch exactly for equality reads, the terminal RealUp seal boundary, componentwise transport, continuation replay, package provenance, and local naming. It receives no quotient stream equality, selected limit, host real equality, trichotomy, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted equality or endpoint-comparison read. The source rows are X and Y, and the carrier requires both rows to be observed through the common finite-window row W.

The dyadic ledger D fixes the requested radius, slack, enclosure budget, and exhausted windows attached to that shared observation. The route-order row I then aligns the two displayed regular Cauchy observations before any real seal is visible.

When the read is an equality request, the zero-tail branch Z supplies the displayed null-sequence handoff from the aligned tail differences. When the read is an endpoint comparison, the carrier uses the displayed empty equality branch, so the comparison still passes through the same route without adding a quotient-equality coordinate.

Only after the shared window, tolerance ledger, reindexing route, and relevant zero-tail branch have been displayed can E expose the $\mathsf{Real}^{\uparrow}$ seal boundary. The structural rows H, C, P, N preserve that same finite route under componentwise transport, continuation replay, provenance, and local naming.

Induction over the displayed route order proves that no later consumer can skip a row: the base stage reads X, Y, W, D, the reindexing step reads I, the equality-branch step reads Z when requested, and the terminal step reads E, H, C, P, N. Because there is no coordinate outside this route, the consumer cannot obtain quotient stream equality, selected limits, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailComparison}^{\uparrow}$ packet is generated from two regular Cauchy source rows, one shared StreamName finite-window row, a DyadicRatCore tolerance ledger, a CauchyReindexing route row, a NullSequence

zero-tail handoff when equality is requested, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTailComparison}\uparrow}$, seed)

Scope closed: Definition 2146.1, Definition 2146.2, and Definition 2146.3 seed the finite common-tail comparison route over shared StreamName windows, RegSeqRat source rows, DyadicRatCore tolerances, CauchyReindexing handoff, NullSequence equality branch, RealUp seal boundary, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailComparison}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-window discipline, dyadic tolerance exactness, route-order discipline, zero-tail confinement, seal-boundary discipline, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailComparisonUp.

Chapter 2147

A Concrete Naming Certificate for $\mathsf{CauchyTailIntersection}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchyTailIntersection}^{\uparrow}$ packet records the finite common tail-window intersection retained after two displayed regular-Cauchy windows have been compared and synchronized. It sits after the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the tail-comparison route of chapter 387, and the shared threshold surface of chapter 560. The packet names the retained intersection carrier itself: a finite row that can be handed to later $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers without choosing a quotient stream, selecting a limit, or invoking ambient completeness.

Definition 2147.1 (CauchyTailIntersection carrier)**.** *A* $\mathsf{CauchyTailIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, W_0, W_1, I, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two regular-Cauchy source rows whose finite tail windows are being compared.*
2. *W_0 and W_1 are the displayed* $\mathsf{StreamName}^{\uparrow}$ *tail-window rows retained from the two sources after the sibling comparison and meet packets have fixed the visible cuts.*
3. *I is the retained common finite tail-window intersection. It stores exactly the inspected cuts lying in both displayed tails, together with their local order and membership evidence.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the retained intersection. It records the dyadic precision requests and budget comparisons used by the common tail rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It reads the retained intersection through the regular rational sequence interface and exposes no independent stream or quotient coordinate.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row. It is visible only after the intersection, dyadic ledger, and regular readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the source rows, windows, retained intersection, dyadic ledger, regular readback, real handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$X, Y, W_0, W_1 \longmapsto I \longmapsto D \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailIntersection}^{\uparrow}$, $\mathsf{CauchyTailComparison}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailIntersection}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these twelve rows. Its classifier compares accepted packets only through the two source rows, the two displayed windows, the retained intersection, the dyadic ledger, the regular readback, the real handoff, componentwise transport, continuation replay, provenance, and local naming. It has no coordinate for quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyTailIntersectionUp.CauchyTailIntersectionTasteGate single carrier alignment`

Theorem 2147.2 (CauchyTailIntersection NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailIntersection}^{\uparrow}$ *carrier*

$$T = (X, Y, W_0, W_1, I, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailIntersection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two source rows, two displayed windows, retained intersection, dyadic ledger, regular readback, real handoff, transport, replay, provenance, and local naming row;*
2. *comparison admission, requiring W_0 and W_1 to be supplied by the sibling* $\mathsf{CauchyTailComparison}^{\uparrow}$ *and* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *routes before I can be read;*
3. *intersection exactness, requiring I to retain only cuts displayed in both windows and to retain every displayed cut certified by both windows inside the finite packet;*
4. *tolerance compatibility, requiring D to read only dyadic tolerance requests attached to the retained intersection;*
5. *readback exactness, requiring R to be the only* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of the retained intersection and E to be the only* $\mathsf{Real}^{\uparrow}$ *handoff downstream of R;*
6. *structural exhaustion, requiring H, C, P, N to preserve, replay, source, and name the listed rows without exporting quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2147.1. The accepted packet displays exactly the two source rows, two tail windows, retained intersection, dyadic ledger, regular readback, real handoff, and structural rows.

Comparison admission is read from the sibling routes named in the provenance row P. The comparison and meet packets expose the two compatible finite tail windows before the local intersection row I can be inspected.

Intersection exactness is a projection of I. Since I is a finite row, membership is checked only against the displayed cuts in W_0 and W_1, and every retained cut carries both displayed membership entries.

Tolerance compatibility is read from D. The dyadic ledger is downstream of I, so every tolerance request is attached to an already retained common cut rather than to a hidden tail oracle.

Readback exactness is read from R and E. The regular readback consumes I and D, and the real handoff is visible only after that readback has been displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Because the carrier has no quotient, selected-limit, choice, host-equality, trichotomy, or completeness coordinate, the six listed obligation rows exhaust the local certificate surface. □

Theorem 2147.3 (CauchyTailIntersection window meet)**.** *Let* $T = (X, Y, W_0, W_1, I, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyTailIntersection}^{\uparrow}$ *carrier. Every consumer read of a retained common tail cut factors through the displayed route*

$$X, Y \longmapsto W_0, W_1 \longmapsto I.$$

The row I *is therefore the unique retained finite intersection surface available to the packet, and no consumer can replace it by an independent tail, quotient stream, selected limit, host equality proof, trichotomy branch, or ambient completeness principle.*

Proof. Start with a consumer read of a retained common tail cut. Projection of the accepted carrier supplies the source rows X, Y and the displayed windows W_0, W_1 before the intersection row is available.

The sibling comparison and meet routes inside P account for the two displayed windows. Their role is to expose finite compatible tail cuts, not to export a completed tail object.

Now inspect I. A cut is readable from I only with membership evidence from both W_0 and W_1, so the consumer cannot bypass either displayed window.

The transport and replay rows H and C preserve the same route through hsame and Cont. The local naming row N names that retained intersection and no second intersection coordinate.

Thus every retained common cut factors through X, Y, W_0, W_1, I, and the packet exports no independent tail, quotient stream, selected limit, host equality, trichotomy branch, or ambient completeness principle. □

Theorem 2147.4 (CauchyTailIntersection RegSeqRat handoff)**.** *Let* $T = (X, Y, W_0, W_1, I, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyTailIntersection}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the retained common tail-window intersection factors through*

$$I \longmapsto D \longmapsto R \longmapsto E$$

after the source-window route X, Y, W_0, W_1 *has been displayed. The handoff exports the finite retained intersection, dyadic tolerance ledger, regular rational readback, and real-name boundary, and it exports no quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness.*

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer request. The source-window route has already displayed X, Y, W_0, W_1 and the retained common intersection I.

The dyadic ledger D is the next visible row. It reads tolerance requests only from the retained intersection, so it cannot introduce a separate budget schedule or unbounded tail selector.

The regular readback R consumes I through D. Since R is the only $\mathsf{RegSeqRat}^{\uparrow}$ row in the carrier, the consumer has no alternate regular-rational channel.

The real handoff E is downstream of R. It seals the displayed finite route for $\mathsf{Real}^{\uparrow}$ consumers but does not assert a host real equality or completeness theorem.

Componentwise transport, continuation replay, package provenance, and local naming preserve this same chain. Therefore every regular or real-facing read factors through I, D, R, E and exports none of the excluded objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailIntersection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailIntersection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2147.1, Definition 2147.2, Definition 2147.3, and Definition 2147.4 seed the finite retained common tail-window intersection carrier for regular-Cauchy and real-name consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailIntersection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison admission, intersection exactness, tolerance compatibility, regular readback exactness, real handoff exactness, and structural exhaustion for BEDC.Derived.CauchyTailIntersection

Constructive story: A $\mathsf{CauchyTailIntersection}^{\uparrow}$ packet is generated from two regular-Cauchy source rows, two displayed finite tail windows, one retained common intersection row, a dyadic tolerance ledger, a regular rational readback, a real-name handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2148

A Concrete Naming Certificate for $\mathsf{YonedaCompletion}^{\uparrow}$

Following Lawvere's enriched metric spaces and the Isbell–Yoneda completion tradition, the $\mathsf{YonedaCompletion}^{\uparrow}$ packet records a presheaf-style completion route as finite BEDC NameCert data. It sits over the formal-ball surfaces of chapter 1510 and chapter 2012, the metric source of chapter 57, the Cauchy-net route of chapter 589, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic radius ledger of chapter 291, and the real-name seal of chapter 38. The packet gives completion consumers a finite Yoneda-style handoff without quotient completion, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2148.1 (Yoneda completion carrier)**.** *A* $\mathsf{YonedaCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (M, B, F, D, S, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier, displayed distance observations, and finite comparison histories read by completion consumers.*
2. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *radius-tagged observation row over M.*
3. *F is the* $\mathsf{FormalBallCompletion}^{\uparrow}$ *row, exposing the rounded formal-ball completion route available before any Yoneda-facing read is exported.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, recording positive-radius witnesses, dyadic refinements, strict comparisons, and radius-sum budgets used by B and F.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for center observations, radius requests, and presheaf-profile probes.*
6. *Q is the* $\mathsf{CauchyNet}^{\uparrow}$ *comparison row. It records the directed-window route through which a finite Yoneda profile can hand off to ordinary Cauchy data.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the retained stream windows and dyadic budgets.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal, reachable only through the displayed D, S, R route and not as an ambient completeness principle.*
9. *H records componentwise* hsame *transport for metric sources, formal balls, formal-ball completion rows, dyadic ledgers, stream windows, Cauchy-net comparisons, regular readbacks, real seals, replay data, provenance, and local naming.*

10. *C records displayed* Cont *replay of the route*

$$M, B, F, D, S \longmapsto Q, R \longmapsto A.$$

11. *P is the* Pkg *provenance over* $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{YonedaCompletion}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these twelve rows. Its classifier compares accepted packets only through $M, B, F, D, S, Q, R, A, H, C, P, N$ and has no coordinate for quotient completion, selected limit representatives, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.YonedaCompletionUp.TasteGate.YonedaCompletionTasteGate single carrier alignment`

Theorem 2148.2 (Yoneda completion NameCert obligations)**.** *For an accepted* $\mathsf{YonedaCompletion}^{\uparrow}$ *carrier*

$$Y = (M, B, F, D, S, Q, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{YonedaCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric source row, formal-ball row, formal-ball completion row, dyadic radius ledger, stream-window schedule, Cauchy-net comparison row, regular rational readback, real seal, transport, replay, provenance, and local naming row;*
2. *Yoneda-profile exposure, requiring every completion-facing profile to be read as a finite formal-ball family over M, B, F before any Cauchy-net or real-facing handoff is available;*
3. *radius and window exactness, requiring each formal-ball radius, refinement, and comparison used by the profile to be accounted for in D and inspected through S;*
4. *Cauchy handoff discipline, requiring Q to compare the finite profile with a displayed* $\mathsf{CauchyNet}^{\uparrow}$ *route rather than replacing it with a quotient of Cauchy names;*
5. *regular rational and real readback discipline, requiring R and A to be downstream of the same D, S, Q ledger;*
6. *classifier transport, requiring H and C to preserve the displayed route componentwise and to replay only the listed coordinates;*
7. *non-escape, excluding quotient completion, selected limits, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2148.1. The accepted packet exposes exactly the metric, formal-ball, formal-ball completion, dyadic, stream-window, Cauchy-net comparison, regular readback, real seal, and structural rows.

Yoneda-profile exposure is forced by the order of the displayed rows. A completion-facing profile first reads M, B, F as finite formal-ball data, so it cannot begin from a quotient completion object or a selected representative.

Radius and window exactness follows from D and S. Every radius comparison and every inspected center observation used by the profile has a dyadic budget and a finite stream-window address before the profile can be consumed.

The Cauchy handoff is the row Q. It compares the same finite profile with a displayed directed-window route, and therefore supplies no quotient of Cauchy names and no countable-choice selector.

The regular rational and real readbacks are downstream. The rows R and A can be read only after the dyadic, stream-window, and Cauchy-net comparison rows have been displayed.

Finally H, C, P, N transport, replay, source, and name only the listed rows. Since the excluded host principles have no coordinate in the carrier, they cannot appear as local NameCert obligations. □

Theorem 2148.3 (Yoneda completion formal-ball density)**.** *Let*

$$Y = (M, B, F, D, S, Q, R, A, H, C, P, N)$$

be an accepted $\mathsf{YonedaCompletion}^{\uparrow}$ *carrier. Every displayed Yoneda profile exported by* Y *is densely probed by finite* $\mathsf{FormalBall}^{\uparrow}$ *data: for each retained profile request there is a formal-ball row in* B*, a formal-ball completion read in* F*, a dyadic radius budget in* D*, and a stream-window address in* S *whose replay through* C *reaches the same profile request. Thus density is recorded as finite formal-ball coverage, not as a selected limit and not as an ambient completion theorem.*

Proof. Fix a retained profile request. By carrier admission the request is part of the displayed $\mathsf{YonedaCompletion}^{\uparrow}$ packet, so its only profile-facing coordinates are M, B, F, D, S before any downstream readback occurs.

The formal-ball row B supplies the radius-tagged probe over the metric source M. The formal-ball completion row F records that the same probe participates in the rounded completion route.

The rows D and S bind the probe to finite data. The radius is accounted for by the dyadic ledger D, and the inspected center observation has a stream-window address in S.

Replay through C identifies this finite formal-ball coverage with the retained profile request. The real-facing rows R, A and the Cauchy-net comparison row Q are downstream of the same coverage route, so they cannot supply a selected limit or ambient completeness principle. □

Theorem 2148.4 (Yoneda completion regular Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{YonedaCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$M, B, F, D, S \longmapsto Q \longmapsto R \longmapsto A.$$

Consequently the packet hands finite Yoneda-profile data to regular Cauchy consumers only through the displayed $\mathsf{FormalBall}^{\uparrow}$*,* $\mathsf{FormalBallCompletion}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyNet}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. It does not export quotient completion, selected limits, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier and project its readback rows. A $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can reach R or A only by following the replay route named in Definition 2148.1.

The first stage of that route is formal-ball data over the metric source. The rows M, B, F expose the metric observations, formal-ball probes, and formal-ball completion reads.

The second stage binds those probes to finite budgets. The dyadic ledger D and stream schedule S record the radius comparisons and inspected windows used by the profile.

The Cauchy comparison row Q then supplies the ordinary directed-window handoff. Since Q is downstream of M, B, F, D, S, it cannot replace the finite profile by a quotient Cauchy object or a selected limit.

Finally R and A are read from that same route. Componentwise transport and replay through H and C, together with provenance and local naming through P, N, preserve the factorization and expose no additional completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{YonedaCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{YonedaCompletion}^{\uparrow}$ packet is generated from a displayed MetricUp source, FormalBallUp probes, FormalBallCompletionUp rounded reads, DyadicRatCore radius ledgers, StreamName windows, CauchyNet comparisons, RegSeqRat readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YonedaCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2148.1, Definition 2148.2, Definition 2148.3, and Definition 2148.4 seed the finite Yoneda completion route over formal-ball profiles, directed Cauchy comparison, regular rational readback, real sealing, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YonedaCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Yoneda-profile exposure, radius and window exactness, Cauchy handoff discipline, regular rational and real readback discipline, classifier transport, formal-ball density, and non-escape for BEDC.Derived.YonedaCompletionUp.

Chapter 2149

A Concrete Naming Certificate for $\mathsf{MetricCompletionReflector}^{\uparrow}$

Following Bourbaki, Kelley, and Bishop–Bridges on metric and uniform completion, the $\mathsf{MetricCompletionReflector}^{\uparrow}$ packet records the metric-specialized reflector surface for the open L10 completion route. It sits after the metric-completion carrier of chapter 1506, the uniform-completion route of chapter 1473, the separated metric boundary of chapter 1411, and the broader reflector surface of chapter 1585. The packet exposes completion reflection through finite metric, uniform, separated, Cauchy-reflector, real-seal, transport, replay, provenance, and local NameCert rows without importing quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Definition 2149.1 (MetricCompletionReflector carrier)**.** *A* $\mathsf{MetricCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, U, S, K, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row. It records the displayed metric-completion source, Cauchy evidence, completion-facing reads, and local object boundary inspected by the reflector.*
2. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *comparison row. It records the uniform completion route that agrees with the metric completion on the displayed entourages and Cauchy data.*
3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row. It supplies the zero-distance uniqueness boundary used before any completed read may be treated as reflector-stable.*
4. *K is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row. It records the unit, counit, idempotent replay, universal-property, and reflection surface from which the metric-specialized reflector is read.*
5. *A is the real-seal handoff row. It records the terminal* $\mathsf{Real}^{\uparrow}$*-facing windows reached by metric-completion consumers only after M, U, S, K have been displayed.*
6. *H records componentwise* hsame *transport for metric completion, uniform completion, separated metric evidence, the Cauchy reflector row, the real-seal handoff, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$M, U, S, K \longmapsto A \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionReflector}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionReflector}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through $M, U, S, K, A, H, C, P, N$ and has no coordinate for quotient completion, selected representatives, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.MetricCompletionReflectorUp.MetricCompletionReflectorTasteGate single carrier alignment`

Theorem 2149.2 (MetricCompletionReflector NameCert obligations)**.** *For an accepted* $\mathsf{MetricCompletionReflector}^{\uparrow}$ *carrier*

$$R = (M, U, S, K, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric-completion row, uniform-completion comparison row, separated metric boundary, Cauchy reflector row, real-seal handoff, transport, replay, provenance, and local naming row;*
2. *metric-reflector source exactness, requiring every reflector-facing read to project M before the uniform comparison row or Cauchy reflector row can be consumed;*
3. *uniform compatibility, requiring U to compare only the displayed metric entourages and Cauchy data already available through M;*
4. *separated uniqueness, requiring S before any completed read is reused by the reflector as a stable metric-completion object;*
5. *reflector route compatibility, requiring K to supply the unit, counit, idempotent replay, universal-property, and reflection reads over the same M, U, S, A surface;*
6. *classifier transport, requiring* hsame *comparison to preserve the metric, uniform, separated, Cauchy-reflector, real-seal, replay, provenance, and local naming rows componentwise;*
7. *non-escape, excluding quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, and bridge checking.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2149.1. The accepted packet exposes exactly the metric-completion, uniform-completion, separated metric, Cauchy-reflector, real-seal, transport, replay, provenance, and local naming rows.

Metric-reflector source exactness starts at M. A consumer cannot inspect the uniform comparison row U or the Cauchy reflector row K until the metric-completion source and completion-facing route in M have been displayed.

Uniform compatibility is confined to U. It compares the displayed metric entourages and Cauchy data already named by M, so it cannot introduce a separate host uniform completion or a selected completed point.

Separated uniqueness is supplied by S. The reflector may reuse a completed read only after the separated metric boundary has classified the zero-distance evidence visible in the same packet.

Finally K, A, H, C, P, N preserve the same finite route. The Cauchy reflector row supplies unit, counit, idempotent, universal-property, and reflection faces over M, U, S, A, while the structural

rows transport, replay, source, and name only displayed coordinates. The excluded host principles have no carrier row, so the listed obligations exhaust the local NameCert surface. □

Theorem 2149.3 (MetricCompletionReflector real-seal handoff)**.** *Let*

$$R = (M, U, S, K, A, H, C, P, N)$$

be an accepted $\mathsf{MetricCompletionReflector}^{\uparrow}$ *carrier. Every real-facing reflector consumer reaches the terminal seal row* A *only through the finite route*

$$M \longmapsto U, S \longmapsto K \longmapsto A \longmapsto H, C, P, N.$$

The handoff specializes the broader $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *surface to the displayed metric-completion and separated-metric rows. It does not export quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.*

Proof. Begin with an accepted carrier R. The metric-completion row M is the only completion-object entry point, so every real-facing reflector consumer first reads the displayed metric-completion route.

The uniform and separated rows are then read as constraints on the same completion data. The row U supplies the uniform-completion comparison over the displayed entourages, and S supplies the separated metric boundary before reuse of a completed read.

The Cauchy reflector row K consumes those rows as its metric-specialized input. Its unit, counit, idempotent replay, universal-property, and reflection faces are therefore attached to the same M, U, S surface rather than to a detached quotient object.

The real-seal row A is downstream of this reflector route. Componentwise transport by H, displayed replay by C, provenance by P, and local naming by N preserve that order, so no excluded host-side principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionReflector}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionReflector}^{\uparrow}$ packet is generated from a MetricCompletionUp row, UniformCompletionUp comparison row, SeparatedMetricUp boundary, CauchyCompletionReflectorUp row, RealUp-facing seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2149.1, Definition 2149.2, and Definition 2149.3 seed the metric-specialized reflector surface for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MetricCompletionReflectorUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-reflector source exactness, uniform compatibility, separated uniqueness, reflector route compatibility, real-seal handoff, classifier transport, and non-escape for BEDC.Derived.MetricCompletionReflectorUp.

Chapter 2150

A Concrete Naming Certificate for $\mathsf{VietorisRipsComplex}^{\uparrow}$

Following Vietoris and Rips on finite threshold complexes, the $\mathsf{VietorisRipsComplex}^{\uparrow}$ packet records the BEDC surface that turns finite metric data into a simplex ledger. It sits over the metric distance interface of chapter 57, the finite net exposure of chapter 1767, the rational radius ledgers of chapter 291 and chapter 37, and the finite face consumer of chapter 238. The packet gives compact-metric approximation and persistent-homology consumers a finite threshold complex without importing host topology, open covers, selected dense subsets, quotient realization, or ambient homology.

Definition 2150.1 (Vietoris–Rips complex carrier)**.** *A* $\mathsf{VietorisRipsComplex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, V, \epsilon, D, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row. It records only the finite point histories and displayed distance witnesses available to the metric consumer.*
2. *V is the finite vertex or net ledger, read through the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *surface when the source data come from an approximation row.*
3. *ϵ is the threshold row. It is displayed through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *rational-radius ledgers before any simplex test can compare distances with the threshold.*
4. *D records pairwise distance witnesses for the displayed vertices. Each row names two vertices from V, the metric-distance witness read from X, and the comparison of that witness with ϵ.*
5. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *handoff row. It records exactly the finite simplex and face rows whose simplex predicate is accepted by threshold tests in D.*
6. *H records componentwise* hsame *transport for the metric source, vertex ledger, threshold row, pairwise distance ledger, simplicial handoff, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay from a simplex request through V, ϵ, D before the request reaches S.*
8. *P is the* Pkg *provenance over* $\mathsf{VietorisRipsComplex}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{VietorisRipsComplex}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through $X, V, \epsilon, D, S, H, C, P, N$ and has no coordinate for host topology, open-cover compactness, selected dense subsets, quotient geometric realization, ambient homology, Lean proof search, or bridge checking.

Lean4 ✓ `BEDC.Derived.VietorisRipsComplexUp.VietorisRipsComplexUpTasteGate single carrier alignment`

Theorem 2150.2 (Vietoris–Rips complex NameCert obligations)**.** *For an accepted* $\mathsf{VietorisRipsComplex}^{\uparrow}$ *carrier*

$$R = (X, V, \epsilon, D, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VietorisRipsComplex}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric source row, finite vertex or net ledger, threshold row, pairwise distance ledger, simplicial handoff row, transport, replay, provenance, and local naming;*
2. *threshold simplex exactness, requiring a displayed simplex of S to be accepted only when every displayed pair of its vertices has a row in D whose metric-distance witness is bounded by ϵ;*
3. *finite-net exposure, requiring vertex reads imported from* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *to remain inside the ledger V before any distance row or simplex row can use them;*
4. $\mathsf{SimplicialComplex}^{\uparrow}$ *compatibility, requiring the simplex and face rows handed to S to be closed under displayed face restriction because every face removes pairwise threshold requests rather than creating new ones;*
5. *classifier transport, requiring* hsame *comparison to preserve the metric source, vertex ledger, threshold row, pairwise distance ledger, simplicial handoff, replay, provenance, and local naming rows componentwise;*
6. *non-escape, excluding host topology, open covers, selected dense subsets, quotient geometric realization, ambient homology, and any simplex not routed through the finite threshold ledger.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2150.1. The accepted packet exposes exactly the metric source, vertex ledger, threshold row, pairwise distance ledger, simplicial handoff, and structural rows H, C, P, N.

Threshold simplex exactness is the route V, ϵ, D, S. A simplex read first lists its vertices in V, then reads the rational threshold ϵ, then checks every displayed pair through the corresponding metric-distance row in D before the simplex row is handed to S.

Finite-net exposure is inherited from V. When the vertices are supplied by a $\mathsf{FiniteEpsilonNet}^{\uparrow}$ packet, the Rips carrier reads them as ledger entries rather than as a selected dense subset or host-level finite set.

Compatibility with $\mathsf{SimplicialComplex}^{\uparrow}$ follows because every face request removes vertices from an already accepted simplex. The remaining pairwise requests are a subledger of the same D rows, so the face row can be handed to S without creating a new metric or threshold coordinate.

Finally H, C, P, N preserve and name only the displayed coordinates. Since topology, open covers, quotient realization, ambient homology, and unrouted simplex predicates have no carrier row, the listed obligations exhaust the local NameCert surface. □

Theorem 2150.3 (Vietoris–Rips simplex threshold handoff)**.** *Let*

$$R = (X, V, \epsilon, D, S, H, C, P, N)$$

be an accepted $\mathsf{VietorisRipsComplex}^{\uparrow}$ *carrier. Every simplex read exported to the* $\mathsf{SimplicialComplex}^{\uparrow}$ *consumer factors through the finite route*

$$V \longmapsto \epsilon \longmapsto D \longmapsto S \longmapsto H, C, P, N.$$

Consequently the simplicial consumer can use only the displayed finite metric threshold rows. It cannot use host topology, open-cover compactness, selected dense subsets, quotient geometric realization, ambient homology, or a simplex predicate detached from D*.*

Proof. Start with a simplex read. Projection gives the vertex ledger V, but the packet exposes no host finite set, no selected dense subset, and no geometric realization at this stage.

The read must next pass through the threshold row ϵ and the pairwise distance ledger D. For each displayed pair of vertices, D supplies the metric-distance witness from X and the finite comparison with ϵ.

Only after those rows have been read is the simplex handed to S. Face reads are handled by the same route because restricting a simplex can only delete pairwise threshold requests already present in D.

Transport, replay, provenance, and local naming are exactly H, C, P, N. They preserve the displayed route and add no topology, cover, representative choice, realization quotient, homology group, or detached simplex classifier. Hence every simplex read factors through the stated finite threshold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{VietorisRipsComplex}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VietorisRipsComplex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2150.1, Definition 2150.2, and Definition 2150.3 seed the finite metric threshold complex packet over displayed metric, net, rational threshold, pairwise distance, simplicial handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VietorisRipsComplex}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.VietorisRipsComplexUp`

Bridge status: none

Not claimed: This chapter does not close persistent homology, Cech complexes, open-cover compactness, quotient geometric realization, selected dense subsets, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold simplex exactness, finite-net exposure, SimplicialComplex compatibility, classifier transport, simplex handoff factorization, and non-escape for BEDC.Derived.VietorisRipsComplexUp.

Constructive story: A $\mathsf{VietorisRipsComplex}^{\uparrow}$ packet is generated from a MetricUp source row, a finite vertex or FiniteEpsilonNet ledger, a DyadicRatCore or Rat threshold row, pairwise distance witnesses, a SimplicialComplex handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2151

A Concrete Naming Certificate for $\mathsf{RegularCauchyTranslation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyTranslation}^{\uparrow}$ packet records constant translation of a regular Cauchy real name as displayed finite BEDC data. It sits beside the two-source addition surface of chapter 417, the sign-flip route of chapter 459, the rational scaling route of chapter 465, the dyadic arithmetic core of chapter 291, the finite observation discipline of chapter 126, the regular rational source boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers one finite route for reading $x + c$ through the displayed source and constant rows, without importing host real addition, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2151.1 (Regular Cauchy translation carrier)**.** *A* $\mathsf{RegularCauchyTranslation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T_c = (X, Q, W_X, W_Q, D_X, D_Q, A, E, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row for the regular Cauchy real name being translated.*
2. *Q is the constant row, displayed either as a dyadic endpoint row or as a rational row whose dyadic readings are supplied through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *W_X and W_Q are synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows. The row W_X opens the requested source observation, while W_Q opens the stationary finite window for the constant row at the same precision request.*
4. *D_X and D_Q are the translated dyadic endpoint rows, recording the source endpoint read from X and the constant endpoint read from Q in the common dyadic ledger.*
5. *A is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *handoff row adding the source regular name to the constant regular row generated from Q.*
6. *E is the finite error ledger combining source tolerance, constant display tolerance, dyadic endpoint addition tolerance, and the output tolerance consumed by the sum handoff.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the displayed sum route.*
8. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $X, Q, W_X, W_Q, D_X, D_Q, A, E, R$ have been displayed.*

9. *H records componentwise* hsame *transport for the source, constant, synchronized windows, dyadic endpoint rows, sum handoff, finite ledger, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from any translation-facing precision request through $X, Q, W_X, W_Q, D_X, D_Q, A$, before the seal row Z is exposed.*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTranslation}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTranslation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Q, W_X, W_Q, D_X, D_Q, A, E, R, Z, H, C, P, N$. The carrier has no coordinate for host real addition, quotient stream equality, a selected representative, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTranslationUp.RegularCauchyTranslationTasteGate single carrier alignment`

Theorem 2151.2 (Regular Cauchy translation NameCert obligations)**.** *For every accepted* RegularCauchyTranslatio *carrier*

$$T_c = (X, Q, W_X, W_Q, D_X, D_Q, A, E, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTranslation}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *source-and-constant admission, requiring the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row X and the displayed constant row Q to be present before any translated read is exposed;*

2. *synchronized-window exposure, requiring W_X and W_Q to open the source and constant observations at the same finite precision request;*

3. *dyadic endpoint and ledger exactness, requiring D_X, D_Q, E to account for the source endpoint, constant endpoint, endpoint addition, and output tolerance used by the translation;*

4. *sum-route handoff, requiring the translated readback R to pass through the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row A and through no host addition operation;*

5. *structural naming, requiring Z, H, C, P, N to expose the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, package provenance, and local* NameCert *row for exactly this finite translation packet.*

No translation obligation is stored outside these five rows, and the surface refuses host real addition, quotient stream equality, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local data.*

Proof. Project the accepted carrier. The source row X, constant row Q, synchronized windows W_X, W_Q, dyadic endpoint rows D_X, D_Q, sum handoff A, finite ledger E, readback row R, seal row Z, and structural rows H, C, P, N are the whole visible packet.

Read the source and constant windows first. The row W_X supplies the finite observation of the source regular name, while W_Q supplies the stationary constant observation at the same precision request. Thus the source endpoint and constant endpoint are compared only after both windows are displayed.

Next read the dyadic and budget rows. The rows D_X and D_Q supply the endpoint data consumed by the $\mathsf{RegularCauchySum}^{\uparrow}$ handoff, and E records the source tolerance, constant tolerance, endpoint-addition tolerance, and output tolerance before R is available.

Finally replay the route through the structural rows. Since A is the only addition handoff and every seal-facing read must pass through R before Z, no quotient stream, selected representative, host addition operation, countable-choice selector, trichotomy witness, ambient completeness theorem, Lean verification, or bridge credential can be read from the local packet. □

Theorem 2151.3 (Regular Cauchy translation real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RegularCauchyTranslation}^{\uparrow}$ *carrier factors through the displayed constant row and sum route*

$$(X, Q) \longmapsto (W_X, W_Q) \longmapsto (D_X, D_Q) \longmapsto A \longmapsto E \longmapsto R \longmapsto Z.$$

Thus the consumer sees the source regular row, the constant dyadic or rational row, synchronized StreamName windows, translated dyadic endpoint rows, the $\mathsf{RegularCauchySum}^{\uparrow}$ *handoff, the finite error ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It receives no host real addition, quotient stream equality, selected representative, countable-choice witness, trichotomy decision, ambient completeness coordinate, Lean verification, or bridge checking.*

Proof. Begin with a Real-facing read of the accepted packet. The carrier exposes the seal row Z only downstream of the readback row R, so the read must first pass through the regular readback route.

The readback route is fixed by the constant row and the sum handoff. The source row X and constant row Q are opened through synchronized windows W_X, W_Q, their dyadic endpoint rows are read as D_X, D_Q, and the displayed $\mathsf{RegularCauchySum}^{\uparrow}$ row A is then the only route forming the translated regular name.

The finite ledger precedes the seal. The row E accounts for source, constant, endpoint-addition, and output tolerances before R and then Z can be consumed.

The structural rows preserve this factorization. Componentwise hsame transport, Cont replay, Pkg provenance, and local naming do not add another Real-facing coordinate, so every accepted seal read factors through the displayed constant row and sum route and cannot escape to the refused principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTranslation}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTranslation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2151.1, Definition 2151.2, and Definition 2151.3 seed the finite constant-translation surface over one $\mathsf{RegSeqRat}^{\uparrow}$ source row, a displayed dyadic or rational constant row, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, a $\mathsf{RegularCauchySum}^{\uparrow}$ handoff, finite error ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTranslation}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyTranslationUp.RegularCauchyTranslationTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close host real addition, quotient stream equality, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-and-constant admission, synchronized-window exposure, dyadic endpoint and ledger exactness, sum-route handoff, Real seal non-escape, componentwise transport, continuation replay, provenance, and local naming for BEDC.Derived.RegularCauchyTranslationUp.

Constructive story: A $\mathsf{RegularCauchyTranslation}^{\uparrow}$ packet is generated from a RegSeqRat source row, a displayed dyadic or rational constant row, synchronized StreamName windows, translated DyadicRatCore endpoint rows, a RegularCauchySum handoff, a finite error ledger, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2152

A Concrete Naming Certificate for $\mathsf{RoundedIntervalDomain}^{\uparrow}$

Following Scott domain theory and Bishop–Bridges interval approximation of constructive reals, the $\mathsf{RoundedIntervalDomain}^{\uparrow}$ packet records the finite rounded dyadic interval-domain route by which regular-Cauchy real names are approximated before the terminal real-name seal is exposed. It refines the plain interval-domain carrier of chapter 1543 by forcing every endpoint, containment, and refinement read through rounded dyadic data from chapter 291, finite stream windows from chapter 126, regular rational readback from chapter 301, and the displayed real-name boundary of chapter 38. The packet gives Real and Completion consumers a finite rounded approximation surface; it is not a Dedekind-cut construction, an open-cover compactness principle, trichotomy, a quotient representative selector, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2152.1 (Rounded interval-domain carrier)**.** *A* $\mathsf{RoundedIntervalDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, B, J, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the rounded lower endpoint row. It records a dyadic rational endpoint, its displayed rounding radius, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison data used to read it.*
2. *U is the rounded upper endpoint row. It records the paired dyadic rational endpoint, its displayed rounding radius, and the same dyadic arithmetic surface.*
3. *B is the rounded containment row. It records lower-below-upper evidence, slack inequalities, and the fact that the exact real-name request lies inside the displayed rounded dyadic interval.*
4. *J is the refinement witness row. It records a finite refinement step from a parent rounded interval to a child rounded interval whose endpoints and radii are again displayed by L, U, B-shaped data.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation window. It records the finite indices at which endpoint and containment observations are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational values read from the same observation window after the dyadic endpoint and containment rows have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is reachable only downstream of L, U, B, J, W, R.*
8. *H records componentwise* hsame *transport for endpoints, containment, refinement, stream windows, regular readback, Real seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the finite route*

$$L, U \longmapsto B \longmapsto J \longmapsto W \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{RoundedIntervalDomain}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RoundedIntervalDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, B, J, W, R, E, H, C, P, N$. It has no coordinate for Dedekind cuts, open-cover compactness, trichotomy, quotient representatives, selected limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RoundedIntervalDomainUp.RoundedIntervalDomainUp`
Lean4 ✓ `BEDC.Derived.RoundedIntervalDomainUp.RoundedIntervalDomainTasteGate single carrier alignment`

Theorem 2152.2 (Rounded interval-domain NameCert obligations)**.** *For every accepted* $\mathsf{RoundedIntervalDomain}^{\uparrow}$ *carrier*

$$I = (L, U, B, J, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RoundedIntervalDomain}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed rounded lower endpoint, rounded upper endpoint, containment, refinement, stream window, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *rounded-refinement stability, requiring every child interval named by J to keep dyadic endpoints, rounding radii, containment evidence, and observation windows inside the displayed packet route;*
3. hsame *transport, requiring H to preserve endpoints, radii, containment checks, refinement witnesses, stream windows, regular readbacks, Real seals, replay rows, provenance, and local naming componentwise;*
4. *containment classifier reflexivity on a displayed interval, symmetry for equality of two displayed rounded presentations with the same endpoint and radius rows, and transitivity along a finite chain of displayed refinement witnesses;*
5. *ledger non-escape, requiring C and P to replay and source only the rows $L, U, B, J, W, R, E, H, C, P, N$;*
6. *Real seal compatibility, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer of E to read the rounded dyadic endpoint ledger, containment row, refinement witness, stream window, and regular rational readback before the seal is inspected.*

No rounded interval-domain obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2152.1. The projection exposes exactly the rounded endpoints, containment, refinement witness, observation window, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Rounded-refinement stability reads L, U, B, J, W. A child interval in J is generated from displayed parent endpoint rows and retains displayed rounding radii and containment evidence before any later stream or regular rational consumer is available.

Transport is componentwise. The row H moves each displayed endpoint, radius, containment check, refinement witness, window, readback, seal, replay row, provenance row, and naming row to its transported counterpart, so no detached analytic coordinate appears during transport.

The containment classifier clauses use only the rounded presentation. Reflexivity is the displayed interval compared with itself, symmetry is available when two presentations expose the same rounded endpoint and radius rows, and transitivity is concatenation of the finite refinement witnesses recorded by J.

Finally, ledger non-escape and Real seal compatibility follow from the replay order in C and the source row P. The terminal seal E is downstream of dyadic endpoint stability, containment, refinement, finite observation, and regular readback, and the carrier has no row for any excluded principle. □

Theorem 2152.3 (Rounded interval-domain Cauchy readback)**.** *Let*

$$I_0, I_1, I_2, \ldots$$

be a nested family of accepted $\mathsf{RoundedIntervalDomain}^{\uparrow}$ *packets whose refinement rows display shrinking dyadic radii and whose observation windows are compatible under* hsame*. Then the public* $\mathsf{Real}^{\uparrow}$ *seal read from the nested rounded dyadic interval route is the same seal exposed by its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route. The identification uses only* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint stability,* $\mathsf{StreamName}^{\uparrow}$ *pointwise observation,* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback, and* $\mathsf{Real}^{\uparrow}$ *classifier transport.*

Proof. First read the dyadic endpoint data. Each packet exposes rounded lower and upper endpoints together with radii, and the refinement row identifies the later endpoint rows as contained rounded refinements of the earlier rows. Shrinking radii make the endpoint ledger stable for every displayed precision request.

Next read the stream windows. Compatibility under hsame means that a fixed finite observation request is eventually served by the same displayed window row, so pointwise $\mathsf{StreamName}^{\uparrow}$ observation is independent of the chosen later packet.

The regular rational readback is then diagonal. For each displayed precision request, choose a packet far enough along the nested route that its radius and window rows cover the request, and read the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ row. The previous two steps ensure that this readback is stable under further displayed refinements.

Finally compare the Real seals. The seal row in each packet is downstream of the same dyadic endpoint, stream-window, and regular-readback route, and $\mathsf{Real}^{\uparrow}$ classifier transport applies along the displayed hsame rows. Hence the nested rounded interval route and the diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback expose the same public $\mathsf{Real}^{\uparrow}$ seal without using quotient representatives, trichotomy, open-cover compactness, Dedekind-cut completeness, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RoundedIntervalDomain}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoundedIntervalDomain}^{\uparrow}}, \mathsf{seed})$

Constructive story: A $\mathsf{RoundedIntervalDomain}^{\uparrow}$ packet is generated from rounded lower and upper dyadic endpoint rows, rounded containment evidence, a refinement witness, StreamName observation windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Scope closed: Definition 2152.1, Definition 2152.2, and Definition 2152.3 seed the finite rounded dyadic interval-domain route from endpoint rounding through refinement, finite observation, regular rational readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoundedIntervalDomain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut completeness, open-cover compactness, trichotomy, quotient representatives, selected limits, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rounded-refinement stability, hsame transport, containment classifier laws for displayed rounded presentations, ledger non-escape, Real seal compatibility, and Cauchy readback for BEDC.Derived.RoundedIntervalDomainUp.

Chapter 2153

A Concrete Naming Certificate for $\mathsf{CantorCylinderBasis}^{\uparrow}$

Following Brouwer's finite-prefix reading of choice sequences and the Bishop–Bridges cylinder terminology for Cantor space, the $\mathsf{CantorCylinderBasis}^{\uparrow}$ packet records the basic clopen cylinder surface of $\mathsf{CantorSpace}^{\uparrow}$ as finite NameCert data. It sits after the Cantor-space carrier of chapter 1475, the unary finite-window interface of chapter 126, the two-endpoint discipline of chapter 32, and the ordered prefix spine of chapter 36. The packet names prefix cylinders by displayed finite routes; it is not a host function extensionality principle, a quotient of infinite streams, a completed infinite product, a fan-theorem compactness argument, a countable-choice selector, or an appeal to $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2153.1 (Cantor cylinder basis carrier)**.** *A* $\mathsf{CantorCylinderBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (C, S, W, B, L, R, H, K, P, N)$$

with the following visible rows:

1. *C is the source* $\mathsf{CantorSpace}^{\uparrow}$ *packet whose public observations are read only through finite prefix windows;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the requested finite prefix positions;*
3. *W is the finite cylinder-window row, including the displayed prefix and the shorter windows used by downstream refinement reads;*
4. *B is the* $\mathsf{Bool}^{\uparrow}$ *endpoint ledger assigning visible Boolean rows to the positions of W;*
5. *L is the* $\mathsf{List}^{\uparrow}$ *spine row ordering the prefix entries and recording their finite length;*
6. *R is the refinement ledger saying which shorter or longer displayed prefix rows are being compared inside the same cylinder family;*
7. *H is the componentwise* hsame *transport row for C, S, W, B, L, R;*
8. *K is the displayed* Cont *replay row for cylinder reads and prefix refinements already accepted by the packet;*
9. *P is the* Pkg *provenance over* $\mathsf{CantorCylinderBasis}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorCylinderBasis}^{\uparrow}}$ *row.*

The carrier has no coordinate for host-level maps $\mathsf{Nat}^{\uparrow} \to \mathsf{Bool}^{\uparrow}$*, quotient stream equality, completed infinite products, fan-theorem compactness, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorCylinderBasisUp.CantorCylinderBasisTasteGate single carrier alignment`

Definition 2153.2 (Cantor cylinder basis classifier)**.** *Two accepted* $\mathsf{CantorCylinderBasis}^{\uparrow}$ *carriers*

$$Z = (C, S, W, B, L, R, H, K, P, N) \quad \textit{and} \quad Z' = (C', S', W', B', L', R', H', K', P', N')$$

are classified as the same basis element exactly when their displayed $\mathsf{StreamName}^{\uparrow}$ *schedules select the same finite prefix length and their* $\mathsf{Bool}^{\uparrow}$ *rows agree componentwise along the ordered* $\mathsf{List}^{\uparrow}$ *spine. The comparison is transported only through* H, H' *and replayed only through* K, K'*. It does not compare host functions, quotient streams, infinite tails, or completed product coordinates.*

Theorem 2153.3 (Cantor cylinder basis NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CantorCylinderBasis}^{\uparrow}}$ *surface of Definition 2153.1 consists exactly of the finite carrier admission, classifier transport, prefix refinement, StreamName–Bool scope, continuation replay, provenance, and non-escape obligations displayed by*

$$C, S, W, B, L, R, H, K, P, N.$$

Every obligation is checked by finite prefix data over the sibling $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*, and* $\mathsf{List}^{\uparrow}$ *packets.*

Proof. Carrier admission is projection of the ten displayed rows in Definition 2153.1. The source Cantor packet supplies the finite observation context, while S, W, B, L expose the requested prefix as StreamName windows, Boolean endpoints, and a List spine.

Classifier transport uses Definition 2153.2. Once the finite prefix length and componentwise Boolean rows are fixed, H transports the same finite rows and K replays them without adding any host-level stream coordinate.

The remaining obligations are inspection of R, H, K, P, N. Prefix refinement is recorded as a finite relation between displayed prefix rows, continuation replay is confined to the accepted rows, and provenance keeps the route inside the listed sibling chapters.

Non-escape follows because no carrier coordinate supplies host function extensionality, quotient stream equality, completed infinite products, fan-theorem compactness, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2153.4 (Cantor cylinder basis prefix refinement)**.** *Let* $Z = (C, S, W, B, L, R, H, K, P, N)$ *be an accepted* $\mathsf{CantorCylinderBasis}^{\uparrow}$ *carrier. If a displayed prefix row in* R *extends another displayed prefix row in the same carrier, then the longer cylinder read factors through the shorter cylinder read together with the additional finite* $\mathsf{Bool}^{\uparrow}$ *rows on the suffix. If the rows are incompatible at a visible position, the classifier rejects the shared basis element at that same finite position.*

Proof. Read the two prefix rows from R. The shorter row and the longer row are both subwindows of the displayed cylinder-window row W, so their positions are already scheduled by the same $\mathsf{StreamName}^{\uparrow}$ row S.

In the extension case, the common part is ordered by the same initial segment of the $\mathsf{List}^{\uparrow}$ spine L. The suffix is a finite list of additional $\mathsf{Bool}^{\uparrow}$ rows from B, and replay through K appends only those visible rows to the already accepted shorter read.

In the incompatible case, some displayed position carries different $\mathsf{Bool}^{\uparrow}$ endpoint rows. The classifier of Definition 2153.2 reads that position directly through the shared finite spine and rejects equality there, without comparing infinite tails or host functions. □

Theorem 2153.5 (Cantor cylinder basis StreamName-Bool scope)**.** *Every public read exported by an accepted* $\mathsf{CantorCylinderBasis}^{\uparrow}$ *carrier reaches downstream countable-name consumers only through the finite route*

$$\mathsf{CantorSpace}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Bool}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{NameCert}_{\mathsf{CantorCylinderBasis}^{\uparrow}}.$$

The route exposes prefix-cylinder membership, refinement, and incompatibility only as displayed BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *data. It does not export host function extensionality, quotient streams, completed infinite products, fan-theorem compactness, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a public consumer read of Z. The Cantor source C can be read only through the finite prefix discipline of chapter 1475; the requested positions are then exposed by the $\mathsf{StreamName}^{\uparrow}$ schedule S and the cylinder window W.

The visible values are exactly the $\mathsf{Bool}^{\uparrow}$ rows in B, ordered by the $\mathsf{List}^{\uparrow}$ spine L. Refinement information is read from R, transported by H, and replayed by K before provenance and local naming are recorded in P, N.

Thus every public route remains inside the displayed finite rows. The excluded objects are not supplied by the carrier, classifier, or refinement ledger, so no downstream consumer can obtain them from the cylinder-basis packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorCylinderBasis}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorCylinderBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2153.1, Definition 2153.2, Definition 2153.3, Definition 2153.4, and Definition 2153.5 seed the finite prefix-cylinder basis surface over CantorSpace, StreamName, Bool, and List rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorCylinderBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close host function extensionality, quotient stream equality, completed infinite products, fan-theorem compactness, countable choice, Real completeness, or a standard bridge.

Upgrade path: The next step is obligationClosure: carrier admission, classifier transport, prefix refinement, StreamName-Bool routing, and non-escape must be discharged as local rows.

Constructive story: The construction starts from a finite CantorSpace prefix, reads the selected positions through StreamName windows, records Bool endpoints along a List spine, and exposes only hsame, Cont, Pkg, and local NameCert rows to downstream consumers.

Chapter 2154

A Concrete Naming Certificate for $\mathsf{SamuelCompactification}^{\uparrow}$

Following Samuel on uniform compactification and Bourbaki–Kelley on uniform spaces, the $\mathsf{SamuelCompactification}^{\uparrow}$ packet records the compactification-facing uniform route as finite BEDC data. It consumes the completion route of chapter 2131, the uniform completion surface of chapter 1473, the dense uniform embedding boundary of chapter 1651, the compact metric boundary of chapter 129, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the bounded-uniform-readout boundary without importing a host compactification space, a selected ultrafilter, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 2154.1 (Samuel compactification carrier)**.** *A* $\mathsf{SamuelCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, B, D, K, W, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the uniform-entourage source row. It records the finite entourage requests and refinement witnesses from which every compactification-facing read begins.*
2. *B is the bounded uniformly continuous readout row. It records only displayed bounded readouts whose uniform continuity has been inspected through U.*
3. *D is the dense uniform embedding row. It records the source embedding, dense image windows, and pullback evidence required before a compact boundary read can be exposed.*
4. *K is the compact-metric boundary row. It records the compact metric recipient, boundary-window requests, and finite compactness witnesses consumed by compactification-facing observers.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which dense-source observations, bounded readouts, and compact-boundary requests are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed stream windows, bounded-readout budgets, and compact-boundary tolerances.*
7. *H records componentwise* hsame *transport for uniform entourages, bounded readouts, dense embeddings, compact-boundary rows, stream windows, regular readbacks, replay data, provenance, and local naming.*

8. *C records displayed* Cont *replay of the route*

$$U, B, D, W \longmapsto R \longmapsto K.$$

9. *P is the* Pkg *provenance over* $\mathsf{SamuelCompactification}^{\uparrow}$, $\mathsf{SamuelCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SamuelCompactification}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $U, B, D, K, W, R, H, C, P, N$ and has no coordinate for a host compactification space, selected ultrafilters, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SamuelCompactificationUp.SamuelCompactificationTasteGate single carrier alignment`

Theorem 2154.2 (Samuel compactification NameCert obligations)**.** *For the carrier of Definition 2154.1, the local* $\mathsf{NameCert}_{\mathsf{SamuelCompactification}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the packet $S = (U, B, D, K, W, R, H, C, P, N)$;*
2. *bounded-readout stability, requiring every bounded uniformly continuous read to remain tied to the displayed entourage row U and the displayed readout row B under componentwise* hsame *transport;*
3. *dense-source handoff, requiring every compactification-facing consumer to pass through the dense uniform embedding row D before reading a compact boundary;*
4. *compact-boundary sealing, requiring compact-boundary observations to be exposed only through K after the stream-window schedule W and regular rational readback row R have been replayed;*
5. *ledger non-escape, excluding host compactification spaces, selected ultrafilters, quotient stream equality, countable-choice schedules, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No obligation is stored outside the displayed carrier rows.

Proof. Carrier admission is projection from Definition 2154.1. The accepted packet displays exactly the uniform source, bounded readout, dense embedding, compact boundary, stream-window, regular readback, transport, replay, provenance, and local naming rows.

Bounded-readout stability is componentwise. The row H compares U and B together, so a readout cannot be transported without the entourage data that witnesses its uniform continuity.

Dense-source handoff is the placement of D before the boundary row in every replay route. A compactification-facing consumer therefore reads the displayed dense embedding and its image-window evidence before it can request a compact boundary observation.

Compact-boundary sealing follows from the route $U, B, D, W \longmapsto R \longmapsto K$. Boundary observations are downstream of the finite windows and regular rational readback, so they cannot appear as an independent host compactification coordinate.

Finally, P and N name only the displayed rows. Since the excluded host-side principles have no carrier coordinate, no replay edge, and no provenance entry, the five obligations exhaust the local NameCert surface. □

Theorem 2154.3 (Samuel compactification uniform handoff)**.** *Every compactification-facing read exported by an accepted* $\mathsf{SamuelCompactification}^{\uparrow}$ *carrier factors through* $\mathsf{SamuelCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *More precisely, the read begins with the uniform-entourage source row U, inspects bounded uniformly continuous readouts through B, passes through the dense uniform embedding row D, replays finite windows through W, reads regular rational data through R, and only then reaches the compact-metric boundary row K named by P, N.*

Proof. Start with an accepted carrier and project its displayed rows. The provenance row P records the allowed sibling surfaces, namely the Samuel and uniform completion routes of chapter 2131 and chapter 1473, the dense embedding route of chapter 1651, the compact metric boundary of chapter 129, the stream-window and regular rational readback routes of chapter 126 and chapter 301, and the real-name seal of chapter 38.

The replay row C orders those surfaces. A compactification-facing read first consumes U, B, D, W, then reaches R, and only after that reaches K.

The transport row H preserves the same order under hsame, and N names no row outside the displayed packet. Hence every exported read factors through the listed BEDC surfaces and cannot expose a host compactification space, selected ultrafilter, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking. □

Theorem 2154.4 (Samuel compactification finite-cover boundary)**.** *Every finite-cover or compact-boundary read of an accepted* $\mathsf{SamuelCompactification}^{\uparrow}$ *packet must pass through* $\mathsf{SamuelCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The boundary exports no selected ultrafilters, quotient compactification points, countable choice, host compact spaces, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the rows of Definition 2154.1. A finite-cover or compact-boundary read can see only the uniform source row U, bounded readout row B, dense embedding row D, compact-metric boundary row K, stream windows W, regular readback R, transport H, replay C, provenance P, and local naming N.

Apply the uniform handoff of Definition 2154.3. It orders the read through Samuel completion, uniform completion, dense uniform embedding, compact metric boundary, stream windows, regular rational readback, and the Real seal before any compactification-facing boundary is public.

The finite-cover boundary is therefore a displayed route through $U, B, D, W, R, K, H, C, P, N$. Since the carrier has no coordinate for selected ultrafilters, quotient compactification points, countable choice, host compact spaces, or ambient Real completeness, no compact-boundary consumer can import those objects from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SamuelCompactification}^{\uparrow}}$.

Constructive story: A $\mathsf{SamuelCompactification}^{\uparrow}$ packet is generated from a uniform-entourage source row, bounded uniformly continuous readouts, DenseUniformEmbeddingUp rows, CompactMetricUp boundary rows, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SamuelCompactification}^{\uparrow}}$, seed)

Scope closed: Definition 2154.1, Definition 2154.2, and Definition 2154.3 seed the L10 compactification route from finite uniform-entourage and bounded-readout data through dense embedding, stream-window, regular readback, compact-metric boundary, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SamuelCompactification}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host compactification spaces, selected ultrafilters, quotient stream equality, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-readout stability, dense-source handoff, compact-boundary sealing, ledger non-escape, provenance, and local naming for BEDC.Derived.SamuelCompactificationUp.

Chapter 2155

A Concrete Naming Certificate for $\mathsf{UniformConvergenceSeries}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{UniformConvergenceSeries}^{\uparrow}$ packet records the finite handoff from uniform Cauchy control of real-series partial sums to a uniform-limit surface. It sits over the real-series packet of chapter 1581, the uniform Cauchy series packet of chapter 1736, the uniform-limit endpoint packet of chapter 463, the majorant-test route of chapter 399, the finite stream windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later power-series, real-function, and continuity-transfer chapters a named theorem-level boundary without treating $\mathsf{UniformCauchySeries}^{\uparrow}$ itself as an infinite-sum object.

Definition 2155.1 (Uniform convergence series carrier)**.** *A* $\mathsf{UniformConvergenceSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, S, W, D, Q, L, M, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the real-valued term-family row. Each summand is read only through displayed finite windows before it is admitted to a partial-sum comparison.*
2. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row. It records finite series windows, displayed partial sums, and the shared real-series tail threshold.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row used by the partial sums and by the uniform tail request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested radius, dyadic slack, finite addition budget, and exhausted comparison windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed partial sums.*
6. *L is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *ledger. It records the single uniform tail threshold that works across the displayed parameter window.*
7. *M is the optional* $\mathsf{WeierstrassMTest}^{\uparrow}$ *majorant route. When present, it supplies the finite domination and majorant-tail rows used to populate L; when absent, L is supplied directly by the uniform Cauchy series packet.*
8. *E is the* $\mathsf{UniformLimit}^{\uparrow}$ *endpoint row. It becomes visible only after S, W, D, Q, L and the applicable majorant route M have been displayed.*

9. *H records componentwise* hsame *transport for the term-family, real-series, stream-window, dyadic, regular-rational, uniform-Cauchy, majorant, uniform-limit, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$A, S, W, D, Q \longmapsto L \longmapsto M \longmapsto E.$$

If the majorant route is not used, the M coordinate is the displayed empty majorant branch rather than a hidden summability principle.

11. *P is the* Pkg *provenance over* $\mathsf{UniformConvergenceSeries}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformConvergenceSeries}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these twelve rows. Its classifier compares accepted packets only through $A, S, W, D, Q, L, M, E, H, C, P, N$ and has no coordinate for host infinite sums, selected limits, quotient equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.UniformConvergenceSeriesUp.UniformConvergenceSeriesTasteGate single carrier alignment`

Theorem 2155.2 (Uniform convergence series NameCert obligations)**.** *For every accepted* UniformConvergenceSeri *carrier*

$$U = (A, S, W, D, Q, L, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformConvergenceSeries}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the term-family row, real-series partial-sum row, stream schedule, dyadic tolerance ledger, regular-rational readback, uniform Cauchy ledger, optional majorant route, uniform-limit endpoint, transport, replay, provenance, and local naming row;*

2. *partial-sum coverage, requiring every convergence request to read the displayed* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row S before reaching any limit endpoint;*

3. *uniform-tail exactness, requiring the single threshold row L to answer all displayed parameter-window requests through the same dyadic tolerance ledger D and schedule row W;*

4. *regular readback discipline, requiring Q to be the only regular-rational route by which the finite partial sums are handed to the uniform-limit endpoint;*

5. *majorant confinement, requiring M to be either the displayed* $\mathsf{WeierstrassMTest}^{\uparrow}$ *domination route or the displayed empty majorant branch, never a host summability assertion;*

6. *endpoint factorization, requiring E to remain downstream of S, W, D, Q, L and the applicable M branch;*

7. *transport, replay, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise;*

8. *non-escape, excluding host infinite sums, selected limits, quotient equality, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No uniform-convergence-series obligation is stored outside these rows.

Proof. Project the accepted packet $U = (A, S, W, D, Q, L, M, E, H, C, P, N)$. The carrier exposes exactly the term-family row, the real-series partial-sum row, the shared stream schedule, the dyadic ledger, the regular readback, the uniform Cauchy ledger, the optional majorant route, the uniform-limit endpoint, and the structural rows.

The convergence request first consumes the real-series partial sums. The row S supplies the finite partial-sum windows, while W fixes the displayed schedule and D fixes the dyadic tolerance budget used by the comparison.

Uniformity is supplied by L. The same threshold row must answer every displayed parameter-window request, so a consumer cannot replace the packet by pointwise convergence data or by a separately chosen limit at each parameter.

The regular readback and majorant branch are then confined. The row Q is the only route into the regular-rational handoff, and M either records the finite Weierstrass majorant route or records that no majorant branch is used.

Finally E, H, C, P, N seal, transport, replay, source, and name that same finite route. Since host infinite sums, selected limits, quotient equality, countable choice, open-cover compactness, and ambient real completeness have no carrier coordinate or replay edge, the listed obligations exhaust the local NameCert surface. □

Theorem 2155.3 (Uniform convergence series RealSeries handoff)**.** *Every* $\mathsf{UniformLimit}^{\uparrow}$ *endpoint read of an accepted* $\mathsf{UniformConvergenceSeries}^{\uparrow}$ *carrier factors through the finite route*

$$A, S, W, D, Q \longmapsto L \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed real-valued term family, $\mathsf{RealSeries}^{\uparrow}$ *partial-sum windows,* $\mathsf{StreamName}^{\uparrow}$ *schedules,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, one* $\mathsf{UniformCauchySeries}^{\uparrow}$ *tail ledger, the applicable* $\mathsf{WeierstrassMTest}^{\uparrow}$ *branch, the* $\mathsf{UniformLimit}^{\uparrow}$ *endpoint row, componentwise transport, continuation replay, package provenance, and local naming. It receives no host infinite sum, selected limit, quotient equality, countable-choice schedule, open-cover compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted endpoint read. The term-family row A is visible only through the real-series partial-sum row S, and those partial sums are inspected along the schedule row W with the tolerance accounting recorded in D.

The regular-rational readback is then forced through Q. It is the unique displayed handoff from the finite partial sums to the uniform Cauchy comparison surface, so no quotient equality of series or selected infinite sum is introduced.

The uniform Cauchy step is the row L. It supplies the common tail threshold that works for every displayed parameter-window request; if a majorant proof is used, the row M records exactly the Weierstrass domination and majorant-tail rows that populate L.

Only after this route is displayed can E expose the $\mathsf{UniformLimit}^{\uparrow}$ endpoint. The structural rows H, C, P, N preserve the same route under componentwise transport, continuation replay, provenance, and local naming.

Induction over the displayed route order proves the factorization. The base stage reads A, S, W, D, Q, the uniform-tail stage reads L, the majorant branch reads M, and the terminal stage reads E, H, C, P, N. There is no coordinate outside this route from which a consumer could extract a host infinite sum, selected limit, quotient equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergenceSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformConvergenceSeries}^{\uparrow}$ packet is generated from a real-valued term-family row, RealSeries partial-sum windows, StreamName schedules, a DyadicRatCore tolerance ledger, RegSeqRat readback, one UniformCauchySeries tail ledger, an optional WeierstrassMTest majorant route, a UniformLimit endpoint row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergenceSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2155.1, Definition 2155.2, and Definition 2155.3 seed the finite theorem-level route from RealSeries partial sums and UniformCauchySeries tail control to the UniformLimit endpoint surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergenceSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partial-sum coverage, uniform-tail exactness, regular readback discipline, majorant confinement, endpoint factorization, transport, replay, provenance, and local naming for BEDC.Derived.UniformConvergenceSeriesUp.

Chapter 2156

A Concrete Naming Certificate for $\mathsf{MetricCompletionMonad}^{\uparrow}$

Following Mac Lane's monad formulation together with Kelley and Bishop-style metric completion, the $\mathsf{MetricCompletionMonad}^{\uparrow}$ packet records the L10 unit-and-flattening interface for displayed metric completions. It consumes the completion carrier of chapter 1506, the extension route of chapter 2124, the finite completion monad surface of chapter 378, and the regular-window monad of chapter 2136. The packet gives later completion functoriality and complete-metric consumers a single monadic handoff without quotient Cauchy-name equality, selected representatives, countable choice, or an ambient completeness assumption.

Definition 2156.1 (MetricCompletionMonad carrier)**.** *A* $\mathsf{MetricCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Q, U, F, V, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier, metric-distance evidence, and finite observation histories consumed by the completion interface.*
2. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion-object row. It names the displayed Cauchy-filter or Cauchy-net completion packet over X.*
3. *U is the unit-embedding row. It inserts a displayed point of X into Q by copying the source metric observations into the completion-facing route.*
4. *F is the multiplication or flattening row. It flattens a completion object whose entries are themselves displayed completion rows by replaying their finite Cauchy evidence through the same metric source.*
5. *V is the* $\mathsf{MetricCompletionUniversalProperty}^{\uparrow}$ *replay row. It records that unit and flattening consumers may be read through the displayed extension-and-uniqueness surface, rather than through a host quotient of Cauchy names.*
6. *S is the separated-comparison row. It compares two monadic handoffs only through the zero-distance classifier route already displayed by the completion packet.*
7. *H records componentwise* hsame *transport for the metric source, completion object, unit row, flattening row, universal-property replay, separated comparison, package row, and local naming row.*

8. *C records displayed* Cont *replay of the route*

$$X, Q \longmapsto U, F \longmapsto V \longmapsto S.$$

9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionMonad}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, MetricCompletionUniversalProp CauchyCompletionMonad$^{\uparrow}$, RegularCauchyCompletionMonad$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionMonad}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $X, Q, U, F, V, S, H, C, P, N$ and has no coordinate for quotient Cauchy-name equality, selected representatives, countable choice, host completion equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MetricCompletionMonadUp.MetricCompletionMonadTasteGate single carrier alignment`

Theorem 2156.2 (MetricCompletionMonad NameCert obligations)**.** *For an accepted* $\mathsf{MetricCompletionMonad}^{\uparrow}$ *carrier*

$$M = (X, Q, U, F, V, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionMonad}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the displayed metric source X and completion object Q;*
2. *monadic row display for the unit embedding U and flattening route F;*
3. *universal-property replay through V and separated comparison through S;*
4. *structural stability by componentwise* hsame *transport H and displayed* Cont *replay C;*
5. *provenance and local naming through P and N, with no exported quotient, selector, choice, or ambient-completeness coordinate.*

Proof. Project the accepted carrier of Definition 2156.1. The projection exposes the metric source, completion object, unit row, flattening row, universal-property replay, separated comparison, transport, replay, provenance, and local naming rows.

The five obligations are grouped from those displayed rows. The first two obligations read the carrier and monadic data, the third reads the extension and comparison surfaces, the fourth reads stability, and the fifth reads provenance and local naming.

Because the carrier contains no additional coordinate, a consumer cannot obtain quotient Cauchy-name equality, a selected representative, countable choice, host completion equality, or ambient completeness from the certificate. □

Theorem 2156.3 (MetricCompletionMonad unit and multiplication handoff)**.** *For every accepted* $\mathsf{MetricCompletionMonad}^{\uparrow}$ *carrier $M = (X, Q, U, F, V, S, H, C, P, N)$, the unit row U and multiplication row F hand completion-facing consumers through the displayed metric-completion rows. The left-unit, right-unit, and associativity comparisons are comparisons of the finite route*

$$X, Q, U, F, V, S, H, C, P, N,$$

not comparisons of quotient Cauchy names or selected representatives.

Proof. The unit handoff starts with X and Q. The row U copies the displayed source observations into the completion object before any universal-property or separated-comparison read is available.

The multiplication handoff starts with a completion row whose entries are themselves displayed completion rows. The row F flattens that packet by replaying the same metric source and completion-object rows, then routes the result through V and S.

Left unit, right unit, and associativity are therefore checked by comparing the displayed route before and after replay. The rows H, C, P, N preserve the route componentwise and record that no quotient equality, selected representative, countable-choice schedule, or ambient completeness witness is present. □

Theorem 2156.4 (MetricCompletionMonad non-escape)**.** *Every public consumer route exported by an accepted* $\mathsf{MetricCompletionMonad}^{\uparrow}$ *carrier is exhausted by the source metric row, completion-object row, unit embedding, flattening route, universal-property replay, separated comparison,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The packet exports no quotient Cauchy-name equality, selected representatives, countable choice, host completion equality, or ambient completeness theorem.*

Proof. Read an accepted carrier through its displayed tuple. The only rows available to a public consumer are $X, Q, U, F, V, S, H, C, P, N$.

The monadic rows U and F are downstream of the metric source and completion object. The universal-property row V and separated-comparison row S are downstream of those same monadic rows, so they cannot introduce an independent completion object.

Finally, the structural rows transport, replay, package, and name the same finite packet. Since none of the excluded principles appears as a row of the carrier, no public route can export such a principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionMonad}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionMonad}^{\uparrow}$ packet is generated from a MetricUp source row, a MetricCompletionUp completion-object row, unit embedding, multiplication or flattening, MetricCompletionUniversalProperty replay, separated comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionMonad}^{\uparrow}}$, seed)

Scope closed: Definition 2156.1, Definition 2156.2, Definition 2156.3, and Definition 2156.4 seed the finite monadic completion interface over displayed metric source, completion object, unit, flattening, universal-property, separated-comparison, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionMonad}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy-name equality, selected representatives, countable choice, host completion equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, five-row NameCert surface, unit and multiplication handoff, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionMonadUp.

Chapter 2157

A Concrete Naming Certificate for $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$

Following Bourbaki and Kelley on first-countability and sequential closure, the $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$ packet records the finite route by which a local countable base supplies Frechet-tail neighbourhood tests and then exposes a displayed sequential-closure witness. It sits after the local-basis surface of chapter 2053, the cofinite-tail interface of chapter 1564, the sequence-closure packet of chapter 1571, the real sequence limit handoff of chapter 1413, the finite windows of chapter 126, the regular rational readback rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names only the displayed route from countable local bases to sequence-limit closure evidence; it does not identify host points, choose subsequences, quotient filters, prove open-cover compactness, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2157.1 (First-countable sequential-closure carrier)**.** *A* $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, T, Q, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FirstCountableSpace}^{\uparrow}$ *local-basis row. It records the accepted point-window, the local countable neighbourhood ledger, and the topology classifier that every closure request must read.*
2. *T is the* $\mathsf{FrechetFilter}^{\uparrow}$ *tail-neighbourhood row. It turns the local countable request into a cofinite-tail budget before any sequence window is inspected.*
3. *Q is the* $\mathsf{SequentialClosure}^{\uparrow}$ *witness row. It names the displayed source subset, candidate closure point, neighbourhood tests, and metric tests supplied to the closure consumer.*
4. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff row, available only when the sequential witness is read through a real-valued sequence limit.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger for the local basis enumeration, the Frechet threshold, the inspected sequence entries, and the limit handoff.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed metric and real-sequence windows into regular rational data.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the neighbourhood radius, Frechet-tail slack, sequence-window budget, and real-limit comparison scale.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, T, Q, L, W, R, D have been displayed.*
9. *H records componentwise* hsame *transport for the local-basis, Frechet-tail, sequential-closure, real-sequence-limit, stream-window, regular-rational, dyadic-tolerance, Real-seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$B, T \longmapsto Q \longmapsto L, W, R, D \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$, $\mathsf{FirstCountableSpace}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{SequentialClosure}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FirstCountableSequentialClosure}^{\uparrow}}$ *row.*

The carrier has no coordinate for host point equality, selected subsequences, quotient filters, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached closure operator.*

Lean4 ✓ `BEDC.Derived.FirstCountableSequentialClosureUp.FirstCountableSequentialClosureTasteGate single carrier alignment`

Theorem 2157.2 (First-countable sequential-closure NameCert obligations)**.** *For every accepted* $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$ *carrier*

$$F = (B, T, Q, L, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FirstCountableSequentialClosure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the first-countable local basis, Frechet tail, sequential-closure witness, real-sequence-limit handoff, stream windows, regular-rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming row;*
2. *local-basis coverage, requiring every closure-neighbourhood request to read the displayed* $\mathsf{FirstCountableSpace}^{\uparrow}$ *row B before it can ask for sequence data;*
3. *Frechet-tail exactness, requiring the cofinite-tail row T to supply the tail threshold used by the same neighbourhood request;*
4. *sequential-witness exposure, requiring Q to be the only row that exports the displayed sequence-closure witness downstream of B, T;*
5. *real-limit handoff, requiring L, W, R, D to be consumed before the terminal Real seal E is exposed;*
6. *transport and replay stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise;*
7. *non-escape, excluding host point equality, selected subsequences, quotient filters, open-cover compactness, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and detached host closure.*

No first-countable sequential-closure obligation is stored outside these rows.

Proof. Project the accepted carrier $F = (B, T, Q, L, W, R, D, E, H, C, P, N)$. The projection exposes exactly the local first-countable basis, the Frechet tail, the sequential-closure witness, the real-sequence-limit handoff, the stream windows, the regular readback, the dyadic ledger, the Real seal, and the structural rows.

The closure request first consumes the local basis row B. This row fixes the displayed point-window and the countable neighbourhood ledger, so the request cannot replace the local basis by a host family of neighbourhoods.

The Frechet tail row T then supplies the cofinite threshold for the same request. Once the threshold is displayed, the sequential witness row Q reads sequence entries through that tail budget rather than through a selected subsequence or quotient filter.

The real-valued limit side is downstream of the witness. The handoff row L, window ledger W, regular readback R, and dyadic ledger D must all be read before the terminal Real seal E becomes visible.

Finally H, C, P, N transport, replay, source, and name only that finite route. Since host point equality, selected subsequences, quotient filters, open-cover compactness, countable choice, ambient real completeness, and detached host closure have no carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 2157.3 (First-countable sequential-closure route)**.** *Let*

$$F = (B, T, Q, L, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$ *carrier. Every consumer that reads the displayed closure witness factors through the finite route*

$$B, T \longmapsto Q \longmapsto L, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a $\mathsf{FirstCountableSpace}^{\uparrow}$ *local basis, a* $\mathsf{FrechetFilter}^{\uparrow}$ *tail-neighbourhood row, a* $\mathsf{SequentialClosure}^{\uparrow}$ *witness, a* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, package provenance, and local naming. It receives no host point equality, selected subsequence, quotient filter, open-cover compactness principle, countable-choice row, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or detached closure operator.*

Proof. Start with an accepted consumer read of the closure witness. Carrier admission gives access to the witness row Q only together with the local-basis row B and the Frechet-tail row T.

Replay the route through C. The consumer first reads the point-window and local neighbourhood ledger from B, then the cofinite threshold and tail-neighbourhood surface from T, and only then reaches the displayed sequential witness Q.

The real-limit data remain downstream. The rows L, W, R, D expose the real sequence limit, finite windows, regular rational readback, and dyadic tolerance accounting before the Real seal E is reached.

Transport by H, provenance by P, and local naming by N preserve that same order. No remaining carrier row can export host point equality, a selected subsequence, quotient filter equality, open-cover compactness, countable choice, ambient Real completeness, or detached host closure, so every accepted consumer factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FirstCountableSequentialClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$ packet is generated from a FirstCountableSpace local-basis row, a FrechetFilter tail-neighbourhood row, a SequentialClosure witness row, a RealSequenceLimit handoff row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FirstCountableSequentialClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2157.1, Definition 2157.2, and Definition 2157.3 seed the finite route from local countable bases and Frechet tails to displayed sequential-closure witnesses.

Formal verification: FormalStatus(NameCert$_{\text{FirstCountableSequentialClosure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host point equality, selected subsequences, quotient filters, open-cover compactness, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-basis coverage, Frechet-tail exactness, sequential-witness exposure, real-limit handoff, transport, replay, provenance, and local naming for BEDC.Derived.FirstCountableSequentialClo

Chapter 2158

A Concrete Naming Certificate for $\mathsf{QuasiMetric}^{\uparrow}$

Following Lawvere, Nachbin, and Kelley, the $\mathsf{QuasiMetric}^{\uparrow}$ packet records the finite directed-distance surface that sits beside the symmetric metric certificate of chapter 57, the directed entourage carrier of chapter 2334, the filter route of chapter 333, the net route of chapter 589, and the completion consumer of chapter 1473. Its Real-valued distance rows read the terminal seal of chapter 38 through the dyadic tolerance source of chapter 291, so completion-facing consumers see an oriented distance ledger before any uniform-entourage handoff is exposed. The chapter names only that directed NameCert surface; it does not assert symmetry, separatedness, metric completeness, open-cover compactness, quotient distance, selected limits, or a standard bridge.

Definition 2158.1 (QuasiMetric carrier surface)**.** *A* $\mathsf{QuasiMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source carrier row. It names the traditional quasi-metric source and the finite observation context in which directed distance requests are admitted.*
2. *X is the point carrier row. It records the admitted point names and their classifier, but it does not identify points by zero distance.*
3. *D is the directed $\mathsf{Real}^{\uparrow}$-valued distance row. It records oriented requests $d(x, y)$ and keeps the reverse request $d(y, x)$ as a separate row when that reverse request is present.*
4. *Z is the zero-on-diagonal row. It records $d(x, x) = 0$ as a displayed boundary condition on directed distance requests.*
5. *T is the forward triangle ledger. It records the directed comparison from $d(x, z)$ through the ordered pair of rows $d(x, y)$ and $d(y, z)$.*
6. *B is the directed-ball row. It records finite requests of the form $B^{+}(x, \varepsilon)$ by displaying the center, radius, and incoming point through D, Z, T.*
7. *F is the $\mathsf{CauchyFilter}^{\uparrow}$ row. It records filter-base Cauchy reads whose directed balls are supplied by B and whose comparisons remain ordered.*
8. *R is the $\mathsf{CauchyNet}^{\uparrow}$ row. It records net-tail Cauchy reads whose eventual directed-ball comparisons are supplied by B.*

9. *E is the uniform-reflection row. It records the finite handoff from directed balls to* $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, *and completion-facing entourage requests without installing symmetry as primitive data.*

10. *H records componentwise* hsame *transport for source, point-carrier, directed distance, zero diagonal, triangle, directed-ball, Cauchy filter, Cauchy net, uniform reflection, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a consumer request through point admission, directed distance readback, zero diagonal or triangle evidence, directed-ball inspection, Cauchy filter or net readback, uniform reflection, provenance, and local naming.*

12. *P is the* Pkg *provenance over* $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, X, D, Z, T, B, F, R, E, H, C, P, N$. It has no coordinate for symmetry, separated point identity, metric completeness, open-cover compactness, quotient distance, selected limits, quotient completion, or bridge checking.

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricTasteGate single carrier alignment`

Theorem 2158.2 (QuasiMetric NameCert obligation surface)**.** *For every accepted* $\mathsf{QuasiMetric}^{\uparrow}$ *carrier*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the source, point carrier, directed* $\mathsf{Real}^{\uparrow}$*-valued distance row, zero diagonal row, forward triangle row, directed-ball row, Cauchy filter row, Cauchy net row, uniform-reflection row, componentwise transport, displayed replay, provenance, and local name;*

2. *asymmetric distance readback, requiring every exported distance request to keep the ordered pair of point rows visible before the* $\mathsf{Real}^{\uparrow}$ *distance seal is read;*

3. *zero diagonal stability, requiring self-distance to be stored in Z rather than imported from a host metric law;*

4. *oriented triangle stability, requiring each triangle comparison to be displayed in T with its ordered endpoints;*

5. *directed-ball handoff, requiring every ball consumer to pass through B after D, Z, T have been displayed;*

6. *Cauchy filter and Cauchy net routing, requiring filter-base and net-tail comparisons to read F, R through the directed-ball row;*

7. *classifier transport, requiring accepted packets to move only by the componentwise* hsame *row H and the replay row C;*

8. *uniform-reflection handoff, requiring every quasi-uniform, uniform, or completion-facing request to pass through E after the directed balls and Cauchy rows have been displayed;*

9. *ledger non-escape, excluding symmetry, separatedness, metric completeness, open-cover compactness, quotient distance, quotient completion, selected limits, and any standard bridge.*

No quasi-metric NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier namecert obligations`

Proof. Project the carrier of Definition 2158.1. The tuple lists exactly the source, point carrier, directed distance, zero diagonal, forward triangle, directed-ball, Cauchy filter, Cauchy net, uniform-reflection, transport, replay, provenance, and local naming rows.

Asymmetric distance readback is forced by D. A request for $d(x, y)$ keeps x and y in that order, and a request for $d(y, x)$ is a distinct displayed row unless the carrier separately records a comparison between them.

The zero diagonal and triangle obligations are the displayed rows Z and T. Thus reflexive zero and forward triangle comparison are local quasi-metric data, not imported symmetry or host metric structure.

Directed-ball reads use B only after D, Z, T have been displayed. The Cauchy filter and net rows F, R read those directed balls rather than a quotient completion object.

Classifier transport is componentwise through H, while C replays the same ordered route for consumers. The uniform-reflection handoff uses E only after the directed distance, ball, and Cauchy rows have been read.

The remaining exclusions follow from the carrier inventory. Since no coordinate names symmetry, separated identity, metric completeness, open-cover compactness, quotient distance, quotient completion, selected limits, or a standard bridge, none of those data can be exported by the local certificate. □

Theorem 2158.3 (QuasiMetric directed ball handoff)**.** *Let*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N)$$

be an accepted $\mathsf{QuasiMetric}^{\uparrow}$ *packet. Every* $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer that asks for a distance-presented directed ball reaches it only through the finite route*

$$S, X, D, Z, T \longmapsto B \longmapsto F, R, E \longmapsto H, C, P, N.$$

The handoff may reflect to quasi-uniform, uniform, Cauchy-filter, Cauchy-net, or completion-facing rows, but it receives no symmetry theorem, no separated point identity, no metric completeness, no open-cover compactness, no quotient distance, no quotient completion, and no standard bridge.

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier directed ball handoff`

Proof. Start with the accepted carrier. The consumer first reads the source and point rows S, X, then the directed distance ledger D.

The diagonal and triangle rows Z, T are read before any ball-facing handoff. They supply the quasi-metric boundary conditions needed to form directed balls without turning the directed distance into a symmetric metric.

Only after those rows are displayed does the consumer reach B. Filter and net consumers then read F, R, while quasi-uniform, uniform, and completion-facing consumers read the reflection row E.

The support rows H, C, P, N transport, replay, package, and name the same finite route. Therefore the handoff exports finite directed-distance and directed-ball data, not symmetry, separatedness, metric completeness, open-cover compactness, quotient distance, quotient completion, or bridge evidence. □

Theorem 2158.4 (QuasiMetric non-escape boundary)**.** *Every accepted* $\mathsf{QuasiMetric}^{\uparrow}$ *read used by* $\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, *or* $\mathsf{UniformCompletion}^{\uparrow}$ *factors through the displayed rows of Definition 2158.1. In particular, a metric or completion consumer cannot bypass the directed-distance row* D*, the forward triangle ledger* T*, the directed-ball row* B*, the Cauchy rows* F, R*, and the uniform-reflection row* E *by importing symmetry, quotient completion, selected limits, host metric equality,* `Classical.choice`*, or* `Quot.sound`*.*

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier nonescape`

Proof. Apply Definition 2158.2. The NameCert surface stores all quasi-metric obligations in $S, X, D, Z, T, B, F, R, E, H, C, P, N$ and stores none outside those rows.

Apply Definition 2158.3. Every directed-ball, Cauchy, quasi-uniform, uniform, and completion-facing consumer reaches the public route only after D, Z, T, B, F, R, E have been displayed.

A metric-facing consumer may read the sibling metric surface of chapter 57 only as a reflected reader named by E or P. Since the carrier has no primitive coordinate for symmetry, quotient completion, selected limits, host equality, `Classical.choice`, or `Quot.sound`, those exits remain unavailable. □

Theorem 2158.5 (QuasiMetric scope tightening)**.** *Let*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N)$$

be an accepted $\mathsf{QuasiMetric}^{\uparrow}$ *packet. Its directed-distance scope is exactly the displayed route through source, point carrier, directed* $\mathsf{Real}^{\uparrow}$ *distance, zero diagonal, forward triangle, directed balls, Cauchy filter, Cauchy net, uniform reflection, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. Consequently every* $\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of* Q *is bounded by the finite route*

$$S, X, D, Z, T \longmapsto B \longmapsto F, R, E \longmapsto H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier scope tightening`

Proof. Apply the obligation surface of Definition 2158.2. It identifies the carrier rows $S, X, D, Z, T, B, F, R, E, H, C,$ as the full local NameCert inventory and places directed distance, zero diagonal, and forward triangle data before every public ball or completion-facing read.

Next use the directed-ball handoff of Definition 2158.3. It routes quasi-uniform, uniform, Cauchy-filter, Cauchy-net, and completion-facing consumers through B, F, R, E only after the directed-distance prefix has been displayed.

Finally apply the non-escape boundary of Definition 2158.4. Since the carrier has no coordinate for symmetry, separated point identity, metric completeness, open-cover compactness, quotient distance, quotient completion, selected limits, host metric equality, `Classical.choice`, or `Quot.sound`, the displayed row route is not merely sufficient but exact for the scoped directed-distance surface. □

Theorem 2158.6 (QuasiMetric directed-ball triangle refinement)**.** *Let*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N)$$

be an accepted $\mathsf{QuasiMetric}^{\uparrow}$ *packet. If two displayed directed-ball reads in* B *have compatible middle endpoint, with the first read routed from* x *to* y *and the second from* y *to* z*, then their composed*

directed-ball read is exposed only through the asymmetric triangle row T, preserving the source row S, point rows X, directed-distance ledger D, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier directed ball triangle refinement`

Proof. Project the carrier surface of Definition 2158.1. The two directed-ball reads have no source other than S, X, D, Z, T, B, and the middle endpoint compatibility is a displayed point-row match inside X rather than a separated point identity.

Use the oriented triangle obligation in Definition 2158.2. It requires each triangle comparison to be stored in T with ordered endpoints, so composing the x to y and y to z ball reads can only read the displayed asymmetric triangle witness.

The handoff theorem Definition 2158.3 then routes the composed directed ball through B and onward to any Cauchy, uniform, or completion-facing consumer. The support rows H, C, P, N transport, replay, package, and name the same directed-distance witnesses, while Definition 2158.4 excludes symmetry, quotient completion, selected limits, host metric equality, `Classical.choice`, and `Quot.sound`. □

Theorem 2158.7 (QuasiMetric directed-distance scope upgrade)**.** *Let*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N)$$

be an accepted $\mathsf{QuasiMetric}^{\uparrow}$ *packet. Every accepted directed-distance read used by* $\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *must pass through the displayed rows $S, X, D, Z, T, B, F, R, E, H, C, P, N$ of Definition 2158.1. The scope is bound to the finite* BHist *carrier, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* NameCert *naming, Real-valued distance readback, dyadic tolerance comparison, and directed-ball routing.*

Consequently the directed-distance route is a scoped BEDC surface, not a host metric object: no consumer receives symmetry, separated point identity, quotient distance, selected completion limit, ambient metric completeness, open-cover compactness, `Classical.choice`, `Quot.sound`, *or bridge evidence from the* $\mathsf{QuasiMetric}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier directed distance scope upgrade`

Proof. Start with Definition 2158.2. It identifies $S, X, D, Z, T, B, F, R, E, H, C, P, N$ as the complete local NameCert inventory and places the Real-valued directed-distance row D, zero row Z, and forward triangle row T before every public read.

Next apply Definition 2158.3. Directed-ball consumers reach B only after S, X, D, Z, T have been displayed, and Cauchy, quasi-uniform, uniform, and completion-facing consumers then pass through F, R, E before the support rows H, C, P, N are read.

Use Definition 2158.4 to close the non-escape boundary. It rules out host symmetry, separated equality, quotient completion, selected limits, `Classical.choice`, and `Quot.sound` as alternate exits from the packet.

Finally invoke Definition 2158.6. The composed directed-ball comparisons read the asymmetric triangle row T and preserve the same BHist, hsame, Cont, Pkg, and NameCert support. Thus every listed consumer receives exactly the directed-distance scope carried by the displayed rows. □

Theorem 2158.8 (QuasiMetric public certificate)**.** *For every accepted* $\mathsf{QuasiMetric}^{\uparrow}$ *packet*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N),$$

the public directed-distance certificate is the assembled row route

$\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, Rea

It is obtained by combining the carrier surface of Definition 2158.1, the NameCert obligations of Definition 2158.2, the directed-ball handoff of Definition 2158.3, the non-escape boundary of Definition 2158.4, the directed-ball triangle refinement of Definition 2158.6, and the directed-distance scope upgrade of Definition 2158.7. The certificate exports directed $\mathsf{Real}^{\uparrow}$*-valued distance, zero diagonal, forward triangle, directed-ball, Cauchy, uniform-reflection, transport, replay, provenance, and local naming rows, but it exports no symmetry, separatedness, quotient completion, selected limits, host equality,* `Classical.choice`*,* `Quot.sound`*, or bridge evidence.*

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier public certificate`

Proof. First read the carrier surface of Definition 2158.1. It displays the source and point rows S, X, the directed $\mathsf{Real}^{\uparrow}$ distance row D, the zero and forward-triangle rows Z, T, the directed-ball row B, Cauchy filter and net rows F, R, the uniform-reflection row E, and the structural rows H, C, P, N.

Next apply the NameCert obligation surface of Definition 2158.2. That theorem identifies carrier admission, directed distance readback, zero diagonal stability, forward triangle stability, directed-ball handoff, Cauchy routing, classifier transport, uniform reflection, and ledger non-escape as the exact local obligations.

Use Definition 2158.3 and Definition 2158.6 to assemble the public route. Directed balls are read only after S, X, D, Z, T, composed directed-ball comparisons read the asymmetric triangle row T, and Cauchy, quasi-uniform, uniform, and completion-facing consumers pass through B, F, R, E before the support rows are read.

Finally use Definition 2158.4 and Definition 2158.7. They close the route as a public certificate over the displayed rows and rule out alternate exits through symmetry, separatedness, quotient completion, selected limits, host equality, `Classical.choice`, `Quot.sound`, or bridge evidence. □

Theorem 2158.9 (QuasiMetric public NameCert export)**.** *For every accepted* $\mathsf{QuasiMetric}^{\uparrow}$ *packet*

$$Q = (S, X, D, Z, T, B, F, R, E, H, C, P, N),$$

the public directed-distance certificate of Definition 2158.8 is exactly the local $\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$ *export over the source row S, point carrier X, directed* $\mathsf{Real}^{\uparrow}$ *distance row D, zero row Z, forward triangle row T, directed-ball row B, Cauchy filter row F, Cauchy net row R, uniform-reflection row E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming row N. The export records dyadic tolerance comparison and directed-ball routing for the Real-valued distance surface, but it exports no symmetry, separated equality, quotient completion, selected limit, ambient completeness, open-cover compactness, or bridge evidence.*

Lean4 ✓ `BEDC.Derived.QuasiMetricUp.QuasiMetricCarrier public namecert export`

Proof. First apply Definition 2158.8. It assembles the public directed-distance certificate from the carrier, obligation surface, directed-ball handoff, triangle refinement, scope route, and non-escape boundary.

Next use Definition 2158.7. It keeps every Real- or dyadic-facing distance read inside $S, X, D, Z, T, B, F, R, E, H$ so the public certificate has no hidden parameter transport outside the displayed packet.

Finally apply Definition 2158.4. Since symmetry, separated equality, quotient completion, selected limits, host equality, `Classical.choice`, `Quot.sound`, and bridge evidence are absent

from the carrier, the public certificate is precisely the local $\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$ export over the listed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{QuasiMetric}^{\uparrow}$ packet is generated from a source row, a point carrier, a directed RealUp-valued distance row, a zero diagonal row, a forward triangle row, a directed-ball row, Cauchy filter and Cauchy net rows, a uniform-reflection row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$, publicClosed)

Scope closed: Definition 2158.8 is the exported public directed-distance route assembled from the displayed source, point, Real-valued distance, zero diagonal, forward triangle, directed-ball, Cauchy, uniform-reflection, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{QuasiMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close symmetry, separatedness, metric completeness, open-cover compactness, quotient distance, quotient completion, selected limits, standard bridge evidence, Lean verification, or bridge checking.

Upgrade path: Public closure requires checked carrier admission, directed distance readback, zero diagonal stability, forward triangle stability, directed-ball handoff, Cauchy routing, uniform reflection, classifier transport, and ledger non-escape for BEDC.Derived.QuasiMetricUp.

Chapter 2159

A Concrete Naming Certificate for LeibnizAlternatingRemainder$^{\uparrow}$

Following Leibniz and Bishop–Bridges constructive alternating-series analysis, the LeibnizAlternatingRemainder$^{\uparrow}$ packet records the finite route by which an alternating real series exposes a next-term remainder budget before any completion-facing consumer may read a regular rational handoff or a real seal. It sits after the finite partial-sum surface of RealSeries$^{\uparrow}$ in chapter 1581, the convergence-test route of AlternatingSeriesTest$^{\uparrow}$ in chapter 1483, the null-tail surface of NullSequence$^{\uparrow}$ in chapter 380, the finite observation windows of StreamName$^{\uparrow}$ in chapter 126, the regular rational readback of RegSeqRat$^{\uparrow}$ in chapter 301, the dyadic tolerance ledger of DyadicRatCore$^{\uparrow}$ in chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38. It also names the finite completion-facing row used by the local Leibniz streams of RealAnalytic$^{\uparrow}$ in chapter 74: the analytic chapter may display unary Leibniz partial sums, while this packet isolates the remainder certificate consumed by Real and Completion routes.

Definition 2159.1 (Leibniz alternating remainder carrier)**.** *A* LeibnizAlternatingRemainder$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, \Sigma, M, T, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* RealSeries$^{\uparrow}$ *source row. It exposes the real-valued summand stream and the displayed partial sums only through the finite series surface already named for real series.*
2. *Σ is the alternating-sign ledger. It records the parity row assigning the sign of every inspected summand and the adjacent partial-sum direction used by the remainder estimate.*
3. *M is the monotone null-tail row. It records nonnegative magnitude reads, the displayed monotonicity comparisons on the inspected tail, and the* NullSequence$^{\uparrow}$ *request ensuring that the next omitted magnitude can be made smaller than any requested dyadic tolerance.*
4. *T is the* AlternatingSeriesTest$^{\uparrow}$ *handoff row. It records that the displayed source, sign ledger, monotone magnitude row, and tail schedule are accepted by the alternating-series-test surface before any remainder read is exported.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *remainder-budget ledger. For each precision request it records the dyadic tolerance, the selected cutoff, the next omitted magnitude, and the finite comparison certifying that the remainder budget is bounded by that next magnitude.*

6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family for summands, signs, magnitudes, partial sums, next omitted terms, dyadic comparisons, and endpoint-facing reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic remainder budgets.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Σ, M, T, D, W, R have been displayed.*
9. *H records componentwise* hsame *transport for the source, sign ledger, monotone null-tail row, alternating-test handoff, dyadic budget, stream windows, regular readback, real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay of the route*

$$S, \Sigma, M, T, D, W \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AlternatingSeriesTest}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAnalytic}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LeibnizAlternatingRemainder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, \Sigma, M, T, D, W, R, E, H, C, P, N$. It has no coordinate for a selected infinite sum, quotient stream equality, host real equality, countable choice, trichotomy outside the displayed dyadic comparisons, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an analytic endpoint not routed through the listed rows.*

Lean4 ✓ `BEDC.Derived.LeibnizAlternatingRemainderUp.LeibnizAlternatingRemainderTasteGate single carrier alignment`

Theorem 2159.2 (Leibniz alternating remainder NameCert obligations)**.** *For every accepted* $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ *carrier*

$$L = (S, \Sigma, M, T, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LeibnizAlternatingRemainder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the twelve displayed rows;*
2. $\mathsf{RealSeries}^{\uparrow}$ *source exposure, requiring every summand and partial-sum read to pass through S;*
3. *alternating-sign exposure, requiring Σ to bind every inspected partial-sum step to its finite parity row;*
4. *monotone null-tail exactness, requiring M to display the nonnegative magnitude row, the observed monotone comparisons, and the* $\mathsf{NullSequence}^{\uparrow}$ *tail request used by the remainder budget;*
5. *alternating-test compatibility, requiring T to consume only S, Σ, M and the displayed tail schedule;*
6. *dyadic remainder-budget exactness, requiring D to pair every requested tolerance with a cutoff, next omitted magnitude, and comparison row;*
7. *finite-window and regular-readback compatibility, requiring W and R to expose the same summand, partial-sum, omitted-term, and budget data;*

8. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring* E *to remain downstream of* S, Σ, M, T, D, W, R*;*

9. *componentwise transport, displayed replay, provenance, and local naming for the same route through* H, C, P, N*.*

No Leibniz remainder obligation is stored outside these rows.

Proof. Project the accepted packet $L = (S, \Sigma, M, T, D, W, R, E, H, C, P, N)$. The carrier exposes exactly the source, sign, magnitude, alternating-test, dyadic-budget, window, readback, seal, and structural rows.

The source and sign obligations come first. The row S provides only finite $\mathsf{RealSeries}^{\uparrow}$ term and partial-sum observations, while Σ attaches each inspected summand to the parity ledger used by the alternating partial sums.

The tail obligations are finite. The row M displays the nonnegative magnitude reads, their monotone comparisons on the inspected tail, and the null-sequence request. The handoff row T then records that these displayed rows enter the $\mathsf{AlternatingSeriesTest}^{\uparrow}$ surface.

The remainder budget is fixed by D. For each requested tolerance, D names a cutoff and the next omitted magnitude, and it records the dyadic comparison that bounds the remainder by that displayed magnitude. The rows W and R expose the same finite observations as stream windows and regular rational readback.

Finally E, H, C, P, N seal, transport, replay, source, and name that route. Since no excluded object occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 2159.3 (Leibniz alternating remainder tail bound)**.** *For every accepted* $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ *carrier*

$$L = (S, \Sigma, M, T, D, W, R, E, H, C, P, N),$$

each endpoint-facing remainder request factors through the finite route

$$S, \Sigma, M, T \longmapsto D, W \longmapsto R.$$

The dyadic row D *therefore binds the absolute remainder budget to the next omitted displayed magnitude read from* M*, and the regular readback* R *may be consumed only after the same cutoff, sign ledger, monotone null-tail row, and stream window have been displayed.*

Proof. Begin with an endpoint-facing remainder request. The carrier first exposes the real-series source S and the alternating-sign ledger Σ, so the request sees only displayed summands and their finite parity data.

Read the monotone null-tail row M and the alternating-test handoff T. These rows provide the displayed nonnegative magnitudes, the observed decrease comparisons, the null-tail request, and the test compatibility needed for the selected cutoff.

The dyadic ledger D then pairs the requested tolerance with that cutoff and the next omitted magnitude. Because the monotone tail and alternating sign have already been displayed, the classical Leibniz estimate is represented here as a finite BEDC comparison row rather than as an external convergence theorem.

The rows W and R expose the same observations as finite windows and regular rational readback. Thus the readback cannot bypass the source, sign, null-tail, test, or budget rows while still serving the remainder request. □

Theorem 2159.4 (Leibniz alternating remainder Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealAnalytic}^{\uparrow}$*-facing read from an accepted* $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ *carrier reaches its terminal seal only through*

$$S, \Sigma, M, T, D, W, R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet exports a finite remainder certificate for Real and Completion consumers, including the local Leibniz stream rows used by $\mathsf{RealAnalytic}^{\uparrow}$*, but it exports no selected infinite sum, quotient stream equality, host real equality, countable-choice selector, unrestricted trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or analytic endpoint detached from the displayed remainder route.*

Proof. Use Definition 2159.3 to place every remainder request behind the source, sign, monotone null-tail, alternating-test, dyadic-budget, window, and regular-readback rows.

The terminal row E is a $\mathsf{Real}^{\uparrow}$ seal for that already displayed route. It is not a selected value of an infinite alternating sum, and it does not assert host completeness for arbitrary real streams.

For a $\mathsf{RealAnalytic}^{\uparrow}$ consumer, the same boundary applies. The analytic chapter may read unary Leibniz partial-sum rows, but the completion-facing endpoint must still pass through the displayed remainder budget and regular readback before it reaches E.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Since the carrier has no coordinate for the excluded principles or for a detached analytic endpoint, none can escape through the seal boundary. □

Falsifiable prediction: Every $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ endpoint-facing read factors through a RealSeriesUp source, alternating-sign ledger, monotone NullSequenceUp tail row, AlternatingSeriesTestUp handoff, DyadicRatCoreUp remainder budget, StreamNameUp windows, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, alternating-series-test, nullsequence, streamname, regseqrat, dyadicratcore, real, real-analytic: $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the next-omitted-term remainder budget, alternating parity, monotone null-tail schedule, regular readback, Real sealing, analytic-stream consumer boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LeibnizAlternatingRemainder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LeibnizAlternatingRemainder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2159.1, Definition 2159.2, Definition 2159.3, and Definition 2159.4 seed the finite Leibniz alternating-remainder certificate surface from displayed real-series partial sums and monotone null tails through dyadic next-omitted-term budgets to regular readback and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LeibnizAlternatingRemainder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient stream equality, host real equality, countable choice, unrestricted trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, detached analytic endpoints, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-ledger exactness, monotone null-tail exactness, dyadic next-omitted-term budget stability, RegSeqRat readback, Real seal non-escape, analytic-stream boundary compatibility, transport, replay, provenance, and local naming for BEDC.Derived.LeibnizAlternatingRemainderUp.

Constructive story: A $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ packet is generated from a RealSeriesUp source, alternating-sign ledger, monotone NullSequenceUp tail row, AlternatingSeriesTestUp handoff, DyadicRatCoreUp remainder budget, StreamNameUp windows, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2160

A Concrete Naming Certificate for $\mathsf{PeanoContinuum}^{\uparrow}$

Following Hahn and Mazurkiewicz, the $\mathsf{PeanoContinuum}^{\uparrow}$ packet records a compact, connected, locally connected metric continuum as finite BEDC NameCert data. It sits over the compact-metric source of chapter 129, the chain-connected route of chapter 2050, the complete separable metric boundary of chapter 1735, the Polish-space readback of chapter 1490, and the continuous-map surface of chapter 59. The packet names the finite continuum interface needed by interval-image and compact-metric consumers without importing host point-set topology, quotient point equality, open-cover compactness, countable choice, or the full Hahn–Mazurkiewicz theorem.

Definition 2160.1 (Peano continuum carrier)**.** *A* $\mathsf{PeanoContinuum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, K, S, L, I, R, H, C, Q, N)$$

with the following displayed rows:

1. *X is the compact-metric source row, including the displayed metric carrier, finite compactness data, total-boundedness ledger, and complete metric handoff read through chapter 129.*
2. *K is the connectedness row. It is either a directly displayed connectedness witness or a* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *route whose finite chain ledgers are admitted as the connectedness-facing evidence for the same metric source.*
3. *S is the complete-separable and Polish readback row. It records the common dense-window and completion boundary consumed by chapter 1735 and chapter 1490.*
4. *L is the finite local-connectedness refinement ledger. For each displayed compact-window request, it records a finite family of connected neighbourhood rows, inclusion refinements, overlap certificates, and radius comparisons over the source metric.*
5. *I is the interval and continuum readback row. It records the finite interval-source windows and continuum-facing observations that later consumers read before asking for an interval image or a compact continuum boundary.*
6. *R is the continuous readback row, exposing only the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and modulus rows that connect the interval windows in I to the compact-metric source row X.*
7. *H records componentwise* hsame *transport for the compact-metric source, connectedness route, complete-separable and Polish readback, local-connectedness ledger, interval and continuum readback, continuous-map rows, provenance, and local naming row.*

8. *C records displayed* Cont *replay of the route*

$$X, K, S, L, I \longmapsto R \longmapsto H, Q, N.$$

9. *Q is the* Pkg *provenance over* PeanoContinuum$^{\uparrow}$, CompactMetric$^{\uparrow}$, ChainConnectedMetric$^{\uparrow}$, CompleteSeparableMe PolishSpace$^{\uparrow}$, ContinuousMap$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{PeanoContinuum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, S, L, I, R, H, C, Q, N$. The carrier has no coordinate for host point-set topology, open-cover compactness, quotient point equality, countable choice, a selected space-filling map, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.PeanoContinuumUp.PeanoContinuumTasteGate single carrier alignment`

Theorem 2160.2 (Peano continuum NameCert obligations)**.** *For every accepted* PeanoContinuum$^{\uparrow}$ *carrier*

$$P = (X, K, S, L, I, R, H, C, Q, N),$$

the local NameCert$_{\text{PeanoContinuum}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact-metric source, connectedness route, complete-separable and Polish readback, local-connectedness ledger, interval and continuum readback, continuous readback, transport, replay, provenance, and local naming row;*

2. *compact-metric handoff, requiring every metric, compactness, finite-net, and completion-facing read to pass through the single source row X;*

3. *connectedness visibility, requiring K to expose either the displayed connectedness evidence or the finite* ChainConnectedMetric$^{\uparrow}$ *route before a continuum-facing consumer may read the packet;*

4. *local-connectedness refinement, requiring L to record finite connected-neighbourhood refinements, inclusion rows, overlap certificates, and radius comparisons for each displayed compact-window request;*

5. *continuous-image readback nonescape, requiring I and R to be displayed before any interval-image or continuum read is exported;*

6. *provenance exhaustion, requiring H, C, Q, N to transport, replay, source, and name exactly the rows listed above and no host point-set topology, open-cover compactness, quotient point equality, countable-choice selector, full Hahn–Mazurkiewicz theorem, Lean verification, or bridge credential.*

No Peano-continuum obligation is stored outside these rows.

Proof. Project the accepted carrier $P = (X, K, S, L, I, R, H, C, Q, N)$. The row list in Definition 2160.1 is the whole visible packet, so carrier admission is projection from the displayed finite BHist data.

The compact-metric handoff is forced by the source coordinate. Every metric, compactness, finite-net, and completion-facing request first reads X, and the complete-separable and Polish row S is only a readback of that same displayed source.

Connectedness is visible through K. If the packet uses direct connectedness evidence, the row is read as displayed data; if it uses chain-connectedness, the finite ChainConnectedMetric$^{\uparrow}$ route supplies the endpoint, chain, radius, and tolerance ledgers over the same source X.

Local connectedness is confined to L. Each refinement request is answered by a finite ledger of connected neighbourhood rows, inclusion refinements, overlap certificates, and radius comparisons, so no host open-set lattice or point-set topology is introduced.

The interval and continuous-image rows are downstream. A consumer must read I and then R before receiving an interval-image or continuum observation, and R exposes only the graph and modulus rows admitted by the continuous-map surface.

Finally H, C, Q, N transport, replay, source, and name the same rows componentwise. Since the refused principles have no carrier coordinate and no replay edge, the listed obligations exhaust the local NameCert surface. □

Theorem 2160.3 (Peano continuum locally connected handoff)**.** *Every continuum-facing consumer read of an accepted* $\mathsf{PeanoContinuum}^{\uparrow}$ *carrier factors through the finite route*

$$X \longmapsto K \longmapsto S \longmapsto L \longmapsto I \longmapsto R \longmapsto H, C, Q, N.$$

Thus the consumer receives the compact-metric row, connectedness row, finite local-connectedness refinement ledger, interval and continuum readback, continuous readback, componentwise transport, continuation replay, package provenance, and local naming. It receives no host point-set topology, open-cover compactness, quotient point equality, countable choice, selected space-filling map, full Hahn–Mazurkiewicz theorem, Lean verification, or bridge checking.

Proof. Start with a continuum-facing read of the accepted packet. The compact-metric source row X is the first admissible row because every later interval, local-connectedness, and completion-facing observation is measured over that source.

The connectedness and complete-separable boundaries are then fixed. The row K supplies the displayed connectedness or chain-connectedness route, while S records the complete-separable and Polish readback for the same metric data rather than for a second host space.

Next read the local-connectedness ledger L. Its finite refinement rows give the connected neighbourhood, inclusion, overlap, and radius-comparison data required by the consumer before the interval readback is exposed.

The interval and continuous readback rows complete the functional handoff. The row I supplies the interval and continuum observations, and R supplies the continuous-map graph and modulus rows through which those observations are replayed.

The structural rows close the route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming preserve exactly this dependency order, so every consumer read factors through the compact-metric row, connectedness row, finite local-connectedness ledger, continuous readback, transport, replay, provenance, and local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{PeanoContinuum}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PeanoContinuum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2160.1, Definition 2160.2, and Definition 2160.3 seed the finite compact, connected, locally connected metric continuum packet over compact-metric, chain-connected, complete-separable, Polish, continuous-map, local-connectedness, interval-readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PeanoContinuum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host point-set topology, open-cover compactness, quotient point equality, countable choice, selected space-filling maps, a full Hahn–Mazurkiewicz theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric handoff, connectedness visibility, local-connectedness refinement, continuous-image readback nonescape, provenance exhaustion, and locally connected handoff for BEDC.Derived.PeanoContinuumUp.

Constructive story: A $\mathsf{PeanoContinuum}^{\uparrow}$ packet is generated from a compact-metric source row, connectedness or ChainConnectedMetric evidence, CompleteSeparableMetric and PolishSpace readback, a finite local-connectedness

refinement ledger, interval and continuum readback rows, ContinuousMap graph and modulus rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2161

A Concrete Naming Certificate for CodonWindowSpectralInverse$^{\uparrow}$

The CodonWindowSpectralInverse$^{\uparrow}$ packet realizes the codon-window spectral inverse vision of subsection 9462.28.22 as finite BEDC NameCert data. It sits beside the stop-face suffix packet of chapter 1374, the finite bit-path carrier of chapter 346, the zero-spine arithmetic route of chapter 277, and the window-six dynamics bridge of subsection 9462.28.20. Its role is a finite inverse packet: it records the codon cube, two-axis atlas, local face spectra, stop-face reconstruction row, adjacency spectra, reassignment spectra, transport, replay, provenance, and local naming without identifying the biological code table with a BEDC kernel primitive.

Definition 2161.1 (Codon-window spectral inverse carrier)**.** *A* CodonWindowSpectralInverse$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (C, A, F, H, R, T, Q, E, K, D, P, N)$$

with the following displayed rows:

1. *C is the codon-cube row. It records the finite Q_6 carrier, the three two-bit base windows, and the displayed* BitVector$^{\uparrow}$ *paths used to read a codon window.*
2. *A is the two-axis atlas row. It records the* $\mathrm{Y/R}$ *and* $\mathrm{W/S}$ *readback for* $\mathrm{U, C, A, G}$ *and keeps RNA/DNA spelling as bridge data rather than as a kernel equality.*
3. *F is the local face enumeration row. It records the finite Q_2 faces, the selected stop/trp face, and the face labels consumed by the inverse spectrum.*
4. *H is the local face spectrum row. It records multiplicity and class-pattern rows for each displayed face named by F.*
5. *R is the Hamming adjacency spectrum row. It records one-bit adjacency boundaries, class changes, and local control-tile comparisons over the same Q_6 carrier.*
6. *T is the reassignment spectrum row. It records finite comparison rows across displayed biological bridge tables or controlled perturbation rows.*
7. *Q is the stop-face row. It records the* $\mathrm{U+RR}$ *square, the family-suffix coordinates* $00, 01, 10, 11$, *and the retained $X_2 = \{00, 01, 10\}$ stop candidates.*
8. *E records componentwise* hsame *transport for codon-cube, atlas, face, spectrum, adjacency, reassignment, stop-face, replay, provenance, and local naming rows.*

9. *K records displayed* Cont *replay from a spectral inverse request through the cube, atlas, face enumeration, local spectra, adjacency spectra, reassignment spectra, stop-face row, provenance, and local name.*

10. *D is the inverse-decision ledger. It records which finite rows are used to constrain a local coding mechanism and refuses any hidden global code-table reconstruction row.*

11. *P is the* Pkg *provenance over* $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$, $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$, $\mathsf{BitVector}^{\uparrow}$, $\mathsf{AxisAdd}^{\uparrow}$, *the codon-window-six and DNA-window-six bridge rows,* BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CodonWindowSpectralInverse}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, A, F, H, R, T, Q, E, K, D, P, N$. It has no coordinate for a host genetic-code table, a selected global inverse, biological universality, quotient codon equality, probabilistic inference, or a choice principle.

Lean4 ✓ `BEDC.Derived.CodonWindowSpectralInverseUp.TasteGate.CodonWindowSpectralInverseTasteGate single carrier alignment`

Theorem 2161.2 (Codon-window spectral inverse NameCert obligations)**.** *For every accepted* $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ *carrier*

$$S = (C, A, F, H, R, T, Q, E, K, D, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CodonWindowSpectralInverse}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the codon cube, two-axis atlas, local face enumeration, local face spectra, Hamming adjacency spectra, reassignment spectra, stop-face row, transport, replay, inverse-decision ledger, provenance, and local naming row;*

2. *cube exactness, requiring every codon-window read to pass through the finite Q_6 row C and its displayed* $\mathsf{BitVector}^{\uparrow}$ *coordinates;*

3. *atlas compatibility, requiring all biological spelling reads to pass through A before any face or spectrum row is consumed;*

4. *local spectrum coverage, requiring F, H, R, T to expose the finite face, multiplicity, adjacency, and reassignment rows used by the inverse packet;*

5. *stop-face reconstruction, requiring Q to display the* $\mathrm{U}+\mathrm{RR}$ *face and the retained X_2 suffix rows before a stop-candidate read is exported;*

6. *transport and replay stability, requiring E and K to move only the displayed rows and preserve the same carrier inventory under* hsame *and* Cont *replay;*

7. *provenance and non-escape, requiring D, P, N to record the consumed sibling packets and to exclude host genetic-code tables, selected global inverses, biological universality, quotient codon equality, probabilistic inference, and choice.*

No codon-window spectral inverse obligation is stored outside these rows.

Proof. Project the accepted carrier $S = (C, A, F, H, R, T, Q, E, K, D, P, N)$. The tuple inventory is the whole visible packet, so carrier admission is projection from the displayed finite BHist data.

Cube exactness is forced by C. Every codon-window request reads the finite Q_6 carrier and its three two-bit $\mathsf{BitVector}^{\uparrow}$ windows before any biological or spectral classifier row is available.

Atlas compatibility is confined to A. The RNA/DNA spelling and the two-axis readback are bridge rows over the finite cube, not kernel equalities and not a host code table.

The local spectrum rows are F, H, R, T. They enumerate the finite faces, attach local face spectra, record one-bit adjacency boundaries, and compare reassignment rows, so the inverse packet can constrain local mechanisms without selecting a global table.

The stop-face row Q supplies the finite $\mathrm{U} + \mathrm{RR}$ square and the retained X_2 suffix rows. Transport through E and replay through K preserve these rows componentwise, while D, P, N record the consumed route and local name. □

Theorem 2161.3 (Codon-window stop-face reconstruction route)**.** *Let $S = (C, A, F, H, R, T, Q, E, K, D, P, N)$ be an accepted* $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ *carrier. Every stop-face reconstruction read exported by S factors through the finite route*

$$C, A, F, H, R, T \longmapsto Q \longmapsto E, K, D, P, N.$$

The exported read receives the codon cube, two-axis atlas, local face enumeration, local face spectra, Hamming adjacency spectra, reassignment spectra, stop-face row, componentwise transport, replay, inverse-decision ledger, provenance, and local name. It receives no host genetic-code table, selected global inverse, biological universality claim, quotient codon equality, probabilistic inference row, or choice principle.

Proof. Start with the accepted packet and read C and A. These rows fix the finite codon carrier and the two-axis spelling bridge before any spectral data are visible.

Next read F, H, R, T. The local faces, local spectra, Hamming adjacency boundaries, and reassignment comparisons are all finite rows over the same displayed cube, so no global code-table search is introduced.

The stop-face row Q then identifies the $\mathrm{U} + \mathrm{RR}$ square and the X_2 suffix subset. This is the only row through which a stop-face reconstruction may pass.

Finally the structural rows E, K, D, P, N transport, replay, audit, source, and name the same route. Since the refused principles have no carrier coordinate and no replay edge, the stop-face reconstruction read exports only the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ stop-face or local inverse read factors through one finite codon-cube row, one two-axis atlas row, finite local face spectra, Hamming adjacency spectra, reassignment spectra, one stop-face row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Empirical comparison may reject a chosen biological bridge by showing that its local face spectra, adjacency spectra, or reassignment spectra do not match observed genetic-code table rows.

Independence witness: stopcodonzeckendorfsuffix, bitvector, axisadd, codon-window-six-bridge, dna-window-six-dynamics-bridge: $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the codon cube, two-axis atlas, local face enumeration, local face spectra, Hamming adjacency spectra, reassignment spectra, stop-face reconstruction row, inverse-decision ledger, transport, replay, provenance, and local naming.

The Lean follow-up file `lean4/BEDC/Derived/CodonWindowSpectralInverseUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{CodonWindowSpectralInverse}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{CodonWindowSpectralInverse}^{\uparrow}$ instances, with field-projection proofs preserving $C, A, F, H, R, T, Q, E, K, D, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{CodonWindowSpectralInverse}^{\uparrow}}$.

Constructive story: A CodonWindowSpectralInverse$^{\uparrow}$ packet is generated from a codon-cube row, two-axis atlas row, local face enumeration, local face spectra, Hamming adjacency spectra, reassignment spectra, stop-face row, componentwise hsame transport, displayed Cont replay, inverse-decision ledger, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CodonWindowSpectralInverse}^{\uparrow}}$, seed)

Scope closed: Definition 2161.1, Definition 2161.2, and Definition 2161.3 seed the finite codon-window spectral inverse packet over codon cube, atlas, face spectra, adjacency spectra, reassignment spectra, stop-face, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CodonWindowSpectralInverse}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host genetic-code tables, selected global inverses, biological universality, quotient codon equality, probabilistic inference, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cube exactness, atlas compatibility, local spectrum coverage, stop-face reconstruction, transport and replay stability, provenance non-escape, Nontrivial CodonWindowSpectralInverseUp, and FieldFaithful CodonWindowSpectralInverseUp for BEDC.Derived.CodonWindowSpectralInverseUp.

Chapter 2162

A Concrete Naming Certificate for $\mathsf{RealApproximationScheme}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealApproximationScheme}^{\uparrow}$ packet records a constructive real approximation interface as finite BEDC NameCert data. It sits between the stream observations of chapter 126, the dyadic tolerance rows of chapter 291, the regular-sequence readback of chapter 301, and the sealed real boundary of chapter 38. The packet names the approximation route needed by later Real, metric, and continuous-map certificates without importing host real equality, quotient streams, selected limits, trichotomy, or ambient completeness.

Definition 2162.1 (Real approximation scheme carrier)**.** *A* $\mathsf{RealApproximationScheme}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It records the finite schedule of requested observations, the visible stream-name windows, and the order in which a consumer may read them.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic radii, comparison cells, shrink steps, and budget rows attached to each displayed observation request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational sequence data that consumes S and D before any real-facing seal is exposed.*
4. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records only the finite real-boundary interface reached through the regular readback, not a host real value.*
5. *H records componentwise* hsame *transport for the stream observations, dyadic tolerance rows, regular readback, real seal row, continuation route, package provenance, and local naming row.*
6. *C records displayed* Cont *replay of the route*

$$S, D \longmapsto R \longmapsto Q \longmapsto H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{RealApproximationScheme}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealApproximationScheme}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, D, R, Q, H, C, P, N. The carrier has no coordinate for host real equality, quotient streams, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RealApproximationSchemeUp.RealApproximationSchemeTasteGate single carrier alignment`

Theorem 2162.2 (Real approximation scheme NameCert obligations)**.** *For every accepted* RealApproximationScher *carrier*

$$A = (S, D, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealApproximationScheme}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream observations, dyadic tolerance ledger, regular readback, real seal boundary, transport, replay, provenance, and local naming row;*
2. *stream observability, requiring every approximation request to enter through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in S;*
3. *dyadic tolerance exactness, requiring every precision demand to be witnessed by a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, shrink, comparison, or budget row in D;*
4. *regular readback routing, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to consume the stream and dyadic rows before a real-facing consumer may read the packet;*
5. *real seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *seal row Q to be reached only through R and never through a host real representative;*
6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the rows listed above and no host real equality, quotient stream, selected limit, trichotomy, ambient completeness, Lean verification, or bridge credential.*

No real-approximation-scheme obligation is stored outside these rows.

Proof. Project the accepted carrier $A = (S, D, R, Q, H, C, P, N)$. The definition lists the whole visible packet, so carrier admission is just the displayed finite BHist data together with its transport, replay, provenance, and naming rows.

The observation side is forced by S. Every approximation request first reads the $\mathsf{StreamName}^{\uparrow}$ windows and schedule before any tolerance or readback row can be consumed.

The precision side is forced by D. The dyadic radii, shrink steps, comparison cells, and budget rows are the only tolerance coordinates available to the packet, so a consumer cannot replace them by an ambient metric or a host real estimate.

The real-facing route passes through R and then Q. The $\mathsf{RegSeqRat}^{\uparrow}$ row reads the stream and dyadic data as a regular rational sequence, and the $\mathsf{Real}^{\uparrow}$ seal row exposes only the finite boundary supplied by that readback.

Finally H, C, P, N transport, replay, source, and name the same rows componentwise. Since the refused principles have no coordinate and no replay edge, the listed obligations exhaust the local NameCert surface. □

Theorem 2162.3 (Real approximation scheme RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{RealApproximationScheme}^{\uparrow}$ *carrier factors through the finite route*

$$S, D \longmapsto R \longmapsto Q \longmapsto H, C, P, N.$$

Thus the consumer receives the $\mathsf{StreamName}^{\uparrow}$ *observation windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. It receives no host real equality, quotient stream, selected limit, trichotomy, ambient completeness, Lean verification, or bridge checking.*

Proof. Start with a consumer read of the accepted packet. The stream observation row S supplies the finite request schedule and visible windows, so the read begins with a named $\mathsf{StreamName}^{\uparrow}$ surface rather than an unbounded stream.

Next read the dyadic tolerance row D. The row provides the $\mathsf{DyadicRatCore}^{\uparrow}$ radii, shrink steps, comparison cells, and budget entries attached to the same observations, so the read has a finite precision ledger before it reaches a regular sequence.

The handoff is then the row R. It packages the observed stream and tolerance data as the $\mathsf{RegSeqRat}^{\uparrow}$ readback consumed by later real-facing certificates.

The real boundary is last. The row Q records only the $\mathsf{Real}^{\uparrow}$ seal reached through R, and the structural rows H, C, P, N preserve exactly this route by componentwise transport, continuation replay, provenance, and local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealApproximationScheme}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealApproximationScheme}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2162.1, Definition 2162.2, and Definition 2162.3 seed the finite approximation packet over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealApproximationScheme}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient streams, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream observability, dyadic tolerance exactness, regular readback routing, real seal nonescape, and provenance exhaustion for BEDC.Derived.RealApproximationSchemeUp.

Constructive story: A $\mathsf{RealApproximationScheme}^{\uparrow}$ packet is generated from StreamName observation windows, DyadicRatCore tolerance rows, RegSeqRat readback, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2163

A Concrete Naming Certificate for $\mathsf{SqueezeTheorem}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SqueezeTheorem}^{\uparrow}$ packet records the constructive comparison sandwich as a finite lower-middle-upper $\mathsf{Real}^{\uparrow}$ comparison packet over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. It sits after the real seal of chapter 38, the regular rational rows of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the displayed sequence-limit route of chapter 1413. The packet gives L10 Real and Completion consumers one named sandwich surface without importing host limits, quotient streams, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2163.1 (Squeeze theorem carrier)**.** *A* $\mathsf{SqueezeTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, M, U, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L, M, and U are the lower, middle, and upper source rows. Each source is read only through the same displayed sequence-limit and real-comparison route before any conclusion is exported.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the inspected tail indices, lower-middle comparison windows, middle-upper comparison windows, and limit-window requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the split tolerance used to compare the lower and upper bounds with the common limit row and the middle row with the displayed sandwich windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled lower, middle, upper, and limit observations.*
5. *E is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *and terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It becomes available only after L, M, U, W, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the three source rows, window row, dyadic ledger, rational readback row, seal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay of the finite route*

$$L, M, U, W, D, Q \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{SqueezeTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{SqueezeTheorem}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $L, M, U, W, D, Q, E, H, C, P, N$ and has no coordinate for host sequence limits, quotient stream equality, trichotomy, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2163.2 (Squeeze theorem NameCert obligations)**.** *For every accepted* $\mathsf{SqueezeTheorem}^{\uparrow}$ *carrier*

$$S = (L, M, U, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SqueezeTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower, middle, and upper source rows, finite window row, dyadic tolerance ledger, regular-rational readback row, displayed sequence-limit and real-seal row, transport, replay, provenance, and local naming row;*
2. *sandwich-window discipline, requiring every lower-middle and middle-upper comparison to be read through the same scheduled W row before the middle limit can be exported;*
3. *dyadic tolerance exactness, requiring D to record the tolerance split consumed by the two bounding convergence reads and the middle comparison read;*
4. *rational readback discipline, requiring Q to expose the scheduled* $\mathsf{RegSeqRat}^{\uparrow}$ *observations for the lower, middle, upper, and limit rows before the terminal seal E is available;*
5. *real-seal nonescape, requiring E to remain downstream of the displayed sequence-limit route and forbidding direct host-limit or completeness reads;*
6. *transport, replay, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise;*
7. *ledger refusal, excluding host sequence limits, quotient stream equality, trichotomy, countable choice, selected representatives, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No squeeze theorem obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.SqueezeTheoremUp.SqueezeTheoremCarrier namecert obligations`

Proof. Project the accepted packet $S = (L, M, U, W, D, Q, E, H, C, P, N)$. The carrier exposes the three source rows, one shared finite-window row, one dyadic tolerance ledger, one regular-rational readback row, one terminal sequence-limit and real-seal row, and the structural rows.

The comparison route starts with the common window. The row W fixes which lower-middle, middle-upper, and limit windows are inspected, so the middle source cannot use an unrelated comparison schedule.

The dyadic and rational data are then forced. The row D supplies the tolerance split, and Q supplies the scheduled $\mathsf{RegSeqRat}^{\uparrow}$ observations attached to that split before any seal is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite rows. Since none of the excluded host objects has a carrier coordinate, replay edge, provenance entry, or local naming row, the listed obligations exhaust the local NameCert surface. □

Theorem 2163.3 (Squeeze theorem comparison sandwich)**.** *Every accepted* $\mathsf{SqueezeTheorem}^{\uparrow}$ *carrier exposes the middle real-sequence limit only through the finite route*

$$L, M, U, W, D, Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed lower-middle-upper comparison sandwich, a shared $\mathsf{StreamName}^{\uparrow}$ *tail-window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff, the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise transport, continuation replay, package provenance, and local naming. It receives no host sequence limit, quotient stream equality, trichotomy, countable choice, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

The comparison sandwich consumes the regular-name enclosure of chapter 1772 and the dyadic lower/upper tolerance route of chapter 3627 before the $\mathsf{RealSequenceLimit}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal rows are exposed.

Proof. Start with an accepted squeeze-theorem read. The source rows are L, M, and U, and the carrier requires all comparison evidence to be observed through the shared finite-window row W.

The dyadic ledger D fixes the tolerance split for the bounding convergence reads and the middle comparison read. The regular-rational row Q then exposes the scheduled lower, middle, upper, and limit observations before the real seal can be reached.

Only after those rows have been displayed can E expose the $\mathsf{RealSequenceLimit}^{\uparrow}$ handoff and terminal $\mathsf{Real}^{\uparrow}$ seal boundary. The structural rows H, C, P, N preserve that same finite route under componentwise transport, continuation replay, provenance, and local naming.

Induction over the displayed route order proves that no later consumer can skip a row: the base stage reads L, M, U, W, D, Q, the terminal step reads E, and the structural step reads H, C, P, N. Because there is no coordinate outside this route, the consumer cannot obtain host sequence limits, quotient stream equality, trichotomy, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness from the packet. □

Theorem 2163.4 (Squeeze theorem real-seal nonescape)**.** *An accepted* $\mathsf{SqueezeTheorem}^{\uparrow}$ *consumer that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal must have already displayed the lower row, middle row, upper row, shared StreamName window row, dyadic tolerance ledger, RegSeqRat readback row, and RealSequenceLimit handoff. Consequently the real seal cannot be used as a shortcut to host limit existence, quotient stream equality, trichotomy, countable choice, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the seal row E from an accepted carrier. By carrier admission, E is not an independent coordinate; it is downstream of L, M, U, W, D, Q and records only the sequence-limit and real-seal boundary reached from those displayed rows.

The replay row C has no branch that starts at E. It replays the route from the three source rows through the window schedule, tolerance ledger, and rational readback before the seal can be consumed.

The transport and provenance rows H and P preserve the same dependency order. The local name N therefore names only the displayed sandwich packet, so no host limit, quotient stream, trichotomy, countable-choice selector, selected representative, or ambient completeness witness can escape through the seal. □

Theorem 2163.5 (Squeeze theorem Real seal handoff)**.** *A* $\mathsf{SqueezeTheorem}^{\uparrow}$ *consumer reaches the middle-row* $\mathsf{Real}^{\uparrow}$ *seal only by first displaying the lower and upper* $\mathsf{RealSequenceLimit}^{\uparrow}$ *rows, the middle sequence row, the shared* $\mathsf{StreamName}^{\uparrow}$ *tail windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff. The resulting route is*

$$L, M, U, W, D, Q \longmapsto E \longmapsto H, C, P, N.$$

It refuses host limits, quotient streams, trichotomy, countable choice, and ambient Real completeness.

Proof. Begin with the comparison sandwich of Definition 2163.3. It forces the lower, middle, and upper rows to pass through one shared finite route L, M, U, W, D, Q before any seal row is available.

Apply the real-seal nonescape theorem Definition 2163.4. The terminal seal E cannot be reached until the shared tail windows, dyadic tolerance ledger, regular rational readbacks, and displayed $\mathsf{RealSequenceLimit}^{\uparrow}$ handoff have all been displayed.

The structural rows H, C, P, N then transport, replay, source, and name the same route. Since neither theorem exposes host limits, quotient streams, trichotomy, countable choice, or ambient Real completeness, the handoff to the middle-row $\mathsf{Real}^{\uparrow}$ seal exports none of those objects. □

Theorem 2163.6 (Squeeze theorem zero-envelope route)**.** *If an accepted* $\mathsf{SqueezeTheorem}^{\uparrow}$ *carrier has lower and upper source rows both read through the displayed zero* $\mathsf{RealSequenceLimit}^{\uparrow}$ *envelope, then every middle-row* $\mathsf{Real}^{\uparrow}$ *seal still factors through* W, D, Q, E, H, C, P, N*. It cannot be read as host zero-limit equality, quotient stream equality, or ambient completeness.*

Proof. Project the accepted carrier $S = (L, M, U, W, D, Q, E, H, C, P, N)$. The lower and upper rows share the same displayed zero envelope, but the carrier still exposes the middle row only through the comparison data and terminal seal rows.

Specialize the comparison sandwich of Definition 2163.3 to the case where L and U read the same zero $\mathsf{RealSequenceLimit}^{\uparrow}$ envelope. The shared envelope fixes the bounding route; it does not remove the finite window row W, dyadic ledger D, or regular-rational readback Q.

Apply the real-seal nonescape theorem Definition 2163.4. The middle-row seal reaches $\mathsf{Real}^{\uparrow}$ only after the displayed tolerance and readback route has been consumed.

Thus the zero-envelope squeeze route is certified by finite dyadic tolerance accounting and $\mathsf{RegSeqRat}^{\uparrow}$ readback. It is not a host zero-limit equality, a quotient stream equality, or an appeal to ambient completeness. □

Theorem 2163.7 (Squeeze theorem Cauchy-real field route)**.** *Let* $S = (L, M, U, W, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{SqueezeTheorem}^{\uparrow}$ *zero-envelope carrier whose lower, middle, and upper rows are read through the* $\mathsf{CauchyRealField}^{\uparrow}$ *surface. Then the middle-row* $\mathsf{Real}^{\uparrow}$ *seal is reached only after the common* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyRealField}^{\uparrow}$*, order, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows are displayed. The route does not claim* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, or host limits.*

Proof. Begin with the zero-envelope route of Definition 2163.6. It already forces the middle-row seal to pass through the shared window row W, dyadic ledger D, regular readback row Q, terminal seal row E, and structural rows H, C, P, N.

Read the lower, middle, and upper rows through the $\mathsf{CauchyRealField}^{\uparrow}$ chapter chapter 1717. That surface supplies the regular-Cauchy addition, product, reciprocal, and order rows as displayed field-facing data before a real-facing consumer can inspect the result.

Finally pass through the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The seal is downstream of the displayed regular readback, stream windows, dyadic tolerance accounting, Cauchy-real field rows, order rows, transport, replay, provenance, and local naming.

Because the proof composes only those displayed chapter surfaces, it adds no Real completeness principle, no trichotomy split, and no host limit object. □

Closure status for $\mathsf{NameCert}_{\mathsf{SqueezeTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SqueezeTheorem}^{\uparrow}$ packet is generated from lower, middle, and upper source rows, one shared StreamName tail-window schedule, a DyadicRatCore tolerance ledger, RegSeqRat readbacks, a RealSequenceLimit handoff, a terminal RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SqueezeTheorem}\uparrow}$, seed)

Scope closed: Definition 2163.1, Definition 2163.2, Definition 2163.3, and Definition 2163.4 seed the finite constructive comparison sandwich over StreamName, RegSeqRat, DyadicRatCore, RealSequenceLimit, and RealUp rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SqueezeTheorem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host sequence limits, quotient stream equality, trichotomy, countable choice, selected representatives, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, sandwich-window discipline, dyadic tolerance exactness, rational readback discipline, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SqueezeTheoremUp.

Chapter 2164

A Concrete Naming Certificate for $\mathsf{FrechetCompletion}^{\uparrow}$

Following Frechet on metric convergence, Bourbaki and Kelley on filters and nets, and Bishop–Bridges on constructive completion, the $\mathsf{FrechetCompletion}^{\uparrow}$ packet records the L10 filter-completion surface as finite BEDC NameCert data. It consumes the completion source of chapter 1506, the filter route of chapter 333, the net route of chapter 589, and the separated-limit boundary of chapter 1612. It also reads finite stream windows from chapter 126, regular rational readbacks from chapter 301, and terminal real seals from chapter 38. The carrier names only finite filter, net, sequential, separated, transport, replay, provenance, and local naming rows; it does not import quotient completions, representative choice, countable choice, a host complete space, or a global convergence selector.

Definition 2164.1 (FrechetCompletion carrier)**.** *A* $\mathsf{FrechetCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, L, N, S, Q, R, H, C, P, K)$$

with the following displayed rows:

1. *A is the* $\mathsf{CauchyFilter}^{\uparrow}$ *admission row, recording the finite filter-base observations and Cauchy refinement checks visible to the packet.*
2. *L is the* $\mathsf{CauchyNet}^{\uparrow}$ *handoff row, displaying the directed finite net observations that read the same completion route without selecting a cofinal subnet.*
3. *N is the* $\mathsf{MetricCompletion}^{\uparrow}$ *neighbour row, exposing only the local completion-facing boundary consumed by later L10 routes.*
4. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *separation row, recording the finite equality and apartness boundary used to prevent two completion reads from being merged by an undisplayed quotient.*
5. *Q is the paired* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *sequential readback row, carrying finite windows and regular rational approximants for consumers that ask for a sequence-like presentation.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed distance and approximation reads.*
7. *H records componentwise* hsame *transport for the Cauchy filter, Cauchy net, metric-completion neighbour, separated-completion boundary, stream window, regular rational readback, real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$A, L, N, S, Q, R \longmapsto H, P, K.$$

9. *P is the* Pkg *provenance over* $\mathsf{FrechetCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *K is the local* $\mathsf{NameCert}_{\mathsf{FrechetCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L, N, S, Q, R, H, C, P, K$. It has no coordinate for quotient completion equality, a chosen representative, a countable-choice schedule, a host complete metric space, a selected cofinal subnet, or an ambient convergence oracle.

Lean4 ✓ `BEDC.Derived.FrechetCompletionUp.FrechetCompletionTasteGate single carrier alignment`

Theorem 2164.2 (FrechetCompletion NameCert obligations)**.** *For every accepted* $\mathsf{FrechetCompletion}^{\uparrow}$ *carrier*

$$F = (A, L, N, S, Q, R, H, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row,* $\mathsf{CauchyNet}^{\uparrow}$ *row,* $\mathsf{MetricCompletion}^{\uparrow}$ *neighbour row,* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *sequential readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public completion read must pass through those rows in the order displayed by C.*

Proof. Project the accepted carrier in Definition 2164.1. The visible mathematical rows are the Cauchy filter row A, Cauchy net row L, local metric-completion neighbour row N, separated-completion boundary row S, sequential readback row Q, and real seal row R.

The replay row C orders these rows before transport and naming are read. Thus a public completion-facing consumer first sees the filter and net routes, then the local completion and separation boundaries, and only then the sequential and real readbacks.

The rows H, P, K transport, source, and name exactly this surface. Since the carrier has no coordinate for quotient completion equality, representative choice, countable choice, a selected cofinal subnet, or a host complete space, the listed rows exhaust the local NameCert obligations. □

Theorem 2164.3 (FrechetCompletion filter handoff)**.** *Let $F = (A, L, N, S, Q, R, H, C, P, K)$ be an accepted* $\mathsf{FrechetCompletion}^{\uparrow}$ *carrier. Every downstream completion consumer that enters through the filter side receives a finite handoff through*

$$A \longmapsto L \longmapsto N \longmapsto S \longmapsto Q \longmapsto R \longmapsto H, C, P, K.$$

The handoff exposes the Cauchy filter row, the matching Cauchy net row, the metric-completion neighbour row, the separated-completion boundary, the sequential readback, the real seal, transport, replay, provenance, and local naming, and it exports no quotient completion, no selected representative, and no choice principle.

Proof. Start with a completion consumer entering through A. The carrier makes A a displayed Cauchy-filter row, so the consumer cannot obtain completion data before reading the finite filter-base observations and Cauchy refinement checks.

The net and local completion rows then fix the same route. The row L records the visible net handoff, and N exposes only the local $\mathsf{MetricCompletion}^{\uparrow}$ neighbour boundary rather than a completed host point.

Separation and sequential readback are downstream checks. The row S prevents the route from being collapsed by an undisplayed quotient, while Q and R expose finite stream windows, regular rational approximants, and real seals for consumers that need a sequence-like read.

The structural rows close the handoff. Componentwise transport, displayed replay, provenance, and local naming preserve exactly the route shown above, so no quotient completion, representative selector, or countable-choice coordinate is available. □

Theorem 2164.4 (FrechetCompletion sequential readback)**.** *Every sequence-like read of an accepted* $\mathsf{FrechetCompletion}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows after the filter, net, metric-completion, and separated-completion rows have been read. Consequently the sequential presentation is a readback of the finite completion route, not a replacement by a host Cauchy sequence quotient or a selected limit.*

Proof. Inspect the accepted carrier. The only sequence-facing coordinate is Q, and it is declared as the paired $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readback row. The only terminal value-facing coordinate is the $\mathsf{Real}^{\uparrow}$ seal row R.

The replay row C places Q and R after the Cauchy filter, Cauchy net, metric-completion neighbour, and separated-completion boundary rows. Thus a sequence-like consumer reads finite windows and rational approximants only as a downstream readback of the displayed completion route.

Because no coordinate stores a host Cauchy sequence quotient, selected limit, representative equality, or ambient completeness theorem, the sequential presentation cannot replace the finite route named by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2164.1, Definition 2164.2, Definition 2164.3, and Definition 2164.4 seed the finite filter-completion packet over Cauchy filter, Cauchy net, metric-completion, separated-completion, sequential readback, real seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, representative choice, countable choice, selected cofinal subnets, host complete spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter handoff, net handoff, metric-completion neighbour routing, separated-completion boundary routing, sequential readback, real seal discipline, transport stability, provenance, and local naming for BEDC.Derived.FrechetCompletionUp.

Constructive story: A $\mathsf{FrechetCompletion}^{\uparrow}$ packet is generated from finite CauchyFilter, CauchyNet, MetricCompletion, SeparatedCompletion, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 2165

A Concrete Naming Certificate for $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$

The $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$ packet realizes the selector-ledger branch of chapter 9399 as finite NameCert data. It refines the one-step boundary selector of chapter 685, the finite selector ledger of chapter 494, the observer-history identity surface of chapter 479, and the inscription event boundary of chapter 519. Its carrier stores the current history, selected mark, displayed Ext route, selector witness, transport, replay, provenance, and local naming in one packet so that an empty-boundary branch is generated by a visible row rather than by a hidden chooser.

Definition 2165.1 (EmptyBoundarySelectorLedger carrier)**.** *An* $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (H, M, R, X, S, L, T, C, P, N)$$

with the following displayed rows:

1. *H is the current* Hist *row whose empty boundary is being inspected.*
2. *M is the selected-mark row, exposing the mark enacted at that boundary.*
3. *R is the resulting* Hist *row after the selected mark has been enacted.*
4. *X is the displayed* $\mathsf{Ext}(H, M, R)$ *route row.*
5. *S is the selector-witness row, recording that M is the enacted local branch for this packet and not a value returned by an undisplayed choice function.*
6. *L is the non-reset ledger row. It records the finite selector ledger continuing from H through M to R, preserving prior history instead of returning to* e*.*
7. *T records componentwise* hsame *transport for H, M, R, X, S, L and for the local naming row.*
8. *C records displayed* Cont *replay of the route*

$$H, M, R, X, S, L \longmapsto T, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$, $\mathsf{EmptyBoundarySelector}^{\uparrow}$, $\mathsf{SelectorLedger}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{InscriptionEvent}^{\uparrow}$, BHist, Ext, hsame, Cont, *and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, M, R, X, S, L, T, C, P, N$. It has no coordinate for observer substance, global branch choice, a reset-to-Empty state, host trace equality, an unrecorded inscription source, or a truth oracle.

Lean4 ✓ `BEDC.Derived.EmptyBoundarySelectorLedgerUp.EmptyBoundarySelectorLedgerTasteGate single carrier alignment`

Theorem 2165.2 (EmptyBoundarySelectorLedger NameCert obligations)**.** *For every accepted* $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$ *carrier*

$$E = (H, M, R, X, S, L, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for the current* Hist *row, selected-mark row, resulting* Hist *row, displayed* Ext *route, selector witness, non-reset ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every branch read must expose both the selected mark M and the route row X before the ledger row L is consumed.*

Proof. Project the accepted carrier in Definition 2165.1. The current history H, selected mark M, resulting history R, extension route X, selector witness S, and ledger L are the complete branch-facing inventory.

The selected mark and extension route are read before the ledger. Thus a consumer cannot treat L as an unexplained sequence of choices; it receives the enacted local mark and the displayed Ext route that produced the next history.

The rows T, C, P, N transport, replay, source, and name exactly these displayed rows. Since the carrier has no coordinate for observer substance, global choice, reset-to-Empty semantics, host trace equality, or truth oracles, the listed rows exhaust the NameCert obligations. □

Theorem 2165.3 (EmptyBoundarySelectorLedger branch separation)**.** *Let $E = (H, M, R, X, S, L, T, C, P, N)$ and $E' = (H, M', R', X', S', L', T', C', P', N')$ be accepted* $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$ *carriers over the same current history row. If the selected-mark rows M and M' are not classified together by the displayed transport rows, then the packets cannot be identified by their ledger rows alone. The branch distinction must pass through the selected mark,* Ext *route, selector witness, and non-reset ledger rows.*

Proof. Begin with the two accepted packets. Each exposes the current history row, selected mark, result row, extension route, selector witness, ledger row, transport, replay, provenance, and local name.

If M and M' are not classified together by the displayed transport rows, then the branch-facing coordinates already differ before the ledger row is read. The route rows X and X' and selector witnesses S and S' are attached to those selected marks.

Reading only L and L' would erase the branch evidence that the carrier explicitly stores. The classifier therefore preserves the distinction through M, X, S, L and their transported routes, rather than collapsing the packets to a hidden ledger equality. □

Theorem 2165.4 (EmptyBoundarySelectorLedger non-reset replay)**.** *Every public replay of an accepted* $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$ *packet factors through the current history row H before it reaches the selected mark M, displayed extension route X, selector witness S, and ledger row L. Consequently the packet records continuation from the current history, not a reset to* e *and not a fresh Empty-as-chooser event.*

Proof. Inspect the replay row C. It displays a route whose first row is the current history H, followed by the selected mark, result row, extension route, selector witness, and ledger.

Because L is declared as a non-reset ledger row, it records the finite selector ledger continuing from H through M to R. The source history is therefore part of the public route, not external memory.

The structural rows preserve that route componentwise. No replay edge starts from e unless H itself is the displayed empty history, and no row supplies a hidden chooser at the boundary. □

Falsifiable prediction: Deleting the selected-mark row makes the packet unable to distinguish the two Ext branches at the empty boundary.

Independence witness: empty-fable-machine, observer-hist-identity, inscriptionevent, finitewindowobserver: the carrier is not bijective to these siblings because it jointly stores the current Hist, selected mark, Ext route, selector witness, and non-reset ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{EmptyBoundarySelectorLedger}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EmptyBoundarySelectorLedger}\uparrow}, \mathsf{seed})$

Scope closed: Definition 2165.1, Definition 2165.2, Definition 2165.3, and Definition 2165.4 seed the finite empty-boundary selector ledger over current history, selected mark, Ext route, selector witness, non-reset ledger, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EmptyBoundarySelectorLedger}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Nontrivial or FieldFaithful Lean instances, bridge checking, observer substance, global branch choice, reset-to-Empty semantics, host trace equality, or truth-oracle semantics.

Upgrade path: Lean follow-up must provide Nontrivial and FieldFaithful instances for BEDC.Derived.EmptyBoundarySelectorLedgerUp while preserving the finite selected-mark and non-reset-ledger route.

Constructive story: An $\mathsf{EmptyBoundarySelectorLedger}^{\uparrow}$ packet is generated from current Hist, selected mark, result Hist, Ext route, selector witness, non-reset ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Chapter 2166

A Concrete Naming Certificate for $\mathsf{FiniteVitaliCover}^{\uparrow}$

Following Vitali's finite covering argument, Bishop–Bridges located interval reasoning, and the dyadic-radius bookkeeping used by constructive real analysis, the $\mathsf{FiniteVitaliCover}^{\uparrow}$ packet records the finite subcover-selection surface as BEDC NameCert data. It sits after the located interval carrier of chapter 394, the dyadic rational core of chapter 291, and the real-value seal of chapter 38. The packet names finite interval rows, radius rows, a disjoint selected subfamily, shadow-coverage rows, componentwise transport, replay, provenance, and local naming only; it does not import measure, arbitrary open-cover compactness, countable choice, or host set equality.

Definition 2166.1 (FiniteVitaliCover carrier)**.** *A* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, R, S, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite located-interval row. It lists the candidate intervals by their* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoints and records the displayed membership windows through which a later real consumer may inspect each interval.*
2. *R is the dyadic radius row. It records the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius attached to each interval, together with the finite comparison windows used to order candidate radii.*
3. *S is the selected subfamily row. It records a finite list of chosen interval indices and the pairwise disjointness checks between the selected located intervals.*
4. *W is the shadow-coverage row. It records, for every candidate interval not selected, a selected interval with comparable or larger dyadic radius whose controlled enlargement covers the candidate's displayed located window.*
5. *H records componentwise* hsame *transport for the located-interval row, dyadic radius row, selected disjoint subfamily row, shadow-coverage row, replay row, provenance row, and local naming row.*
6. *C records displayed* Cont *replay of the finite route*

$$I, R \longmapsto S, W \longmapsto H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{FiniteVitaliCover}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

8. N is the local $\mathsf{NameCert}_{\mathsf{FiniteVitaliCover}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through I, R, S, W, H, C, P, N. It has no coordinate for Lebesgue measure, a countable choice sequence, open-cover compactness, a host set equality predicate, or a global family of balls.

Lean4 ✓ `BEDC.Derived.FiniteVitaliCoverUp.FiniteVitaliCoverTasteGate single carrier alignment`

Theorem 2166.2 (FiniteVitaliCover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *carrier*

$$V = (I, R, S, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteVitaliCover}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite located-interval row, dyadic radius row, selected disjoint subfamily row, shadow-coverage row, component-wise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The shadow row must witness that every unselected candidate interval is covered by the controlled enlargement of a selected interval whose dyadic radius is comparable or larger, and every public cover read must pass through the route displayed by C.*

Lean4 ✓ `BEDC.Derived.FiniteVitaliCoverUp.FiniteVitaliCoverCarrier namecert obligations`

Proof. Project the accepted carrier in Definition 2166.1. The only mathematical data exposed to a cover consumer are the located interval row I, dyadic radius row R, selected subfamily row S, and shadow-coverage row W.

The selected row records pairwise disjointness directly, while the shadow row records the finite witness from each unselected interval to a selected controlling interval. Thus the usual finite Vitali conclusion is read as a bounded finite shadow of the selected subfamily rather than as a measure-theoretic covering theorem.

The rows H, C, P, N transport, replay, source, and name exactly this finite surface. Since the carrier contains no coordinate for measure, countable choice, arbitrary open-cover compactness, host set equality, or an infinite ball family, the listed obligations exhaust the local NameCert surface. □

Theorem 2166.3 (Finite Vitali cover Real-completion subcover route)**.** *Every Real and Completion consumer of an accepted* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *packet factors through the finite located-interval row I, dyadic radius row R, selected finite subfamily row S, and shadow-coverage row W before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. The route supplies finite shadow subcover evidence only and exports no measure estimate, arbitrary open-cover compactness, countable choice, host set equality, or global ball family.*

Proof. Project the accepted carrier

$$V = (I, R, S, W, H, C, P, N)$$

from Definition 2166.1. The rows I, R, S, W are the only cover-facing rows available before the structural transport, replay, provenance, and naming rows are read.

Use Definition 2166.2. The selected row S supplies the finite disjoint subfamily, while the shadow row W supplies, for each unselected candidate, a selected controlling interval with comparable or larger dyadic radius.

Route every Real-facing read through located intervals and dyadic radii. The located row I exposes the interval windows, the radius row R exposes the dyadic comparisons, and C replays this finite path before any downstream consumer may inspect a terminal real seal.

The ledger is nonescaping because H, C, P, N transport, replay, source, and name only the displayed rows. Since no row stores a measure estimate, arbitrary open-cover compactness, countable choice, host set equality, or a global ball family, the route exports exactly the finite shadow subcover evidence stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVitaliCover}\uparrow}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteVitaliCover}\uparrow}$, seed)

Scope closed: Definition 2166.1 and Definition 2166.2 seed the finite Vitali-cover packet over located interval, dyadic radius, selected disjoint subfamily, shadow coverage, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteVitaliCover}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure estimates, open-cover compactness, countable choice, host set equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic radius ordering, selected-subfamily disjointness, shadow coverage, componentwise transport, provenance, and local naming for BEDC.Derived.FiniteVitaliCoverUp.

Constructive story: A $\mathsf{FiniteVitaliCover}^{\uparrow}$ packet is generated from finite LocatedInterval, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 2167

A Concrete Naming Certificate for $\mathsf{StarRefinementUniformCover}^{\uparrow}$

Following Kelley and Bourbaki on uniform spaces and star refinements of uniform covers, the $\mathsf{StarRefinementUniformCover}^{\uparrow}$ packet records the finite cover-refinement surface needed by the L10 completion route. It sits after the uniform-space surface of chapter 339, the entourage-base surface of chapter 1819, the filter-base surface of chapter 1601, the rounded-ideal completion surface of chapter 1883, and the metric-completion surface of chapter 1506. The packet names displayed cover and star-refinement rows only; it does not import open-cover compactness, selected refinements, choice, or ambient completeness.

Definition 2167.1 (StarRefinementUniformCover carrier)**.** *A* $\mathsf{StarRefinementUniformCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, E, F, R, M, H, C, P, N)$$

with the following displayed rows:

1. *U is the uniform-cover row. It records the finite cover family read from the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage interface and the membership windows through which a downstream completion consumer may inspect it.*
2. *E is the* $\mathsf{EntourageBase}^{\uparrow}$ *row. It supplies the entourage-basis refinement data whose square or composite containment witnesses the star-refinement relation.*
3. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *row. It records the directed finite base route that transports cover refinements to Cauchy and completion consumers.*
4. *R is the* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *row. It records the rounded-ideal completion consumer that may request the refinement as a formal-ball neighbourhood boundary.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row. It records the metric-completion consumer that may read the same refinement through metric entourage or ball data.*
6. *H records componentwise* hsame *transport for the uniform cover, entourage base, filter base, rounded-ideal completion, metric completion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$U, E, F \longmapsto R, M \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{StarRefinementUniformCover}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{RoundedIdealCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{StarRefinementUniformCover}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through $U, E, F, R, M, H, C, P, N$ and has no coordinate for open-cover compactness, a choice-selected refinement, a host star operation, or ambient completeness.

Lean4 ✓ `BEDC.Derived.StarRefinementUniformCoverUp.StarRefinementUniformCoverTasteGate single carrier alignment`

Theorem 2167.2 (StarRefinementUniformCover NameCert obligations)**.** *For an accepted* StarRefinementUniformC *carrier*

$$S = (U, E, F, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StarRefinementUniformCover}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the uniform-cover row, entourage-base row, filter-base row, rounded-ideal completion row, metric-completion row, transport, replay, provenance, and local naming row;*
2. *star-refinement containment, requiring the displayed entourage basis in E to witness that every star of the refined cover lies inside a displayed member of the cover row U;*
3. *filter-base handoff, requiring the directed base row F to preserve the same refinement relation for Cauchy and completion consumers;*
4. *rounded-ideal completion handoff, requiring R to read the refinement only as a formal-ball neighbourhood boundary already routed through U, E, F;*
5. *metric-completion handoff, requiring M to read the same refinement only through the displayed metric entourage or ball data already routed through U, E, F;*
6. *classifier transport, requiring* hsame *comparison to preserve the uniform-cover, entourage-base, filter-base, rounded-ideal, metric-completion, replay, provenance, and local naming rows componentwise;*
7. *non-escape, excluding open-cover compactness, choice, selected refinements, host star operations, and ambient completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2167.1. The accepted packet exposes exactly the uniform-cover, entourage-base, filter-base, rounded-ideal completion, metric-completion, transport, replay, provenance, and local naming rows.

Star-refinement containment is read from E against U. The entourage-basis row supplies the finite refinement witness, and the cover row supplies the displayed members into which each star is contained.

The completion handoffs then consume the same route. The filter-base row F carries directed refinement data to Cauchy-style consumers, while R and M read the route as rounded-ideal and metric-completion neighbourhood data.

Finally H, C, P, N preserve the route componentwise. Since the carrier has no row for compactness of arbitrary open covers, selected refinements, choice, a host star operation, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 2167.3 (StarRefinementUniformCover completion handoff)**.** *Let*

$$S = (U, E, F, R, M, H, C, P, N)$$

be an accepted $\mathsf{StarRefinementUniformCover}^{\uparrow}$ *carrier. Every completion-facing consumer of the star-refinement row factors through the finite route*

$$U \longmapsto E \longmapsto F \longmapsto R, M \longmapsto H, C, P, N.$$

The handoff supplies $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *with a displayed refinement row for uniform-cover arguments. It does not export open-cover compactness, choice, selected refinements, a host star operation, or ambient completeness.*

Proof. Begin with the accepted carrier S. The uniform-cover row U is the only cover entry point, so every completion-facing read first exposes the finite cover family and its membership windows.

The entourage-base row E then supplies the star-refinement witness. Its containment data refine the cover row already displayed by U, and the filter-base row F preserves that relation as a directed finite base route.

The completion consumers are downstream of this route. The rounded-ideal row R reads the refinement as a formal-ball neighbourhood boundary, while the metric-completion row M reads it through displayed metric entourage or ball data.

Transport by H, replay by C, provenance by P, and naming by N preserve the same finite route. No excluded host-side principle is available to any completion consumer. □

Theorem 2167.4 (StarRefinementUniformCover filter-base determinacy)**.** *Let*

$$S = (U, E, F, R, M, H, C, P, N)$$

be an accepted $\mathsf{StarRefinementUniformCover}^{\uparrow}$ *carrier. Any completion-facing consumer of a star-refinement row must preserve the same directed* $\mathsf{FilterBase}^{\uparrow}$ *route* F *when passing to* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *through* R *or to* $\mathsf{MetricCompletion}^{\uparrow}$ *through* M*. No selected refinement, host star operation, or ambient completeness row can replace* F*.*

Proof. Project the carrier of Definition 2167.1. The only directed completion-facing base row is F, and it is stored between the uniform cover U, the entourage-base refinement witness E, and the two completion consumer rows R, M.

Apply Definition 2167.2. Its filter-base handoff obligation requires the directed base row F to preserve the same refinement relation for Cauchy and completion consumers.

Finally apply Definition 2167.3. Both the rounded-ideal row R and the metric-completion row M are downstream of U, E, F and the structural rows H, C, P, N. Since the carrier has no selected refinement, host star operation, or ambient completeness coordinate, no completion consumer can replace the displayed filter-base route. □

Closure status for $\mathsf{NameCert}_{\mathsf{StarRefinementUniformCover}^{\uparrow}}$.

Constructive story: A $\mathsf{StarRefinementUniformCover}^{\uparrow}$ packet is generated from a uniform-cover row, an EntourageBaseUp refinement witness, a FilterBaseUp directed base route, RoundedIdealCompletionUp and MetricCompletionUp consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StarRefinementUniformCover}^{\uparrow}}$, seed)

Scope closed: Definition 2167.1, Definition 2167.2, and Definition 2167.3 seed the uniform-cover star-refinement surface for L10 completion routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StarRefinementUniformCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice, selected refinements, host star operations, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, star-refinement containment, filter-base handoff, rounded-ideal completion handoff, metric-completion handoff, classifier transport, and non-escape for BEDC.Derived.StarRefinementUniformCo

Chapter 2168

A Concrete Naming Certificate for $\mathsf{InverseLimitMetric}^{\uparrow}$

Following Bourbaki and Kelley on inverse limits of metric systems, the $\mathsf{InverseLimitMetric}^{\uparrow}$ packet records the L10 completion-neighbour obtained from finite projection rows rather than from a host inverse-limit object. It consumes the metric surface of chapter 57, the finite window discipline of chapter 126, the regular rational readbacks of chapter 301, the real-valued distance seals of chapter 38, and the completion-facing boundary of chapter 1506. The certificate names only finite diagram observations, projection compatibility, and local completion-neighbour data; it does not assert a host inverse limit, quotient completion equality, selected representatives, countable choice, or ambient completeness.

Definition 2168.1 (InverseLimitMetric carrier)**.** *An* $\mathsf{InverseLimitMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, \Pi, W, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite diagram row, listing the visible metric nodes, displayed bonding arrows, and nodewise* $\mathsf{Met}^{\uparrow}$ *evidence consumed by the packet.*
2. *Π is the projection row. Each projection observation names its source node, target node, finite bonding path, and compatibility check against the diagram row.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to address finite node histories and finite projection histories.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for distance comparisons inside the displayed nodes and along displayed projection paths.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-seal row. It seals the real-valued distance read after the finite window and regular readback rows have been displayed.*
6. *L is the local completion-neighbour row. It records the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff used by later completion consumers, without quotienting Cauchy names or selecting a representative point.*
7. *H records componentwise* hsame *transport for diagram rows, projection rows, stream windows, regular readbacks, real distance seals, local completion-neighbour rows, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay of the route*

$$D \longmapsto \Pi \longmapsto W \longmapsto Q \longmapsto R \longmapsto L.$$

9. *P is the* Pkg *provenance over* $\mathsf{InverseLimitMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{InverseLimitMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, \Pi, W, Q, R, L, H, C, P, N$. It has no coordinate for a host inverse-limit carrier, quotient completion equality, selected representatives, countable-choice selectors, or an ambient complete metric space.

Lean4 (definition) `BEDC.Derived.InverseLimitMetricUp.InverseLimitMetricUp`

Theorem 2168.2 (InverseLimitMetric NameCert obligations)**.** *For every accepted* $\mathsf{InverseLimitMetric}^{\uparrow}$ *carrier $I = (D, \Pi, W, Q, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{InverseLimitMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed diagram rows, finite projection rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *distance seals, local* $\mathsf{MetricCompletion}^{\uparrow}$ *neighbour handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public read must pass through those rows in the order displayed by C.*

Proof. Project the accepted carrier in Definition 2168.1. The only available mathematical rows are the finite diagram D, projection data Π, stream windows W, regular readbacks Q, real distance seals R, and local completion-neighbour row L.

The replay row C orders those rows before the structural support is consumed. Thus a public read first sees finite diagram and projection data, then finite windows and regular readbacks, then the real distance seal and the completion-neighbour handoff.

The rows H, P, N transport, source, and name exactly this surface. Since the carrier has no coordinate for a host inverse-limit object, quotient completion equality, selected representatives, choice, or ambient completeness, the listed obligations exhaust the local certificate. □

Theorem 2168.3 (InverseLimitMetric projection stability)**.** *Let $I = (D, \Pi, W, Q, R, L, H, C, P, N)$ be an accepted* $\mathsf{InverseLimitMetric}^{\uparrow}$ *carrier. If a consumer transports I componentwise along the* hsame *rows recorded in H, then every finite projection compatibility check still factors through*

$$D, \Pi, W, Q, R, L, H, C, P, N.$$

In particular, transported projection rows cannot be replaced by a host inverse-limit point, a selected completion representative, a countable-choice schedule, or an ambient completeness witness.

Proof. The projection row Π is named as a coordinate of the carrier, and the transport row H stores componentwise hsame data for that coordinate together with the diagram, windows, readbacks, distance seals, and completion-neighbour row.

After transport, the only projection evidence available is the transported instance of Π over the transported diagram row D. The replay row C still routes finite projection observations through W, Q, R, L before provenance and local naming are read.

No coordinate remains from which a host inverse-limit point, chosen representative, choice schedule, or ambient complete metric space could be recovered. Therefore projection compatibility is stable exactly along the finite NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{InverseLimitMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InverseLimitMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2168.1, Definition 2168.2, and Definition 2168.3 seed the finite inverse-limit metric packet over diagram rows, projection rows, stream windows, regular readbacks, real distance seals, local completion-neighbour evidence, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InverseLimitMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse limits, quotient completion equality, selected representatives, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite projection compatibility, StreamName window routing, RegSeqRat readback, RealUp distance sealing, MetricCompletionUp neighbour handoff, transport stability, provenance, and local naming for BEDC.Derived.InverseLimitMetricUp.

Constructive story: An $\mathsf{InverseLimitMetric}^{\uparrow}$ packet is generated from finite metric diagram rows, projection rows, StreamName windows, RegSeqRat readbacks, RealUp distance seals, local MetricCompletionUp neighbour data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 2169

A Concrete Naming Certificate for $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$ packet records the finite boundary between regular Cauchy rational names and real-name seals. It sits after the regular rational sequence surface of chapter 301, the finite stream naming surface of chapter 126, the dyadic tolerance ledger of chapter 291, the real-name packet of chapter 38, and the uniform embedding surface of chapter 1662. The certificate lets completion consumers see the regular-name evidence and the terminal $\mathsf{Real}^{\uparrow}$ handoff while refusing to identify classifier equality with quotient-class equality.

Definition 2169.1 (RegularCauchyQuotientRefusal carrier)**.** *A* $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to name finite denominator and radius requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite observation schedule inspected at the requested tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row, read only through D and S.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row available after the regular rational name has been displayed.*
5. *U is the* $\mathsf{RealUniformEmbedding}^{\uparrow}$ *row, recording that the real-facing handoff is read through the displayed uniform embedding boundary rather than through quotient equality of Cauchy names.*
6. *H records componentwise* hsame *transport for tolerance ledgers, stream windows, regular rational names, real seals, uniform embedding rows, replay, provenance, and local naming.*
7. *C records the displayed* Cont *replay of the route*

$$D, S, R \longmapsto E, U \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealUniformEmbedding}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient streams, host real equality, selected representatives, countable choice, or a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyQuotientRefusalUp.RegularCauchyQuotientRefusalTasteGate single carrier alignment`

Theorem 2169.2 (RegularCauchyQuotientRefusal NameCert obligations)**.** *For an accepted* RegularCauchyQuotien *carrier*

$$Q = (D, S, R, E, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the dyadic tolerance ledger, finite stream window, regular rational name, real seal, uniform embedding row, componentwise transport, replay, provenance, and local naming row;*
2. *regular-name exposure, requiring every real-facing consumer to read D, S, and R before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *row;*
3. *classifier non-escape, requiring any comparison between two accepted packets to use only componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows;*
4. *real-seal handoff, requiring the* $\mathsf{Real}^{\uparrow}$ *consumer to pass through E and U without receiving quotient-stream equality, host real equality, selected representatives, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2169.1. The displayed packet lists the tolerance ledger, window schedule, regular rational name, real-facing seal, uniform embedding row, and the structural support rows.

Regular-name exposure is the dependency order of the carrier. A consumer cannot reach the real-seal row E until the finite dyadic request, stream window, and regular rational readback have all been displayed.

Classifier non-escape is componentwise. The rows H and C transport and replay only the displayed coordinates, while P and N record provenance and local naming for those coordinates.

The excluded principles are absent from the carrier. Since no field stores quotient streams, host real equality, selected representatives, countable choice, or a $\mathsf{Real}^{\uparrow}$ completeness witness, no NameCert obligation can export such data. □

Theorem 2169.3 (RegularCauchyQuotientRefusal classifier non-escape)**.** *Let $Q = (D, S, R, E, U, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$ *packet. Every classifier comparison exported by Q is exhausted by the rows*

$$D, S, R, E, U, H, C, P, N.$$

In particular, equality of two displayed classifier reads cannot be promoted to quotient equality of regular Cauchy streams, host equality of reals, a selected representative, a countable-choice schedule, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Read the classifier through the carrier rows of Definition 2169.1. The rows D, S, R expose the finite regular-name evidence before any real-facing comparison is available.

The rows E and U then record the terminal real seal and uniform embedding boundary. They are handoff rows, not quotient constructors, so they do not add a coordinate for equality of Cauchy streams or equality in a host real object.

Transport and replay remain componentwise through H and C. Provenance and local naming through P and N close the route at the same displayed rows.

Because no further row exists, the classifier cannot manufacture the excluded quotient, representative, choice, host-equality, or completeness data downstream. □

Theorem 2169.4 (RegularCauchyQuotientRefusal RealUp seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$ *packet factors through the finite route*

$$D \longmapsto S \longmapsto R \longmapsto E, U \longmapsto H, C, P, N.$$

Thus the consumer may read the dyadic tolerance ledger, finite stream window, regular rational name, terminal real seal, real-uniform-embedding boundary, componentwise transports, replay, provenance, and local NameCert *row. It receives no quotient stream, host real equality, selected representative, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project an accepted carrier Q. The only route to a real-facing read begins with the dyadic tolerance row D, then the finite stream window S, then the regular rational name row R.

The terminal seal rows are downstream of that route. Row E records the $\mathsf{Real}^{\uparrow}$-facing handoff, and row U records the uniform embedding boundary through which the handoff is read.

The structural rows preserve the same route. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming do not supply a quotient coordinate or a selected representative.

Therefore every $\mathsf{Real}^{\uparrow}$ consumer receives exactly the displayed finite handoff and none of the excluded quotient, host-equality, choice, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite window, RegSeqRat regular rational name, RealUp seal, RealUniformEmbedding boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2169.1, Definition 2169.2, Definition 2169.3, and Definition 2169.4 seed the finite regular-Cauchy-to-real handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientRefusal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter refuses quotient streams, host real equality, selected representatives, countable choice, and completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, classifier non-escape, and RealUp seal handoff for BEDC.Derived.RegularCauchyQuotientRefusalUp.

Chapter 2170

A Concrete Naming Certificate for $\mathsf{SeparatedCompletionReflector}^{\uparrow}$

Following Bishop–Bridges on constructive metric completion and Kelley on separated uniform reflection, the $\mathsf{SeparatedCompletionReflector}^{\uparrow}$ packet records the L10 boundary where a displayed completion route may be read as separated before later complete-metric and real-completion consumers use it. It sits after the metric-completion carrier of chapter 1506, the separated metric boundary of chapter 1411, the uniform-completion route of chapter 1473, the completion universal-property row of chapter 1473, the Cauchy-filter surface of chapter 333, the Cauchy-net surface of chapter 589, the regular-rational readback surface of chapter 301, and the real seal of chapter 38. The reflector consumes the separated-completion row route of chapter 1612 when it turns metric-completion reads into separated reusable completion data. The packet is a finite reflector boundary, not a quotient completion, selected-limit principle, ambient complete space, host-equality bridge, or countable-choice schedule.

Definition 2170.1 (SeparatedCompletionReflector carrier)**.** *A* $\mathsf{SeparatedCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, S, U, Q, F, D, T, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row exposing the displayed metric-completion source and completion-facing read route.*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row supplying the zero-distance classifier boundary before any completed read is treated as reusable.*
3. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row comparing the same Cauchy data through the displayed uniform route.*
4. *Q is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *handoff row read only after M, S, U have been displayed.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch row when the completion evidence is filter-presented.*
6. *D is the* $\mathsf{CauchyNet}^{\uparrow}$ *branch row when the completion evidence is net-presented.*
7. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance-readback row used by numerical consumers.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by real-completion consumers.*

9. *H records componentwise* hsame *transport for the completion, separation, uniform, universal-property, Cauchy, tolerance, real-seal, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$M, S, U, F, D, T \longmapsto Q \longmapsto A \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* SeparatedCompletionReflector$^{\uparrow}$, MetricCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, CauchyFilter$^{\uparrow}$, CauchyNet$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{SeparatedCompletionReflector}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these twelve rows. Its classifier compares accepted reflector packets only through $M, S, U, Q, F, D, T, A, H, C, P, N$ and has no coordinate for quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.SeparatedCompletionReflectorUp.SeparatedCompletionReflectorTasteGate`
`single carrier alignment`

Theorem 2170.2 (SeparatedCompletionReflector NameCert obligations)**.** *For an accepted* SeparatedCompletionRe *carrier*

$$R = (M, S, U, Q, F, D, T, A, H, C, P, N),$$

the local NameCert$_{\text{SeparatedCompletionReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric-completion, separated-metric, uniform-completion, universal-property, Cauchy-filter, Cauchy-net, regular-rational, real-seal, transport, replay, provenance, and local naming rows;*

2. *separated-source exactness, requiring every reflector-facing completion read to project M and then S before U, Q, A can be consumed;*

3. *branch visibility, requiring every Cauchy read to use the displayed filter branch F or net branch D before tolerance data in T may be read;*

4. *universal handoff locality, requiring Q to consume only the displayed M, S, U, F, D, T surface and to export only the real-seal route A plus structural rows;*

5. *classifier transport, requiring* hsame *comparison to preserve the completion, separation, uniform, universal-property, Cauchy, tolerance, real-seal, replay, provenance, and local naming rows componentwise;*

6. *non-escape, excluding quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, and bridge checking.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2170.1. The accepted packet exposes exactly the metric-completion, separated-metric, uniform-completion, universal-property, Cauchy-branch, tolerance, real-seal, transport, replay, provenance, and local naming rows.

Separated-source exactness starts at M and S. A consumer cannot read the uniform route U, the universal-property handoff Q, or the terminal real seal A until the displayed completion source and separated zero-distance classifier boundary have both been exposed.

Branch visibility is confined to F, D, T. The packet records whether the Cauchy evidence is filter-presented or net-presented before any regular-rational tolerance row can be inspected.

Finally Q, A, H, C, P, N preserve the same finite route. The universal-property row consumes only the displayed completion, separation, uniform, Cauchy, and tolerance rows; the real-seal row is downstream of that handoff; and the structural rows transport, replay, source, and name only displayed coordinates. Since no excluded host principle has a carrier row, the listed obligations exhaust the local NameCert surface. □

Theorem 2170.3 (SeparatedCompletionReflector universal handoff)**.** *Let*

$$R = (M, S, U, Q, F, D, T, A, H, C, P, N)$$

be an accepted $\mathsf{SeparatedCompletionReflector}^{\uparrow}$ *carrier. Every complete-metric or real-completion consumer reaches the universal-property row Q and the terminal real-seal row A only through the finite route*

$$M \longmapsto S, U \longmapsto F, D, T \longmapsto Q \longmapsto A \longmapsto H, C, P, N.$$

The handoff refines the $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *surfaces by inserting the* $\mathsf{SeparatedMetric}^{\uparrow}$ *boundary before universal extension data are exported. It does not export quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification, or bridge checking.*

Proof. Begin with an accepted carrier R. The metric-completion row M is the only completion-object entry point, and the separated metric row S is the only row that authorizes reuse of completed reads through zero-distance classifier evidence.

The uniform row U and Cauchy branch rows F, D are then read as constraints on the same completion data. The tolerance row T supplies finite regular-rational readback before the universal-property row is allowed to export a consumer-facing extension route.

The row Q is therefore downstream of the displayed completion, separation, uniform, Cauchy, and tolerance data. The real-seal row A and the structural rows H, C, P, N preserve that order, so the handoff reaches consumers without introducing any excluded host-side principle. □

Theorem 2170.4 (SeparatedCompletionReflector non-escape)**.** *Every consumer of an accepted* $\mathsf{SeparatedCompletionReflector}^{\uparrow}$ *carrier may inspect completion reflection only through the displayed rows*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow},\ \mathsf{CompletionUniversalProperty}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{CauchyNe}$$

No consumer route can read a quotient completion, selected limit, host equality of completed points, countable-choice schedule, ambient complete object, Lean verification certificate, or standard bridge from this packet.

Proof. The non-escape claim is field exclusion. The carrier of Definition 2170.1 lists the only rows admitted by the packet, and the NameCert obligations of Definition 2170.2 require every accepted read to project through those rows.

Any route asking for a quotient completion, selected limit, host equality, countable choice, ambient completeness, Lean verification, or standard bridge would require an additional coordinate. Since no such coordinate occurs in R, the local classifier has no accepted read for that request. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCompletionReflector}^{\uparrow}$ packet is generated from MetricCompletionUp, SeparatedMetricUp, UniformCompletionUp, CompletionUniversalPropertyUp, CauchyFilterUp, CauchyNetUp, RegSeqRatUp, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2170.1, Definition 2170.2, Definition 2170.3, and Definition 2170.4 seed the separated reflector boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflector}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.SeparatedCompletionReflectorUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, host equality, countable choice, ambient completeness, Lean verification beyond the encoded carrier, or bridge checking.

Upgrade path: Obligation closure requires checked separated-source exactness, Cauchy-branch visibility, universal handoff locality, classifier transport, and non-escape for BEDC.Derived.SeparatedCompletionReflectorUp.

Chapter 2171

A Concrete Naming Certificate for $\mathsf{LocalTimeFiber}^{\uparrow}$

The $\mathsf{LocalTimeFiber}^{\uparrow}$ packet realizes the observer-local reading of section 9462.22 as finite NameCert data. It sits between the observer-history identity surface of chapter 479, the local time-stream claims of Definition 9462.592, the no-global-clock boundary of Definition 9462.602, the local clock budget of chapter 665, and the synchronization certificate of chapter 1189. The packet exposes observer-local Hist growth as finite source, Cont-step, transport, refusal, provenance, and NameCert rows rather than as a global time axis.

Definition 2171.1 (LocalTimeFiber carrier)**.** *A* $\mathsf{LocalTimeFiber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, S, K, B, R, T, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *source row naming the observer as a displayed history surface.*
2. *S is the hist-time-stream row recording the local sequence of* Hist *constructor growth for that observer.*
3. *K is the local-clock-budget row bounding which local steps may be read by a consumer.*
4. *B is the* $\mathsf{SynchronizationCertificate}^{\uparrow}$ *boundary row, present only as a certified comparison surface and not as a global clock.*
5. *R is the refusal row excluding a global present, absolute clock, detached observer frame, and host equality of time fibers.*
6. *T records componentwise* hsame *transport for observer identity, local stream, local budget, synchronization boundary, refusal, provenance, and local naming.*
7. *C records displayed* Cont *replay of the observer-local step route*

$$O, S, K \longmapsto B, R \longmapsto T, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{LocalTimeFiber}^{\uparrow}$*,* $\mathsf{ObserverHistIdentity}^{\uparrow}$*, hist-time-stream, local-clock-budget,* $\mathsf{SynchronizationCertificate}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalTimeFiber}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted local time fibers only through $O, S, K, B, R, T, C, P, N$ and has no coordinate for a global clock, absolute present, detached observer substance, unbudgeted step selector, host equality of histories, Lean verification beyond the encoded carrier, or bridge checking.

Lean4 ✓ `BEDC.Derived.LocalTimeFiberUp.TasteGate.LocalTimeFiberTasteGate single carrier alignment`

Theorem 2171.2 (LocalTimeFiber NameCert obligations)**.** *For an accepted* $\mathsf{LocalTimeFiber}^{\uparrow}$ *carrier*

$$L = (O, S, K, B, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocalTimeFiber}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the observer-history source, local Hist time stream, local clock budget, synchronization boundary, refusal, transport, replay, provenance, and local naming rows;*
2. *observer-time-step exactness, requiring every time read to project the observer-history row O before it projects a local step from S;*
3. *hist-time-stream locality, requiring each step read to stay within the displayed local stream rather than a shared external index;*
4. *local-clock-budget boundedness, requiring K before any consumer can request a local step window;*
5. *synchronizationcertificate confinement, allowing B only as a finite comparison certificate and never as a global clock or absolute present;*
6. *observerhistidentity transport, requiring* hsame *comparison to preserve the observer, stream, budget, synchronization, refusal, replay, provenance, and local naming rows componentwise;*
7. *non-escape, excluding a global clock, detached observer frame, host equality of histories, unbudgeted local-step selection, Lean verification beyond the encoded carrier, and bridge checking.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2171.1. The accepted packet exposes exactly the observer-history source, local stream, budget, synchronization boundary, refusal, transport, replay, provenance, and local naming rows.

Observer-time-step exactness starts at O. A consumer cannot inspect a local time step until the observer-history source has been displayed, so the time fiber is attached to an observer history rather than to a detached clock carrier.

The stream and budget obligations are confined to S and K. The stream row supplies local Hist growth, and the budget row bounds which local windows may be read by downstream consumers.

The synchronization and refusal obligations are supplied by B and R. A synchronization certificate may compare displayed local fibers, but the refusal row blocks any reading of that comparison as a global present, absolute clock, detached frame, or host equality.

Finally T, C, P, N preserve the same finite route. Since no excluded host-side time principle has a carrier row, the listed obligations exhaust the local NameCert surface. □

Theorem 2171.3 (LocalTimeFiber no-global-clock boundary)**.** *Every consumer of an accepted* $\mathsf{LocalTimeFiber}^{\uparrow}$ *carrier reads observer-local time only through*

$\mathsf{ObserverHistIdentity}^{\uparrow}$, *hist-time-stream*, *local-clock-budget*, $\mathsf{SynchronizationCertificate}^{\uparrow}$, BHist, hsame, Cont, Pkg, N

It cannot read a global clock, absolute present, detached observer frame, host equality of histories, unbudgeted local-step selector, Lean verification beyond the encoded carrier, or standard bridge from this packet.

Proof. The boundary is field exclusion. The carrier of Definition 2171.1 lists the only rows admitted by the packet, and the NameCert obligations of Definition 2171.2 force every accepted read to project through those rows.

A global clock, absolute present, detached observer frame, host equality of histories, unbudgeted step selector, or standard bridge would require an additional coordinate. Since no such coordinate occurs in L, the local classifier has no accepted read for that request. □

Falsifiable prediction: A LocalTimeFiberUp read fails whenever a consumer asks for a global clock, absolute present, detached observer frame, host equality of histories, or unbudgeted local-step selector not displayed in the local fiber packet.

Independence witness: observer-time-step, hist-time-stream, local-clock-budget, observerhistidentity, synchronizationcertificate: none is bijective to $\mathsf{LocalTimeFiber}^{\uparrow}$ because the local fiber jointly carries observer source, local Hist stream, budget, synchronization boundary, refusal, transport, replay, provenance, and local NameCert rows, while each sibling exposes only one surface of that route.

The Lean follow-up must provide `Nontrivial LocalTimeFiberUp` and `FieldFaithful LocalTimeFiberUp` in `lean4/BEDC/Derived/LocalTimeFiberUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalTimeFiber}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalTimeFiber}^{\uparrow}$ packet is generated from an ObserverHistIdentityUp source row, local Hist time stream, local clock budget, SynchronizationCertificateUp boundary, global-clock refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalTimeFiber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2171.1, Definition 2171.2, and Definition 2171.3 seed the observer-local time-fiber surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalTimeFiber}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.LocalTimeFiberUp`

Bridge status: none

Not claimed: This chapter does not close a global clock, absolute present, detached observer frame, host equality of histories, unbudgeted step selection, Lean verification beyond the encoded carrier, or bridge checking.

Upgrade path: Obligation closure requires checked observer-time-step exactness, hist-time-stream locality, local-clock-budget boundedness, synchronizationcertificate confinement, observerhistidentity transport, and non-escape for BEDC.Derived.LocalTimeFiberUp.

Chapter 2172

A Concrete Naming Certificate for $\mathsf{CauchyInterleavingProduct}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyInterleavingProduct}^{\uparrow}$ packet records the finite product route obtained by alternating two regular Cauchy observation schedules before exposing the pointwise product readback. It sits between the interleaving surface of chapter 414, the product budget surface of chapter 461, and the root Cauchy product route of chapter 464. Its dependencies are the dyadic arithmetic core of chapter 291, the finite stream windows of chapter 126, the regular rational sequence route of chapter 301, and the terminal real seal of chapter 38.

Definition 2172.1 (CauchyInterleavingProduct carrier)**.** *A* $\mathsf{CauchyInterleavingProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, S_A, S_B, \sigma, M, D_A, D_B, D, E, R, I, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source names whose scheduled rational observations may be inspected;*
2. *S_A and S_B are the two* $\mathsf{StreamName}^{\uparrow}$ *windows used to expose the selected source observations;*
3. *σ is the alternating selector row, with even reads attached to A and odd reads attached to B;*
4. *M is the shared modulus and product-budget ledger recording the selected source precisions, endpoint magnitude bounds, and output tolerance;*
5. *D_A and D_B are the selected* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows obtained from the two scheduled windows;*
6. *D is the displayed dyadic product row for $D_A \cdot D_B$ at the common exponent named by M;*
7. *E is the finite product-error ledger attached to the dyadic product row;*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *product readback whose scheduled point row is D with tolerance budget E;*
9. *I is the interleaving provenance row binding R to the alternating selector, both schedules, and the two source names;*
10. *H stores componentwise* hsame *transports for the source names, schedules, selector, modulus ledger, dyadic endpoint rows, product ledger, readback, and interleaving provenance;*

11. *C stores the displayed* Cont *routes for selecting a source side, reading the two windows needed by the product, forming the dyadic endpoint product, checking the product budget, and exposing the readback;*
12. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingProduct}^{\uparrow}}$ *row.*

The carrier is a finite observation certificate. It stores no quotient stream, selected real limit, ambient completeness object, or host-level multiplication law over completed reals.

Lean4 ✓ `BEDC.Derived.CauchyInterleavingProductUp.CauchyInterleavingProductTasteGate single carrier alignment`

Theorem 2172.2 (CauchyInterleavingProduct NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingProduct}^{\uparrow}}$ *surface for the carrier of Definition 2172.1 consists exactly of carrier admission, selector-window coverage, dyadic product formation, finite product-budget exactness, regular readback handoff, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every consumer route for Q factors through*

$$A, B, S_A, S_B, \sigma, M, D_A, D_B, D, E, R, I, H, C, P, N.$$

No obligation exports quotient stream equality, a selected limit, host real equality, ambient Real completeness, or completed-real multiplication.

Proof. Carrier admission is projection from the displayed tuple Q. The two source names, two schedules, selector, modulus ledger, dyadic endpoint rows, product row, product-error ledger, readback row, and interleaving provenance are explicit coordinates.

Selector-window coverage follows the same even-and-odd partition used by the regular Cauchy interleaving packet. Product formation then reads the selected windows through the dyadic core and records the output tolerance in the finite product ledger.

The readback row R is downstream of those displayed rows. The transport, continuation, package, and naming coordinates attach the same finite route to every accepted consumer, so no omitted quotient, selected limit, host equality, completeness, or completed multiplication row can enter the local NameCert surface. □

Theorem 2172.3 (CauchyInterleavingProduct diagonal product route)**.** *For every accepted* CauchyInterleavingProd *carrier Q, the diagonal product route first reads the alternating selector σ, then exposes the two scheduled windows S_A, S_B at the common product request, then forms the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product row D from D_A and D_B, and only then exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R. The route is diagonal because both selected source observations are checked against the same ledger M before the product row is accepted.*

Proof. Project the selector, schedule, and modulus coordinates of Q. The selector chooses the active interleaving side, while the common product request still displays both windows needed to form the product.

Read D_A and D_B through S_A, S_B under the ledger M. The dyadic product row D is then a finite core row at the displayed common exponent, and the product-error row E records the tolerance assigned to that row.

Finally repack D and E as the regular readback R with interleaving provenance I. Since the route never leaves the displayed tuple, the product is diagonal over the finite schedules rather than a multiplication of selected completed limits. □

Theorem 2172.4 (CauchyInterleavingProduct nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{CauchyInterleavingProduct}^{\uparrow}$ *carrier must pass through the regular readback* R*, the interleaving provenance* I*, the dyadic product row* D*, the product-error ledger* E*, the two source schedules, the shared ledger* M*, and the structural rows* H, C, P, N*. The packet exposes no route to quotient stream equality, selected host limits, ambient completeness, or completed-real multiplication.*

Proof. The real-facing row is downstream of the regular readback. By the carrier definition, R is not available without the source schedules, dyadic endpoint product, and finite product-error ledger.

The interleaving provenance row I keeps the readback attached to the alternating selector and to the two source names. The structural rows H, C, P, N preserve this route under transport and consumer replay.

No field of Q names a quotient stream, a selected limit, an ambient completeness witness, or a completed-real multiplication operation. Thus every real-facing consumer remains inside the finite interleaving-product certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInterleavingProduct}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyInterleavingProduct}^{\uparrow}$ packet is generated from two regular Cauchy source names, two stream windows, an alternating selector, a shared modulus and product-budget ledger, dyadic endpoint rows, a dyadic product row, a product-error ledger, a regular readback, interleaving provenance, transport, replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyInterleavingProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2172.1, Definition 2172.2, Definition 2172.3, and Definition 2172.4 bind the finite product/interleaving certificate for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyInterleavingProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected real limits, ambient completeness, host real equality, or completed-real multiplication.

Upgrade path: Lean closure requires carrier admission, selector-window coverage, dyadic product formation, product-budget exactness, regular readback handoff, nonescape, and TasteGate field faithfulness for BEDC.Derived.CauchyInterleavingProductUp.

Chapter 2173

A Concrete Naming Certificate for $\mathsf{DenseExtensionMetric}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{DenseExtensionMetric}^{\uparrow}$ packet records the finite BEDC surface for extending a uniformly continuous map from a dense metric source into a displayed complete metric target. It consumes the metric-completion route of chapter 1506, the unit admission route of chapter 1527, the complete target boundary of chapter 128, and the naming spine of chapter 126, chapter 301, chapter 291, and chapter 38. The packet is a constructive dense-extension certificate over displayed rows; it is not quotient completion equality, not a selected host limit, not countable choice, and not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 2173.1 (Dense extension metric carrier)**.** *A* $\mathsf{DenseExtensionMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, J, \omega, M, Y, S, R, D, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric row, including the source point histories and distance-read interface inspected before completion data are consumed.*
2. *J is the dense embedding row, recording the displayed source-to-completion admission through the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *and the dense image boundary used by completion consumers.*
3. *ω is the uniform-continuity modulus row for the source map on dense points, carrying the finite tolerance conversion from source metric reads to target metric reads.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row through which completion-facing source names are read.*
5. *Y is the* $\mathsf{CompleteMetric}^{\uparrow}$ *target row, carrying the displayed complete-metric limit interface for the transported image stream.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window route for the dense source names and transported image names.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route for rational regularity checks attached to S.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic budgets consumed by X, J, ω, M, Y, S, R.*
9. *Q is the* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after the stream, regular-rational, and dyadic routes have been displayed.*

10. *T is the extension transport row, assigning each admitted completion-side source name a target read through Y and recording agreement with the dense source map on the image of J.*

11. *H is the componentwise* hsame *transport ledger for the source metric, dense embedding, modulus, completion handoff, complete target, stream, rational, dyadic, real seal, and extension transport rows.*

12. *C is the displayed* Cont *replay route forcing every extension read to pass through*

$$X, J, \omega \longmapsto M, S, R, D \longmapsto Y, Q, T.$$

13. *P is the* Pkg *provenance over* $\mathsf{DenseExtensionMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseExtensionMetric}^{\uparrow}}$ *row.*

No coordinate of the carrier stores quotient completion equality, selected representatives, countable-choice schedules, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DenseExtensionMetricUp.DenseExtensionMetricTasteGate single carrier alignment`

Theorem 2173.2 (Dense extension metric NameCert obligations)**.** *For an accepted* $\mathsf{DenseExtensionMetric}^{\uparrow}$ *carrier $E = (X, J, \omega, M, Y, S, R, D, Q, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseExtensionMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source metric, dense embedding, modulus, metric-completion handoff, complete target, stream windows, regular readbacks, dyadic ledger, real seal, extension transport, componentwise transport, replay, provenance, and local naming rows;*

2. *dense-entry exposure, requiring every completion-side source read to enter through J before M is consumed;*

3. *modulus transport, requiring every target Cauchy request to use ω after the source distance reads in X and before the complete-target row Y is queried;*

4. *completion handoff, requiring source completion names to pass through M, S, R, D, Q before an extension value is offered;*

5. *target completeness handoff, requiring the transported image stream to reach a target read only through Y and T;*

6. *dense agreement, requiring T to restrict to the original dense-source map on the image carried by J;*

7. *ledger non-escape, stating that H, C, P, N export no quotient completion, selected representative, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Carrier admission is projection from Definition 2173.1. The tuple lists the source metric, dense embedding, modulus, completion handoff, complete target, stream, rational, dyadic, real, transport, replay, provenance, and local naming rows.

Dense-entry exposure uses J as the only carrier row connecting source points to completion-facing names. Thus a completion-side source read must pass through the displayed dense embedding before M can be consumed.

Modulus transport uses ω between the source metric row X and the target complete-metric row Y. The modulus row is the only tolerance-conversion coordinate in the packet, so every transported image request is routed through it.

Completion handoff is the ordered read of M, S, R, D, Q. The metric-completion row supplies the completion-facing source name, while the stream, regular-rational, dyadic, and real-seal rows provide the finite readback surface required before the target extension row is reached.

The complete-target and dense-agreement clauses are then projections to Y and T. The target read is accepted only through the displayed complete metric row, and T records agreement on the dense image carried by J.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no excluded host-side object appears as a coordinate, the listed obligations exhaust the local certificate surface. □

Theorem 2173.3 (Dense extension metric completion route)**.** *Let $E = (X, J, \omega, M, Y, S, R, D, Q, T, H, C, P, N)$ be an accepted* $\mathsf{DenseExtensionMetric}^{\uparrow}$ *carrier. Every completion-side extension read exported by E factors through*

$$X, J, \omega \longmapsto M, S, R, D, Q \longmapsto Y, T \longmapsto H, C, P, N.$$

Consequently the packet exports a displayed dense-extension handoff from source metric rows to complete target rows, not quotient completion equality, not a selected limit, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a completion-side source read. The carrier first exposes the source metric row X and the dense embedding row J, so the request enters the completion interface through displayed dense-source data.

The modulus row ω is then consumed before target convergence can be queried. This fixes the finite tolerance conversion used to transport source Cauchy evidence into the target metric row.

The completion handoff is read through M, S, R, D, Q. These rows provide the metric-completion surface, finite windows, regular rational readbacks, dyadic budgets, and terminal real seal for the source-side request.

Only then can the complete target row Y and extension transport row T be consumed. The structural rows H, C, P, N preserve that route componentwise, so no quotient completion, selected limit, choice schedule, host equality, or $\mathsf{Real}^{\uparrow}$ completeness theorem is introduced. □

Theorem 2173.4 (Dense extension metric downstream non-escape)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenseExtensionMetric}^{\uparrow}$ *carrier receives only the rows named in Definition 2173.1. In particular, downstream consumers receive no quotient completion equality, selected representative, countable-choice schedule, host equality of completed objects, or completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. A $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives M only after the source metric row X, the dense embedding row J, and the modulus row ω have been displayed. The stream, regular-rational, dyadic, and real-seal consumers are confined to S, R, D, Q along the same route.

A $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives Y only after the source completion handoff and finite readback rows have been fixed. The extension transport row T records the target read and dense agreement, but it has no coordinate for a host completion object or a chosen representative.

The structural rows H, C, P, N preserve and name this route. Since every downstream read is a projection from the same finite packet, the excluded quotient, choice, host-equality, and ambient-completeness data cannot escape to any listed consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{DenseExtensionMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseExtensionMetric}^{\uparrow}$ packet is generated from a source metric row, dense embedding row, uniform-continuity modulus row, MetricCompletion handoff, CompleteMetric target row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, extension transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseExtensionMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2173.1, Definition 2173.2, Definition 2173.3, and Definition 2173.4 seed the finite dense-extension theorem route over metric completion and complete target rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseExtensionMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, selected limits, countable choice, host equality of completed objects, open-cover compactness, Lean verification, bridge checking, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dense-entry exposure, modulus transport, completion handoff, complete-target handoff, dense agreement, transport replay, and ledger non-escape for BEDC.Derived.DenseExtensionMetricUp

Chapter 2174

A Concrete Naming Certificate for $\mathsf{CauchyApproximationScheme}^{\uparrow}$

Following Bishop and Bridges constructive approximation of Cauchy names, the $\mathsf{CauchyApproximationScheme}^{\uparrow}$ packet records the finite schedule that lets a consumer request dyadic precision, read a finite window of a name, and hand the resulting regular rational data toward the real boundary. It sits between the dyadic tolerance core of chapter 291, the stream observation surface of chapter 126, the regular rational sequence readback of chapter 301, the convergence schedule of chapter 1438, the net-facing carrier of chapter 589, and the sealed real interface of chapter 38. The chapter packages the approximation schedule before quotient completion, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness is available.

Definition 2174.1 (Cauchy approximation scheme carrier)**.** *A* $\mathsf{CauchyApproximationScheme}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, M, R, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic radii, comparison cells, shrink rows, and precision budgets available to the approximation consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It records the finite name windows whose entries may be inspected at each displayed precision demand.*
3. *M is the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *schedule row. It assigns to each tolerance request a finite window boundary that is allowed to justify a Cauchy comparison.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed dyadic ledger, stream windows, and schedule.*
5. *W is the* $\mathsf{CauchyNet}^{\uparrow}$ *compatibility row. It records the net-facing approximation window reached from the same finite schedule.*
6. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records only the boundary interface reached through R and W, not a host real representative.*
7. *H records componentwise* hsame *transport for the tolerance ledger, stream windows, convergence schedule, regular readback, net window, real seal, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$D, S, M \longmapsto R, W \longmapsto Q \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationScheme}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the ten displayed rows. It has no coordinate for quotient completion, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyApproximationSchemeUp.CauchyApproximationSchemeTasteGate single carrier alignment`

Theorem 2174.2 (Cauchy approximation scheme NameCert obligations)**.** *For every accepted* $\mathsf{CauchyApproximationScheme}^{\uparrow}$ *carrier*

$$A = (D, S, M, R, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyApproximationScheme}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic tolerance ledger, stream observation windows, convergence schedule, regular readback, net window, real seal, transport, replay, provenance, and local naming row;*
2. *dyadic precision exposure, requiring every tolerance demand to be witnessed by a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, shrink row, comparison cell, or budget entry in D;*
3. *stream-window exposure, requiring every inspected name value to enter through the finite* $\mathsf{StreamName}^{\uparrow}$ *row S;*
4. *modulus routing, requiring M to bind each displayed precision request to a finite Cauchy window before R, W, or Q is read;*
5. *regular and net handoff, requiring R and W to consume the same displayed D, S, M data before any real-facing boundary is exposed;*
6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the rows listed above and no quotient completion, selected limit, countable-choice row, trichotomy row, host real equality, or ambient completeness principle.*

No Cauchy-approximation-scheme obligation is stored outside these rows.

Proof. Project the carrier tuple $A = (D, S, M, R, W, Q, H, C, P, N)$. The carrier definition lists every coordinate visible to the local certificate, so admission is just the displayed finite packet with its transport, replay, provenance, and naming rows.

The precision request first reads D and S. The dyadic ledger supplies the tolerance data, while the stream row supplies only finite windows of the Cauchy name.

The schedule row M then fixes the Cauchy window that may justify the request. Since M is displayed before R, W, Q, no later consumer can replace the finite window by a selected limit or an ambient completeness assertion.

Finally R and W are the regular-sequence and net-facing handoffs, and Q is only the real seal reached after those handoffs. The rows H, C, P, N preserve and name that same route, so the listed obligations exhaust the NameCert surface. □

Theorem 2174.3 (Cauchy approximation scheme window stability)**.** *Let*

$$A = (D, S, M, R, W, Q, H, C, P, N)$$

and

$$A' = (D', S', M', R', W', Q', H', C', P', N')$$

be accepted $\mathsf{CauchyApproximationScheme}^{\uparrow}$ *packets. If the displayed* hsame *rows identify the dyadic tolerance ledgers, stream windows, and convergence schedules* D, S, M *with* D', S', M' *componentwise, then every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer sees the same finite approximation window from* A *and* A'*. The consumer can distinguish packets only through the displayed route*

$$D, S, M \longmapsto R, W \longmapsto Q$$

together with its transport, continuation replay, provenance, and local naming rows.

Proof. Start with the NameCert obligation theorem. Every consumer-facing read of the packet must pass through the dyadic ledger, stream windows, and convergence schedule before it reaches a regular readback, net window, or real seal.

Apply the componentwise hsame hypotheses to those first three rows. They identify the tolerance request, the inspected stream window, and the scheduled Cauchy boundary in the two packets.

The handoff rows R, W, Q are read only after the identified data, and the structural rows H, C, P, N and H', C', P', N' transport, replay, source, and name that same route. Thus the consumer-visible approximation window is stable under the displayed transport, with no additional coordinate available to refine the comparison. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationScheme}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationScheme}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2174.1, Definition 2174.2, and Definition 2174.3 seed the finite Cauchy approximation schedule over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationScheme}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic precision exposure, stream-window exposure, modulus routing, regular and net handoff, window stability, and provenance exhaustion for BEDC.Derived.CauchyApproximationSchemeU

Constructive story: A $\mathsf{CauchyApproximationScheme}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite StreamName windows, a Cauchy convergence schedule, RegSeqRat readback, CauchyNet compatibility, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2175

A Concrete Naming Certificate for $\mathsf{DyadicCompactness}^{\uparrow}$

Following Bishop and Bridges on constructive compactness, the $\mathsf{DyadicCompactness}^{\uparrow}$ packet records the finite dyadic net surface for a located closed bounded real interval before any Real or Completion consumer reads a compactness-shaped seal. It sits after the interval-net carrier of chapter 1250, the dyadic cell surface of chapter 306, the rational interval ledger of chapter 354, the finite stream-window interface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The chapter names finite-net compactness data only; it does not assert Heine–Borel open-cover compactness, select subcovers, quotient streams, host real equality, host limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2175.1 (Dyadic compactness carrier)**.** *A* $\mathsf{DyadicCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, Q, D, M, Z, F, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located closed bounded interval-net row supplied by* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$*, including lower and upper located endpoint windows;*
2. *Q is the finite* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger attached to the located endpoint row;*
3. *D is the finite* $\mathsf{DyadicInterval}^{\uparrow}$ *cell ledger refining the rational cells of Q;*
4. *M is the unary mesh scale naming the dyadic precision at which coverage is read;*
5. *Z is the* $\mathsf{ProbeBundle}$ *center ledger, with one displayed center for each accepted dyadic cell;*
6. *F is the finite coverage ledger saying that each displayed interval read enters a rational cell in Q, its dyadic refinement in D, and the corresponding center row in Z;*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect endpoints, cells, and centers at mesh scale M;*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same endpoint, cell, and center windows;*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, Q, D, M, Z, F, S, R have been displayed;*
10. *H records componentwise* hsame *transport for located endpoints, rational cells, dyadic cells, mesh scale, centers, coverage rows, stream windows, regular-rational readbacks, and the Real seal;*

11. *C records displayed* Cont *replay from the closed bounded interval net through rational cells, dyadic cells, mesh scale, center rows, finite coverage, StreamName windows, RegSeqRat readback, and RealUp sealing;*
12. *P is the* Pkg *provenance over* $\mathsf{DyadicCompactness}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCompactness}^{\uparrow}}$ *row.*

The carrier exports no open cover, chosen finite subcover, quotient stream representative, host real equality, selected host limit, hidden compactness principle, or ambient Real-completeness row.

Lean4 ✓ `BEDC.Derived.DyadicCompactnessUp.DyadicCompactnessTasteGate single carrier alignment`

Theorem 2175.2 (Dyadic compactness NameCert obligations)**.** *For the carrier of Definition 2175.1, the local* $\mathsf{NameCert}_{\mathsf{DyadicCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (L, Q, D, M, Z, F, S, R, E, I$ closed bounded interval-net admission through L, rational interval cell admission through Q, dyadic cell admission through D, unary mesh admission through M, ProbeBundle center admission through Z, finite coverage admission through F, StreamName and RegSeqRat readback through S and R, RealUp sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier row by row. The first block displays a closed bounded interval net, rational interval cells, dyadic refinements, a unary mesh scale, ProbeBundle centers, and a finite coverage ledger.

Read the analytic handoff only after the finite rows have been fixed. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks inspect endpoints, cells, and centers at the named mesh scale, and the $\mathsf{Real}^{\uparrow}$ seal is downstream of those windows.

The structural rows close the NameCert surface. The transport row H, replay row C, package row P, and local name N preserve only the displayed finite packet, so no further obligation can enter from an open cover, a chosen subcover, a quotient stream, a host real equality test, a selected limit, or ambient completeness. □

Theorem 2175.3 (Dyadic compactness finite-net coverage)**.** *Every accepted containment read of a* $\mathsf{DyadicCompactness}^{\uparrow}$ *carrier factors through the finite route*

$$L, Q, D, M, Z, F, H, C, P, N.$$

The read consumes the closed bounded interval-net row, the rational interval cell ledger, the dyadic refinement ledger, the unary mesh scale, the matching ProbeBundle center row, and the finite coverage row. It receives no open-cover compactness principle, hidden subcover choice, quotient stream representative, host real equality, selected host limit, or ambient Real-completeness row.

Proof. Induct over the finite mesh cells displayed by Q and D. In the base cell, the located endpoint read is admitted by L, refined by the first dyadic cell in D, and routed to its displayed ProbeBundle center in Z at mesh scale M.

For the successor step, keep the previously admitted cells fixed and read the next rational cell with its dyadic refinement. The coverage row F appends only that displayed cell-center route, while H transports the same finite rows componentwise.

Finally replay the accumulated route through C and package it through P, N. Since the carrier has no coordinate for open covers, subcover choices, quotient stream representatives, host real equality, selected limits, or ambient completeness, the induction cannot leave the finite dyadic net. □

Theorem 2175.4 (Dyadic compactness Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{DyadicCompactness}^{\uparrow}$ *packet reads the compactness data through the finite route*

$$L, Q, D, M, Z, F, S, R, E, H, C, P, N.$$

The Real seal row E is exposed only after the closed bounded interval net, rational cells, dyadic cells, unary mesh, ProbeBundle centers, finite coverage rows, StreamName windows, and RegSeqRat readbacks have been displayed. Consequently the downstream Real and Completion route receives a finite dyadic net packet and receives no Heine–Borel open-cover theorem, hidden finite-subcover selection, quotient stream equality, selected host real limit, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness premise.*

Proof. Start with Definition 2175.2. It places E after the finite rows L, Q, D, M, Z, F, S, R, so a Real-facing consumer cannot inspect a seal before the mesh, center, coverage, and readback data have been displayed.

Use Definition 2175.3 for the containment side. The coverage read is already confined to rational cells, dyadic refinements, a unary mesh scale, and ProbeBundle centers, so replacing it by an open cover or by a chosen finite subcover would require a row absent from the carrier.

The remaining structural rows H, C, P, N transport, replay, source, and name the same finite packet. Therefore every Real and Completion consumer receives the displayed dyadic net route and no quotient stream equality, selected host real limit, host real equality, or ambient completeness premise. □

Falsifiable prediction: Every Real or Completion read of a DyadicCompactnessUp packet factors through the displayed finite dyadic net route and not through an open-cover compactness row.

Independence witness: closedboundedintervalnet, dyadicinterval, rationalinterval, streamname, regseqrat, real: DyadicCompactnessUp is not bijective to any listed sibling because it jointly carries a closed bounded interval-net row, rational cells, dyadic cells, a unary mesh scale, ProbeBundle centers, finite coverage rows, StreamName windows, RegSeqRat readbacks, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCompactness}^{\uparrow}$ packet is generated from a closed bounded interval-net row, rational interval cells, dyadic cells, a unary mesh scale, ProbeBundle centers, finite coverage rows, StreamName windows, RegSeqRat readbacks, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2175.1, Definition 2175.2, Definition 2175.3, and Definition 2175.4 bind finite dyadic net compactness for the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCompactness}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DyadicCompactnessUp`

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, Heine–Borel compactness, open-cover compactness, hidden finite-subcover choice, quotient streams, host real equality, selected host limits, or ambient Real completeness.

Upgrade path: Upgrade to scoped finite-net obligations by proving carrier admission, finite-net coverage, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.DyadicCompactnessUp.

Chapter 2176

A Concrete Naming Certificate for $\mathsf{LocatedBoundedRealSet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ packet records the finite located-membership, boundedness, and approximation rows that a supremum-facing consumer may inspect before any least-upper-bound principle is invoked. It sits over the closed interval boundary of chapter 394, the dyadic rational core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies the finite source rows consumed by the located supremum route of chapter 1427 and the dyadic supremum boundary of chapter 1653; it does not assert that every bounded located subset has a supremum.

Definition 2176.1 (Located bounded real set carrier)**.** *A* $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the located-membership window row. It records the finite membership and apartness requests that have been opened for the displayed real-name family.*
2. *I is the closed interval bound row, carried through* $\mathsf{LocatedInterval}^{\uparrow}$*. It supplies the lower and upper endpoint windows that bound every accepted member row.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation ledger. It records the lower and upper dyadic approximants used by membership, interval containment, and supremum-facing reads.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected member windows, interval endpoint windows, and dyadic comparison windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed member observations and interval endpoint observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located-membership, interval-bound, dyadic, stream-window, and regular-readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the membership window, interval bound, dyadic approximation ledger, stream windows, regular readbacks, real seals, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each set-facing or supremum-facing request through $M, I, D, W, R, E, H, P,$*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedBoundedRealSet}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSet}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $M, I, D, W, R, E, H, C, P, N$ and has no coordinate for Heine–Borel compactness, arbitrary least-upper-bound completeness, trichotomy, countable choice, host set equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedBoundedRealSetUp.LocatedBoundedRealSetCarrier displayed route`

Theorem 2176.2 (Located bounded real set NameCert obligations)**.** *For every accepted* $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ *carrier*

$$B = (M, I, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located-membership window, the closed interval bound, the dyadic approximation ledger, the stream windows, the regular readbacks, the real seal, transport, replay, provenance, and local naming row;*
2. *located-membership exposure, requiring every membership or apartness request to enter through the displayed row M and through one of the finite windows named by W;*
3. *interval-bound exposure, requiring every accepted member read to retain the* $\mathsf{LocatedInterval}^{\uparrow}$ *row I before a boundedness conclusion is exported;*
4. *dyadic approximation exactness, requiring every lower or upper approximation read to use the dyadic scales and comparison rows recorded in D;*
5. *regular readback handoff, requiring R to be the only route from the displayed dyadic and stream-window data into regular rational observations;*
6. *real-seal non-escape, requiring E to remain downstream of M, I, D, W, R and to export no completed supremum or host set object;*
7. *transport, continuation, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise.*

No located-bounded-set obligation is stored outside those rows.

Proof. Project the accepted packet $B = (M, I, D, W, R, E, H, C, P, N)$. The carrier exposes the located-membership row, the interval bound, the dyadic ledger, the finite windows, the regular readbacks, and the real seal as the whole analytic surface.

A membership read starts with M and W. The row M supplies the displayed membership or apartness question, while W fixes the finite real-name and endpoint windows in which that question is read.

The boundedness read then passes through I and D. The $\mathsf{LocatedInterval}^{\uparrow}$ row supplies the closed interval boundary, and the dyadic ledger supplies the lower and upper approximation rows used to compare the inspected member data with that boundary.

The regular and real-facing rows are downstream. The row R is the only regular rational handoff, and the row E is exposed only after the membership, interval, dyadic, and window rows have been retained.

Finally H, C, P, N transport, replay, source, and name the same packet. Since Heine–Borel compactness, arbitrary least-upper-bound completeness, trichotomy, countable choice, host set equality, and $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate or replay edge, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.LocatedBoundedRealSetUp.LocatedBoundedRealSetCarrier namecert obligations`

Theorem 2176.3 (Located bounded real set interval-bound handoff)**.** *Every* $\mathsf{LocatedSupremum}^{\uparrow}$ *or* $\mathsf{DyadicSupremum}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ *carrier factors through the finite route*

$$M, I \longmapsto D, W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives located membership windows, the $\mathsf{LocatedInterval}^{\uparrow}$ *closed bound,* $\mathsf{DyadicRatCore}^{\uparrow}$ *lower and upper approximation rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, package provenance, and local naming. It receives no Heine–Borel compactness, arbitrary least-upper-bound completeness, trichotomy, countable-choice schedule, host set equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.LocatedBoundedRealSetUp.LocatedBoundedRealSetCarrier interval bound handoff`

Proof. Start with a supremum-facing read of the accepted carrier. The packet contains no supremum coordinate, so the read must first enter through the located-membership row M and the closed interval bound row I.

The approximation stage is finite. The dyadic row D records the lower and upper comparison scales, and the stream row W names exactly the inspected member and endpoint windows used by those comparisons.

The readback and seal rows then fix the public handoff. The row R translates the displayed dyadic and stream-window data into regular rational observations, and E seals only that observed finite boundary.

The structural rows preserve this route for both sibling consumers. A $\mathsf{LocatedSupremum}^{\uparrow}$ reader obtains its located family, upper-bound, and lower-approximation source rows from the displayed package, while a $\mathsf{DyadicSupremum}^{\uparrow}$ reader obtains the dyadic bound and approximation rows from D, W, R. No structural row can introduce compactness, completeness, trichotomy, countable choice, or host set equality because those data are absent from the carrier. □

Theorem 2176.4 (Located bounded real set non-escape)**.** *Let* $B = (M, I, D, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ *carrier. Every real-facing, interval-facing, or supremum-facing read exported by* B *is exhausted by the rows* $M, I, D, W, R, E, H, C, P, N$*. In particular, the packet exports a finite bounded located-set source and not a Heine–Borel theorem, an arbitrary least-upper-bound theorem, a trichotomy decision, a countable-choice selector, a host set equality witness, or a* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the accepted packet coordinate by coordinate. The only set-facing coordinate is M, the only bound coordinate is I, the only approximation coordinate is D, and the only finite observation coordinate is W.

The only handoff to regular rational and real-name consumers is R followed by E. Any read that skips these rows has not followed the displayed carrier route, and any read that stays on the route can expose only the rows already named in the packet.

Transport, continuation replay, provenance, and naming do not enlarge the analytic surface. They preserve the same finite rows under hsame, Cont, Pkg, and $\mathsf{NameCert}$, so no escaped compactness, completeness, trichotomy, choice, or host set equality coordinate remains to be read. □

Lean4 ✓ `BEDC.Derived.LocatedBoundedRealSetUp.LocatedBoundedRealSetCarrier nonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2176.1, Definition 2176.2, Definition 2176.3, and Definition 2176.4 seed the finite bounded located-set source over LocatedInterval, DyadicRatCore, StreamName, RegSeqRat, Real, LocatedSupremum, and DyadicSupremum consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Heine–Borel compactness, arbitrary least-upper-bound completeness, trichotomy, countable choice, host set equality, $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked located-membership exposure, interval-bound exposure, dyadic approximation exactness, regular readback handoff, real-seal non-escape, componentwise transport, continuation replay, provenance, and local naming for BEDC.Derived.LocatedBoundedRealSetUp.

Constructive story: A $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ packet is generated from located-membership windows, a $\mathsf{LocatedInterval}^{\uparrow}$ closed bound, $\mathsf{DyadicRatCore}^{\uparrow}$ lower and upper approximation rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2177

A Concrete Naming Certificate for $\mathsf{ViscositySolution}^{\uparrow}$

Following Crandall–Ishii–Lions viscosity-solutions theory, the $\mathsf{ViscositySolution}^{\uparrow}$ packet records the weak PDE solution interface by finite contact-test data rather than by ambient differentiability of the unknown. It sits over the Sobolev carrier of chapter 440, the Lipschitz-map modulus surface of chapter 410, the metric observation boundary of chapter 57, and the real seal of chapter 38. The packet names the finite viscosity subsolution and supersolution obligation surface needed by PDE-facing consumers without importing existence, uniqueness, comparison principles, classical differentiability, or ambient PDE regularity.

Definition 2177.1 (Viscosity solution carrier)**.** *A* $\mathsf{ViscositySolution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (D, M, U, F, T_-, T_+, B, L, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain row. It records the metric observation windows, boundary faces, interior-window tags, and localization radii read through the* $\mathsf{Met}^{\uparrow}$ *surface.*
2. *M is the regularity row. It exposes the Sobolev-facing and Lipschitz-facing bounds used to keep test functions local to the same displayed domain row.*
3. *U is the candidate scalar row. It records the observed real values, semicontinuity side, boundary trace windows, and finite comparison requests through the* $\mathsf{Real}^{\uparrow}$ *seal.*
4. *F is the finite PDE operator row. It records only the inspected operator values $F(x, r, p, X)$ at named contact jets and has no coordinate for a global host PDE algebra.*
5. *T_- is the subsolution test-function row. Each entry contains a smooth-test name, a local touching-above certificate, the inspected first and second jet data, and the resulting inequality check.*
6. *T_+ is the supersolution test-function row. Each entry contains a smooth-test name, a local touching-below certificate, the inspected first and second jet data, and the resulting inequality check.*
7. *B is the boundary compatibility row. It records boundary-window reads, admissible trace comparisons, and the refusal of uninspected boundary regularity.*

8. *L is the finite localization ledger. It ties every test-function contact, operator read, and boundary read back to the same displayed domain and tolerance windows.*

9. *R records* $\mathsf{Real}^{\uparrow}$ *readback for the candidate values, operator values, comparison inequalities, and boundary traces.*

10. *H records componentwise* hsame *transport for the domain, regularity, candidate, operator, subsolution tests, supersolution tests, boundary, localization, real-readback, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the finite route*

$$D, M, U, F, T_-, T_+, B, L, R \longmapsto H, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{ViscositySolution}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{ViscositySolution}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, U, F, T_-, T_+, B, L, R, H, C, P, N$. The carrier has no coordinate for solution existence, uniqueness, comparison principles, classical differentiability of the candidate, global PDE regularity, host function equality, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.ViscositySolutionUp.ViscositySolutionUp`

Theorem 2177.2 (Viscosity solution NameCert obligations)**.** *For every accepted* $\mathsf{ViscositySolution}^{\uparrow}$ *carrier*

$$V = (D, M, U, F, T_-, T_+, B, L, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ViscositySolution}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the domain, regularity, candidate scalar, PDE operator, subsolution test, supersolution test, boundary, localization, real-readback, transport, replay, provenance, and local naming rows;*

2. *common-domain discipline, requiring every Sobolev, Lipschitz, metric, candidate-value, operator, and boundary read to pass through the same displayed domain row D;*

3. *contact-test exactness, requiring each entry of T_- and T_+ to record the touching side, localization window, inspected jet data, operator value, and inequality sign for that contact;*

4. *boundary compatibility, requiring B to expose only the named trace windows and comparison rows before any boundary-facing consumer may read the packet;*

5. *localization stability, requiring L to bind every contact test and boundary read to the same finite metric windows and tolerance rows;*

6. *real-readback nonescape, requiring R to expose only the displayed candidate values, operator values, comparison inequalities, and trace rows;*

7. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the displayed rows and no solution existence theorem, uniqueness theorem, comparison principle, classical differentiability witness, global PDE regularity, host function equality, Lean verification, or bridge credential.*

No viscosity-solution obligation is stored outside these rows.

Proof. Project the accepted packet $V = (D, M, U, F, T_-, T_+, B, L, R, H, C, P, N)$. The carrier definition lists the entire visible packet, so carrier admission is projection from the displayed finite BHist data.

The common-domain discipline is forced by the source row D. The Sobolev and Lipschitz regularity row M, the scalar candidate row U, the operator row F, and the boundary row B all refer back to the same metric observation windows and localization radii.

The contact obligations are exactly the two test rows. A subsolution read must pass through T_- and therefore displays a touching-above certificate, inspected jet data, the operator value, and the required inequality. A supersolution read is the dual read through T_+ with touching-below data and its displayed inequality.

Boundary and localization data are finite ledgers. The row B exposes only named trace comparisons, while L binds each interior or boundary contact to the same domain windows and tolerance data.

Finally R, H, C, P, N read back, transport, replay, source, and name those rows componentwise. Since the excluded analytic principles have no carrier coordinate and no replay edge, the listed rows exhaust the local NameCert surface. □

Theorem 2177.3 (Viscosity solution test-function boundary)**.** *Every PDE-facing consumer read of an accepted* $\mathsf{ViscositySolution}^{\uparrow}$ *carrier factors through the finite route*

$$D, M, U, F, T_-, T_+, B, L, R \longmapsto H, C, P, N.$$

Thus the consumer receives the displayed metric domain windows, Sobolev and Lipschitz regularity rows, candidate real-value observations, finite PDE-operator values, subsolution and supersolution contact-test ledgers, boundary trace comparisons, localization data, real-readback rows, componentwise transport, continuation replay, package provenance, and local naming. It receives no solution existence theorem, uniqueness theorem, comparison principle, classical differentiability of the candidate, ambient PDE regularity, or host function equality.

Proof. Start with a PDE-facing read of the accepted packet. The domain row D is the first admissible source because every contact test, boundary trace, and operator value is localized over its metric observation windows.

The regularity and candidate rows are then fixed. The row M supplies only Sobolev-facing and Lipschitz-facing bounds, while U supplies the observed real values and semicontinuity side used by the contact tests.

The operator and test-function rows form the viscosity boundary. The row F supplies only inspected operator values at named contact jets, and the rows T_- and T_+ expose the touching side, jet data, and inequality signs required for subsolution and supersolution reads.

Boundary traces cannot bypass the contact route. The row B contributes named trace comparisons, and L ties them to the same localization windows before R exposes the corresponding real-readback inequalities.

The structural rows H, C, P, N preserve exactly this dependency order. Therefore every consumer read factors through the finite route above and cannot obtain existence, uniqueness, comparison, differentiability, global regularity, or host equality data from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ViscositySolution}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ViscositySolution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2177.1, Definition 2177.2, and Definition 2177.3 seed the finite viscosity-solution packet over metric domain windows, Sobolev and Lipschitz regularity rows, real candidate observations, PDE operator reads, contact-test ledgers, boundary traces, localization, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{ViscositySolution}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close solution existence, uniqueness, comparison principles, classical differentiability, ambient PDE regularity, host function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-domain discipline, contact-test exactness, boundary compatibility, localization stability, real-readback nonescape, and provenance exhaustion for BEDC.Derived.ViscositySolutionUp

Constructive story: A ViscositySolution$^{\uparrow}$ packet is generated from metric domain windows, Sobolev and Lipschitz regularity rows, candidate RealUp observations, finite PDE-operator values, subsolution and supersolution contact-test ledgers, boundary trace comparisons, localization rows, RealUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2178

A Concrete Naming Certificate for $\mathsf{PreReal}^{\uparrow}$

Following Bishop and Bridges' regular Cauchy construction of the reals, the $\mathsf{PreReal}^{\uparrow}$ packet records the unsealed regular-Cauchy name boundary between regular rational sequences and the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits over the dyadic tolerance ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, and the real-name boundary of chapter 38. The packet exposes the finite name data available before a Real seal is consumed; it is not quotient stream equality, a selected limit, host real equality, countable choice, or completeness.

Definition 2178.1 (PreReal carrier)**.** *A* $\mathsf{PreReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (D, S, R, H, C, K, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording finite precision requests, denominator windows, and dyadic radius bookkeeping.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row opened by the same tolerance request, recording the finite schedule of inspected name entries.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, read only through D and S, and carrying the displayed Cauchy regularity evidence available before a real seal is consumed.*
4. *H records componentwise* hsame *transport for tolerance, observation, regularity, replay, provenance, and local naming rows.*
5. *C records displayed* Cont *replay of the route*

$$D, S \longmapsto R \longmapsto H, K, N.$$

6. *K is the* Pkg *provenance over* $\mathsf{PreReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{PreReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected representatives, host real equality, countable choice, a selected limit, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PreRealUp.PreRealTasteGate single carrier alignment`

Theorem 2178.2 (PreReal NameCert obligations)**.** *For an accepted* $\mathsf{PreReal}^{\uparrow}$ *carrier*

$$P = (D, S, R, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{PreReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic tolerance, StreamName observation, RegSeqRat regularity, componentwise transport, replay, provenance, and local naming rows;*
2. *tolerance-window exposure, requiring every PreReal read to start from the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *and the matching* $\mathsf{StreamName}^{\uparrow}$ *row* S*;*
3. *regularity handoff, requiring the opened finite name window to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before any Real-facing boundary is named;*
4. *transport and replay stability, requiring* H *and* C *to preserve the same displayed rows componentwise;*
5. *provenance non-escape, requiring* K *and* N *to export no quotient streams, selected representatives, host real equality, countable choice, selected limit, or completeness principle.*

No PreReal obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2178.1. The packet lists the tolerance row, finite observation row, regularity row, transport, replay, provenance, and local naming row, so admission has no additional source.

The tolerance-window exposure obligation reads D and S first. These two rows bind the same finite precision request, so a PreReal consumer cannot skip directly to a selected limit or quotient stream.

The regularity handoff is row R. It consumes the opened finite window through the regular rational sequence surface, and therefore presents only regular Cauchy name data to any later Real-facing boundary.

Finally H, C, K, N transport, replay, source, and name exactly the displayed route. Since the carrier contains no coordinate for the excluded host objects or choice principles, the listed rows exhaust the local NameCert surface. □

Theorem 2178.3 (PreReal constant dyadic route)**.** *Every constant dyadic name admitted by a* $\mathsf{PreReal}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{PreReal}^{\uparrow}.$$

For a carrier $P = (D, S, R, H, C, K, N)$*, the route reads the constant dyadic tolerance data from* D*, opens the matching finite StreamName observation row* S*, records regularity in* R*, and then consumes only* H, C, K, N *as structural support for the local* $\mathsf{NameCert}_{\mathsf{PreReal}^{\uparrow}}$ *row.*

Proof. Project the accepted packet $P = (D, S, R, H, C, K, N)$. The constant dyadic request first reads D, because this is the only tolerance row exposed by the carrier.

The matching StreamName observation row is S. It records the finite schedule at which the constant dyadic data are inspected, and it supplies no selected limit or quotient coordinate.

The regularity evidence is then read from R. A constant dyadic name satisfies the regular rational route by the displayed tolerance and observation rows, so the PreReal packet receives a regular name rather than host real data.

The remaining rows H, C, K, N preserve, replay, source, and name the same route. Thus the constant dyadic route reaches $\mathsf{PreReal}^{\uparrow}$ without exporting quotient streams, selected limits, host real equality, countable choice, or Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{PreReal}^{\uparrow}}$.

Constructive story: A $\mathsf{PreReal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName finite observation row, RegSeqRat regularity row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any RealUp seal is consumed.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PreReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2178.1, Definition 2178.2, and Definition 2178.3 seed the unsealed regular-Cauchy name boundary between RegSeqRat rows and RealUp seal consumption.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PreReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter refuses quotient streams, selected limits, host real equality, countable choice, selected representatives, and completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window exposure, regularity handoff, transport and replay stability, provenance non-escape, and constant dyadic routing for BEDC.Derived.PreRealUp.

Chapter 2179

A Concrete Naming Certificate for $\mathsf{BishopSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopSequence}^{\uparrow}$ packet records a constructive sequence of real-facing approximants as finite BEDC NameCert data. It sits beside the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the explicit convergence row of chapter 332, and the terminal real-name seal of chapter 38. The packet keeps the sequence surface visible to later Real and Completion consumers before any $\mathsf{Real}^{\uparrow}$ seal is read; it does not quotient streams, choose limits, invoke countable choice, or assert ambient completeness.

Definition 2179.1 (Bishop sequence carrier)**.** *A* $\mathsf{BishopSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, M, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It records the finite sequence indices, inspected windows, and read schedule exposed to the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational sequence values read from the same windows.*
3. *M is the* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *row. It records the displayed threshold discipline by which later tail requests are answered.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic radii, shrink steps, denominator budgets, and comparison cells attached to S, R, M.*
5. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records only the finite real-facing boundary reached after the regular readback and modulus rows have been displayed.*
6. *H records componentwise* hsame *transport for stream observations, regular readback, convergence modulus, dyadic tolerance ledger, real seal data, continuation replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$S, D \longmapsto R, M \longmapsto Q \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ModulusOfConvergence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, M, D, Q, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BishopSequenceUp.BishopSequenceTasteGate single carrier alignment`

Theorem 2179.2 (Bishop sequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopSequence}^{\uparrow}$ *carrier*

$$B = (S, R, M, D, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream windows, regular rational readback, convergence modulus, dyadic tolerance ledger, real seal boundary, transport, replay, provenance, and local naming row;*
2. *observation visibility, requiring every sequence index read to pass through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows in S;*
3. *regular readback, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to consume the same finite observations before any real-facing consumer reads the packet;*
4. *modulus accountability, requiring the* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *row M to expose the threshold used by any tail or completion request;*
5. *tolerance exactness, requiring every threshold and readback comparison to be witnessed by a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *entry in D;*
6. *real seal confinement, requiring Q to expose only the finite* $\mathsf{Real}^{\uparrow}$ *boundary reached through R, M, D;*
7. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the rows listed above and no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, ambient completeness, Lean verification, or bridge credential.*

No Bishop-sequence obligation is stored outside these rows.

Proof. Project the accepted packet $B = (S, R, M, D, Q, H, C, P, N)$. The carrier definition lists every visible row, so admission is exactly the displayed finite BHist data together with its transport, replay, provenance, and naming rows.

The observation and readback rows are forced first. The schedule and finite windows live in S, and the regular rational values live in R, so a consumer has no route to an unbounded stream or to a host sequence representative.

The convergence discipline is the row M together with the dyadic ledger D. Every threshold request must read the displayed modulus row and the displayed tolerance entries before it can be presented to a completion-facing consumer.

The real-facing boundary is last. The row Q records only the $\mathsf{Real}^{\uparrow}$ seal reached through the regular readback, convergence modulus, and tolerance ledger.

Finally H, C, P, N preserve exactly this route under componentwise transport, continuation replay, provenance, and local naming. Since the refused principles have no coordinate and no replay edge, the listed obligations exhaust the local NameCert surface. □

Theorem 2179.3 (Bishop sequence StreamName–Real route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ModulusOfConvergence}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{BishopSequence}^{\uparrow}$ *carrier factors through the finite route*

$$S, D \longmapsto R, M \longmapsto Q \longmapsto H, C, P, N.$$

Thus the consumer receives the $\mathsf{StreamName}^{\uparrow}$ *observation windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *threshold row, the* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It receives no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Start with a consumer read of the accepted carrier. The read begins at S, where the packet displays the finite sequence indices, observation windows, and schedule.

The tolerance row D is read with the same windows. It supplies the dyadic radii, shrink steps, denominator budgets, and comparison cells needed for both regular readback and convergence thresholds.

The middle handoff is R, M. The $\mathsf{RegSeqRat}^{\uparrow}$ row exposes the regular rational sequence data, while the $\mathsf{ModulusOfConvergence}^{\uparrow}$ row exposes the threshold discipline used by tail and completion requests.

The real boundary is then Q. It is reachable only after R, M, D have been displayed, so a $\mathsf{Real}^{\uparrow}$ consumer reads a seal rather than a selected host limit.

The structural rows H, C, P, N keep the same route stable under transport, replay, provenance, and local naming. Therefore every listed consumer factors through the displayed finite route and cannot access any excluded principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2179.1, Definition 2179.2, and Definition 2179.3 seed the finite constructive sequence packet over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ModulusOfConvergence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observation visibility, regular readback, modulus accountability, tolerance exactness, real seal confinement, provenance exhaustion, and local naming for BEDC.Derived.BishopSequenceUp.

Constructive story: A $\mathsf{BishopSequence}^{\uparrow}$ packet is generated from StreamName observation windows, RegSeqRat readback, a ModulusOfConvergence threshold row, a DyadicRatCore tolerance ledger, RealUp seal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2180

A Concrete Naming Certificate for $\mathsf{CauchyRealEquality}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealEquality}^{\uparrow}$ packet records equality of constructive Cauchy reals as a finite regular-name classifier surface. It sits after the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the sealed real boundary of chapter 38. The packet lets Real-facing consumers compare two displayed regular Cauchy names without importing quotient stream equality, host real equality, selected representatives, countable choice, or an ambient completeness theorem.

Definition 2180.1 (Cauchy real equality carrier)**.** *A* $\mathsf{CauchyRealEquality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L_0, L_1, S_0, S_1, R_0, R_1, D, H, C, P, N)$$

with the following displayed rows:

1. L_0 *and* L_1 *are the two* $\mathsf{Real}^{\uparrow}$ *seal rows. They record only the terminal real-name boundaries reached by the two compared regular names.*
2. S_0 *and* S_1 *are the paired* $\mathsf{StreamName}^{\uparrow}$ *window rows. They expose the finite observation schedules inspected on the two sides.*
3. R_0 *and* R_1 *are the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows. Each readback consumes its own stream window before the corresponding* $\mathsf{Real}^{\uparrow}$ *seal is available.*
4. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic precision requests and comparison budgets used to test the two regular readbacks at the same requested tolerance.*
5. H *records componentwise* hsame *transport for both real seals, both stream windows, both regular readbacks, the dyadic ledger, continuation replay, provenance, and local naming.*
6. C *records displayed* Cont *replay of the comparison route*

$$S_0, S_1, D \longmapsto R_0, R_1 \longmapsto L_0, L_1 \longmapsto H, P, N.$$

7. P *is the* Pkg *provenance over* $\mathsf{CauchyRealEquality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealEquality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. The carrier has no coordinate for quotient stream equality, host real equality, selected representatives, countable choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyRealEqualityUp.TasteGate.CauchyRealEqualityTasteGate single carrier alignment`

Theorem 2180.2 (Cauchy real equality NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealEquality}^{\uparrow}$ *carrier*

$$E = (L_0, L_1, S_0, S_1, R_0, R_1, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealEquality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{Real}^{\uparrow}$ *seals, paired stream windows, paired regular readbacks, shared dyadic tolerance ledger, transport, replay, provenance, and local naming row;*
2. *two-sided window exposure, requiring every equality read to inspect* S_0 *and* S_1 *before reaching either regular readback;*
3. *regular-readback comparison, requiring* R_0 *and* R_1 *to be compared only at tolerance requests named by* D*;*
4. *Real-seal nonescape, requiring* L_0 *and* L_1 *to be read only after the paired regular readbacks and never as host real representatives;*
5. *provenance exhaustion, requiring* H, C, P, N *to transport, replay, source, and name exactly the displayed rows and no quotient stream equality, host real equality, selected representative, countable-choice schedule, ambient completeness theorem, Lean verification, or bridge credential.*

No Cauchy-real-equality obligation is stored outside these rows.

Proof. Project the accepted carrier. Its displayed rows are the whole finite packet, so carrier admission is exactly the listed pair of real seals, the two stream windows, the two regular rational readbacks, the shared dyadic tolerance ledger, and the four structural rows.

The comparison first reads the windows S_0 and S_1. Those rows name the finite observations available on each side, so an equality consumer cannot begin from an unbounded stream.

The readbacks R_0 and R_1 are then compared only through D. The dyadic ledger supplies the common precision budget and prevents the comparison from appealing to an ambient metric or a host real value.

Finally L_0, L_1, H, C, P, N close the route. The real seals are terminal rows reached through the regular readbacks, while transport, replay, provenance, and local naming preserve the same coordinates componentwise. Since the refused principles have no coordinate and no replay edge, the listed obligations exhaust the local certificate surface. □

Theorem 2180.3 (Cauchy real equality RegSeqRat classifier handoff)**.** *Every classifier comparison exported by an accepted* $\mathsf{CauchyRealEquality}^{\uparrow}$ *packet factors through the finite route*

$$S_0, S_1, D \longmapsto R_0, R_1 \longmapsto L_0, L_1 \longmapsto H, C, P, N.$$

Thus the consumer receives paired $\mathsf{StreamName}^{\uparrow}$ *windows, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the two* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It receives no quotient equality of streams, host real equality, selected representative, countable-choice schedule, or ambient completeness witness.*

Proof. Start with an exported classifier comparison. The source rows are the paired stream windows S_0 and S_1, so the comparison is anchored at finite observation schedules rather than at total streams.

Next read the shared dyadic ledger D and the paired regular readbacks R_0, R_1. The ledger supplies the tolerance requests, and the readbacks supply the only rational sequence data visible to the classifier.

The terminal real-facing data are L_0 and L_1. These rows are seals reached through R_0 and R_1, not host real values and not quotient representatives.

The structural rows H, C, P, N preserve the same route by componentwise transport, replay, provenance, and local naming. Therefore the classifier handoff is exactly the displayed RegSeqRat-to-Real route and cannot export any of the excluded equality or choice data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealEquality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealEquality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2180.1, Definition 2180.2, and Definition 2180.3 seed the finite equality-classifier packet over two Real seals, two StreamName windows, two RegSeqRat readbacks, one DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealEquality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected representatives, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-sided window exposure, regular-readback comparison, Real-seal nonescape, and provenance exhaustion for BEDC.Derived.CauchyRealEqualityUp.

Constructive story: A $\mathsf{CauchyRealEquality}^{\uparrow}$ packet is generated from two RealUp seal rows, paired StreamName observation windows, paired RegSeqRat regular readbacks, a shared DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2181

A Concrete Naming Certificate for MetaCICResidualSubstitutionBoundary$^{\uparrow}$

The MetaCICResidualSubstitutionBoundary$^{\uparrow}$ packet realizes the residual-substitution compatibility boundary of chapter 9378 as finite NameCert data. It sits beside the confluence audit packet of chapter 735, the closed-normal fragment of chapter 737, and the substitution audit surface of chapter 1102. The downstream parallel-diamond frontier of chapter 4238 consumes this packet specifically as the visible residual-substitution premise row while retaining the conditional boundary. The packet names exactly the row needed by the conditional parallel-diamond handoff without turning the checked fragments into unconditional MetaCIC confluence.

Definition 2181.1 (MetaCIC residual-substitution boundary carrier)**.** *A* MetaCICResidualSubstitutionBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, S, A, J, N, F, L, H, C, P, K)$$

with the following displayed rows:

1. *R is the residual beta-branch row. It records the two residual branches whose componentwise join is blocked without substitution compatibility.*
2. *S is the substitution-compatibility boundary row. It names the* BetaParallelSubstitutionCompatibility *input as a required row, not as a theorem produced by the packet.*
3. *A is the application-branch audit row. It records the beta-application shape where the substitution boundary is consumed by the parallel diamond route.*
4. *J is the conditional join row. It records the route from S and A to the parallel-diamond handoff while keeping the premise visible.*
5. *N is the closed-normal fragment row, read through chapter 737 as an available sibling fragment rather than as a discharge of S.*
6. *F is the confluence audit packet row, read through chapter 735 as the larger audit context that consumes this boundary.*
7. *L is the substitution audit ledger, read through chapter 1102, recording which closed substitution routes are audited before a consumer cites S.*
8. *H records componentwise* hsame *transport for residual branches, substitution boundary, application audit, conditional join, sibling fragment, audit packet, ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$R, S, A, L \longmapsto J \longmapsto F, N \longmapsto H, P, K.$$

10. *P is the* Pkg *provenance over* MetaCICResidualSubstitutionBoundary$^{\uparrow}$*, MetaCIC beta reduction,* BetaParallel*,* BetaStarStep*, closedness rows, the named sibling packets,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *K is the local* NameCert$_{\text{MetaCICResidualSubstitutionBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate proving BetaParallelSubstitutionCompatibility*, no coordinate proving full parallel diamond without S, no coordinate proving arbitrary closed Church–Rosser, and no coordinate for host substitution semantics.*

Theorem 2181.2 (MetaCIC residual-substitution boundary NameCert obligations)**.** *For every accepted* MetaCICResidualSubstitutionBoundary$^{\uparrow}$ *carrier*

$$B = (R, S, A, J, N, F, L, H, C, P, K),$$

the local NameCert$_{\text{MetaCICResidualSubstitutionBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the residual beta branches, substitution-compatibility boundary, application-branch audit, conditional join, closed-normal fragment, confluence audit packet, substitution audit ledger, transport, replay, provenance, and local naming row;*
2. *residual-row exposure, requiring a consumer to read the beta residual branches R before citing the boundary;*
3. *substitution-boundary visibility, requiring S to remain a named premise row whenever the conditional join J is exported;*
4. *sibling separation, requiring N and F to be read as contextual fragments and audit packets rather than as proofs of S;*
5. *ledger exactness, requiring L to record the audited closed substitution rows visible to the boundary;*
6. *provenance exhaustion, requiring H, C, P, K to transport, replay, source, and name exactly the displayed rows and no proof of* BetaParallelSubstitutionCompatibility*, no premise-free parallel diamond, no arbitrary closed Church–Rosser theorem, and no host substitution semantics.*

No residual-substitution-boundary obligation is stored outside these rows.

Proof. Project the accepted carrier $B = (R, S, A, J, N, F, L, H, C, P, K)$. The carrier definition lists the whole finite packet, so carrier admission is projection from the displayed rows.

The residual branch data are read first. Row R records the beta branches whose join requires substitution compatibility, and row A records the application shape where the branch interaction occurs.

The boundary row S remains visible through the conditional join J. Since S is a premise row rather than a produced theorem, the packet can expose the conditional handoff but cannot erase the input.

Rows N and F keep the siblings separate. The closed-normal fragment and the confluence audit packet are useful context, but neither contains a projection that proves the residual substitution boundary row.

The ledger row L records the audited closed substitution data that may be cited before the boundary is consumed. Finally H, C, P, K transport, replay, source, and name exactly those rows. With no coordinate for the refused endpoint claims, the listed obligations exhaust the local NameCert surface. □

Theorem 2181.3 (MetaCIC residual-substitution premise preservation)**.** *Let $B = (R, S, A, J, N, F, L, H, C, P, K)$ be an accepted* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *carrier. Any consumer of B that exports a parallel-diamond handoff or a closed Church–Rosser handoff must keep the substitution row S visible as a premise through the route*

$$R, S, A, L \longmapsto J \longmapsto F, N \longmapsto H, P, K.$$

Thus the consumer may export only a conditional handoff whose displayed route still contains S; it does not obtain $\mathsf{BetaParallelSubstitutionCompatibility}$ *as a theorem of the packet.*

Proof. Project the carrier of Definition 2181.1. The rows R, S, A, L are the only entry surface for the residual beta branches, the substitution-compatibility boundary, the application audit, and the substitution audit ledger.

Apply Definition 2181.2. Its substitution-boundary visibility clause requires S to remain a named premise whenever the conditional join row J is exported, while its ledger exactness clause keeps L attached to the audited closed substitution rows.

The sibling separation rows then route the handoff through the confluence audit packet F and the closed-normal fragment N without turning either sibling into a proof of S. The confluence audit map may consume the conditional route, but the visible premise row remains part of the exported packet.

Finally H, P, K transport, source, and name the same finite route. Since the carrier has no coordinate proving $\mathsf{BetaParallelSubstitutionCompatibility}$, a parallel-diamond or closed Church–Rosser consumer can receive only the premise-preserving handoff displayed above. □

Theorem 2181.4 (MetaCIC residual-substitution closed-face consumer)**.** *Let $B = (R, S, A, J, N, F, L, H, C, P, K)$ be an accepted* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *carrier. Any closed-face confluence consumer or subject-reduction consumer of B must keep the substitution row S and the closed-face audit ledger L visible through the route*

$$R, S, A, L \longmapsto J \longmapsto F, N \longmapsto H, P, K.$$

The sibling confluence-audit packet F and closed-normal row N may be used as context for the closed face, but neither sibling discharges S or turns the route into unrestricted substitution compatibility.

Proof. Start with Definition 2181.2. Its substitution-boundary visibility clause keeps S named whenever the conditional join J is exported, and its ledger exactness clause keeps L attached to the audited closed substitution rows.

Apply Definition 2181.3. It routes any parallel-diamond or closed Church–Rosser handoff through

$$R, S, A, L \longmapsto J \longmapsto F, N \longmapsto H, P, K.$$

The closed-face consumer may inspect the sibling confluence-audit row F and the closed-normal row N only after the visible premise route has reached J. Those rows provide closed-face context, while S remains the named substitution-compatibility premise.

Finally H, C, P, K transport, replay, source, and name the same route. Since the carrier has no coordinate proving the substitution row, no closed-face consumer can erase S or obtain unrestricted substitution compatibility from the sibling context. □

Falsifiable prediction: A packet lacking the residual-substitution row is rejected even if it carries closed-normal confluence rows.

Independence witness: metacicconfluenceauditpacket, metacicconfluencenormalfragment, metacicredexfrontier, closedsubstitutionboundary, substitutionboundaryaudit: the residual-substitution boundary carrier is not bijective to any sibling because it carries the dedicated premise row S coupled to the conditional join row J and the residual beta-branch row R.

The proposed Lean follow-up supplies Nontrivial and FieldFaithful instances in `lean4/BEDC/Derived/MetaCICRe` by giving two explicit boundary packets, one with the residual-substitution row present and one refused by that row, and by matching on the fields $R, S, A, J, N, F, L, H, C, P, K$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}}$ ·

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2181.1 and Definition 2181.2 seed the finite residual-substitution boundary packet over residual beta branches, the visible substitution premise row, application audit, conditional join, sibling fragments, substitution ledger, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close BetaParallelSubstitutionCompatibility, premise-free parallel diamond, arbitrary closed Church–Rosser, host substitution semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-row exposure, substitution-boundary visibility, sibling separation, ledger exactness, provenance exhaustion, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetaCICResidualSubstitutionBoundaryUp.

Constructive story: A $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ packet is generated from residual beta branches, a visible substitution-compatibility premise row, application audit data, conditional join data, closed-normal and confluence-audit sibling rows, a substitution audit ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2182

A Concrete Naming Certificate for $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$

The $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ packet realizes the MetaCIC decidability audit map of chapter 9379 as a finite checker seal. It sits beside the subject-reduction obstruction of chapter 9377 and the confluence audit map of chapter 9378: those maps expose preservation and residual-substitution boundaries, while this packet records the closed typing-checker surface that can be consumed without promoting bounded normal equality into unrestricted beta-conversion decidability.

Definition 2182.1 (Closed type-checker seal carrier)**.** *A* $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (C, T, Q, E, N, R, O, H, K, P, L)$$

with the following displayed rows:

1. *C is the closed input row, carrying the represented closed MetaCIC term and the displayed closed context boundary;*
2. *T is the* `inferTypeCtxClosed` *checker row, including the soundness and completeness surfaces for the represented* `HasType` *relation;*
3. *Q is the structural* `Term.eq` *and* `checkSameTerm` *row used by the checker;*
4. *E is the checker-exactness row tying successful checking to the represented typing judgement and tying represented typing back to checker success;*
5. *N is the bounded normal-equality row over* `normalizeBounded` *and* `decideClosedBetaConv`*;*
6. *R is the finished-normalization boundary row required before a bounded-normal comparison is read as a statement about named finished normal forms;*
7. *O is the non-escape row excluding unrestricted closed beta-conversion decidability and any standalone closedness-decision theorem not displayed in the packet;*
8. *H records componentwise* hsame *transport across the closed input, checker, equality, exactness, bounded-normal, boundary, obstruction, replay, provenance, and local naming rows;*
9. *K records displayed* Cont *routes for closed typing checks, structural equality readback, bounded-normal comparison, finished-boundary replay, and non-escape readback;*

10. *P is the* Pkg *provenance over the decidability audit map, the checker seal of chapter 747, the decidability audit packet of chapter 746, the bounded normal-equality checker of chapter 752, the residual-substitution boundary of chapter 2181,* BHist, hsame, Cont, *and* NameCert *rows;*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{ClosedTypeCheckerSeal}^{\uparrow}}$ *row.*

The carrier exposes closed typing-checker exactness and bounded normal-equality data only through the displayed rows. It has no coordinate for unrestricted beta-conversion decidability, no hidden normalization endpoint, and no host-side closed-term oracle.

Theorem 2182.2 (Closed type-checker seal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedTypeCheckerSeal}^{\uparrow}}$ *surface consists of six obligation rows:*

1. *carrier: formation of the finite packet of Definition 2182.1;*
2. *checker exactness: the* `inferTypeCtxClosed` *row exposes soundness and completeness for the represented typing relation through T and E;*
3. *equality readback: structural term equality and same-term checking are read only through Q;*
4. *bounded normal equality: bounded-normal comparison is read only through N and the finished-normalization boundary row R;*
5. *non-escape: unrestricted closed beta-conversion decidability and standalone closedness decidability are refused by O;*
6. *ledger exactness: every transport, replay, provenance, and local naming read factors through H, K, P, L.*

Proof. Project the carrier tuple of Definition 2182.1. The visible checker data are C, T, Q, E, N, R, O, and the structural replay data are H, K, P, L.

The checker-exactness row uses the positive part of chapter 9379. The closed wrapper `inferTypeCtxClosed` supplies the typing-checker soundness and completeness surface, while E records that this surface is the exact public route for represented typing.

The equality and bounded-normal rows stay separate. Structural term equality and same-term checking are consumed through Q, while bounded normal equality is consumed through N and becomes a finished-normal statement only when R is displayed.

The non-escape row O records the missing endpoint. Because chapter 9377 and chapter 9378 keep their own preservation and residual-substitution boundaries visible, this seal cannot erase those boundaries by citing a checker row.

Finally H, K, P, L transport, replay, source, and name exactly the displayed rows. No additional carrier coordinate exists, so the listed rows exhaust the local NameCert obligations. □

Theorem 2182.3 (Closed type-checker seal bounded endpoint boundary)**.** *Every accepted* $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ *carrier permits downstream consumers to read checked closed typing, structural term equality, same-term checking, bounded normal equality, finished-normalization consequences when their witness row is displayed, and the corresponding transport, replay, provenance, and naming rows. It does not permit a consumer to export unrestricted closed beta-conversion decidability without a finished-normalization witness.*

Proof. Read the positive checker routes first. Rows C, T, Q, E expose the closed input boundary, the closed type-checker result, the structural equality row, and the exactness relation between checking and represented typing.

Next read the bounded-normal route. Row N compares bounded normalizer outputs, and row R is the only route that turns the bounded comparison into a finished-normal statement.

The obstruction row O is part of the same carrier. It refuses any consumer route that omits R while claiming unrestricted closed beta-conversion decidability.

Thus the seal separates checked typing decidability from the bounded conversion boundary. The public endpoint is the finite checker packet, not a global conversion oracle. □

Theorem 2182.4 (Closed type-checker seal non-escape)**.** *The public boundary of* $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ *exports only the finite rows*

$$C, T, Q, E, N, R, O, H, K, P, L.$$

It exports no subject-reduction theorem, no confluence theorem, no residual-substitution discharge, no unrestricted closed beta-conversion decider, no hidden normalization endpoint, and no host equality oracle.

Proof. Inspect the accepted carrier. Its checker-facing rows are C, T, Q, E, N, R, O, and its structural rows are H, K, P, L.

Apply Definition 2182.2. Every public read projects through the carrier, checker-exactness, equality-readback, bounded-normal, non-escape, or ledger-exactness rows.

Apply Definition 2182.3. The bounded-normal route reaches a finished-normal statement only when the witness row is displayed, and the same route refuses unrestricted beta-conversion decidability without that witness.

Since no coordinate names subject reduction, confluence, residual-substitution discharge, a hidden normalizer endpoint, or a host equality oracle, none of those objects can escape the seal. □

Theorem 2182.5 (Closed type-checker seal residual-substitution forward link)**.** *Every accepted* $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ *packet that exports checked closed typing and bounded normal-equality data to a residual-substitution or confluence-facing consumer must pass through the displayed residual-substitution boundary and the finished-normalization row R. Without that row the packet cannot export subject reduction, confluence, residual-substitution discharge, unrestricted closed beta-conversion decidability, or global normalization.*

Proof. Project the carrier rows of Definition 2182.1. The checker-facing export is carried by C, T, Q, E, N, while the finished-normalization boundary is the separate row R and the non-escape row is O.

Apply Definition 2182.3. It permits bounded normal equality to become a finished-normal statement only when the witness row is displayed, so a consumer that omits R receives checked typing and bounded comparison data but no normalization endpoint.

Apply Definition 2182.4. The same carrier has no coordinate for subject reduction, confluence, residual-substitution discharge, unrestricted beta-conversion decidability, or global normalization.

The residual-substitution boundary of chapter 2181 is therefore the sibling route through which a confluence-facing consumer must pass before reading this seal as part of a residual-substitution argument. The seal forwards bounded checker data to that route; it does not replace the route by a global normalization theorem. □

Theorem 2182.6 (Closed type-checker seal substitution-frontier handoff)**.** *Every accepted* $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ *packet used by a confluence-facing consumer must expose the closed input row C, the* `inferTypeCtxClosed` *exactness rows T, E, the bounded-normal row N, the finished-normalization boundary row R, and the residual-substitution boundary before any confluence or subject-reduction read is consumed. The packet may feed the residual-substitution route of chapter 2181 and the conditional confluence map*

of chapter 9378, but it does not discharge residual substitution, subject reduction, full confluence, unrestricted beta-conversion decidability, or global normalization.

Proof. Project the carrier of Definition 2182.1. The closed input, checker, exactness, bounded-normal, finished-boundary, and non-escape rows are displayed as C, T, E, N, R, O.

Apply the non-escape theorem Definition 2182.4. It prevents the seal from exporting subject reduction, confluence, residual-substitution discharge, unrestricted beta-conversion decidability, hidden normalization endpoints, or host equality.

Then route the confluence-facing read through chapter 2181 and chapter 9378. Those sibling surfaces keep the residual-substitution frontier visible before any confluence or subject-reduction consumer can cite the checker seal. □

Falsifiable prediction: The seal has no carrier route exporting unrestricted closed beta-conversion decidability without a finished-normalization witness.

Independence witness: metacicdecidableboundary, metacicdecidableauditpacket, metacicdecidablecheckerseal, metacic-residual-substitution-boundary: the closed type-checker seal is not bijective to any listed sibling because it binds the closed input row, inferTypeCtxClosed exactness row, structural equality readback, bounded-normal row, finished-normalization boundary, and non-escape row in one finite carrier.

The Lean follow-up supplies Nontrivial and FieldFaithful instances in `lean4/BEDC/Derived/ClosedTypeChecker` by exhibiting distinct accepted and refused closed checker packets and by matching on the rows $C, T, Q, E, N, R, O, H, K, P, L$.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedTypeCheckerSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ packet is generated from a closed input row, inferTypeCtxClosed checker row, structural Term.eq and checkSameTerm row, checker-exactness row, bounded normal-equality row, finished-normalization boundary row, non-escape row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedTypeCheckerSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2182.1, Definition 2182.2, Definition 2182.3, and Definition 2182.4 seed the finite closed type-checker seal and its bounded conversion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedTypeCheckerSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, confluence, residual-substitution discharge, unrestricted closed beta-conversion decidability, global normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inferTypeCtxClosed exactness routing, equality readback, bounded-normal boundary routing, non-escape, and TasteGate nontriviality with field faithfulness for BEDC.Derived.ClosedTypeChec

Chapter 2183

A Concrete Naming Certificate for $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ packet records a bounded located sequence of real names as finite BEDC NameCert data before any compactness, supremum, or completeness principle is available. It sits after the real seal of chapter 38, the located real boundary of **??**, the regular rational readback surface of chapter 301, the finite stream-name discipline of chapter 126, and the dyadic rational core of chapter 291. The packet gives L10 Real and Completion consumers one named sequence-boundary object whose rows can later feed limit, Cauchy, and boundedness arguments without importing Heine–Borel compactness, sequential compactness, host suprema, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2183.1 (Located bounded real sequence carrier)**.** *A* $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, L, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected-index row. It records the finite sequence positions and tail windows opened by the current consumer.*
2. *L is the located-real row. It records the* $\mathsf{LocatedReal}^{\uparrow}$ *membership and apartness windows attached to the inspected entries.*
3. *U is the boundedness row. It records the displayed lower and upper real-boundary windows that bound every inspected entry.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger. It records the dyadic radii, shrink steps, lower-bound comparisons, upper-bound comparisons, and tolerance budgets used by L and U.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It names the finite stream windows for the inspected indices, located-real reads, bound reads, and dyadic comparisons.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational observations obtained from W and D before any real-facing seal is exported.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It exposes only the real-name boundary reached through L, U, D, W, R.*

8. *H records componentwise* hsame *transport for the index row, located-real row, boundedness row, dyadic ledger, stream windows, regular readbacks, real seal, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay of the finite route*

$$I, L, U \longmapsto D, W \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSequence}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these eleven rows. Its classifier compares accepted packets only through $I, L, U, D, W, R, E, H, C, P, N$ and has no coordinate for Heine–Borel compactness, sequential compactness, host suprema, countable choice, selected subsequences, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedBoundedRealSequenceUp.TasteGate.LocatedBoundedRealSequenceTasteGate single carrier alignment`

Theorem 2183.2 (Located bounded real sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ *carrier*

$$S = (I, L, U, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected-index row, located-real row, boundedness row, dyadic comparison ledger, stream observation row, regular rational readback row, real seal, transport, replay, provenance, and local naming row;*

2. *located-entry exposure, requiring every inspected sequence entry to pass through the* $\mathsf{LocatedReal}^{\uparrow}$ *windows in L and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in W;*

3. *boundedness exposure, requiring every lower-bound or upper-bound read to be displayed in U and compared through the dyadic ledger D;*

4. *dyadic exactness, requiring every tolerance, shrink, and comparison step used by an inspected entry to be recorded in D;*

5. *regular readback discipline, requiring R to be the only route from the displayed stream and dyadic rows into regular rational observations;*

6. *real-seal nonescape, requiring E to remain downstream of I, L, U, D, W, R and to export no host supremum, compactness theorem, selected subsequence, or ambient completeness witness;*

7. *transport, continuation, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise.*

No located-bounded-real-sequence obligation is stored outside these rows.

Proof. Project the accepted packet $S = (I, L, U, D, W, R, E, H, C, P, N)$. The carrier exposes the inspected indices, located-real entry windows, boundedness windows, dyadic comparison ledger, stream observations, regular readbacks, and terminal real seal as the whole analytic surface.

An entry read starts with I, L, W. The row I fixes the finite positions under inspection, L supplies the located-real windows for those positions, and W names the stream windows through which the observations are read.

The boundedness read then passes through U and D. The row U supplies the displayed lower and upper real-boundary windows, while D supplies the dyadic radii, shrink steps, and comparison cells used to relate the inspected entries to those bounds.

The readback and seal rows are downstream. The row R is the only regular rational handoff from the displayed stream and dyadic data, and the row E is exposed only after the index, located-entry, boundedness, dyadic, stream, and readback rows have been retained.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since compactness, selected subsequences, host suprema, countable choice, and $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate or replay edge, the listed rows exhaust the local NameCert surface. □

Theorem 2183.3 (Located bounded real sequence Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read of an accepted* $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ *carrier factors through the finite route*

$$I, L, U \longmapsto D, W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives inspected sequence indices, located real entry windows, displayed lower and upper real-boundary windows, $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison rows, finite* $\mathsf{StreamName}^{\uparrow}$ *observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. It receives no Heine–Borel compactness, sequential compactness, host supremum, countable-choice schedule, selected subsequence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a real-facing or regular-rational consumer read of the accepted packet. The carrier contains no global sequence object outside the displayed finite rows, so the read first enters through the inspected-index row I and the located-entry row L.

The bounded sequence boundary is then finite. The row U records the displayed lower and upper real-boundary windows, and D records the dyadic comparisons that bind the inspected entries to those windows. The row W names the exact stream observations used by both the entry reads and the bound reads.

The public handoff is R followed by E. The $\mathsf{RegSeqRat}^{\uparrow}$ row translates the displayed stream and dyadic rows into regular rational observations, and the $\mathsf{Real}^{\uparrow}$ seal exposes only the real-name boundary reached through that readback.

The structural rows preserve the same dependency order. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row can preserve or source the route, but they cannot introduce compactness, selected subsequences, host suprema, countable choice, or completeness data absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2183.1, Definition 2183.2, and Definition 2183.3 seed the finite located bounded real sequence packet over $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedBoundedRealSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Heine–Borel compactness, sequential compactness, host suprema, countable choice, selected subsequences, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked located-entry exposure, boundedness exposure, dyadic exactness, regular readback discipline, real-seal nonescape, componentwise transport, continuation replay, provenance, and local naming for BEDC.Derived.LocatedBoundedRealSequenceUp.

Constructive story: A LocatedBoundedRealSequence$^{\uparrow}$ packet is generated from inspected sequence indices, LocatedReal$^{\uparrow}$ entry windows, displayed lower and upper Real$^{\uparrow}$ bound windows, DyadicRatCore$^{\uparrow}$ comparison rows, finite StreamName$^{\uparrow}$ observation windows, RegSeqRat$^{\uparrow}$ readbacks, a terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2184

A Concrete Naming Certificate for $\mathsf{VitaliCover}^{\uparrow}$

Following Vitali and Bishop–Bridges constructive analysis, the $\mathsf{VitaliCover}^{\uparrow}$ packet records the finite ledger by which a displayed interval family offers disjoint candidates for later measure-facing arguments. It sits after the dyadic interval surface of chapter 306, the finite epsilon-net route of chapter 1767, the measure interface of chapter 92, and the real-name seal of chapter 38. The packet names finite interval selection data only; it does not assert the full Vitali covering theorem, measure completion, countable selection, open-cover compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2184.1 (VitaliCover carrier)**.** *A* $\mathsf{VitaliCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, D, E, F, M, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite interval-family row. Each listed candidate is read through the* $\mathsf{DyadicInterval}^{\uparrow}$ *interface and carries its displayed endpoints and radius ledger.*
2. *D is the disjointness ledger. It records the finite pairwise separation checks used to certify that selected intervals do not overlap.*
3. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witness row. It records the finite demand points or cells whose local cover requests are visible to the packet.*
4. *F is the finite selection row. It records the chosen subfamily, its ordering, and the dependency of each chosen interval on a displayed request in E.*
5. *M is the* $\mathsf{Measure}^{\uparrow}$ *handoff row. It records only the finite additive ledger exposed to a measure-facing consumer after I, D, E, F have been displayed.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *boundary row. It records endpoint and radius reads through real-name seals rather than host real values.*
7. *H records componentwise* hsame *transport for the interval family, disjointness ledger, epsilon-net row, selection row, measure handoff, real boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$I, D, E, F \longmapsto M, R \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{VitaliCover}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{VitaliCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, E, F, M, R, H, C, P, N$. It has no coordinate for an infinite subcover, a countable selector, completed measure, host open-cover compactness, or quotient equality of real endpoints.

Lean4 ✓ `BEDC.Derived.VitaliCoverUp.VitaliCoverTasteGate single carrier alignment`

Theorem 2184.2 (VitaliCover NameCert obligations)**.** *For every accepted* $\mathsf{VitaliCover}^{\uparrow}$ *carrier*

$$V = (I, D, E, F, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VitaliCover}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval family, disjointness ledger, epsilon-net witnesses, finite selection row, measure handoff, real boundary, transport, replay, provenance, and local naming row;*
2. *interval locality, requiring every candidate interval to be read through the* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint and radius data in I;*
3. *finite request coverage, requiring each selected interval in F to answer a displayed request in the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row E;*
4. *disjointness exactness, requiring the pairwise ledger D to certify all overlaps refused by the selected finite subfamily;*
5. *measure handoff, requiring the* $\mathsf{Measure}^{\uparrow}$ *row M to consume only the selected disjoint finite family and its displayed dyadic endpoint data;*
6. *real-boundary nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row R to expose only endpoint and radius seals already routed through I, D, E, F;*
7. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the rows above.*

No obligation row supplies the full Vitali covering theorem, measure completion, countable selection, open-cover compactness, quotient real equality, or ambient real completeness.

Proof. Project the carrier in Definition 2184.1. The packet exposes only the interval family I, disjointness ledger D, epsilon-net requests E, finite selection row F, measure handoff M, real boundary R, and the structural rows H, C, P, N.

The locality and request-coverage obligations are read before any measure-facing consumer is reached. Candidate intervals enter through $\mathsf{DyadicInterval}^{\uparrow}$, and every selected interval is tied to a displayed finite request in $\mathsf{FiniteEpsilonNet}^{\uparrow}$.

The disjointness ledger is then the only selected-subfamily compatibility row. It records pairwise finite separation checks, so a later consumer may not replace it by a host almost-disjoint family or an infinite extraction principle.

Finally M and R consume the same finite route, while H, C, P, N transport, replay, source, and name it. Since no other coordinate is available, the listed rows exhaust the NameCert surface. □

Theorem 2184.3 (VitaliCover finite selection handoff)**.** *Let*

$$V = (I, D, E, F, M, R, H, C, P, N)$$

be an accepted $\mathsf{VitaliCover}^{\uparrow}$ *carrier. Every measure-facing read of the finite disjoint selection factors through the route*

$$I \longmapsto D \longmapsto E \longmapsto F \longmapsto M, R \longmapsto H, C, P, N.$$

The handoff supplies $\mathsf{Measure}^{\uparrow}$ *with a selected finite disjoint interval ledger and supplies* $\mathsf{Real}^{\uparrow}$ *with the endpoint and radius seals used by that ledger. It does not export the full Vitali covering theorem, measure completion, countable selection, open-cover compactness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a measure-facing read of V. The candidate intervals are first read through I, so their endpoint and radius information remains inside the dyadic interval surface.

The pairwise compatibility check is then D, and the finite request source is E. The selected row F can therefore name only intervals whose requests and disjointness witnesses have already been displayed.

The consumer handoff is downstream of those rows. The $\mathsf{Measure}^{\uparrow}$ row M reads the finite additive ledger for the selected disjoint family, and the $\mathsf{Real}^{\uparrow}$ row R supplies the endpoint and radius seals used by that ledger.

Transport by H, replay by C, provenance by P, and naming by N preserve the same finite route. No excluded infinite or completed covering principle has a carrier coordinate from which it could be exported. □

Theorem 2184.4 (VitaliCover Besicovitch finite-overlap boundary)**.** *Let*

$$V = (I, D, E, F, M, R, H, C, P, N)$$

be an accepted $\mathsf{VitaliCover}^{\uparrow}$ *carrier. Every measure-facing read of its accepted finite selection may be routed through a bounded finite-overlap shadow ledger when the selected intervals are compared against the finite Vitali request rows and the finite epsilon-net request rows of chapter 2166 and chapter 1767.*

The shadow ledger is bounded entirely by the displayed rows $I, D, E, F, M, R, H, C, P, N$*:* I *supplies the finite interval candidates,* D *supplies pairwise disjointness for selected rows,* E *and* F *supply finite request coverage and selected-subfamily membership, and* M *is the only* $\mathsf{Measure}^{\uparrow}$*-facing additive read. The boundary exports no measure completion, countable selection, open-cover compactness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier along Definition 2184.1. The finite interval rows I are the only source of candidate intervals, and the selected rows of F can be read only after their finite request witnesses in E have been displayed.

The bounded-overlap shadow is therefore not an additional covering theorem. It is the finite ledger obtained by comparing the selected rows in F against the finite Vitali and epsilon-net request surfaces named by chapter 2166 and chapter 1767.

Use D as the pairwise disjointness boundary for the selected subfamily. Since every selected interval is checked against that ledger before the measure handoff, a measure-facing consumer can count overlaps only through the finite shadow already exposed by I, D, E, F.

Finally route the additive read through M and the endpoint seals through R, with H, C, P, N transporting, replaying, sourcing, and naming the same rows. By chapter 92, this is a finite measure-facing ledger, not a completion, countable-selection, compactness, quotient-real, or ambient-completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{VitaliCover}^{\uparrow}$ measure-facing read factors through a finite DyadicInterval family, a pairwise disjointness ledger, a FiniteEpsilonNet request row, a finite selection row, a Measure handoff, a Real endpoint boundary, transport, continuation, provenance, and local naming.

Independence witness: dyadicinterval, finite-epsilon-net, measure, real: $\mathsf{VitaliCover}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries interval candidates, finite request coverage, pairwise disjointness, selected-subfamily ordering, measure handoff, real endpoint seals, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{VitaliCover}^{\uparrow}}$.

Constructive story: A $\mathsf{VitaliCover}^{\uparrow}$ packet is generated from a finite DyadicInterval family, pairwise disjointness ledger, FiniteEpsilonNet request row, finite selection row, Measure handoff, Real endpoint boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VitaliCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2184.1, Definition 2184.2, and Definition 2184.3 seed the finite disjoint interval selection ledger for measure-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VitaliCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full Vitali covering theorem, measure completion, countable selection, open-cover compactness, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite request coverage, disjointness exactness, measure handoff, real-boundary nonescape, and provenance exhaustion for BEDC.Derived.VitaliCoverUp.

Chapter 2185

A Concrete Naming Certificate for $\mathsf{FastCauchySequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{FastCauchySequence}^{\uparrow}$ packet records a standard constructive source object for the L10 Real and Completion route. It sits after the dyadic arithmetic ledger of chapter 291, the finite window surface of chapter 126, and the regular rational readback surface of chapter 301. The packet names a fast Cauchy sequence as finite BEDC carrier data; it is not a quotient stream, selected limit, trichotomy principle, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 2185.1 (Fast Cauchy sequence carrier)**.** *A* $\mathsf{FastCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, M, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger. It stores the dyadic terms visible at each requested index, the positive dyadic tolerance rows, and the comparison windows used by the fast Cauchy test.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It specifies which term observations and tolerance requests are visible to downstream consumers.*
3. *M is the explicit fast Cauchy modulus ledger. For every displayed request level k, it records a finite budget row forcing all scheduled later windows to be within the dyadic tolerance named by D at level k.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the same dyadic observations, stream windows, and modulus ledger.*
5. *H stores componentwise* hsame *transport for D, S, M, R, C, P, N.*
6. *C stores displayed* Cont *replay from dyadic observations through stream windows and modulus checks to the regular rational handoff row.*
7. *P is the* Pkg *provenance over* $\mathsf{FastCauchySequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FastCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted fast Cauchy sequence packets only through D, S, M, R, H, C, P, N. It has no coordinate for quotient streams, selected limits, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchySequenceUp.FastCauchySequenceTasteGate single carrier alignment`

Theorem 2185.2 (Fast Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchySequence}^{\uparrow}$ *carrier $F = (D, S, M, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FastCauchySequence}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic observation exposure, finite window exposure, explicit fast Cauchy modulus ledger exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside D, S, M, R, H, C, P, N.*

Lean4 ✓ `BEDC.Derived.FastCauchySequenceUp.FastCauchySequenceCarrier namecert obligations`

Proof. Project the carrier of Definition 2185.1. The analytic rows are exactly the dyadic observation ledger D, finite stream windows S, explicit modulus ledger M, and regular rational handoff R.

The fast Cauchy obligation is the defining use of M. Each displayed request level reads its dyadic tolerance from D, its visible windows from S, and its later-window comparison budget from M.

The handoff obligation is then the projection to R. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the displayed list exhausts the local NameCert surface. □

Theorem 2185.3 (Fast Cauchy sequence RegSeqRat handoff)**.** *For every accepted* $\mathsf{FastCauchySequence}^{\uparrow}$ *carrier $F = (D, S, M, R, H, C, P, N)$, any* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer reaches the readback row R only through*

$$D \longmapsto S \longmapsto M \longmapsto R.$$

Thus the route from fast Cauchy sequence data to regular rational data must display the $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{StreamName}^{\uparrow}$ *windows, and explicit fast Cauchy modulus ledger before the handoff is consumed.*

Proof. Start with a consumer asking for regular rational readback from the packet. The only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate is R, and the carrier places it downstream of D, S, M.

The dyadic row D supplies the observed terms and tolerances, while S selects the finite windows that may be inspected. The modulus ledger M binds those windows to the fast Cauchy comparison budget.

Transport, replay, provenance, and local naming preserve that route without adding an alternate source for readback data. Hence the consumer reaches R only after the displayed dyadic, stream, and modulus rows are present. □

Theorem 2185.4 (Fast Cauchy sequence prefix-window tightening)**.** *For every accepted* $\mathsf{FastCauchySequence}^{\uparrow}$ *carrier $F = (D, S, M, R, H, C, P, N)$ and every displayed request level k, any finite* $\mathsf{StreamName}^{\uparrow}$ *window retained by S for the k-request reads its later-window comparison budget from the same modulus row M and dyadic tolerance row D before the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R is available. Consequently the handoff exposes no selected limit, quotient-stream equality, trichotomy, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier rows from Definition 2185.1. The retained finite window is a row of S, while the tolerance visible at request level k is stored in the dyadic ledger D.

The row M is the displayed fast Cauchy modulus ledger. It is the only carrier coordinate that binds later-window comparisons to the tolerance selected at the same request level, so the k-window cannot draw a separate budget from R or from an external completion surface.

Now compose this projection with the route of Definition 2185.3. Since every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reaches R only after $D \longmapsto S \longmapsto M$ is present, the finite prefix-window tightening is consumed before the handoff and carries no additional limit, quotient, trichotomy, choice, or $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 2185.5 (Fast Cauchy sequence Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FastCauchySequence}^{\uparrow}$ *packet reaches the terminal Real seal only through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row D, the* $\mathsf{StreamName}^{\uparrow}$ *window row S, the explicit modulus ledger M, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R. The handoff exports no selected limit, quotient stream equality, countable-choice selector, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier in Definition 2185.1. The only Real-facing route available to the packet begins with D, S, M and then reaches the regular readback row R.

Apply the RegSeqRat handoff theorem Definition 2185.3. It places every read of R downstream of the dyadic observations, stream windows, and explicit modulus ledger.

Use the prefix-window tightening theorem Definition 2185.4. It rules out any separate selected limit, quotient stream equality, countable-choice selector, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness row before the handoff is consumed. The terminal seal therefore carries only the displayed finite route through D, S, M, R. □

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchySequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FastCauchySequence}^{\uparrow}$ packet is generated from DyadicRatCore observations, StreamName windows, an explicit fast Cauchy modulus ledger, RegSeqRat handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2185.1, Definition 2185.2, Definition 2185.3, Definition 2185.4, and Definition 2185.5 seed the finite fast Cauchy sequence source object for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, trichotomy, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic observation exposure, finite window exposure, explicit modulus-ledger exposure, RegSeqRat handoff, transport, replay, provenance, and local naming for BEDC.Derived.FastCauchySequenceUp.

Chapter 2186

A Concrete Naming Certificate for NormalFamily$^{\uparrow}$

Following Montel and Arzela–Ascoli, the NormalFamily$^{\uparrow}$ packet names the finite compact-continuity surface used to read a normal family of maps from a compact metric source into a complete metric target. It consumes the ArzelaAscoli$^{\uparrow}$ handoff of chapter 412, the compact source rows of chapter 129, the complete target rows of chapter 128, the continuous-map family rows of chapter 130, and the pointwise image rows of TotallyBounded$^{\uparrow}$ as finite carrier data.

The chapter records the normal-family object as a naming certificate surface, not as an ambient compact-open topology, a selected convergent subsequence, or a choice principle. Every consumer read must pass through the displayed family ledger, compact source net, complete target ledger, equicontinuity rows, pointwise total-bounded image rows, finite ProbeBundle net data, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Definition 2186.1 (Normal-family carrier)**.** *A* NormalFamily$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (F, X, Y, M, E, I, Q, H, C, P, L)$$

with the following visible coordinates:

1. *F is the finite family ledger whose entries are* ContinuousMap$^{\uparrow}$ *rows from the source row X to the target row Y;*
2. *X is the compact source row, read through* CompactMetric$^{\uparrow}$ *and its finite* ProbeBundle *net surface;*
3. *Y is the complete target row, read through* CompleteMetric$^{\uparrow}$ *and its displayed limit-witness ledgers;*
4. *M is the compact-continuity handoff row supplied by* ArzelaAscoli$^{\uparrow}$ *for the same source, target, and family ledger;*
5. *E records equicontinuity rows binding target tolerances to finite source-radius rows uniformly over F;*
6. *I records pointwise* TotallyBounded$^{\uparrow}$ *image rows for the displayed target values over the bundled source probes;*
7. *Q records the finite* ProbeBundle *net data used by the compact source and by the Arzela–Ascoli handoff;*

8. *H records componentwise* hsame *transport for the family ledger, compact source, complete target, equicontinuity rows, pointwise image rows, probe rows, and handoff row;*
9. *C records the displayed* Cont *replay routes for compact-metric, complete-metric, continuous-map, total-bounded, and Arzela–Ascoli consumers;*
10. *P is the* Pkg *provenance over* $\mathsf{NormalFamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, ProbeBundle, hsame, *and* Cont *rows;*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{NormalFamily}^{\uparrow}}$ *row.*

The packet contains no host function-space carrier, open-cover compactness row, selected subsequence, ambient holomorphic-function principle, or choice-selected cluster point.

Lean4 (definition) `BEDC.Derived.NormalFamilyUp.TasteGate.NormalFamilyUp`
Lean4 ✓ `BEDC.Derived.NormalFamilyUp.TasteGate.NormalFamilyTasteGate single carrier alignment`

Theorem 2186.2 (Normal-family NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{NormalFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for the packet of Definition 2186.1; classifier transport of the family ledger, compact source, complete target, Arzela–Ascoli handoff, equicontinuity rows, pointwise total-bounded image rows, finite probe rows, and displayed provenance; and non-escape through the recorded* hsame, Cont, Pkg, *and local* NameCert *rows.*

Proof. Carrier admission is the displayed tuple $N = (F, X, Y, M, E, I, Q, H, C, P, L)$. Each analytic coordinate is visible before the local certificate may be read: the family ledger F, compact source X, complete target Y, Arzela–Ascoli handoff M, equicontinuity rows E, pointwise image rows I, and probe rows Q.

Classifier transport is componentwise. The $\mathsf{ContinuousMap}^{\uparrow}$ rows transport the family graph data, the $\mathsf{CompactMetric}^{\uparrow}$ row transports source finite-net data, the $\mathsf{CompleteMetric}^{\uparrow}$ row transports target limit ledgers, and the $\mathsf{TotallyBounded}^{\uparrow}$ rows transport pointwise image bundles.

The remaining rows H, C, P, L preserve the same coordinates under hsame transport, replay them through displayed Cont routes, record their Pkg provenance, and name the packet locally. Since no omitted coordinate names a host function space, open-cover compactness, selected subsequence, or choice-selected cluster point, the certificate exports only the displayed normal-family surface. □

Theorem 2186.3 (Normal-family Arzela-Ascoli handoff)**.** *Every compact-continuity consumer reading an accepted* $\mathsf{NormalFamily}^{\uparrow}$ *packet factors through the* $\mathsf{ArzelaAscoli}^{\uparrow}$ *row M, the compact source row X, the complete target row Y, the continuous-map family ledger F, the equicontinuity rows E, the pointwise* $\mathsf{TotallyBounded}^{\uparrow}$ *image rows I, the finite* ProbeBundle *data Q, and the displayed* hsame, Cont, Pkg, *and* NameCert *provenance.*

Consequently the handoff supplies the finite data needed for the constructive normal-family reading and supplies no ambient compact-open topology, open-cover compactness principle, selected subsequence, or host choice principle.

Proof. Project the Arzela–Ascoli coordinate M. Its role is only to consume the same compact source, complete target, family ledger, equicontinuity rows, pointwise image rows, and finite probe rows already displayed in the $\mathsf{NormalFamily}^{\uparrow}$ carrier.

Next read X, Y, F, E, I, Q. These rows provide the compact source net, the complete target ledger, the continuous-map family entries, the uniform equicontinuity witnesses, the pointwise total-bounded image bundles, and the probe data that the handoff needs.

Finally attach H, C, P, L. They ensure that every downstream read uses the transported and replayed carrier rows rather than an ambient function-space object. The absence of any further coordinate rules out open-cover compactness, selected subsequences, and host choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{NormalFamily}^{\uparrow}$ packet is generated from a finite family ledger, compact source row, complete target row, Arzela-Ascoli handoff row, equicontinuity rows, pointwise total-bounded image rows, finite ProbeBundle net data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2186.1, Definition 2186.2, and Definition 2186.3 seed the finite normal-family certificate over ArzelaAscoliUp, CompactMetricUp, CompleteMetricUp, ContinuousMapUp, TotallyBoundedUp, ProbeBundle, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ambient compact-open topology, open-cover compactness, selected subsequences, holomorphic compactness, or host choice.

Upgrade path: Obligation closure requires checked carrier projection, classifier transport, Arzela-Ascoli handoff confinement, provenance replay, and local naming for the $\mathsf{NormalFamily}^{\uparrow}$ packet.

Chapter 2187

A Concrete Naming Certificate for $\mathsf{MetricCoveringNumber}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{MetricCoveringNumber}^{\uparrow}$ packet records the quantitative finite-net count attached to a displayed metric tolerance. It sits between the metric source of chapter 57, the finite epsilon-net route of chapter 1767, the total-bounded surface of chapter 127, the compact-metric consumer of chapter 129, and the dyadic tolerance core of chapter 291. The packet names the covering-number boundary as finite BEDC data, not as a host finite set, a minimal-cardinality proof, or an open-cover compactness argument.

Definition 2187.1 (Metric covering-number carrier)**.** *A* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, \varepsilon, P, C, D, B, H, R, S, N)$$

with the following visible rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the point classifier, distance classifier, and metric-law ledger read by the packet.*
2. *ε is the positive tolerance row, read through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *together with the displayed positivity evidence used by coverage consumers.*
3. *P is the closed* $\mathsf{ProbeBundle}$ *of centers admitted for the selected tolerance.*
4. *C is the center-carrier ledger, recording for every accepted center of P the corresponding point-classifier admission in X.*
5. *D is the distance and coverage ledger pairing each inspected source-point history with an admitted center and a metric-distance row bounded by ε.*
6. *B is the unary budget row naming the number of center entries exposed by P and replayed by the coverage ledger.*
7. *H records componentwise* hsame *transport for the metric source, tolerance row, center bundle, center-carrier ledger, coverage ledger, budget row, replay row, provenance row, and local naming row.*
8. *R records displayed* Cont *replay from a covering-number request through $X, \varepsilon, P, C, D, B, H, S, N$.*
9. *S is the* Pkg *provenance over* $\mathsf{MetricCoveringNumber}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCoveringNumber}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, \varepsilon, P, C, D, B, H, R, S, N$. It has no coordinate for an ambient finite subset, host enumeration, least-cardinality selector, open-cover refinement, sequential compactness proof, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCoveringNumberUp.MetricCoveringNumberTasteGate single carrier alignment`

Theorem 2187.2 (Metric covering-number NameCert obligations)**.** *For every accepted* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *carrier $K = (X, \varepsilon, P, C, D, B, H, R, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCoveringNumber}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, positive tolerance, center bundle, center-carrier ledger, coverage-distance ledger, unary budget, transport, replay, provenance, and local naming rows;*
2. *center visibility, requiring each center counted by B and used by D to enter through the same displayed* $\mathsf{ProbeBundle}$ *row P and center-carrier ledger C;*
3. *coverage exactness, requiring every inspected point of X to be paired by D with a displayed distance row bounded by ε;*
4. *budget exactness, requiring the exported covering number to count exactly the visible center entries of P used by the coverage ledger;*
5. *tolerance transport, requiring the* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row to remain fixed under H before any consumer reads the count;*
6. *ledger nonescape, excluding ambient finite subsets, host enumerations, least-cardinality selectors, open-cover compactness, sequential compactness, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No metric covering-number obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 2187.1. The analytic rows are exactly the metric source X, positive tolerance ε, center bundle P, center-carrier ledger C, coverage-distance ledger D, and unary budget row B.

Center visibility and coverage exactness are rowwise. A center can be counted only after it is visible in P and admitted by C as a point of X, and a source point is covered only through one of the distance rows displayed by D.

The budget row then names the quantitative boundary. Because B counts the same visible entries that P, C, D use, a consumer cannot replace the packet by a smaller host set, an external enumeration, or a minimal-cardinality argument.

The transport and replay rows preserve the same route. The row H moves no coordinate beyond $X, \varepsilon, P, C, D, B, R, S, N$, and R replays covering-number requests through the same ordered data. The refusal clauses follow from absence of coordinates for open covers, selected compactness proofs, countable choice, sequential compactness, and ambient completeness. □

Theorem 2187.3 (Metric covering-number finite-net handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer reading an accepted* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *carrier factors through the finite route*

$$X, \varepsilon \longmapsto P, C, D, B \longmapsto H, R, S, N.$$

Consequently the consumer receives the finite center bundle, positive tolerance row, coverage witnesses, and unary covering budget before any total-bounded or compact-metric conclusion is available. The handoff exports no ambient finite subset, host enumeration, least-cardinality selector,

open-cover compactness proof, sequential compactness proof, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a total-bounded or compact-metric consumer of K. By Definition 2187.1, the consumer can enter the packet only through the displayed metric source X and the displayed tolerance row ε.

The finite-net data are opened next. The closed bundle P names the centers, C admits those centers as points of X, and D supplies the coverage-distance rows. The budget row B then records the quantitative count of exactly those center entries.

Finally H, R, S, N package the same route under classifier transport, continuation replay, provenance, and local naming. Applying Definition 2187.2, the consumer cannot bypass the finite-net route through a host finite subset, an open-cover compactness proof, or a choice-selected enumeration. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCoveringNumber}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCoveringNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2187.1, Definition 2187.2, and Definition 2187.3 seed the quantitative finite-net packet over displayed metric sources, positive rational or dyadic tolerances, center bundles, coverage ledgers, unary budgets, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCoveringNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close minimal covering numbers, total boundedness, compact metric completeness, open-cover compactness, sequential compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, center visibility, coverage exactness, budget exactness, tolerance transport, ledger nonescape, and finite-net consumer handoff for BEDC.Derived.MetricCoveringNumberUp.

Constructive story: A $\mathsf{MetricCoveringNumber}^{\uparrow}$ packet is generated from a MetricUp source row, a positive RatUp or DyadicRatCoreUp tolerance, a closed ProbeBundle of centers, a center-carrier ledger, distance and coverage rows, a unary center budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2188

A Concrete Naming Certificate for $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$ packet names the complete finite-net route by which compact metric data and continuous-map pointwise moduli yield a uniform-modulus ledger. It consumes the compact metric source of chapter 129, the continuous-map rows of chapter 130, the metric triangle surface of chapter 57, the finite rational lower-bound fold of chapter 619, the uniform-modulus consumer row of chapter 369, and the rational tolerance source of chapter 37. The scheme records the Heine–Cantor proof as one BEDC packet, with no appeal to open-cover compactness, a host modulus selector, or choice.

Definition 2188.1 (Compact uniform-continuity scheme carrier)**.** *A* $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, F, E, P, M, Q, T, G, H, R, S, N)$$

with the following visible rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite* $\mathsf{ProbeBundle}$ *net surface used at the requested tolerance.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose triangle ledger reads the final estimate.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row from X to Y.*
4. *E is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row, including the rational subdivision data used for the source and target triangle estimates.*
5. *P is the finite center bundle supplied by the compact metric row.*
6. *M is the pointwise-modulus ledger at the centers of P.*
7. *Q is the subordinate-radius ledger binding each center radius to the pointwise-modulus precision at that center.*
8. *T is the* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *lower-bound fold over the finite radius ledger.*
9. *G is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row produced from E, T, M, Q and the metric triangle ledgers of X and Y.*
10. *H records componentwise* hsame *transport for the compact source, target metric, continuous map, tolerance row, center bundle, pointwise rows, subordinate radii, finite fold, uniform-modulus handoff, replay, provenance, and local naming.*

11. *R records displayed* Cont *replay from a uniform-modulus request through* $X, Y, F, E, P, M, Q, T, G, H, S, N$.
12. *S is the* Pkg *provenance over* $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityScheme}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, Y, F, E, P, M, Q, T, G, H, R, S, N$. It contains no open-cover compactness coordinate, selected Lebesgue-number proof, host modulus function, countable-choice schedule, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuitySchemeUp.CompactUniformContinuitySchemeTasteGate`
`single carrier alignment`

Theorem 2188.2 (Compact uniform-continuity scheme NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$ *carrier* $U = (X, Y, F, E, P, M, Q, T, G, H, R, S, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityScheme}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed compact source, target metric, continuous-map ledger, positive rational tolerance, finite center bundle, pointwise-modulus rows, subordinate-radius ledger, finite lower-bound fold, uniform-modulus handoff, transport, replay, provenance, and local naming rows;*
2. *source lock, requiring the compact metric row X and continuous-map source row in F to expose the same metric carrier before any center or modulus row is read;*
3. *finite-net extraction, requiring the centers in P and coverage rows in X to be the only compactness data consumed by the scheme;*
4. *pointwise-modulus binding, requiring each row of M and Q to attach to a displayed center of P and to the same rational tolerance row E;*
5. *rational-fold exactness, requiring T to be the finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the displayed subordinate radii rather than an external minimum selector;*
6. *uniform-modulus handoff, requiring G to be obtained from the finite fold, pointwise rows, and source and target metric triangle ledgers;*
7. *ledger nonescape, excluding open-cover compactness, selected Lebesgue numbers, host modulus functions, choice, sequential compactness, and ambient completeness as local certificate data.*

No compact uniform-continuity scheme obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 2188.1. The analytic rows are the compact source X, target metric Y, continuous-map ledger F, rational tolerance E, center bundle P, pointwise rows M, subordinate radii Q, rational fold T, and uniform-modulus handoff G.

The source lock is forced before any compact-continuity read. The compact metric row and the continuous-map source row are the same displayed metric carrier, so the center rows and pointwise-modulus rows cannot be read over different sources.

The finite-net and pointwise-modulus obligations are rowwise. The bundle P supplies the centers, M supplies the local modulus rows at those centers, and Q attaches each subordinate radius to the corresponding local precision.

The lower-bound fold T is the quantitative step. Since it is carried by $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ over the displayed $\mathsf{Rat}^{\uparrow}$ radii, the scheme exports a classifier-stable precision history rather than a host-selected minimum.

Finally G reads the source and target triangle ledgers through X and Y and packages the result as a $\mathsf{UniformModulus}^{\uparrow}$ row. The structural rows H, R, S, N replay only the displayed route, so open-cover compactness, selected Lebesgue numbers, host modulus functions, choice, and ambient completeness have no coordinate from which to enter the local certificate. □

Theorem 2188.3 (Compact uniform-continuity scheme handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer reading an accepted* $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$ *carrier factors through the finite route*

$$X, F, E \longmapsto P, M, Q, T \longmapsto G, H, R, S, N.$$

Thus the consumer receives compact finite-net data, continuous-map pointwise-modulus rows, rational subordinate-radius rows, the finite lower-bound fold, and the metric-triangle estimate before the uniform-modulus row is public. The handoff exports no open-cover compactness, selected Lebesgue number, host modulus selector, countable-choice schedule, sequential compactness argument, or ambient completeness theorem.

Proof. Begin with a uniform-modulus consumer of U. By Definition 2188.1, the consumer first reads the compact source X, the continuous-map row F, and the rational tolerance E.

The finite compactness and continuity data are opened next. The center bundle P comes from the compact metric row, the pointwise rows M come from the continuous-map ledger at those centers, and the subordinate-radius ledger Q binds the two surfaces to the same tolerance request.

The lower-bound fold T then computes the tolerance-only precision history over the displayed finite rational radius ledger. The handoff row G applies the metric triangle rows in the source and target metrics and records the result as a $\mathsf{UniformModulus}^{\uparrow}$ row.

The transport, replay, provenance, and local naming rows expose exactly this finite route. Applying Definition 2188.2, the consumer cannot replace it by an open-cover proof, a selected Lebesgue number, an external modulus function, countable choice, sequential compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityScheme}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityScheme}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2188.1, Definition 2188.2, and Definition 2188.3 seed the compact-uniform-continuity proof scheme over compact metric finite nets, continuous-map pointwise moduli, rational subordinate radii, finite lower-bound folds, metric triangle ledgers, uniform-modulus handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityScheme}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, host modulus functions, sequential compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source lock, finite-net extraction, pointwise-modulus binding, rational-fold exactness, uniform-modulus handoff, and ledger nonescape for BEDC.Derived.CompactUniformContinuitySchem

Constructive story: A $\mathsf{CompactUniformContinuityScheme}^{\uparrow}$ packet is generated from CompactMetricUp source finite-net rows, a target MetricUp row, ContinuousMapUp pointwise-modulus rows, a positive RatUp tolerance, subordinate center radii, a FiniteNetMinimumFoldUp lower-bound fold, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2189

A Concrete Naming Certificate for $\mathsf{BanachAlgebra}^{\uparrow}$

Following Bourbaki and Gelfand–Naimark, the $\mathsf{BanachAlgebra}^{\uparrow}$ packet records the classical complete normed algebra interface as finite BEDC NameCert data. It sits between the Banach carrier of chapter 90, the multiplication surface of chapter 43, the norm rows of chapter 89, the completion witnesses of chapter 128 and chapter 95, and the C*-algebra consumer of chapter 211. The packet names a complete normed algebra row before involution, spectrum, representation, or C^*-identity data are available.

Definition 2189.1 (Banach algebra carrier)**.** *A* $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, N, B, Q, M, H, C, P, L)$$

with the following displayed rows:

1. *R is the* $\mathsf{Ring}^{\uparrow}$ *multiplication row, including product, additive carrier compatibility, distributivity, associativity, and unit data when the source algebra displays a unit.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *norm row over the same carried additive carrier, including non-negativity, zero exactness, homogeneity, triangle, and classifier transport for norm values.*
3. *B is the* $\mathsf{Banach}^{\uparrow}$ *complete normed carrier row. It supplies the vector-additive carrier, scalar action, norm-induced metric, and regular Cauchy limit surface used by the algebra packet.*
4. *Q is the product-norm control row. For carried endpoints x, y, it records the finite ledger comparing the norm of the displayed product with the product of the displayed norms:*

$$\nu(x \cdot y) \leq \nu(x)\nu(y).$$

5. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *completion seal. It states that completion-facing reads of the norm-induced metric land back in the same algebra carrier and may inspect multiplication only through the displayed product row R and product-control row Q.*
6. *H records componentwise* hsame *transport for the RingUp multiplication row, NormUp norm row, BanachUp complete carrier row, completion seal, product-control ledger, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$\mathsf{Ring}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{Banach}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{BanachAlgebra}^{\uparrow}.$$

8. *P is the* Pkg *provenance over* $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through $R, N, B, Q, M, H, C, P, L$ and has no coordinate for involution, spectrum, Gelfand transform, weak-operator closure, Hilbert-space representation, host algebra equality, quotient completion, selected limits, or countable choice.

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraTasteGate single carrier alignment`

Theorem 2189.2 (Banach algebra complete product carrier)**.** *For an accepted* $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier $A = (R, N, B, Q, M, H, C, P, L)$, every algebra product consumer first reads the displayed* BHist *rows for* $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, *and multiplication before it may inspect a Cauchy product. The complete product carrier is therefore the* Pkg*-named surface transported by* hsame, *replayed by* Cont, *and locally sealed by* $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$*; a* $\mathsf{CStarAlg}^{\uparrow}$ *consumer sees only that complete normed product boundary before adding involution data.*

Proof. Project the accepted packet onto $R, N, B, Q, M, H, C, P, L$. The multiplication row is R, the norm row is N, the complete Banach carrier row is B, and the complete-metric seal is M.

A Cauchy product read must pass through these rows in this order. The product is not available from $\mathsf{CompleteMetric}^{\uparrow}$ alone, and the Cauchy limit service is not available from $\mathsf{Ring}^{\uparrow}$ alone; the Banach algebra carrier exposes their joint surface.

The rows H, C, P, L then transport, replay, source, and name the same surface. Thus the $\mathsf{CStarAlg}^{\uparrow}$ endpoint receives a complete normed product carrier, not an involutive or spectral object supplied by the root packet. □

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraCompleteProductCarrier`

Theorem 2189.3 (Banach algebra norm submultiplicativity ledger)**.** *For an accepted* $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier $A = (R, N, B, Q, M, H, C, P, L)$, submultiplicative norm control is the displayed* BHist *ledger row Q over the* $\mathsf{Ring}^{\uparrow}$ *multiplication route and the* $\mathsf{Norm}^{\uparrow}$ *route. It is not a host inequality oracle: any read of $\nu(x \cdot y) \leq \nu(x)\nu(y)$ must cite the product row R, the norm row N, the ledger row Q, the* hsame *transport row H, the* Cont *replay row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$ *row L.*

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraNormSubmultiplicativityLedger`

Proof. The comparison row Q is part of the accepted packet, so norm control is projected rather than inferred from an ambient ordered field oracle. It displays the product named by R and the norm values named by N.

Transport through H keeps the product endpoint and norm endpoints aligned over the same Banach carrier B. Replay through C preserves the route from $\mathsf{Ring}^{\uparrow}$ and $\mathsf{Norm}^{\uparrow}$ into $\mathsf{BanachAlgebra}^{\uparrow}$ before the comparison is exported.

The provenance row P and local naming row L seal that ledger as BEDC data. A $\mathsf{CStarAlg}^{\uparrow}$ consumer may reuse the ledger, but it must add its own involution and C^*-identity rows outside this theorem. □

Theorem 2189.4 (Banach algebra Cauchy product stability)**.** *Let $A = (R, N, B, Q, M, H, C, P, L)$ be an accepted* $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier. Cauchy input rows transported by* hsame *through H and replayed by* Cont *through C remain inside the complete product carrier named by B, M, Q, P, L. In*

particular, a completion-facing product read cannot leave the $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, *and* $\mathsf{Norm}^{\uparrow}$ *sibling rows before the local* $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$ *exports data to a* $\mathsf{CStarAlg}^{\uparrow}$ *consumer.*

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraCauchyProductStability`

Proof. Start with Cauchy input rows read through the norm-induced metric of B and the completion seal M. The carrier requires these rows to return to the same Banach algebra surface before multiplication is replayed.

The product row R and norm row N are then read through the product-control ledger Q. Componentwise hsame transport through H prevents a transported Cauchy row from changing the displayed product or norm route.

Finally, Cont replay through C and provenance through P, L export only the complete product carrier. Hence the read remains inside the $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, and $\mathsf{Norm}^{\uparrow}$ sibling surface until a downstream $\mathsf{CStarAlg}^{\uparrow}$ packet supplies additional rows. □

Theorem 2189.5 (Banach algebra NameCert obligations)**.** *For an accepted* $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier*

$$A = (R, N, B, Q, M, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed* $\mathsf{Ring}^{\uparrow}$ *multiplication row,* $\mathsf{Norm}^{\uparrow}$ *norm row,* $\mathsf{Banach}^{\uparrow}$ *complete normed carrier row, product-control row, completion seal, transport, replay, provenance, and local naming row;*
2. *algebra-norm compatibility, requiring the product row R and norm row N to share the carried additive carrier supplied by the Banach row B;*
3. *submultiplicative product control, requiring each product read to pass through the ledger Q before a norm estimate can be exported;*
4. *completion stability, requiring every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *read to return to the same carried algebra surface before multiplication is replayed;*
5. *classifier transport, requiring H and C to preserve the product, norm, Banach, completion, and product-control coordinates componentwise;*
6. *consumer non-escape, allowing* $\mathsf{CStarAlg}^{\uparrow}$ *to consume the complete normed algebra surface while excluding involution, C^*-identity, spectrum, representation, and host star-algebra data from the root packet.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2189.1. The accepted packet exposes exactly the multiplication, norm, Banach, product-control, completion, transport, replay, provenance, and local naming rows.

Algebra-norm compatibility is forced by the shared carrier. The RingUp multiplication row and NormUp row are read over the same additive carrier already packaged by the BanachUp row, so a product read and a norm read cannot move to different representatives without passing through the same hsame transport.

Submultiplicative control is the row Q. Every product estimate has to name the product from R, the norm values from N, and the comparison endpoint displayed by Q before it can be exported.

Completion stability is the row M. A completion-facing consumer first reads the $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ seal, and the seal returns to the same Banach carrier before multiplication is replayed.

Finally H, C, P, L transport, replay, source, and name only the listed rows. Since the excluded operator-algebra and host-completion principles have no coordinate in the carrier, they cannot appear as local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraNameCertObligations`

Theorem 2189.6 (Banach algebra completion-product nonescape)**.** *Let*

$$A = (R, N, B, Q, M, H, C, P, L)$$

be an accepted $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier. Every completion-facing product read exported by A factors through the finite route*

$$\mathsf{Ring}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{Banach}^{\uparrow} \longmapsto Q \longmapsto \mathsf{CompleteMetric}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{BanachAlgebra}^{\uparrow}.$$

Consequently a $\mathsf{CStarAlg}^{\uparrow}$ *consumer may cite the complete normed algebra surface only as displayed multiplication, norm, completeness, product-control, transport, replay, provenance, and local naming data. The route exports no involution, no C^*-identity, no spectrum, no representation, no weak-operator closure, no quotient completion, and no selected limit.*

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraCompletionProductNonescape`

Proof. Start with an accepted carrier and project its completion and product rows. The product row R and norm row N are already tied to the complete Banach row B by the carrier predicate.

The product-control row Q is the only place where multiplication and norm estimates meet. Thus a product read cannot pass directly from the RingUp row into a completion consumer; it must first expose the norm comparison ledger.

The completion seal M then checks the same norm-induced metric surface through $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$. Because M returns to the displayed Banach carrier, completion does not add a quotient product or a selected representative.

Replay through C and transport through H preserve the route componentwise, while P and L name only that finite surface. A $\mathsf{CStarAlg}^{\uparrow}$ consumer can therefore use the complete normed algebra boundary as a dependency, but its involution and C^*-identity rows must be supplied by the C*-algebra packet itself. □

Theorem 2189.7 (Banach algebra public export surface)**.** *Every complete normed algebra consumer of an accepted* $\mathsf{BanachAlgebra}^{\uparrow}$ *carrier reads only the displayed multiplication row, norm row, Banach completeness row, product-control ledger, completion seal, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$ *row. In carrier notation the public export is the finite surface*

$$A = (R, N, B, Q, M, H, C, P, L).$$

It does not export involution, a C^*-identity, spectrum, representation data, weak-operator closure, quotient completion, selected limits, host algebra equality, or any ambient normed-algebra oracle.

Lean4 ✓ `BEDC.Derived.BanachAlgebraUp.BanachAlgebraPublicExportSurface`

Proof. Project an accepted carrier onto $R, N, B, Q, M, H, C, P, L$. The earlier carrier, product, submultiplicativity, stability, obligation, and nonescape theorems show that every complete product read is already routed through these rows.

A public consumer therefore receives the multiplication from R, the norm from N, completeness from B and M, and product control from Q. The rows H, C, P, L transport, replay, source, and name that same finite surface.

No excluded operator-algebra or host-completion coordinate appears in the carrier predicate. Since there is no row for such data, the public export cannot expose it. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachAlgebra}^{\uparrow}$ packet is generated from a displayed RingUp multiplication row, a NormUp norm row over the same carried additive carrier, a BanachUp complete normed carrier row, a product-control ledger, a CompleteMetricUp and MetricCompletionUp completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 2189.1, Definition 2189.5, Definition 2189.3, Definition 2189.6, and Definition 2189.7 display the finite complete normed algebra public surface over RingUp multiplication, NormUp norm, BanachUp completeness, completion seals, product control, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim involution, the C^*-identity, spectrum, representation theory, weak-operator closure, host algebra equality, quotient completion, selected limits, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, complete product carrier routing, submultiplicativity ledger exposure, Cauchy product stability, NameCert obligation coverage, completion-product nonescape, and public export coverage for BEDC.Derived.BanachAlgebraUp.

Chapter 2190

A Concrete Naming Certificate for $\mathsf{MooreSmithCompletion}^{\uparrow}$

Following Kelley, Moore–Smith, and Bourbaki, the $\mathsf{MooreSmithCompletion}^{\uparrow}$ packet records the directed-net completion route as finite BEDC NameCert data. It sits after the directed-index substrate of chapter 1607, the Cauchy-net surface of chapter 589, and the Moore–Smith convergence boundary of chapter 1521; it is read by the metric completion interface of chapter 1506, the uniform completion boundary of chapter 1473, and the separated comparison row of chapter 1411. Its numerical readback is only the finite regular-rational and real-name route of chapter 301 and chapter 38. The packet names the completion-facing net interface without selecting limits, quotienting nets, assuming ambient completeness, invoking countable choice, or asserting completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2190.1 (Moore–Smith completion carrier)**.** *A* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, C, G, Q, S, R, A, H, K, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index substrate, including the finite comparison windows and common upper-window witnesses used by the net route.*
2. *C is the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row over D, recording the displayed Cauchy windows before any completion-facing read occurs.*
3. *G is the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *convergence row, tying the same directed windows to a visible boundary request.*
4. *Q is the completion boundary row read by* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *consumers.*
5. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance comparison row available when two displayed boundary reads must be compared.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite tolerance readback row attached to the retained net windows.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *terminal seal reached only after D, C, G, Q, S, R have been displayed.*
8. *H records componentwise* hsame *transport for directed indices, Cauchy-net tails, convergence rows, completion-boundary reads, separated comparison rows, readback rows, replay data, provenance, and local naming.*

9. *K records displayed* Cont *replay from directed windows through Cauchy-net evidence, Moore–Smith convergence, completion-boundary reads, separated comparison, regular rational readback, and real-name sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{MooreSmithCompletion}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MooreSmithConvergence}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected limit, a quotient net, a host completion object, ambient completeness, countable choice, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MooreSmithCompletionUp.MooreSmithCompletionTasteGate single carrier alignment`

Definition 2190.2 (Moore–Smith completion classifier)**.** *Two accepted* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *packets are classified as the same displayed completion read exactly when their directed substrates, Cauchy-net tails, Moore–Smith convergence rows, completion-boundary rows, separated comparison rows, regular rational readbacks, and terminal real seals are related componentwise by the displayed* hsame *transports and replayed by the same* Cont, Pkg, *and* NameCert *route. The classifier compares boundary reads through the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance row when such a comparison is requested; it does not compare host completion points, quotient classes of nets, or selected representatives.*

Theorem 2190.3 (Moore–Smith completion NameCert obligations)**.** *For an accepted* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *carrier $M = (D, C, G, Q, S, R, A, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the directed substrate, Cauchy-net tail row, Moore–Smith convergence row, completion boundary row, separated comparison row, finite readback row, real seal, transport, replay, provenance, and local naming row;*

2. *directed-net coverage, requiring every completion-facing request to begin with the displayed* $\mathsf{DirectedSet}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *rows;*

3. *convergence boundary exposure, requiring G and Q to be read before any metric or uniform completion consumer receives the packet;*

4. *separated comparison discipline, requiring all comparison of two displayed boundary reads to pass through S rather than host equality or quotient equality;*

5. *readback discipline, requiring every numerical tolerance request to pass through R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal A is inspected;*

6. *structural transport, requiring H, K, P, N to preserve and name only the displayed route;*

7. *ledger non-escape, excluding selected limits, quotient nets, ambient completeness, countable choice, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2190.1. The accepted packet exposes exactly the directed-index, Cauchy-net, convergence, boundary, separatedness, readback, real-seal, and structural rows.

Directed-net coverage follows from the first two rows. A completion-facing request cannot reach G, Q, S, R, A until the directed substrate D and Cauchy-net evidence C have been displayed.

The convergence and completion boundary obligations are the roles of G and Q. These rows place the Moore–Smith convergence read before the metric or uniform completion consumer receives any boundary data.

Separated comparison and readback discipline are local to S and R. The classifier of Definition 2190.2 uses S for zero-distance comparison, and every numerical read uses R before the terminal $\mathsf{Real}^{\uparrow}$ seal A.

Finally H, K, P, N transport, replay, source, and name only the listed coordinates. Since the excluded completion principles have no carrier coordinate, they cannot appear as local NameCert obligations. □

Theorem 2190.4 (Moore–Smith net filter completion route)**.** *Let $M = (D, C, G, Q, S, R, A, H, K, P, N)$ be an accepted* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *carrier, and let a completion-facing L10 read of M display the same directed tail windows as a* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *bridge. Then every Cauchy-net read exported by M factors through the finite route*

$$\mathsf{DirectedSet}^{\uparrow} \longmapsto \mathsf{CauchyNet}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The completion consumer may inspect a limit boundary only after the directed-index rows D, the retained finite tail windows in C, the Cauchy-filter bridge, the $\mathsf{StreamName}^{\uparrow}$ *window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal A have all been displayed through H, K, P, N. The route exports no quotient equality of nets or filters, selected limit, host completion point, countable-choice schedule, or ambient completeness theorem.*

Proof. Project the accepted carrier. The rows D and C expose the directed index substrate and the Cauchy-net tail evidence before the convergence row G or completion boundary row Q is read.

Now route the displayed tail windows through the Cauchy-filter bridge. The bridge hypothesis says that the same finite windows are served by the Cauchy-filter completion criterion surface, so the read passes from the net tail row into $\mathsf{CauchyFilter}^{\uparrow}$ data without quotienting nets or filters.

The L10 numerical handoff is then forced through finite names. The bridge supplies the $\mathsf{StreamName}^{\uparrow}$ inspection schedule, while the Moore–Smith carrier retains the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R and the terminal $\mathsf{Real}^{\uparrow}$ seal A as downstream coordinates of the same route.

Finally the structural rows H, K, P, N preserve, replay, source, and name only these displayed coordinates. Since no carrier coordinate contains a selected limit, quotient equality, host completion point, choice schedule, or ambient completeness theorem, a completion consumer can read a limit boundary only through the route in the statement. □

Theorem 2190.5 (Moore–Smith completion net boundary)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *packet reads the boundary through the finite route*

$$D \longmapsto C \longmapsto G \longmapsto Q.$$

Thus the completion boundary is exposed only after the displayed $\mathsf{DirectedSet}^{\uparrow}$ *index substrate, the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row, and the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *convergence row have been read. The packet provides no selected Moore–Smith limit, quotient of nets, ambient complete object, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a completion-facing consumer and project the carrier rows. The directed substrate D names the finite index windows and upper-window witnesses, while C records the Cauchy-net tail evidence over those windows.

The convergence row G is the next boundary-facing row. It ties the same directed windows to the Moore–Smith convergence test before any completion boundary is exported.

The row Q is therefore downstream of D, C, G. Any $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{UniformCompletion}^{\uparrow}$ consumer reads the boundary from Q with the same transport, replay, provenance, and local name recorded by H, K, P, N.

No carrier coordinate stores a selected limit, a quotient net, an ambient complete object, a countable-choice schedule, or a $\mathsf{Real}^{\uparrow}$ completeness theorem. The exported boundary is exactly the displayed directed-net route. □

Theorem 2190.6 (Moore–Smith completion nonescape)**.** *For an accepted* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *carrier* $M = (D, C, G, Q, S, R, A, H, K, P, N)$*, every comparison, tolerance read, and terminal real-name read exported by* M *is exhausted by*

$$D, C, G, Q, S, R, A, H, K, P, N.$$

Consequently the packet cannot introduce selected limits, quotient nets, ambient completeness, countable choice, host equality of completion points, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Comparison requests use the classifier of Definition 2190.2. That classifier compares displayed completion reads through componentwise transport and the separated zero-distance row S.

Tolerance requests use R. Since R is downstream of D, C, G, Q, S, each numerical read remains attached to the same directed-net completion route.

Terminal real-name reads use A only after the regular rational readback has been displayed. Thus A is a seal on the same finite route, not an ambient real-completeness principle.

The structural rows H, K, P, N preserve, replay, source, and name only these coordinates. Since no other completion or choice data is present in the carrier, the listed rows exhaust the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithCompletion}^{\uparrow}$ packet is generated from a DirectedSetUp substrate, CauchyNetUp tail evidence, MooreSmithConvergenceUp boundary evidence, MetricCompletionUp and UniformCompletionUp completion reads, SeparatedMetricUp zero-distance comparison, RegSeqRatUp readback, a RealUp seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2190.1, Definition 2190.2, Definition 2190.3, Definition 2190.4, Definition 2190.5, and Definition 2190.6 seed the finite directed-net completion route between Moore–Smith convergence and metric or uniform completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient nets, ambient completeness, countable choice, host equality of completion points, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, directed-net coverage, convergence boundary exposure, separated comparison discipline, finite readback discipline, transport preservation, and nonescape for BEDC.Derived.MooreSmithCompletionUp.

Chapter 2191

A Concrete Naming Certificate for $\mathsf{OpenBall}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{OpenBall}^{\uparrow}$ packet records the open metric neighbourhood around a displayed centre as finite BEDC NameCert data. It sits after the metric source of chapter 57, the real-name and dyadic-radius routes of chapter 38, the located-distance discipline of chapter 1533, and the boundary comparison supplied by chapter 1451. The packet gives topology and continuity consumers a reusable neighbourhood row without importing host set openness, quotient point equality, selected radii, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2191.1 (OpenBall carrier)**.** *An* $\mathsf{OpenBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (M, C, R, X, D, B, H, Q, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier, metric-distance operation, symmetry, triangle, and zero-distance discipline available from the displayed metric certificate.*
2. *C is the centre point row, classified as a point of the carrier named by M.*
3. *R is the positive radius row, read either as a* $\mathsf{Real}^{\uparrow}$ *radius name or as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger sealed into the* $\mathsf{Real}^{\uparrow}$ *order surface.*
4. *X is the point row for the point whose neighbourhood membership is being tested.*
5. *D is the metric-distance witness row for the displayed distance value $d(C, X)$ over the metric source M.*
6. *B is the distance-below-radius ledger, recording the constructive strict comparison*

$$d(C, X) <_{\mathsf{R}} R.$$

7. *H records componentwise* hsame *transport for the metric source, centre, radius, point, distance witness, strict comparison, replay data, provenance, and local name.*
8. *Q records displayed* Cont *replay of distance evaluation, Real or dyadic radius readback, strict comparison, boundary comparison with* $\mathsf{MetricClosedBall}^{\uparrow}$*, and neighbourhood handoff to later topology and continuity consumers.*

9. *P is the* Pkg *provenance over* $\mathsf{OpenBall}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OpenBall}^{\uparrow}}$ *row.*

The classifier accepts exactly the rows $M, C, R, X, D, B, H, Q, P, N$. It compares accepted packets only through the displayed metric classifier, radius readback, strict ordered-real comparison, structural transports, replay route, provenance, and local naming row.

Lean4 ✓ `BEDC.Derived.OpenBallUp.OpenBallTasteGate single carrier alignment`

Theorem 2191.2 (OpenBall NameCert obligations)**.** *For an accepted* $\mathsf{OpenBall}^{\uparrow}$ *carrier*

$$O = (M, C, R, X, D, B, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OpenBall}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure, centre-point admission, positive radius admission through the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *route, point admission, distance-witness readback, strict distance-below-radius comparison, componentwise* hsame *transport, displayed* Cont *replay, provenance, local naming, and ledger non-escape for the displayed rows $M, C, R, X, D, B, H, Q, P, N$.*

Proof. Carrier admission projects the finite packet. The metric source row M supplies the carried point classifier and distance operation, while C and X are admitted only as points over that source.

Radius admission reads R through the displayed real or dyadic route. A dyadic radius is consumed only after its finite ledger is sealed into the ordered $\mathsf{Real}^{\uparrow}$ comparison surface.

The distance and membership obligations are the rows D and B. The row D names the distance value $d(C, X)$, and B records the strict comparison $d(C, X) <_{\mathsf{R}} R$ that makes the point an open-neighbourhood member.

Finally H, Q, P, N transport, replay, source, and name only these rows. Since no other coordinate is present, the packet cannot export host openness, quotient point equality, selected radii, compactness, or ambient real completeness. □

Theorem 2191.3 (OpenBall metric neighbourhood handoff)**.** *Every topology or continuity consumer that reads an* $\mathsf{OpenBall}^{\uparrow}$ *neighbourhood receives the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto (C, R, X) \longmapsto D \longmapsto B \longmapsto \mathsf{NameCert}_{\mathsf{OpenBall}^{\uparrow}}.$$

The handoff factors through the metric source of chapter 57, the located-distance discipline of chapter 1533, and the boundary comparison of chapter 1451; it does not supply a host open set, a generated topology theorem, a compactness argument, a selected limit, or quotient equality of metric points.

Proof. Start with a consumer request for an open metric neighbourhood. The packet first exposes M, so the request is tied to the displayed metric carrier and its point classifier before any distance comparison is read.

The centre, radius, and tested point are then the rows C, R, X. The located metric route supplies the distance witness D, and the strict ledger B turns that witness into the membership comparison.

Boundary comparison with $\mathsf{MetricClosedBall}^{\uparrow}$ is available only as a comparison route in Q. The open packet keeps the strict row as the exported neighbourhood witness; the closed-ball chapter remains the sibling non-strict boundary, not a replacement for the open membership comparison.

Thus topology and continuity consumers receive exactly the finite neighbourhood route named by N and replayed by Q. The carrier contains no coordinate from which host openness, generated topology closure, compactness, selected limits, or quotient point equality can be recovered. □

Theorem 2191.4 (OpenBall real-radius boundary)**.** *For an accepted* $\mathsf{OpenBall}^{\uparrow}$ *packet* $O = (M, C, R, X, D, B, H, Q, P, N)$*, every radius-sensitive read is exhausted by the positive* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row* R*, the distance witness* D*, and the strict comparison ledger* B*. The packet does not assert completeness of* $\mathsf{Real}^{\uparrow}$*, trichotomy of real order, a selected rational approximation schedule, or equality of host real values.*

Proof. Inspect the radius row R. If it is read as a real radius, the packet uses only the displayed ordered-real comparison needed by B; if it is read through the dyadic route, the dyadic ledger is first sealed into the same comparison surface.

The distance witness D supplies the other endpoint of the comparison. The membership row is therefore the strict ledger B, not a separate real-number construction or a host subset predicate.

Transport through H and replay through Q preserve this finite comparison route. Provenance P and local naming N identify the route as an $\mathsf{OpenBall}^{\uparrow}$ certificate, so no real-completeness theorem, trichotomy oracle, selected approximation schedule, or host equality of real values is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{OpenBall}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OpenBall}^{\uparrow}$ packet is generated from a MetricUp source row, a centre point row, a positive RealUp or DyadicRatCoreUp radius row, a point row, a MetricDistanceWitness row, a strict distance-below-radius ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OpenBall}^{\uparrow}}$, seed)

Scope closed: Definition 2191.1, Definition 2191.2, Definition 2191.3, and Definition 2191.4 seed the finite open-neighbourhood route over metric distance and positive real or dyadic radius data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OpenBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host set openness, generated topology closure, compactness, quotient equality for metric points, selected radii, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exposure, positive-radius admission, distance-witness readback, strict comparison transport, neighbourhood handoff, real-radius boundary, and ledger non-escape for BEDC.Derived.OpenBallUp.

Chapter 2192

A Concrete Naming Certificate for $\mathsf{MetricCompletionFunctor}^{\uparrow}$

Following Bourbaki, Kelley, and Bishop-style completion functoriality, the $\mathsf{MetricCompletionFunctor}^{\uparrow}$ packet records the L10 route that transports uniformly continuous metric maps across the displayed completion surface. It specializes the metric-completion carrier of chapter 1506, the functorial transport surface of chapter 426, and the Cauchy-name functor packet of chapter 423. Its cofinal evidence is read through the Cauchy-filter branch of chapter 333 or the Cauchy-net branch of chapter 589; the packet itself adds no quotient completion, selected representative, host completed metric space, or ambient completeness principle.

Definition 2192.1 (MetricCompletionFunctor carrier)**.** *A* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M_0, M_1, G, E, T, H, C, P, N)$$

with the following visible rows:

1. *M_0 is the source* $\mathsf{MetricCompletion}^{\uparrow}$ *row, including the displayed metric source, its Cauchy-filter or Cauchy-net cofinal evidence, finite readback, and separated-limit comparison row.*
2. *M_1 is the target* $\mathsf{MetricCompletion}^{\uparrow}$ *row with the same kind of displayed completion evidence and readback surface.*
3. *G is the metric-map row whose finite modulus and graph ledger send source observations to target observations before completion-facing reads are taken.*
4. *E is the extension row inherited from the* $\mathsf{CompletionFunctor}^{\uparrow}$ *and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *surfaces, routing the displayed map through the two completion rows.*
5. *T is the functoriality ledger comparing identity and composition reads by finite* hsame *transport over M_0, M_1, G, and E.*
6. *H records componentwise* hsame *transport for the two metric-completion rows, the map row, the extension row, the functoriality ledger, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$M_0, G, M_1 \longmapsto E \longmapsto T, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionFunctor}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctor}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, selected limits, host function equality, a host completed metric space, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MetricCompletionFunctorUp.MetricCompletionFunctorTasteGate single carrier alignment`

Theorem 2192.2 (MetricCompletionFunctor NameCert obligations)**.** *For an accepted* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *carrier* $F = (M_0, M_1, G, E, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, source and target metric-completion exactness, map-modulus compatibility, extension-ledger exactness, identity and composition functoriality, classifier transport, and non-escape of quotient completions, selected limits, host function equality, countable choice, and ambient completeness. Every obligation is read from the displayed rows* $M_0, M_1, G, E, T, H, C, P, N$ *and their finite* hsame *and* Cont *routes.*

Proof. Carrier admission is projection from Definition 2192.1. The accepted packet exposes exactly the two metric-completion rows, the displayed map ledger, the extension row, functoriality ledger, transport rows, replay rows, provenance, and local naming row.

The source and target exactness clauses require every completion-facing read to pass through M_0 or M_1 before the extension row is inspected. The map-modulus clause keeps the graph ledger G attached to the finite source observations and target observations already visible in those rows.

Extension exactness is the coordinate E. It is read from the existing completion-functor and Cauchy-completion-functor surfaces, so no second extension route or host function equality is available.

Identity and composition are the public roles of T, transported componentwise by H and replayed through C. The provenance and local naming rows then exhaust the packet, leaving no coordinate for quotient completion equality, selected representatives, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.MetricCompletionFunctorUp.MetricCompletionFunctorCarrier namecert obligations`

Theorem 2192.3 (MetricCompletionFunctor L10 route)**.** *Every L10 completion-route consumer of an accepted* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *packet factors through the finite chain*

$$M_0, G, M_1 \longmapsto E \longmapsto T, H, C, P, N.$$

The route first reads the source $\mathsf{MetricCompletion}^{\uparrow}$ *packet, then the displayed map ledger, then the target* $\mathsf{MetricCompletion}^{\uparrow}$ *packet, and only then the extension and functoriality rows supplied by the completion-functor surfaces. It therefore connects* $\mathsf{MetricCompletion}^{\uparrow}$ *to* $\mathsf{CompletionFunctor}^{\uparrow}$ *and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *by displayed finite data rather than by a quotient completion object or a host-level completed metric functor.*

Proof. Project the carrier of Definition 2192.1. The first completion-facing coordinate is M_0, so the consumer begins with the source metric-completion evidence, including its filter or net branch and finite readback row.

The next analytic coordinate is the map ledger G. Its finite modulus and graph rows move displayed source observations to target observations before any extension read is taken.

The target completion row M_1 supplies the completion-facing landing surface. The extension row E then repacks the displayed map through the completion-functor and Cauchy-completion-functor interfaces, while the functoriality ledger T records identity and composition comparisons as finite transport.

The rows H, C, P, N preserve and name the same route. Since the carrier has no quotient, selected-limit, host-function-equality, or ambient-completeness coordinate, every L10 consumer receives only the displayed finite route. □

Theorem 2192.4 (MetricCompletionFunctor map-modulus compatibility)**.** *For an accepted* MetricCompletionFunc *carrier* $F = (M_0, M_1, G, E, T, H, C, P, N)$*, every consumer read of map-modulus compatibility is forced through the displayed map row* G *of Definition 2192.1. The source observations come from* M_0*, the target observations land in* M_1*, and the modulus row is read before the extension row* E *can be consumed. No consumer may replace this finite row by host uniform continuity or a function-space equality.*

Proof. Read the carrier coordinates. The only row that relates source observations to target observations is G, and it is displayed between the source and target completion rows M_0 and M_1.

The extension row E is downstream of that graph and modulus data. A consumer therefore cannot request an extension read until the finite modulus and graph ledger in G have already been exposed.

Transport and replay are supplied by H and C, with provenance and naming through P and N. Since no host function-space row exists in the carrier, the compatibility claim is exactly the visible finite row. □

Theorem 2192.5 (MetricCompletionFunctor extension-ledger exactness)**.** *For an accepted* MetricCompletionFunct *carrier* $F = (M_0, M_1, G, E, T, H, C, P, N)$*, every extension read is exactly the displayed row* E *named in Definition 2192.1. The row* E *must be read after the source completion row* M_0*, the metric-map row* G*, and the target completion row* M_1*, and it may only export the completion handoff already visible through* $\mathsf{CompletionFunctor}^{\uparrow}$ *and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *rows.*

Proof. Project the route in Definition 2192.3. The extension coordinate is not an independent host map; it is the displayed row encountered after the two completion packets and the map ledger have been read.

Exactness means that a consumer cannot choose another extension witness or compare two extensions by host function equality. The only usable extension data are the entries of E, transported by H and replayed by C.

The provenance row P records the source of the completion-functor handoff, and N names the local certificate. These rows exhaust the extension ledger visible to downstream completion consumers. □

Theorem 2192.6 (MetricCompletionFunctor identity and composition functoriality)**.** *For an accepted* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *carrier* $F = (M_0, M_1, G, E, T, H, C, P, N)$*, every identity or composition read is forced through the functoriality ledger* T *displayed in Definition 2192.1. Identity reads compare the visible completion row with its own displayed map ledger, and composition reads compare two displayed map rows only after their extension rows have been read. The comparison is finite* hsame *transport, not host equality of completed maps.*

Proof. The route theorem places T after the extension row E. Thus identity and composition are not prerequisites for constructing a host functor; they are ledger reads over already displayed completion and extension data.

For identity, T records the finite transport comparing the source completion row with the identity map ledger. For composition, T records the finite transport comparing the two-stage displayed map read with the displayed composite read after their extension rows are available.

The rows H, C, P, N transport, replay, source, and name those comparisons. Because the carrier has no host completed-map equality coordinate, the functoriality surface is exactly the finite ledger T. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionFunctor}^{\uparrow}$ packet is generated from source and target MetricCompletionUp rows, a displayed metric-map ledger, a completion-functor extension row, a functoriality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2192.1, Definition 2192.2, and Definition 2192.3 seed the functorial L10 transport route between metric completion and the existing completion-functor surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host completed metric spaces, host function equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target metric-completion exactness, map-modulus compatibility, extension-ledger exactness, functoriality, classifier transport, and non-escape for BEDC.Derived.MetricCompletionFunctorUp.

Chapter 2193

A Concrete Naming Certificate for $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$

Following Bishop and Bridges, strongly extensional maps on real names are read as graph certificates that preserve apartness and RegSeqRat classifier data. The $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$ packet connects the regular Cauchy real-name surface of chapter 38, the rational readback discipline of chapter 301, the finite observation windows of chapter 126, and the dyadic tolerance ledger of chapter 291. It records only displayed finite graph rows and transport obligations; it is not a host real function, a quotient-function equality, a trichotomy principle, an open-cover compactness object, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 2193.1 (Strongly extensional real-map carrier)**.** *A* $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, G, A, S, R, D, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Real}^{\uparrow}$ *name row, including its regular Cauchy presentation and finite observation boundary.*
2. *Y is the target* $\mathsf{Real}^{\uparrow}$ *name row reached after the displayed graph route is consumed.*
3. *G is the finite graph certificate, pairing inspected source windows with inspected target windows.*
4. *A is the apartness-preservation ledger: every displayed apartness witness between source names is routed to a displayed apartness witness between target names.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened by the graph certificate before any regular rational readback is taken.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier-readback row attached to the source and target windows in S.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the displayed rational approximants and apartness margins.*
8. *H records componentwise* hsame *transport for the two real-name rows, graph row, apartness ledger, stream windows, rational readbacks, dyadic tolerances, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay of the route*

$$X, G, S, R, D \longmapsto Y, A, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{StronglyExtensionalRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, G, A, S, R, D, H, C, P, N$. It has no coordinate for host functions, quotient equality of real names, trichotomy, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.StronglyExtensionalRealMapUp.StronglyExtensionalRealMapTasteGate single carrier alignment`

Theorem 2193.2 (Strongly extensional real-map NameCert obligations)**.** *For every accepted* $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$ *carrier $F = (X, Y, G, A, S, R, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{StronglyExtensionalRealMap}^{\uparrow}}$ *surface consists exactly of carrier exposure, source and target real-name exposure, graph-window exactness, apartness-preservation exposure,* $\mathsf{StreamName}^{\uparrow}$ *window discipline,* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance service, classifier transport, and non-escape of host functions, quotient equality, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every obligation is read from $X, Y, G, A, S, R, D, H, C, P, N$ and their displayed* hsame *and* Cont *routes.*

Proof. Project the carrier of Definition 2193.1. The visible inventory is exactly the two real-name rows, graph row, apartness ledger, stream windows, regular rational readbacks, dyadic tolerance ledger, transport, replay, provenance, and local naming.

Graph-window exactness is forced through G and S: each inspected source window is paired with a displayed target window before any target real-name row is consumed. The apartness-preservation obligation is the row A, and it records only displayed apartness witnesses rather than a global host-function property.

Regular rational classifier data then pass through R, while dyadic tolerance comparisons pass through D. Transport by H and replay by C preserve the same finite route, and P, N source and name it locally. Since no carrier coordinate names a host function, quotient equality, trichotomy, compact cover, or ambient completeness theorem, none can be exported by the local certificate. □

Theorem 2193.3 (Strongly extensional real-map RegSeqRat transport)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$ *carrier factors through the finite chain*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the graph row G, apartness ledger A, and structural rows H, C, P, N. If two displayed source reads are classifier-equal on the same finite regular Cauchy window, then their transported target reads are compared only by the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ *row and dyadic tolerance ledger in the carrier. The theorem does not assert equality of host functions or equality of ambient real-number quotients.*

Proof. Start from the accepted carrier $F = (X, Y, G, A, S, R, D, H, C, P, N)$. A regular-rational consumer first reads the source real-name row X and then the stream windows S selected by the graph certificate G.

The classifier readback is the row R. Any comparison of source reads on the same finite regular Cauchy window must therefore pass through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ classifier data before reaching a target read.

The dyadic tolerance ledger D supplies the numeric comparison margins, while the apartness ledger A records the strongly extensional direction on displayed witnesses. The structural

rows H, C, P, N transport, replay, source, and name the same route, so the transported target comparison remains a finite RegSeqRat-and-dyadic read rather than a host-function equality or quotient-real equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{StronglyExtensionalRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{StronglyExtensionalRealMap}^{\uparrow}$ packet is generated from source and target RealUp name rows, a finite graph certificate, an apartness-preservation ledger, StreamName windows, RegSeqRat classifier readback, a DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StronglyExtensionalRealMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2193.1, Definition 2193.2, and Definition 2193.3 seed the finite graph-certificate route for strongly extensional maps on regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StronglyExtensionalRealMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, host function equality, quotient equality of real names, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph-window exactness, apartness-preservation exposure, StreamName window discipline, RegSeqRat classifier transport, DyadicRatCore tolerance service, and non-escape for BEDC.Derived.StronglyExtensionalRealMapUp.

Chapter 2194

A Concrete Naming Certificate for $\mathsf{EulerTransform}^{\uparrow}$

Following Euler and Hardy on divergent series and Bishop–Bridges constructive analysis, the $\mathsf{EulerTransform}^{\uparrow}$ packet records finite Euler acceleration for alternating real series as a displayed BEDC route. It consumes the source-series surface of chapter 1581, the alternating-sign route of chapter 1483, the Abel and Dirichlet neighboring handoffs of chapter 1496 and chapter 1497, the summable tail budget of chapter 1799, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet supplies a finite acceleration boundary for Real and Completion series consumers; it is not a host infinite sum, selected limit, quotient series equality, classical convergence transfer, ambient completeness theorem, Lean verification, or bridge checking.

Definition 2194.1 (Euler transform carrier)**.** *An* $\mathsf{EulerTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, A, D, T, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RealSeries}^{\uparrow}$ *row, exposing only the inspected real-series windows and partial-sum windows used by the current alternating-tail request.*
2. *A is the alternating-sign row, recording the finite parity and sign windows consumed by the* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *surface.*
3. *D is the finite forward-difference triangle, displaying the finitely many iterated difference rows used by the Euler acceleration step.*
4. *T is the transformed tail-window row, naming the accelerated tail windows obtained from S, A, D.*
5. *B is the summable tail and modulus budget, requiring the transformed windows to be served through* $\mathsf{SummableTailModulus}^{\uparrow}$ *before any endpoint read is available.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff reached only after the transformed tail windows and the summable budget have been displayed.*
7. *H stores componentwise* hsame *transport for the source, alternating, difference, transformed-window, budget, readback, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a tail request through D, T, B, R.*
9. *P is the* Pkg *provenance over* $\mathsf{EulerTransform}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AlternatingSeriesTest}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerTransform}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, A, D, T, B, R, H, C, P, N$. It has no coordinate for host infinite sums, selected limits, quotient series equality, classical convergence transfer, ambient $\mathsf{Real}^\uparrow$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.EulerTransformUp.EulerTransformTasteGate single carrier alignment`

Theorem 2194.2 (Euler transform NameCert obligations)**.** *For every accepted* $\mathsf{EulerTransform}^\uparrow$ *carrier*

$$E = (S, A, D, T, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EulerTransform}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the source* $\mathsf{RealSeries}^\uparrow$ *row, alternating-sign row, finite forward-difference triangle, transformed tail windows, summable tail budget,* $\mathsf{RegSeqRat}^\uparrow$ *handoff, transport, replay, provenance, and local naming row;*
2. *alternating-window exactness, requiring A to supply the only sign and parity data used by the acceleration step;*
3. *difference-triangle stability, requiring each displayed forward-difference row in D to be read from the same finite source windows in S and transported componentwise by H;*
4. *transformed-tail coherence, requiring T to name only windows obtained from the displayed difference triangle and alternating route;*
5. *budget service, requiring B to provide the summable tail and modulus boundary before the regular rational handoff R can be consumed;*
6. *neighboring-test discipline, requiring Abel and Dirichlet rows to appear only as provenance faces for the same tail-window route and not as independent endpoint seals;*
7. *nonescape, requiring H, C, P, N to transport, replay, source, and name exactly this route and no unrecorded analytic principle.*

Proof. Project the carrier of Definition 2194.1. The visible inventory is $S, A, D, T, B, R, H, C, P, N$, so the local certificate has no detached row for a host sum, selected limit, quotient equality, classical convergence transfer, or ambient completeness theorem.

The alternating and difference data are read before any transformed endpoint is available. The row A supplies the finite sign and parity windows, while D displays only the forward-difference triangle computed from the same inspected source windows in S.

The transformed-tail row is then forced through T. It can name only acceleration windows obtained from S, A, D, and the summable tail budget B is the only row that turns those windows into a modulus-bearing endpoint service.

Finally, R, H, C, P, N supply regular readback, transport, replay, provenance, and local naming for the same route. The Abel and Dirichlet faces appear only in the provenance of the shared tail-window discipline, so no independent endpoint seal or stronger convergence principle is exported. □

Theorem 2194.3 (Euler transform alternating acceleration handoff)**.** *Every endpoint-facing read of an accepted* $\mathsf{EulerTransform}^\uparrow$ *carrier factors through the ordered route*

$$\mathsf{RealSeries}^\uparrow \longmapsto \mathsf{AlternatingSeriesTest}^\uparrow \longmapsto \mathsf{SummableTailModulus}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The Abel and Dirichlet rows may be read only as neighboring provenance for the same transformed tail-window route. No endpoint-facing consumer reaches $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *before the finite forward-difference triangle and summable tail budget have been displayed.*

Proof. Start from the accepted carrier $E = (S, A, D, T, B, R, H, C, P, N)$. The only source row is S, and the only alternating information is the sign-window row A.

The acceleration handoff is carried by D and T. The finite difference triangle is read from the displayed source windows, and the transformed tail windows are the only rows passed downstream.

The budget row B supplies the summable tail and modulus service for those transformed windows. Only after that service appears may the route enter R and then the terminal $\mathsf{Real}^{\uparrow}$ read. Since Abel and Dirichlet data occur only inside the provenance row P, they cannot replace the displayed alternating, difference, budget, or regular-rational rows. □

Theorem 2194.4 (Euler transform Real seal nonescape)**.** *For every accepted* $\mathsf{EulerTransform}^{\uparrow}$ *carrier* $E = (S, A, D, T, B, R, H, C, P, N)$*, any consumer that reaches a* $\mathsf{Real}^{\uparrow}$ *endpoint seal without the displayed source-series windows, alternating-sign row, finite forward-difference triangle, transformed tail windows, summable tail budget, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff has left the local* $\mathsf{NameCert}_{\mathsf{EulerTransform}^{\uparrow}}$ *surface.*

Proof. Read the obligation rows in Definition 2194.2. Endpoint-facing data must pass through carrier exposure, alternating-window exactness, difference-triangle stability, transformed-tail coherence, budget service, regular readback, transport, replay, provenance, and naming.

The only Real-facing route named by the carrier is downstream of R. Therefore a consumer that omits any of S, A, D, T, B, R is asking for a row absent from the carrier and absent from the local certificate. The rows H, C, P, N preserve the same route rather than adding host sums, selected limits, quotient equality, classical convergence transfer, ambient completeness, Lean verification, or bridge data. □

Falsifiable prediction: Every accepted $\mathsf{EulerTransform}^{\uparrow}$ endpoint-facing read factors through source RealSeries windows, alternating-sign windows, a finite forward-difference triangle, transformed tail windows, a SummableTailModulus budget, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, alternating-series-test, abel-test, dirichlet-test, summable-tail-modulus, regseqrat, real: $\mathsf{EulerTransform}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, alternating signs, finite forward differences, transformed tail windows, summable tail budgets, regular rational readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EulerTransform}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EulerTransform}^{\uparrow}$ packet is generated from source RealSeries windows, alternating-sign rows, a finite forward-difference triangle, transformed tail windows, a SummableTailModulus budget, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EulerTransform}^{\uparrow}}$, seed)

Scope closed: Definition 2194.1, Definition 2194.2, Definition 2194.3, and Definition 2194.4 seed the finite Euler acceleration boundary over displayed source series, alternating signs, forward differences, transformed tail budgets, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EulerTransform}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.EulerTransformUp.EulerTransformTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient series equality, classical convergence transfer, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier exposure, alternating-window exactness, difference-triangle stability, transformed-tail coherence, summable budget service, regular-rational handoff, Real seal nonescape, and transport, replay, provenance, and local naming discipline for BEDC.Derived.EulerTransformUp.

Chapter 2195

A Concrete Naming Certificate for BishopCompactnessCriterion$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the BishopCompactnessCriterion$^{\uparrow}$ packet records the compactness criterion for metric spaces as a finite-net plus complete-limit BEDC route. It consumes the compact metric surface of chapter 129, the total-bounded finite-net rows of chapter 127, the complete-metric limit-readback rows of chapter 128, and the completion-facing landing surface of chapter 1506. The packet gives L10 compact metric consumers a constructive criterion surface without invoking open-cover compactness, host sequential compactness, countable choice, or an ambient selected completion.

Definition 2195.1 (Bishop compactness criterion carrier)**.** *A* BishopCompactnessCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, F, C, L, Q, H, R, P, N)$$

with the following displayed rows:

1. *M is the* CompactMetric$^{\uparrow}$ *source row, exposing the metric carrier and the public compact-metric certificate surface.*
2. *T is the* TotallyBounded$^{\uparrow}$ *finite-net row, including the requested tolerance, finite* ProbeBundle *centers, membership constructors, coverage distances, and rational comparison ledgers.*
3. *F is the finite-net handoff row reading the centers and coverage witnesses from T as the compactness criterion input rather than as an external subcover.*
4. *C is the* CompleteMetric$^{\uparrow}$ *row for regular Cauchy streams over the same metric carrier.*
5. *L is the limit-readback row supplied by C, including the stream name, modulus, displayed limit history, late-observation thresholds, metric-distance witnesses, and rational comparison ledgers.*
6. *Q is the* MetricCompletion$^{\uparrow}$ *handoff row used by completion-facing consumers of the same finite-net and complete-limit data.*
7. *H records componentwise* hsame *transport for M, T, F, C, L, Q and the local certificate row.*
8. *R records displayed* Cont *replay from a compactness request through finite-net extraction, complete-limit readback, metric-completion handoff, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* BishopCompactnessCriterion$^{\uparrow}$*,* CompactMetric$^{\uparrow}$*,* TotallyBounded$^{\uparrow}$*,* CompleteMetric$^{\uparrow}$*,* MetricCompletion$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactnessCriterion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, T, F, C, L, Q, H, R, P, N$. It has no coordinate for open-cover compactness, a selected subsequence, countable choice, quotient completion equality, host compactness, or an ambient complete metric space.

Lean4 ✓ `BEDC.Derived.BishopCompactnessCriterionUp.BishopCompactnessCriterionTasteGate single carrier alignment`

Theorem 2195.2 (Bishop compactness criterion NameCert obligations)**.** *For every accepted* BishopCompactnessCri *carrier*

$$K = (M, T, F, C, L, Q, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompactnessCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the compact metric source, total-bounded finite-net row, finite-net handoff, complete-metric row, limit-readback row, metric-completion handoff, transport, replay, provenance, and local naming rows;*
2. *compact-source lock, requiring M to be the common metric carrier read by both the* $\mathsf{TotallyBounded}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *faces;*
3. *finite-net exactness, requiring T and F to expose only the finite* ProbeBundle *centers, membership constructors, coverage distances, and rational comparison rows supplied by total boundedness;*
4. *complete-limit readback, requiring C and L to expose regular Cauchy stream, modulus, limit, threshold, distance-witness, and rational-bound rows over the same metric source;*
5. *metric-completion handoff, requiring completion-facing consumers to read Q only after the finite-net and complete-limit rows have been displayed;*
6. *nonescape, requiring H, R, P, N to transport, replay, source, and name exactly this route and no open-cover, choice, quotient, host compactness, or ambient-completion datum.*

Proof. Project the carrier of Definition 2195.1. The visible inventory is $M, T, F, C, L, Q, H, R, P, N$, so every local obligation must be read from those rows.

The compact-source lock is forced first. The finite-net row and the complete-limit row both attach to the metric carrier named by M; otherwise the criterion would compare total boundedness and completeness over different sources.

The finite-net obligations are the rows T and F. They expose the tolerance, centers, membership constructors, coverage distances, and rational ledgers already provided by $\mathsf{TotallyBounded}^{\uparrow}$, and they do not create an open cover or a selected finite subcover.

The complete-limit obligations are the rows C and L. They expose the regular Cauchy name, modulus, displayed limit, threshold histories, metric-distance witnesses, and rational comparison ledgers already provided by $\mathsf{CompleteMetric}^{\uparrow}$.

Finally Q, H, R, P, N provide the completion-facing handoff, transport, replay, provenance, and naming for the same route. Since no other coordinate occurs in the carrier, the excluded open-cover, choice, quotient, host compactness, and ambient-completion principles cannot enter the local certificate. □

Theorem 2195.3 (Bishop compactness criterion net-completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopCompactnessCriterion}^{\uparrow}$ *carrier factors through the ordered route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}.$$

The finite-net side is read through T, F*, the complete-limit side is read through* C, L*, and the terminal completion handoff is* Q*. No consumer reaches* $\mathsf{MetricCompletion}^{\uparrow}$ *from this packet before the finite-net and complete-limit rows have both been displayed over the same compact metric source.*

Proof. Begin with the compact metric source row M. It names the metric carrier that both the total-bounded and complete-metric faces must use.

The finite-net side is read next through T and F. These rows expose the finite ProbeBundle centers and coverage ledgers needed by the constructive compactness criterion.

The complete-limit side is read through C and L. These rows expose the regular Cauchy limit-readback data over the same metric source, including the modulus, displayed limit, late thresholds, and metric-distance witnesses.

Only after those two faces are visible does Q supply the metric-completion handoff. The transport, replay, provenance, and local naming rows preserve this order, so a completion-facing consumer receives no selected representative, quotient completion equality, open-cover compactness, countable-choice schedule, or host complete-space datum. □

Theorem 2195.4 (Bishop compactness criterion compact metric scope)**.** *The* $\mathsf{BishopCompactnessCriterion}^{\uparrow}$ *packet closes exactly the constructive compact-metric criterion surface obtained from a displayed compact metric carrier, total-bounded finite-net data, complete-metric limit-readback data,* hsame *transport,* Cont *replay,* Pkg *provenance, local* NameCert *rows, and the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff. It does not claim open-cover compactness, host sequential compactness, a selected convergent subsequence, countable choice, quotient completion equality, or completeness of an ambient metric space outside the displayed rows.*

Proof. Apply Definition 2195.2. The obligation surface lists the compact source, finite-net face, complete-limit face, completion handoff, and structural support rows as the entire local certificate.

Apply Definition 2195.3. It fixes the only completion-facing route and requires the finite-net and complete-limit rows to be displayed before the $\mathsf{MetricCompletion}^{\uparrow}$ handoff is consumed.

The remaining scope claim is boundary discipline. Open covers, host sequential compactness, selected subsequences, countable choice, quotient completion equality, and ambient complete spaces all require coordinates absent from K. The rows H, R, P, N preserve and name the displayed route rather than adding any of those data, so the compact metric scope is exactly the stated constructive criterion surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactnessCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCompactnessCriterion}^{\uparrow}$ packet is generated from a CompactMetricUp source row, TotallyBoundedUp finite-net data, CompleteMetricUp limit-readback data, a MetricCompletionUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompactnessCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 2195.1, Definition 2195.2, Definition 2195.3, and Definition 2195.4 seed the constructive compactness criterion over compact metric source rows, total-bounded finite nets, complete-metric limit readback, metric-completion handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompactnessCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host sequential compactness, selected subsequences, countable choice, quotient completion equality, ambient complete metric spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source lock, finite-net exactness, complete-limit readback, metric-completion handoff, and nonescape for BEDC.Derived.BishopCompactnessCriterionUp.

Chapter 2196

A Concrete Naming Certificate for $\mathsf{DiniContinuity}^{\uparrow}$

Following Dini's monotone convergence theorem and Bishop–Bridges constructive compactness, the $\mathsf{DiniContinuity}^{\uparrow}$ packet records the finite surface by which a monotone family of continuous maps on a compact metric source yields a uniform tolerance handoff. It consumes the compact source rows of chapter 129, the map-continuity boundary of chapter 130, the uniform-limit target of chapter 463, the pointwise-to-uniform budget discipline of chapter 369, and the rational tolerance ledger of chapter 37. The packet does not choose a host supremum, import classical open-cover compactness, or identify completed real functions outside the displayed NameCert rows.

Definition 2196.1 (Dini continuity carrier)**.** *A* $\mathsf{DiniContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, M, L, R, V, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row. It supplies the carried metric source, compact finite-cover interface, and cover-refinement ledger used by the tolerance request.*
2. *M is the monotone-family row. It records the displayed family indices, pointwise comparison order, and the assertion that later family rows move monotonically toward the limiting row on the carried source.*
3. *L is the pointwise convergence row. It records, for each carried probe, the finite observation route by which the family reaches the limiting value within the requested rational tolerance.*
4. *R is the positive rational tolerance budget, read through chapter 37; it stores the requested tolerance, the finite subdivisions used in the cover argument, and the budget comparisons needed by the handoff.*
5. *V is a finite* $\mathsf{ProbeBundle}$ *cover extracted from the compact source row. Each probe cell carries a local continuity witness, a monotone-family comparison witness, and a rational budget slice.*
6. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row. It records that the finite cover and tolerance budget have been assembled into one uniform read for the limiting map.*
7. *H records componentwise* hsame *transport for compact source data, monotone family data, pointwise convergence rows, rational budgets, cover probes, uniform-limit handoff, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay of the route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{UniformModulus}^{\uparrow}, \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{ProbeBundle} \longmapsto \mathsf{UniformLimit}^{\uparrow} \longmapsto \mathsf{DiniContinuity}$$

9. *P is the* Pkg *provenance over* $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, ProbeBundle, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniContinuity}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $K, M, L, R, V, U, H, C, P, N$ and has no coordinate for host suprema, classical excluded-middle compactness, selected subcovers outside the finite ProbeBundle*, quotient real-function equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.DiniContinuityUp.DiniContinuityTasteGate single carrier alignment`

Theorem 2196.2 (Dini continuity NameCert obligation surface)**.** *For an accepted* $\mathsf{DiniContinuity}^{\uparrow}$ *carrier*

$$D = (K, M, L, R, V, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the compact metric source row, monotone family row, pointwise convergence row, rational tolerance budget, finite probe cover, uniform-limit handoff, transport, replay, provenance, and local naming row;*
2. *monotone-family visibility, requiring every family comparison used by the packet to be read from M before a pointwise convergence row from L can be applied;*
3. *compact finite-cover extraction, requiring the uniform request to be reduced through the* ProbeBundle *cover V supplied by the compact source row K;*
4. *uniform tolerance budgeting, requiring the positive rational request and every cover-cell budget slice to be read through R before the* $\mathsf{UniformModulus}^{\uparrow}$ *and* $\mathsf{UniformLimit}^{\uparrow}$ *handoff U is exported;*
5. *ledger non-escape, requiring H, C, P, N to preserve exactly the rows K, M, L, R, V, U and to export no host supremum, no external subcover selection, no quotient function equality, and no ambient completeness principle.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2196.1. The accepted packet exposes exactly the compact source, monotone family, pointwise convergence, rational budget, finite probe cover, uniform-limit handoff, transport, replay, provenance, and local naming rows.

Monotone-family visibility is forced by the row order. A pointwise convergence read from L can only be used after the relevant family comparison has been displayed by M, so the packet cannot replace monotone convergence by an unrecorded host limit argument.

Compactness enters only through K and V. The compact source row supplies the finite-cover interface, and the ProbeBundle row stores the actual cover cells that the uniform request inspects.

The tolerance ledger is R. Each local continuity or monotonicity estimate reads a rational slice before the uniform-limit handoff U is exported, so the final tolerance bound is assembled from finite rows.

Finally H, C, P, N transport, replay, source, and name only the listed coordinates. Since the excluded host principles have no carrier coordinate, they cannot appear as local $\mathsf{NameCert}_{\mathsf{DiniContinuity}^{\uparrow}}$ obligations. □

Theorem 2196.3 (Dini continuity uniform-Cauchy handoff)**.** *For an accepted* $\mathsf{DiniContinuity}^{\uparrow}$ *carrier*

$$D = (K, M, L, R, V, U, H, C, P, N),$$

every uniform-Cauchy consumer of D must read compact finite-cover extraction through K, V, pointwise convergence through L, monotone-family visibility through M, rational tolerance budgeting through R, and only then the $\mathsf{UniformLimit}^{\uparrow}$ *handoff U. The exported route contains no host supremum, selected subcover, quotient function equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier into its displayed rows. The compact source row K supplies the finite-cover interface, while V records the actual $\mathsf{ProbeBundle}$ cells inspected by the consumer.

The convergence and monotonicity reads are separate obligations. A pointwise convergence row from L may be used only for a displayed probe, and the monotone-family comparison supporting that read must already be visible through M.

The tolerance handoff then reads the positive rational budget R. Each cover cell receives its finite budget slice before the packet exports the $\mathsf{UniformLimit}^{\uparrow}$ row U, so the consumer receives a uniform-Cauchy route assembled from finite compact-cover and rational-budget data.

Finally H, C, P, N transport, replay, source, and name exactly the rows K, M, L, R, V, U. Since the carrier has no coordinate for host suprema, selected subcovers outside V, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the exported handoff cannot read any such principle. □

Theorem 2196.4 (Dini continuity compact finite-cover route)**.** *Every accepted* $\mathsf{DiniContinuity}^{\uparrow}$ *carrier routes a monotone continuous-family tolerance request through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *finite* $\mathsf{ProbeBundle}$ *cover rows,* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *before any* $\mathsf{Real}^{\uparrow}$*-facing uniform conclusion is read. In particular, the compact source and finite cover are displayed before the rational budget, the continuous-map rows expose pointwise monotone visibility, and the shared tolerance is then handed through the uniform-modulus and uniform-limit rows without reading a host supremum, selected minimum radius outside the packet, open-cover compactness, or ambient real completeness.*

Proof. Project the carrier rows of Definition 2196.1. The compact source row K and finite $\mathsf{ProbeBundle}$ cover row V are visible before the rational tolerance budget R is consumed.

Use the continuous-map rows carried by M and L for pointwise monotone visibility. These rows expose only displayed family comparisons and probe-wise convergence data, so they cannot substitute a host supremum or a detached pointwise limit.

Route the shared tolerance through R, then through the $\mathsf{UniformModulus}^{\uparrow}$ and $\mathsf{UniformLimit}^{\uparrow}$ handoff row U. The selected cover cells and their local radius data are already stored in V, so the minimum-radius and finite-cover steps remain finite packet data.

The structural rows H, C, P, N preserve exactly this compact-cover route. Therefore every Real-facing uniform conclusion stays downstream of the compact source, finite cover, rational budget, continuous-family rows, and uniform handoff, with no noncarried compactness or completeness principle available. □

Theorem 2196.5 (Dini continuity monotone cover budget)**.** *Let*

$$D = (K, M, L, R, V, U, H, C, P, N)$$

be an accepted $\mathsf{DiniContinuity}^{\uparrow}$ *carrier. Refining the finite* $\mathsf{ProbeBundle}$ *cover row V while preserving the compact source row K, the monotone continuous-family row M, the pointwise convergence rows L, and the positive rational tolerance budget R preserves the* $\mathsf{UniformModulus}^{\uparrow}$ *and* $\mathsf{UniformLimit}^{\uparrow}$

handoff U. The refined route cannot export a host supremum, selected minimum outside the packet, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 2196.1. The old and refined covers are both finite ProbeBundle rows over the same compact source row K, so each refined cell reads its source and local radius through the displayed cover ledger.

Compare the old and refined finite cover rows componentwise. The refinement does not change the monotone-family row M, the pointwise convergence rows L, or the positive rational budget R; it only replaces a cover cell by finitely many displayed subcells whose provenance remains inside V.

Replay the same rational tolerance budget through the monotone rows. The monotone comparison keeps the local estimates ordered, and the pointwise rows remain attached to the displayed probes of the refined finite cover.

Apply Definition 2196.4 to the refined cover. The $\mathsf{UniformModulus}^{\uparrow}$ and $\mathsf{UniformLimit}^{\uparrow}$ handoff still reads only $K, M, L, R, V, U, H, C, P, N$, so no host supremum, selected external minimum, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness is introduced. □

Theorem 2196.6 (Dini continuity uniform-window tightening)**.** *For an accepted* $\mathsf{DiniContinuity}^{\uparrow}$ *carrier*

$$D = (K, M, L, R, V, U, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$*-facing uniform-window request must pass through the compact source row K, the continuous-map family data carried by M, the pointwise convergence row L, the monotone visibility row M, the rational budget R, the finite* ProbeBundle *cover V, the* $\mathsf{UniformModulus}^{\uparrow}$ *and* $\mathsf{UniformLimit}^{\uparrow}$ *handoff U, and then the* hsame, Cont, Pkg, *and local* NameCert *rows. The tightened window exports no host supremum, open-cover compactness, quotient function equality, selected minimum radius outside V, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the carrier definition of Definition 2196.1. The accepted packet displays the compact source, continuous-family data, pointwise convergence, monotone visibility, rational budget, finite cover, handoff, and structural certificate rows.

The uniform-Cauchy handoff of Definition 2196.3 fixes the tolerance order. A consumer must read the rational budget and the finite cover before the uniform-limit row can be exported.

The compact finite-cover route of Definition 2196.4 fixes the compactness boundary. The cover cells come from the displayed ProbeBundle row rather than from an arbitrary open-cover principle or a selected global radius.

Finally the NameCert obligation surface of Definition 2196.2 repacks the route through H, C, P, N. Since the excluded Real-facing principles have no carrier coordinate, the tightened uniform window remains a finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiniContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiniContinuity}^{\uparrow}$ packet is generated from a compact metric source row, a monotone continuous-family row, pointwise convergence rows, a positive rational tolerance budget, a finite ProbeBundle cover, a UniformLimitUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiniContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 2196.1 and Definition 2196.2 seed the finite compact-metric monotone-continuity certificate surface for Dini-style uniform handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiniContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, open-cover compactness beyond the displayed finite ProbeBundle, quotient real-function equality, host suprema, ambient completeness, selected subcovers outside the carrier, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-family visibility, compact finite-cover extraction, uniform tolerance budgeting, and ledger non-escape for BEDC.Derived.DiniContinuityUp.

Chapter 2197

A Concrete Naming Certificate for $\mathsf{GroebnerBasis}^{\uparrow}$

Following Buchberger's finite basis construction, the $\mathsf{GroebnerBasis}^{\uparrow}$ packet names the reduction certificate that turns a finite polynomial generator list into a displayed leading-term and S-polynomial completion surface. It consumes the normalized coefficient-list and operation rows of chapter 50 together with the membership and absorption rows of chapter 81. The chapter records a finite reduction trace, not a host polynomial-ring quotient, algebraic closure, selected term order outside the ledger, or global ideal-membership decision procedure.

Definition 2197.1 (Groebner basis carrier)**.** *A* $\mathsf{GroebnerBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, I, O, L, S, R, F, H, C, K, N)$$

with the following displayed rows:

1. *P is the polynomial source row. It records the ambient* $\mathsf{Poly}^{\uparrow}$ *coefficient ledger, the finite variable list, the displayed addition and multiplication rows, and the normal-form syntax used by every polynomial in the packet.*
2. *I is the ideal-generator row. It lists the carried generator polynomials and the* $\mathsf{Ideal}^{\uparrow}$ *predicate row that certifies their ambient ideal membership and closure under displayed polynomial multiplication.*
3. *O is the monomial-order row. It is a finite comparison ledger for the monomials inspected by this packet, including well-founded descent evidence for the listed reduction steps and no coordinate for an external global ordering oracle.*
4. *L is the leading-term ledger. For each displayed polynomial it records the leading monomial, leading coefficient, leading term, and divisibility comparison against the inspected reducers.*
5. *S is the S-polynomial row. It records each critical pair, common multiple row, multiplier row, subtraction row, and the source polynomials used to form the displayed S-polynomial.*
6. *R is the finite reduction trace. It lists the ordered reducer choices, multiplier rows, subtraction steps, strictly descending leading monomial witnesses, and terminal remainder for every inspected S-polynomial.*
7. *F is the normal-form row. It records exactly which inspected reductions terminate at zero and which terminal remainders remain visible as refusal rows for stronger ideal-membership claims.*

8. *H records componentwise* hsame *transport for polynomial sources, ideal generators, monomial-order comparisons, leading-term rows, S-polynomial rows, reduction traces, normal-form rows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a requested reduction certificate through polynomial inspection, ideal-generator lookup, leading-term comparison, S-polynomial construction, finite reduction, and normal-form readback.*
10. *K is the* Pkg *provenance over* $\mathsf{GroebnerBasis}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a host quotient ring, a hidden global monomial-order oracle, algebraic closure, a completed ideal-membership algorithm, selected normal forms outside F, or Lean-side verification.

Lean4 ✓ `BEDC.Derived.GroebnerBasisUp.GroebnerBasisTasteGate single carrier alignment`

Theorem 2197.2 (Groebner basis NameCert obligations)**.** *For every accepted* $\mathsf{GroebnerBasis}^{\uparrow}$ *carrier $G = (P, I, O, L, S, R, F, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the polynomial source, ideal-generator list, monomial-order ledger, leading-term ledger, S-polynomial row, finite reduction trace, normal-form row, transport, replay, provenance, and local naming;*
2. *polynomial-source compatibility, requiring every polynomial used by I, L, S, R, F to be read through the same* $\mathsf{Poly}^{\uparrow}$ *coefficient and operation rows;*
3. *ideal-source compatibility, requiring every generator in I and every reducer used by R to be carried by the displayed* $\mathsf{Ideal}^{\uparrow}$ *predicate surface;*
4. *monomial-order and leading-term exposure, requiring O and L to display every comparison and leading-term read used by the reduction trace;*
5. *S-polynomial exactness, requiring S to display the two source polynomials, common multiple, multiplier rows, and subtraction row for each critical pair;*
6. *reduction-trace exactness, requiring R to display each reducer choice, multiplier, subtraction, and strictly descending leading-monomial witness until the terminal row in F is reached;*
7. *transport, continuation, provenance, and naming, requiring H, C, K, N to replay only the displayed rows of the same packet.*

No Groebner-basis obligation is stored outside these rows.

Proof. Open the carrier of Definition 2197.1. The rows P and I give the only polynomial and ideal sources. Every later row must project back to those two sources before it can be read as part of the packet.

The monomial-order and leading-term obligations are finite because O and L list the comparisons actually used in the displayed reductions. The certificate never asks for an unbounded ordering oracle; it asks only for the inspected comparison rows and their descent witnesses.

For each critical pair, the row S displays the common multiple, the two multipliers, and the subtraction that forms the S-polynomial. The reduction row R then records the finite sequence of reducer choices and subtraction steps, and each step carries its strictly descending leading-monomial witness from O and L.

The terminal row F records whether the inspected S-polynomial reduces to zero or leaves a visible remainder. Zero terminal rows support the displayed basis obligation. Nonzero terminal rows remain refusal data, so the certificate does not promote the packet to a complete ideal-membership decision procedure.

Finally, componentwise transport in H, continuation replay in C, package provenance in K, and local naming in N preserve exactly the rows already listed. Since the carrier has no coordinate for host quotient rings, hidden ordering oracles, algebraic closure, or selected normal forms outside F, no additional NameCert obligation can be read from the packet. □

Definition 2197.3 (Groebner basis finite reduction carrier)**.** *A* $\mathsf{GroebnerBasis}^{\uparrow}$ *finite reduction carrier is a displayed refinement*

$$G_{\mathrm{red}} = (P, A, I, L, S, T, F, H, C, K, N)$$

of the carrier in Definition 2197.1. The row P is the finite $\mathsf{Poly}^{\uparrow}$ *row over the coefficient* $\mathsf{Ring}^{\uparrow}$ *and* $\mathsf{CommRing}^{\uparrow}$ *surfaces, A records the finite polynomial list inspected by the packet, I is the displayed* $\mathsf{Ideal}^{\uparrow}$ *generator source, L is the leading-term ledger for the inspected rows, S is the finite S-polynomial ledger, T is the reduction-trace ledger, and F is the terminal normal-form or refusal ledger. The row H transports P, A, I, L, S, T, F by componentwise* hsame*, C replays the same finite trace by* Cont*, K records* Pkg *provenance over* $\mathsf{GroebnerBasis}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{Ideal}^{\uparrow}$*,* $\mathsf{Ring}^{\uparrow}$*,* $\mathsf{CommRing}^{\uparrow}$*, and* $\mathsf{HilbertBasis}^{\uparrow}$*, and N is the local* $\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}$ *naming row.*

The classifier of G_{red} compares two accepted packets only by matching these rows and their displayed descent witnesses. It has no coordinate for quotient ideal equality, a selected infinite basis, a hidden term-order oracle, a completed ideal-membership decision procedure, or a normal form chosen outside F.

Theorem 2197.4 (Groebner basis finite reduction NameCert obligations)**.** *For every accepted finite reduction carrier*

$$G_{\mathrm{red}} = (P, A, I, L, S, T, F, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}$ *surface consists exactly of finite polynomial-row admission through P and A, ideal-generator admission through I, leading-term exposure through L, S-polynomial construction through S, reduction-trace exactness through T, terminal normal-form or refusal exposure through F, componentwise transport through H, displayed replay through C, provenance through K, and local naming through N.*

Proof. Project the refinement to the carrier of Definition 2197.1. The rows P, A, I, L, S, T, F are the finite algebraic rows visible before transport or replay is applied, and every row is read through the existing $\mathsf{Poly}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, and $\mathsf{CommRing}^{\uparrow}$ surfaces.

Induct over the displayed reduction ledger T. The base row is the S-polynomial displayed in S with its leading-term data from L. In the step case, the reducer, multiplier, subtraction, and descent witness are all rows of T, so the next polynomial remains inside the finite polynomial ledger and no hidden basis element is introduced.

At the terminal row, F records either a zero normal form or a visible refusal remainder. The zero case exports the finite reduction certificate; the refusal case blocks any stronger ideal-membership or completed-basis claim.

The structural rows H, C, K, N then transport, replay, source, and name the same finite ledger. Since none of these rows contains quotient ideal equality, an infinite basis selector, or a normal form outside F, the listed rows exhaust the finite reduction obligations. □

Theorem 2197.5 (Groebner basis Buchberger handoff)**.** *Every Buchberger-style read of an accepted* $\mathsf{GroebnerBasis}^{\uparrow}$ *finite reduction carrier factors through the finite handoff*

$$\mathsf{Poly}^{\uparrow},\ \mathsf{Ring}^{\uparrow},\ \mathsf{CommRing}^{\uparrow},\ \mathsf{Ideal}^{\uparrow},\ L,\ S,\ T,\ F,\ \mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}.$$

The handoff supplies the reduction rows that a downstream $\mathsf{HilbertBasis}^{\uparrow}$ *or polynomial-normal-form consumer may inspect. It does not supply quotient ideal equality, a selected infinite basis, a global ideal-membership decision procedure, or a normal-form oracle outside the displayed terminal ledger.*

Proof. Start with the finite reduction carrier of Definition 2197.3. The polynomial, coefficient-ring, commutative-ring, and ideal rows give the only algebraic sources available to the handoff.

For each critical pair, the S-polynomial row S points to the leading-term data in L and to the ordered reduction ledger T. Induction over T shows that every subtraction step is justified by a displayed reducer and a displayed descent witness, so the handoff remains finite.

Finally read the terminal row F. A zero terminal row is the Buchberger reduction certificate exported to downstream consumers, while a nonzero terminal row is refusal data. The $\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}$ naming row, together with H, C, K, preserves that distinction and prevents the handoff from being read as a quotient equality or an infinite-basis selection. □

Theorem 2197.6 (Groebner basis reduction certificate)**.** *Let* $G = (P, I, O, L, S, R, F, H, C, K, N)$ *be an accepted* $\mathsf{GroebnerBasis}^{\uparrow}$ *carrier. For every S-polynomial row displayed in* S*, the reduction certificate exported to downstream polynomial-normal-form and ideal-membership consumers factors through the finite route*

$$P, I, O, L, S \longmapsto R \longmapsto F, H, C, K, N.$$

If the corresponding terminal row in F *is zero, the inspected critical-pair reduction is certified by displayed polynomial operations and ideal-generator membership rows. If the terminal row is nonzero, the same row is retained as refusal data for any claim that would require a completed Groebner basis beyond the displayed packet.*

Proof. Fix an inspected S-polynomial row in S. Its source polynomials, common multiple, multipliers, and subtraction row are already displayed over the polynomial source P and the ideal-generator source I.

Read the ordered reduction trace in R. Each step chooses a displayed reducer, checks divisibility against the current leading term using O and L, forms the multiplier row through P, subtracts the corresponding multiple, and records the descent witness needed for the next step.

Because R is finite, the route reaches the terminal row recorded in F. If that row is zero, the certificate exports exactly the displayed zero-reduction trace and the ideal-generator membership needed by downstream consumers. If it is not zero, the terminal polynomial remains visible as a refusal row, so a consumer cannot silently read a stronger ideal-membership or normal-form claim.

The structural rows H, C, K, N then transport, replay, source, and name the same reduction route. They add no hidden basis completion, quotient-ring equality, external term ordering, algebraic closure, or selected normal form outside the displayed trace. □

Falsifiable prediction: Every $\mathsf{GroebnerBasis}^{\uparrow}$ read factors through one $\mathsf{Poly}^{\uparrow}$ source row, one $\mathsf{Ideal}^{\uparrow}$ generator row, one finite monomial-order comparison ledger, one leading-term ledger, one S-polynomial table, one finite reduction trace, one normal-form or refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row.

Independence witness: polynomial, ideal: $\mathsf{GroebnerBasis}^{\uparrow}$ is not bijective to either listed sibling because it jointly carries critical-pair formation, leading-term comparison, finite reduction traces, and terminal normal-form or refusal rows over the shared polynomial-and-ideal source.

Closure status for $\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2197.1, Definition 2197.3, Definition 2197.2, Definition 2197.4, Definition 2197.5, and Definition 2197.6 seed the finite Groebner reduction packet over displayed $\mathsf{Poly}^{\uparrow}$ and $\mathsf{Ideal}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroebnerBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global ideal-membership decision procedure, a quotient-ring normal-form theorem, algebraic closure, a host monomial-order oracle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, polynomial and ideal source compatibility, leading-term exposure, S-polynomial exactness, reduction-trace exactness, terminal-row discipline, and transport-replay coverage for BEDC.Derived.GroebnerBasisUp.

Constructive story: A $\mathsf{GroebnerBasis}^{\uparrow}$ packet is generated from a polynomial source row, an ideal-generator list, a monomial-order comparison ledger, a leading-term ledger, S-polynomial rows, finite reduction traces, terminal normal-form or refusal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2198

A Concrete Naming Certificate for $\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}$

Following Kelley-style nets and the standard Hausdorff uniqueness principle, the $\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}$ packet records the finite BEDC route by which two accepted limit reads of the same Cauchy net are identified only at a displayed separated zero-distance row. It sits downstream of the directed-window Cauchy-net surface of chapter 589, the zero-distance classifier of chapter 1411, the completion-facing handoff of chapter 1506, and the terminal real-name seal of chapter 38. The packet gives completion consumers a uniqueness boundary without importing quotient nets, selected limit representatives, host equality, countable choice, or ambient completeness.

Definition 2198.1 (CauchyNetHausdorffUniqueness carrier)**.** *A* $\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, L_0, L_1, S, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window route, including the index preorder, late-window Cauchy rows, and finite metric-distance reads for the same net;*
2. *L_0 and L_1 are two displayed limit reads over D, written through the finite routes*

$$D \longmapsto L_0$$

and

$$D \longmapsto L_1;$$

3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *or Hausdorff-metric separation row that displays zero distance between the two limit reads after both are read from the same directed-window route;*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row, recording that completion-facing consumers see only the Cauchy-net route, the two displayed limit reads, and the separated comparison row;*
5. *H records componentwise* hsame *transport for $D, L_0, L_1, S, M, C, P, N$;*
6. *C records displayed* Cont *replay through the directed Cauchy windows, the two limit reads, the separated comparison, and the metric-completion handoff;*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

8. N is the local $\mathsf{NameCert}_{\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}}$ *row.*
The carrier contains no quotient-net equality, no selected representative limit, no host equality of points, no countable-choice schedule, and no ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyNetHausdorffUniquenessUp.CauchyNetHausdorffUniquenessTasteGate`
`single carrier alignment`

Theorem 2198.2 (CauchyNetHausdorffUniqueness NameCert obligations)**.** *For the carrier of Definition 2198.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}}$ *surface consists exactly of carrier admission for $U = (D, L_0, L_1, S, M, H, C, P, N)$, the shared* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window route D, Hausdorff separation through S, endpoint uniqueness through the displayed zero-distance comparison,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

The obligations do not include quotienting nets, choosing a canonical limit, comparing host equality, importing countable choice, or asserting ambient completeness.

Proof. Carrier admission is projection from Definition 2198.1. The rows $D, L_0, L_1, S, M, H, C, P, N$ are the complete displayed packet.

The shared Cauchy-net route is the first obligation. Both limit reads are attached to the same directed-window row D, so a consumer cannot compare endpoints before reading the same Cauchy evidence.

The Hausdorff step is the row S. It is read only after L_0 and L_1 have both been displayed over D, and it identifies the endpoints through separated zero-distance evidence rather than through host equality.

The rows M, H, C, P, N preserve and expose that same route. The metric-completion handoff, transport, replay, provenance, and local naming rows add no coordinate for quotient nets, selected representatives, choice, or ambient completeness. □

Theorem 2198.3 (CauchyNetHausdorff limit separation)**.** *Let*

$$U = (D, L_0, L_1, S, M, H, C, P, N)$$

be an accepted $\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}$ *packet. If L_0 and L_1 are two accepted limit reads over the same* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window route D, then the packet identifies them only through the displayed separated zero-distance row S, transported by H and replayed by C into the same* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff M.*

Thus two accepted limit reads of the same directed-window Cauchy route are equal for the exported classifier exactly at the $\mathsf{SeparatedMetric}^{\uparrow}$ *row. The conclusion is not quotient-net equality, not host point equality, and not a selected-limit principle.*

Proof. Read the accepted packet through the carrier definition. The two limit rows L_0 and L_1 share the same source coordinate D, so every comparison begins with the displayed $\mathsf{CauchyNet}^{\uparrow}$ directed-window evidence.

The only comparison row is S. It records separated zero-distance evidence for the two displayed limit reads and is therefore the unique route by which the exported classifier identifies them.

Transport and replay do not change the comparison target. The rows H and C move and replay D, L_0, L_1, S componentwise, while M, P, N record the completion handoff, provenance, and local name.

Since no remaining coordinate contains quotient-net equality, host equality, a selected representative, choice, or ambient completeness, the uniqueness conclusion stays at the displayed separated row. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}$ packet is generated from one displayed CauchyNet directed-window route, two displayed limit reads over that route, a separated zero-distance comparison row, a MetricCompletion handoff row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2198.1, Definition 2198.2, and Definition 2198.3 seed the finite Cauchy-net Hausdorff uniqueness route over directed windows, displayed limit reads, separated zero-distance evidence, and MetricCompletion handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNetHausdorffUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient-net equality, selected representatives, host equality, countable choice, ambient completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, shared Cauchy-net route stability, separated zero-distance comparison, MetricCompletion handoff exactness, and ledger non-escape for BEDC.Derived.CauchyNetHausdorffUniquenessUp.

Chapter 2199

A Concrete Naming Certificate for $\mathsf{CantorCompleteMetric}^{\uparrow}$

Following Cantor's intersection theorem and Bishop–Bridges constructive metric completion, the $\mathsf{CantorCompleteMetric}^{\uparrow}$ packet records the nested closed-ball criterion for reading a complete-metric point from finite BEDC data. It sits after the complete-metric surface of chapter 128, the completion route of chapter 1506, the Cauchy-filter interface of chapter 333, the nested-interval spine of chapter 320, and the L10 real-name route through chapter 126, chapter 301, and chapter 38. The packet names a constructive closed-ball handoff; it does not import open-cover compactness, countable choice, quotient completions, selected limits, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2199.1 (CantorCompleteMetric carrier)**.** *A* $\mathsf{CantorCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{ccm}} = (M, B, F, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row whose metric and convergence obligations are the only complete-metric data available to the packet.*
2. *B is the nested closed-ball row, listing a descending finite window of closed metric balls with each later ball displayed inside the earlier ball.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row generated by the nested ball spine and read only through the displayed ball inclusions.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, storing the requested tolerances and the visible shrink bounds for the ball radii.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting the inspected nested-ball prefix.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the numerical radius and center schedule needed by the completion route.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, F, D, W, Q have been displayed.*
8. *H records componentwise* hsame *transport for the metric source, nested closed balls, Cauchy filter, dyadic radius ledger, finite windows, regular readback, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from closed-ball inclusion through Cauchy-filter generation, dyadic radius shrinkage, finite windows, regular readback, and the terminal real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorCompleteMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. There is no coordinate for an open cover, a countable-choice selector, a quotient completion, a selected limit, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CantorCompleteMetricUp.CantorCompleteMetricTasteGate single carrier alignment`

Theorem 2199.2 (CantorCompleteMetric NameCert obligations)**.** *For every accepted* $\mathsf{CantorCompleteMetric}^{\uparrow}$ *carrier*

$$K_{\mathrm{ccm}} = (M, B, F, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorCompleteMetric}^{\uparrow}}$ *surface consists exactly of carrier admission, nested closed-ball inclusion, radius shrinkage, Cauchy-filter generation, finite-window exposure, regular-rational readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows displayed in Definition 2199.1. It has no obligation row for open-cover compactness, countable choice, quotient completions, selected limits, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier K_{ccm}. The row M supplies only the complete-metric source already named by chapter 128, while B supplies the nested closed-ball spine and F repacks that spine as the Cauchy-filter surface of chapter 333.

The radius data are read next. The dyadic ledger D records the visible shrink bounds, and the finite window W determines which closed balls are inspected at the requested tolerance.

The numerical readback and seal are downstream. The row Q exposes the regular-rational schedule used by chapter 301, and the row E seals that read as the $\mathsf{Real}^{\uparrow}$ output only after the nested-ball and filter rows have been displayed.

The structural rows H, C, P, N preserve the same route. Since no row contains an open cover, a countable-choice selector, a quotient completion, a selected limit, or full $\mathsf{Real}^{\uparrow}$ completeness data, none of those objects can become a local NameCert obligation. □

Theorem 2199.3 (CantorCompleteMetric nested closed-ball handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{CantorCompleteMetric}^{\uparrow}$ *carrier factors through the finite route*

$$M, B \longmapsto F, D, W \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus a later $\mathsf{CompactMetric}^{\uparrow}$ *or Real-and-Completion consumer receives the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row, descending closed-ball window,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff, dyadic radius ledger, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local* NameCert *rows. The route exports no open-cover compactness, countable choice, quotient completion, selected limit, or full* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with a completion-facing consumer request. The request can inspect the packet only through the accepted carrier, so the first visible data are the complete-metric row M and the nested closed-ball spine B.

The handoff then passes through the generated filter and radius ledger. The row F records the Cauchy-filter surface coming from the nested balls, while D and W bind each tolerance request to a displayed finite window.

The regular-rational readback follows the same finite route. The row Q is read after the ball, filter, radius, and window rows, and E seals only that displayed read as the Real-facing output.

Finally H, C, P, N transport, replay, source, and name the route. No step opens an open cover, chooses countably many centers, quotients a completion, selects a host limit, or invokes full $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorCompleteMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorCompleteMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2199.1, Definition 2199.2, and Definition 2199.3 seed the finite nested closed-ball criterion for complete-metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorCompleteMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient completions, selected limits, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested closed-ball inclusion, radius shrinkage, Cauchy-filter generation, finite-window exposure, regular readback, Real sealing, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.CantorCompleteMetricUp.

Constructive story: A $\mathsf{CantorCompleteMetric}^{\uparrow}$ packet is generated from a CompleteMetric source row, descending closed-ball window, CauchyFilter handoff, DyadicRatCore radius ledger, StreamName window, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2200

A Concrete Naming Certificate for $\mathsf{UniformLimitTheorem}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformLimitTheorem}^{\uparrow}$ packet records the finite NameCert route by which a uniformly convergent sequence of continuous maps exports continuity of its limit. It consumes the continuous-map rows of chapter 130, the uniform-limit ledger of chapter 463, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seals of chapter 38, and the metric source and target rows of chapter 57. The packet names the theorem handoff as finite certificate data; it is not an ambient function-space topology, a quotient stream equality, a selected host limit, or a global completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 2200.1 (Uniform-limit theorem carrier)**.** *A* $\mathsf{UniformLimitTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, L, W, R, E, X, Y, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *sequence ledger. Each entry records a continuous map from the displayed metric source X to the displayed metric target Y.*
2. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *modulus ledger binding target tolerances to a finite tail stage and to the shared source-radius information used by the limit read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family exposing exactly the finite values of the sequence and of the limit candidate needed for the displayed tolerance request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in W after the uniform-limit budget in L has fixed the tail.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows and regular-rational readbacks have been displayed.*
6. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the local source-radius requests consumed by the continuity rows in F.*
7. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, including the target tolerance ledger consumed by L, R, E.*
8. *H records componentwise* hsame *transport for $F, L, W, R, E, X, Y, C, P, N$.*
9. *C records displayed* Cont *replay from a limit-continuity request through X, Y, F, L, W, R, E and then through the structural rows.*

10. *P is the* Pkg *provenance over* UniformLimitTheorem$^\uparrow$, ContinuousMap$^\uparrow$, UniformLimit$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, Met$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformLimitTheorem}^\uparrow}$ *row.*

The carrier has no coordinate for an ambient topology on maps, a host-level selected limit function, quotient stream equality, countable choice, or completeness of the target metric space beyond the displayed rows.

Lean4 ✓ `BEDC.Derived.UniformLimitTheoremUp.UniformLimitTheoremTasteGate single carrier alignment`

Theorem 2200.2 (Uniform-limit theorem NameCert obligations)**.** *For an accepted* UniformLimitTheorem$^\uparrow$ *carrier $U = (F, L, W, R, E, X, Y, H, C, P, N)$, the local* NameCert$_{\text{UniformLimitTheorem}^\uparrow}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed tuple over the* ContinuousMap$^\uparrow$ *sequence,* UniformLimit$^\uparrow$ *ledger, finite* StreamName$^\uparrow$ *windows,* RegSeqRat$^\uparrow$ *readbacks,* Real$^\uparrow$ *seals, and source and target* Met$^\uparrow$ *rows;*
2. *uniform-limit visibility, requiring every limit-continuity read to pass through the modulus ledger L before any window or real-seal row is exposed;*
3. *continuity inheritance, requiring the source-radius row read from a member of F and the tail bound read from L to be jointly visible before the limit row is named continuous;*
4. *finite-window discipline, requiring every sequence value and limit candidate used by the handoff to be read through W and then through R;*
5. Real$^\uparrow$*-seal nonescape, requiring the terminal real seal E to appear only after L, W, R and the target metric row Y have been displayed;*
6. *transport and replay stability through the componentwise* hsame *row H and displayed* Cont *row C;*
7. *provenance exhaustion through P and the local naming row N.*

Proof. Carrier admission is projection from Definition 2200.1. It exposes the continuous-map sequence, the uniform-limit ledger, finite windows, regular readbacks, real seals, metric rows, transport, replay, provenance, and local naming rows.

Uniform-limit visibility is the role of L. A target tolerance first selects a displayed tail stage and the source-radius information needed for the limit read. Only then may the route inspect the finite windows W and regular readbacks R.

Continuity inheritance uses F together with L. The chosen member of the continuous sequence supplies the local source-radius row, while the uniform-limit ledger supplies the tail comparison that transfers the target tolerance to the limit candidate.

The Real-facing end of the route is W, R, E. The windows expose only finite observations, the readback row repacks those observations as regular rational data, and the Real$^\uparrow$ seal appears after these rows and the target metric row have been displayed.

Finally H, C, P, N transport, replay, package, and name the same route. Since the carrier lacks ambient map topology, quotient stream equality, selected host limits, choice, and target-completeness coordinates, no further obligation can be read from the local certificate. □

Theorem 2200.3 (Uniform limit preserves continuity as a BEDC handoff)**.** *Every continuity read of the limit named by an accepted* UniformLimitTheorem$^\uparrow$ *carrier factors through the displayed route*

$$X, Y \longmapsto F, L \longmapsto W, R \longmapsto E, H, C, P, N.$$

Thus the source and target $\mathsf{Met}^{\uparrow}$ *rows are read first, the* $\mathsf{ContinuousMap}^{\uparrow}$ *sequence and* $\mathsf{UniformLimit}^{\uparrow}$ *ledger supply the continuity and tail witnesses, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows expose only finite readbacks, and the* $\mathsf{Real}^{\uparrow}$ *seal is reached only at the end of the route. No consumer of the packet receives an ambient function-space topology, a selected host limit, quotient stream equality, countable choice, or target completeness not present in the carrier.*

Proof. Begin with a continuity request for the limit. The only source and target data available are the metric rows X and Y, so the request first reads the source-radius and target-tolerance surfaces recorded there.

Next the route reads F and L. The sequence row F provides the continuous-map witness at the displayed tail stage, while L provides the uniform-limit budget that lets the same target tolerance be compared with the limit candidate.

The finite observation stage is W, R. The selected sequence value and the limit candidate are exposed through StreamName windows and then through RegSeqRat readbacks; no quotient stream or host function value is available.

The terminal stage is E, H, C, P, N. The Real seal is reached only after the finite readbacks have been fixed, and the structural rows transport, replay, package, and name the same finite route. This proves that continuity of the limit is a BEDC handoff through the displayed uniform-limit ledger rather than an appeal to an ambient theorem outside the packet. □

Theorem 2200.4 (Uniform-limit regular-Cauchy modulus handoff)**.** *Let* $U = (F, L, W, R, E, X, Y, H, C, P, N)$ *be an accepted* $\mathsf{UniformLimitTheorem}^{\uparrow}$ *carrier. Every limit-continuity modulus read of* U *passes from the source and target* $\mathsf{Met}^{\uparrow}$ *rows* X, Y *through the* $\mathsf{ContinuousMap}^{\uparrow}$ *row* F*, the* $\mathsf{UniformLimit}^{\uparrow}$ *ledger* L*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*.*

The route L, W, R, E *is the only modulus-to-real route carried by the packet. It exports no ambient function-space theorem, quotient stream equality, selected host limit, countable-choice schedule, or target-completeness principle beyond the displayed metric, window, readback, and real-seal rows.*

Proof. Project the carrier of Definition 2200.1. The only metric data are X, Y, the only continuity data are stored in F, and the only uniform convergence modulus is the finite ledger L.

Apply Definition 2200.2. Its visibility and finite-window clauses force a limit-continuity request to read the uniform-limit budget before inspecting W, then to recover regular rational data through R, and only then to consume the real seal E.

Finally use Definition 2200.3. It identifies the same route as the BEDC continuity handoff, so L, W, R, E exhaust the modulus-to-real path for RealUp-sealed uniform-limit arguments. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformLimitTheorem}^{\uparrow}$ packet is generated from a ContinuousMapUp sequence ledger, a UniformLimitUp modulus ledger, finite StreamNameUp windows, RegSeqRatUp readbacks, RealUp seals, source and target MetricUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformLimitTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 2200.1, Definition 2200.2, and Definition 2200.3 seed the finite theorem handoff from ContinuousMapUp and UniformLimitUp rows through StreamNameUp, RegSeqRatUp, RealUp, and MetricUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformLimitTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ambient function-space topology, quotient stream equality, selected host limits, countable choice, or target completeness beyond the displayed rows.

Upgrade path: Obligation closure requires checked carrier admission, uniform-limit visibility, continuity inheritance, finite-window discipline, Real-seal nonescape, transport and replay stability, and provenance exhaustion for BEDC.Derived.UniformLimitTheorem

Chapter 2201

A Concrete Naming Certificate for $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$ packet isolates the explicit rational and dyadic bound surface used when a displayed $\mathsf{Real}^{\uparrow}$ name is read by order-facing or completion-facing consumers. It sits between the real-name seal of chapter 38, the regular Cauchy handoff of chapter 301, the stream window of chapter 126, the rational carrier of chapter 37, the dyadic presentation of chapter 291, and the Archimedean bound packet of chapter 430. The schema records the finite ledger through which a bound is inspected; it does not assert a supremum, trichotomy, quotient equality of real names, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2201.1 (Real Archimedean bound schema carrier)**.** *A* $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, Q, D, S, G, B, H, C, P, N)$$

with the following visible rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *name whose bound route is being displayed.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *row naming the rational bound used by order and completion consumers.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *presentation of the same bound at the dyadic inspection surface.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window through which finite reads of R are exposed.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff connecting the stream window to regular rational approximants.*
6. *B is the finite bound ledger comparing the inspected rational approximants with the rational and dyadic bound rows.*
7. *H stores componentwise* hsame *transports for the real name, rational row, dyadic row, stream window, regular-sequence handoff, bound ledger, route rows, provenance, and local naming.*
8. *C stores the displayed* Cont *route from a consumer request through $R, Q, D, S, G, B, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{ArchimedeanReal}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanBoundSchema}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, Q, D, S, G, B, H, C, P, N$. No host supremum, selected least bound, trichotomy oracle, quotient equality of real names, or ambient completeness datum is a coordinate of the carrier.

Lean4 ✓ `BEDC.Derived.RealArchimedeanBoundSchemaUp.RealArchimedeanBoundSchemaTasteGate` single carrier alignment

Theorem 2201.2 (Real Archimedean bound schema obligations)**.** *For every accepted* RealArchimedeanBoundSchem *carrier $A = (R, Q, D, S, G, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanBoundSchema}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real name, rational bound row, dyadic presentation, stream window, regular rational handoff, finite bound ledger, transport rows, continuation routes, provenance, and local naming;*
2. *rational-dyadic coherence, requiring Q and D to be read as one bound witness for the same displayed real name;*
3. *window/readback compatibility, requiring every finite inspection of R to pass through S and then through the regular rational handoff G before the ledger B is consulted;*
4. *ledger non-escape, excluding host suprema, selected least bounds, trichotomy, quotient equality, and ambient completeness from the local certificate;*
5. *consumer handoff, requiring each* $\mathsf{Real}^{\uparrow}$ *order-facing, locatedness-facing, or completion-facing read to receive $Q, D, S, G, B, H, C, P, N$ before using the displayed bound.*

No Real Archimedean bound schema obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 2201.1. The bound rows are Q and D, the real-name inspection rows are S and G, and the finite comparison surface is B.

Rational-dyadic coherence is componentwise: both bound rows are coordinates of the same packet and are transported by the same H row. The continuation row C gives a single route from a consumer request to those two rows, so the rational and dyadic presentations cannot be separated by the classifier.

Window/readback compatibility follows from the route shape. A finite read of R first opens the stream window S, then the regular rational handoff G, and only then reaches the bound ledger B.

The remaining clauses are the non-escape and handoff boundary. Since the carrier has no coordinate for a supremum, selected least bound, trichotomy oracle, quotient equality, or completeness theorem, the only public bound route is the displayed $Q, D, S, G, B, H, C, P, N$ ledger. □

Theorem 2201.3 (Real Archimedean rational-dyadic handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *order-facing, locatedness-facing, or completion-facing consumer of an accepted* $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$ *carrier reads the rational row Q and the dyadic row D through the same finite route*

$$R \longmapsto S, G \longmapsto B \longmapsto Q, D, H, C, P, N.$$

Thus the consumer receives one rational-dyadic bound surface, with the stream window, regular rational readback, bound ledger, transport, continuation, provenance, and local naming rows already displayed. The packet exports no supremum, trichotomy, quotient equality of real names, selected least bound, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with a consumer of the accepted carrier A. By Definition 2201.1, the consumer can inspect the real name R only through the window S and the regular rational handoff G.

The bound ledger B is then the only comparison row connecting those finite reads to the rational row Q and the dyadic row D. The structural rows H, C, P, N transport, replay, record provenance for, and name exactly that route.

Apply Definition 2201.2. Its coherence, compatibility, non-escape, and handoff clauses force order-facing, locatedness-facing, and completion-facing consumers to use the same S, G, B, H, C, P, N route for both Q and D. □

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealArchimedeanBoundSchema}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close suprema, trichotomy, quotient equality of real names, selected least bounds, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-dyadic coherence, window/readback compatibility, ledger non-escape, and consumer handoff for BEDC.Derived.RealArchimedeanBoundSchemaUp.

Constructive story: A $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$ packet is generated from a RealUp name, RatUp and DyadicRatCoreUp bound rows, a StreamNameUp inspection window, a RegSeqRatUp readback handoff, a finite bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2202

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$ packet realizes the finite extractor route named in chapter 9237: compact finite-net rows and continuous-map pointwise-modulus rows are folded over a finite ProbeBundle of rational radii to produce a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff. It consumes the compact metric surface of chapter 129, the continuous-map pointwise rows of chapter 130, the rational lower-bound machinery of chapter 619, the uniform-modulus consumer row of chapter 369, the rational carrier of chapter 37, and the ProbeBundle finite-net selectors of chapter 914. The packet records the finite fold itself; it does not import open-cover compactness, sequential compactness, a choice-selected Lebesgue number, or an ambient completeness theorem.

Definition 2202.1 (Compact uniform modulus extractor carrier)**.** *A* $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, T, P, L, M, U, H, C, G, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the finite* ProbeBundle *of centers at the requested rational tolerance.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row over the same compact metric source.*
3. *T is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row requested by the downstream uniform-modulus consumer.*
4. *P is the finite* ProbeBundle *readback row listing the centers and coverage radii supplied by K.*
5. *L is the center-indexed lower-bound ledger whose entries are rational radii certified by the pointwise-modulus rows of F.*
6. *M is the finite rational-fold row that takes the lower bound of the displayed L entries without a host minimum selector.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from T, P, L, M and the source and target metric triangle ledgers.*
8. *H stores componentwise* hsame *transport for the compact source, continuous map, tolerance row, ProbeBundle readback, lower-bound ledger, rational fold, uniform-modulus handoff, replay, provenance, and local naming.*

9. *C stores displayed* Cont *replay from a uniform-modulus request through $K, F, T, P, L, M, U, H, G, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, F, T, P, L, M, U, H, C, G, N$. No open cover, selected subcover, sequential compactness argument, host lower-bound function, choice-selected Lebesgue number, or ambient completeness coordinate is part of the extractor.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusExtractorUp.CompactUniformModulusExtractorTasteGate`
`single carrier alignment`

Theorem 2202.2 (Compact uniform modulus extractor obligations)**.** *For every accepted* CompactUniformModulusE *carrier $E = (K, F, T, P, L, M, U, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtractor}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric finite-net row, continuous-map pointwise-modulus row, rational tolerance row, ProbeBundle readback, lower-bound ledger, rational fold, uniform-modulus handoff, transport, replay, provenance, and local naming;*
2. *compact-source lock, requiring K and the source row of F to name the same metric carrier before the center bundle P is read;*
3. *pointwise-radius binding, requiring every entry of L to be attached to a center of P and to a displayed pointwise-modulus row of F;*
4. *rational-fold exactness, requiring M to be the finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over L rather than a host minimum selector;*
5. *uniform-modulus handoff, requiring U to be read only after T, P, L, M and the metric triangle rows have been displayed;*
6. *structural transport, requiring* hsame, Cont, Pkg, *and local* NameCert *rows to replay the same finite extractor route;*
7. *ledger non-escape, excluding open-cover compactness, selected Lebesgue numbers, sequential compactness, choice, and ambient completeness from the local packet.*

No compact uniform modulus extractor obligation is stored outside these rows.

Proof. Project the carrier of Definition 2202.1. The compact source is K, the pointwise-modulus source is F, the requested tolerance is T, and the finite center bundle is P.

The source lock is required before the fold begins. The center rows in P and the pointwise-modulus rows in F are read over the same compact metric carrier, so the lower-bound ledger L cannot mix centers from one source with moduli from another.

The finite extractor step is the transition from L to M. Since M is a rational fold over the displayed finite ledger, it is classifier-stable data in the packet rather than a host-selected minimum.

Finally U is read only after the fold and the triangle rows are visible. The transport, replay, provenance, and local naming rows follow this same route, so open-cover compactness, selected Lebesgue numbers, sequential compactness, choice, and ambient completeness have no coordinate from which to enter the certificate. □

Theorem 2202.3 (Compact uniform modulus finite-fold handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer reading an accepted* $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$ *carrier factors through the finite route*

$$K, F, T \longmapsto P, L, M \longmapsto U, H, C, G, N.$$

Thus the consumer receives compact finite-net rows, continuous-map pointwise-modulus rows, the $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the displayed* ProbeBundle *radii, and the structural handoff rows before any tolerance-only modulus is public. The packet exports no open-cover compactness, selected subcover, selected Lebesgue number, host minimum selector, sequential compactness argument, choice principle, or ambient completeness theorem.*

Proof. Begin with a uniform-modulus consumer of E. The carrier of Definition 2202.1 exposes the compact metric source K, continuous-map row F, and rational tolerance T as the only input rows.

The finite center data are then read through P. Each center contributes a pointwise-modulus radius to L, and the fold row M computes the displayed rational lower bound over that finite ledger.

The handoff row U packages the folded radius as a tolerance-only uniform modulus, while H, C, G, N transport, replay, record provenance for, and name the same route. Applying Definition 2202.2, no consumer can replace this finite path by an open-cover proof, selected subcover, selected Lebesgue number, host minimum selector, sequential compactness argument, choice principle, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtractor}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2202.1, Definition 2202.2, and Definition 2202.3 seed the finite ProbeBundle rational-fold extractor from compact metric finite nets and continuous-map pointwise moduli to UniformModulusUp handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtractor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected Lebesgue numbers, sequential compactness, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source lock, pointwise-radius binding, rational-fold exactness, uniform-modulus handoff, structural transport, and ledger non-escape for BEDC.Derived.CompactUniformModulusExtr

Constructive story: A $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$ packet is generated from CompactMetricUp finite-net rows, ContinuousMapUp pointwise-modulus rows, a RatUp tolerance, a finite ProbeBundle center ledger, a rational lower-bound fold, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2203

A Concrete Naming Certificate for $\mathsf{DyadicIntermediateValue}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicIntermediateValue}^{\uparrow}$ packet records the finite dyadic bisection surface that sits between a displayed intermediate-value sign route and the later real-name seal. It is a neighbour of the $\mathsf{IntermediateValue}^{\uparrow}$ route of chapter 1402: the packet consumes the finite branch discipline of chapter 361, the endpoint carrier of chapter 394, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The chapter names the finite bisection certificate consumed by Real and Completion phases; it does not select a root, quotient real names, decide real trichotomy, invoke open-cover compactness, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2203.1 (Dyadic intermediate-value carrier)**.** *A* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, S, B, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, including lower and upper endpoint windows, rational cells, and dyadic refinements visible to the bisection route.*
2. *S is the displayed sign-change ledger inherited from an* $\mathsf{IntermediateValue}^{\uparrow}$ *sign route; it records only the inspected endpoint signs and the midpoint signs used by the finite branch prefix.*
3. *B is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, retaining the finite sequence of dyadic child intervals whose displayed signs preserve the intermediate-value boundary.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic radius, midpoint arithmetic, and width comparison used to stop the branch prefix at the requested precision.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family for the retained endpoint names and midpoint observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W after the dyadic tolerance row Q has fixed the finite window.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row available only after I, S, B, Q, W, R have been displayed.*

8. *H records componentwise* hsame *transport for the interval, sign ledger, bisection ledger, dyadic tolerance, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$I, S \longmapsto B, Q \longmapsto W, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{DyadicIntermediateValue}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntermediateValue}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $I, S, B, Q, W, R, E, H, C, P, N$ and has no coordinate for a selected root, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntermediateValueUp.DyadicIntermediateValueTasteGate single carrier alignment`

Theorem 2203.2 (Dyadic intermediate-value NameCert obligations)**.** *For an accepted* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *carrier*

$$D = (I, S, B, Q, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntermediateValue}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed located interval, sign ledger, bisection ledger, dyadic tolerance row, stream windows, regular readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *sign-ledger visibility, requiring every endpoint or midpoint sign consumed by the packet to pass through I and S before a branch row in B is read;*

3. *dyadic branch exactness, requiring every retained child interval in B to expose its midpoint arithmetic and width comparison through Q;*

4. *finite-window discipline, requiring every retained endpoint read to pass through W and then through R before the Real-facing row E is exposed;*

5. *transport and replay stability through H and C;*

6. *provenance exhaustion through P and the local naming row N.*

No $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2203.1. The projection exposes exactly the located interval, sign ledger, dyadic branch ledger, tolerance row, finite windows, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Sign-ledger visibility reads I and S before B. Endpoint and midpoint sign rows are therefore attached to the displayed located interval cells before any retained child interval is named.

Dyadic branch exactness reads B together with Q. Each branch step carries a midpoint and a width comparison through the dyadic arithmetic row, so the finite prefix cannot be replaced by an unrecorded host search.

The finite-window and Real-facing stages are W, R, E. The retained endpoints are first observed through StreamName windows, then repacked as regular rational data, and only then offered to the Real seal row.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for selected roots, quotient real equality, trichotomy, open-cover compactness, or ambient completeness, those principles cannot appear as local obligations. □

Theorem 2203.3 (Dyadic intermediate-value bisection route)**.** *Every branch read exported by an accepted* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *packet factors through*

$$\mathsf{IntermediateValue}^{\uparrow} \longmapsto I, S \longmapsto B, Q \longmapsto W, R.$$

Thus the packet consumes the intermediate-value sign route only as displayed finite sign data, refines it through a $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger and a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and exposes retained windows only through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*.*

Proof. Begin with an exported branch read. The only sign data visible to the packet are the rows I and S, so the read first passes through the located interval endpoint carrier and the displayed sign-change ledger inherited from the neighbouring intermediate-value route.

Next the retained child interval is read from B. The dyadic tolerance row Q supplies the midpoint arithmetic and width comparison attached to the branch prefix, so the branch read remains a finite dyadic bisection route.

Finally the retained endpoints are exposed through W and R. The StreamName windows record the finite observations, and the RegSeqRat row repacks them as regular rational readback. No selected root, quotient real, trichotomy decision, compactness argument, or ambient completeness theorem is used by the branch route. □

Theorem 2203.4 (DyadicIntermediateValue finite branch determinacy)**.** *Let*

$$D = (I, S, B, Q, W, R, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *carrier. Every accepted branch row in B is determined by the displayed located interval row I, sign ledger S, dyadic tolerance row Q,* $\mathsf{StreamName}^{\uparrow}$ *windows W, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route R before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed. The rows H, C, P, N transport, replay, source, and name this same finite determination.*

Consequently the packet exports no selected root, quotient stream, quotient real, trichotomy decision, unrecorded host search, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier $D = (I, S, B, Q, W, R, E, H, C, P, N)$. The branch ledger B is read only after the located interval row I and sign ledger S have displayed the endpoint and midpoint sign data.

Apply Definition 2203.3. It identifies the branch read as a finite route through $\mathsf{IntermediateValue}^{\uparrow}$, I, S, then B, Q, then W, R. Thus each accepted branch row is fixed by the displayed sign data, dyadic tolerance row, StreamName windows, and RegSeqRat readback before the Real-facing seal appears.

Finally apply Definition 2203.5. The handoff to E is downstream from I, S, B, Q, W, R and is preserved by H, C, P, N, so no hidden search or root-selection coordinate can be inserted after the branch row. □

Theorem 2203.5 (Dyadic intermediate-value Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *carrier receives the finite route*

$$I, S, B, Q, W, R, E, H, C, P, N.$$

The handoff reads the located endpoint packet, sign ledger, dyadic bisection prefix, dyadic tolerance row, finite StreamName windows, and RegSeqRat readback before the Real seal. It exports a finite bisection certificate, not a selected root, quotient real construction, trichotomy principle, open-cover compactness argument, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier $D = (I, S, B, Q, W, R, E, H, C, P, N)$. A Real-facing consumer can reach the seal only through the displayed continuation row C, whose route lists the interval, sign, branch, tolerance, window, and readback rows before E.

The sign and branch rows are finite. The rows I, S, B, Q bind the endpoint signs, midpoint signs, retained child intervals, and dyadic width comparisons before any readback row is visible.

The readback stage is W followed by R. StreamName exposes only the finite retained endpoint observations, and RegSeqRat turns those observations into the regular rational data consumed by the Real boundary.

The structural rows H, C, P, N preserve and name the same route. Therefore the Real seal handoff is exactly the displayed finite bisection certificate, with no available coordinate for selected roots, quotient reals, trichotomy, open-cover compactness, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntermediateValue}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicIntermediateValue}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint packet, an $\mathsf{IntermediateValue}^{\uparrow}$ sign ledger, a $\mathsf{DyadicBisection}^{\uparrow}$ branch prefix, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntermediateValue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2203.1, Definition 2203.2, Definition 2203.3, Definition 2203.4, and Definition 2203.5 seed the finite dyadic bisection certificate between the intermediate-value sign route and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntermediateValue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected roots, quotient reals, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-ledger visibility, dyadic branch exactness, finite-window discipline, Real-seal handoff, transport and replay stability, and provenance exhaustion for BEDC.Derived.DyadicIntermediateValu

Chapter 2204

A Concrete Naming Certificate for $\mathsf{Egorov}^{\uparrow}$

Following Egorov and Bishop–Bridges constructive measure theory, the $\mathsf{Egorov}^{\uparrow}$ packet records almost-everywhere convergence as finite exceptional-set and finite-window uniformity data rather than as a host measure-theoretic selector. It sits after the measurable carrier discipline of chapter 92, the probability-space ledger of chapter 184, the random-variable preimage surface of chapter 185, the stream observation windows of chapter 126, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The carrier keeps every convergence claim inside a displayed finite budget and exports no selected exceptional set, ambient almost-everywhere equality predicate, or completeness principle.

The exceptional-window row is a measure-window sibling of the finite cover ledger in chapter 2166 and forms a later consumer boundary for maximal-function domination routes such as chapter 3581. This dependency is only finite exceptional-window and ledger routing; it is not measure completion, selected null-set construction, or host almost-everywhere equality.

Definition 2204.1 (Egorov carrier)**.** *An* $\mathsf{Egorov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, \Omega, F, X, S, R, A, W, U, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Measure}^{\uparrow}$ *row whose measurable-set ledger supplies the finite exceptional-set budget.*
2. *Ω is the* $\mathsf{ProbSpace}^{\uparrow}$ *normalization row used to read the budget as a probability-bound request.*
3. *F is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *rows whose pointwise convergence boundary is being inspected.*
4. *X is the limiting* $\mathsf{RandomVar}^{\uparrow}$ *row, kept as a named random-variable packet rather than as a host almost-everywhere equivalence class.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for the family F and the limit row X.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route that turns each observed real value into a regular-rational comparison surface.*
7. *A is the finite exceptional-window row. It records the displayed measurable approximants, their finite measure budget, and the containment checks used by later uniformity reads.*

8. *W is the finite convergence window of indices, precision requests, and admissible observation sites outside A.*
9. *U is the uniformity row asserting that all reads in W meet the displayed regular-rational tolerance route outside the recorded exceptional window.*
10. *L is the measure ledger connecting A to M and Ω without selecting a countable exceptional set.*
11. *H records componentwise* hsame *transport for the measure, probability, random-variable, stream, regular-rational, exceptional-window, uniformity, ledger, replay, provenance, and local-name rows.*
12. *C records displayed* Cont *replay of the finite route*

$$M, \Omega, F, X, S, R, A, W, U, L \longmapsto H, P, N.$$

13. *P is the* Pkg *provenance over* $\mathsf{Egorov}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{Egorov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, \Omega, F, X, S, R, A, W, U, L, H, C, P, N$. It has no coordinate for full measure convergence theorems, countable choice, selected exceptional sets, host almost-everywhere equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EgorovUp.EgorovTasteGate single carrier alignment`

Theorem 2204.2 (Egorov NameCert obligations)**.** *For every accepted* $\mathsf{Egorov}^{\uparrow}$ *carrier*

$$E = (M, \Omega, F, X, S, R, A, W, U, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Egorov}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure row, probability row, finite random-variable family, limit random-variable row, finite stream observation schedule, regular-rational readback route, exceptional-window row, finite convergence window, uniformity row, measure ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public convergence read must pass through A, W, U, L before it can be exported as a local name.*

Proof. Project the accepted carrier in Definition 2204.1. The only convergence-facing rows are the exceptional-window row A, the finite convergence window W, the uniformity row U, and the measure ledger L.

The rows M, Ω, F, X, S, R supply the measurable, probabilistic, random-variable, stream, and regular-rational dependency surface on which those four rows are interpreted. The rows H, C, P, N transport, replay, source, and name exactly the same finite route.

Because no row stores a selected countable exceptional set, a host almost-everywhere equality predicate, a full measure convergence theorem, or an ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.EgorovUp.EgorovCarrier namecert obligations`

Theorem 2204.3 (Egorov finite-window uniformity)**.** *For every accepted* $\mathsf{Egorov}^{\uparrow}$ *carrier E, any public uniform-convergence read of E is determined by the displayed finite convergence window W together with the regular-rational readback route R and the uniformity row U. Refining the observation schedule through the same R, W, U leaves the public verdict unchanged outside the exceptional window A.*

Proof. The finite convergence window W lists the only indices, precision requests, and observation sites that the classifier may inspect. Each such request is evaluated through the regular-rational readback row R and then compared by the uniformity row U.

If the observation schedule is refined while the same R, W, U remain displayed, the classifier receives the same finite comparison data for every public read. The exceptional-window row A fixes the sites that are not part of the uniformity read, so the verdict outside A is unchanged. □

Lean4 ✓ `BEDC.Derived.EgorovUp.Egorov finite window uniformity`

Theorem 2204.4 (Egorov measure ledger nonescape)**.** *For every accepted* $\mathsf{Egorov}^{\uparrow}$ *carrier* E*, the measure information exported by the packet is exactly the finite ledger* L *attached to the exceptional-window row* A *and the ambient rows* M, Ω*. No consumer of the local* $\mathsf{NameCert}_{\mathsf{Egorov}^{\uparrow}}$ *may replace* L *by a selected exceptional set, a countable null-set union, host almost-everywhere equality, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness argument.*

Lean4 ✓ `BEDC.Derived.EgorovUp.Egorov measure ledger nonescape`

Proof. The measure-facing coordinates of the carrier are M, Ω, A, L. The ledger L records the finite budget and containment checks for the displayed exceptional window A against the ambient measure and probability rows.

All replay into the public certificate passes through C, whose source includes L but contains no row for a selected exceptional set, countable null-set union, host almost-everywhere equality, or completeness of $\mathsf{Real}^{\uparrow}$. Thus the local name can export only the finite measure ledger already present in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{Egorov}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Egorov}^{\uparrow}}$, obligation)

Scope closed: Definition 2204.1, Definition 2204.2, Definition 2204.3, and Definition 2204.4 seed the finite almost-everywhere uniformity packet over measure, probability, random-variable, stream, regular-rational, exceptional-window, uniformity, ledger, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Egorov}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full measure convergence theorems, countable choice, selected exceptional sets, host almost-everywhere equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exceptional-window budget exactness, finite-window uniformity, measure-ledger nonescape, componentwise transport, provenance, and local naming for BEDC.Derived.EgorovUp.

Constructive story: An $\mathsf{Egorov}^{\uparrow}$ packet is generated from Measure, ProbSpace, RandomVar, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 2205

A Concrete Naming Certificate for $\mathsf{UniformEntourageSpace}^{\uparrow}$

Following Kelley and Bourbaki on uniform spaces as entourage systems, the $\mathsf{UniformEntourageSpace}^{\uparrow}$ packet records the finite BEDC surface where diagonal, symmetry, refinement, and composition entourages are visible before any L10 completion consumer reads the route. It sits between the uniform-completion carrier of chapter 1473, the Cauchy-entourage request layer of chapter 1791, the real uniform structure of chapter 1624, and the metric completion boundary of chapter 1506. The packet names the entourage-side uniformity interface for completion handoff; it is not a quotient uniform space, a selected limit, an open-cover compactness theorem, countable choice, or ambient completeness.

Definition 2205.1 (Uniform entourage-space carrier)**.** *A* $\mathsf{UniformEntourageSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (E, D, S, R, C, L, T, K, P, N)$$

with the following displayed rows:

1. *E is the finite entourage-family row. It records the displayed binary neighborhoods used by every later Cauchy-entourage and completion-facing read.*
2. *D is the diagonal row, requiring each accepted entourage request to expose the finite diagonal witness it uses.*
3. *S is the symmetry row, recording the displayed reversal witness for the same entourage request.*
4. *R is the refinement row, recording how a smaller displayed entourage is chosen inside a larger displayed request without using a host filter quotient.*
5. *C is the composition row, recording the finite two-step entourage whose composite lies inside the requested entourage.*
6. *L is the L10 completion handoff row linking the displayed entourage data to* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyEntourageFilter}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$ *consumers.*
7. *T records componentwise* hsame *transport for the entourage family, diagonal, symmetry, refinement, composition, handoff, provenance, and local naming rows.*
8. *K records displayed* Cont *replay of the route*

$$E, D, S, R, C \longmapsto L \longmapsto T, P, N.$$

9. *P is the* Pkg *provenance over* UniformEntourageSpace$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CauchyEntourageFilter$^{\uparrow}$, RealUniformStructure$^{\uparrow}$, MetricCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{UniformEntourageSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $E, D, S, R, C, L, T, K, P, N$. The carrier has no coordinate for quotient uniform spaces, selected limits, open-cover compactness, countable choice, host equality, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.UniformEntourageSpaceUp.UniformEntourageSpaceTasteGate single carrier alignment`

Theorem 2205.2 (Uniform entourage-space NameCert obligations)**.** *For every accepted* UniformEntourageSpace$^{\uparrow}$ *carrier*

$$U = (E, D, S, R, C, L, T, K, P, N),$$

the local NameCert$_{\text{UniformEntourageSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the entourage family, diagonal, symmetry, refinement, composition, L10 handoff, transport, replay, provenance, and local naming rows;*
2. *diagonal, symmetry, refinement, and composition exactness, requiring every uniformity read to remain inside the displayed rows D, S, R, C attached to the same entourage-family row E;*
3. *completion handoff, requiring each* UniformCompletion$^{\uparrow}$, CauchyEntourageFilter$^{\uparrow}$, RealUniformStructure$^{\uparrow}$, *and* MetricCompletion$^{\uparrow}$ *consumer named by L or P to read the displayed entourage route before any completion-facing boundary is available;*
4. *transport and replay stability through componentwise* hsame *in T and displayed* Cont *replay in K;*
5. *provenance exhaustion, requiring P and N to export no quotient uniform space, selected limit, open-cover compactness theorem, countable-choice selector, host equality, ambient completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2205.1. The projection exposes the entourage-family row, diagonal row, symmetry row, refinement row, composition row, L10 handoff, transport, replay, provenance, and local naming rows.

The uniformity obligations are componentwise. Diagonal reads are confined to D, symmetry reads to S, refinement reads to R, and composition reads to C, all over the same displayed entourage family E.

The completion handoff is the row L. A consumer for UniformCompletion$^{\uparrow}$, CauchyEntourageFilter$^{\uparrow}$, RealUniformStructure$^{\uparrow}$, or MetricCompletion$^{\uparrow}$ reaches the completion corridor only after the displayed route E, D, S, R, C has been replayed.

Finally T, K, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient, selected-limit, compactness, choice, host-equality, completeness, verification, or bridge coordinate, these rows exhaust the local certificate surface. □

Theorem 2205.3 (Uniform entourage-space completion handoff)**.** *Every L10 completion consumer of an accepted* UniformEntourageSpace$^{\uparrow}$ *carrier factors through the displayed route*

$$E, D, S, R, C \longmapsto L \longmapsto T, K, P, N.$$

Thus the consumer first reads the finite entourage family together with its diagonal, symmetry, refinement, and composition witnesses, and only then reaches the completion-facing handoff row. No consumer receives a quotient uniform space, selected limit, open-cover compactness theorem, countable-choice selector, host equality, or ambient completeness principle from this packet.

Proof. Project the accepted carrier $U = (E, D, S, R, C, L, T, K, P, N)$. The only uniformity data available to a consumer are the displayed entourage row and its four structural witnesses.

The handoff row L is downstream of those witnesses. It can name $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyEntourageFilter}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ consumers only as readers of the already displayed entourage route.

The structural rows preserve the same order. Componentwise hsame in T and displayed Cont replay in K cannot introduce a new quotient, selected-limit, compactness, choice, host-equality, or completeness coordinate.

Therefore every completion-facing read factors through the stated finite route and remains an entourage-surface handoff rather than an ambient completion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEntourageSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformEntourageSpace}^{\uparrow}$ packet is generated from a finite entourage-family row, diagonal row, symmetry row, refinement row, composition row, L10 completion handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEntourageSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2205.1, Definition 2205.2, and Definition 2205.3 seed the Kelley–Bourbaki entourage surface feeding UniformCompletion, CauchyEntourageFilter, RealUniformStructure, and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEntourageSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient uniform spaces, selected limits, open-cover compactness, countable choice, host equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, diagonal exactness, symmetry exactness, refinement exactness, composition exactness, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformEntourageSpaceUp.

Chapter 2206

A Concrete Naming Certificate for $\mathsf{RealPrefixDiagnostic}^{\uparrow}$

Following Bishop–Bridges regular Cauchy real names and the finite-readback route of chapter 9238, the $\mathsf{RealPrefixDiagnostic}^{\uparrow}$ packet records the prefix-window diagnostic surface used before a $\mathsf{Real}^{\uparrow}$ seal is read. It sits after the finite cylinder interface of chapter 1685, the observation windows of chapter 126, the regular rational source rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite diagnostic object for the Real-completeness route; it is not a proof of $\mathsf{Real}^{\uparrow}$ completeness, a quotient of Cauchy names, a selected host limit, countable choice, trichotomy, or host real equality.

Definition 2206.1 (Real prefix-diagnostic carrier)**.** *A* $\mathsf{RealPrefixDiagnostic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, W, S, R, D, E, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{RealBaireCylinder}^{\uparrow}$ *prefix-cylinder row naming the finite branch of the real-name read.*
2. *W is the prefix-window budget row, recording the bounded observation depth and the precision request that opened the diagnostic.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row inspected inside the same finite window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the inspected StreamName entries.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row comparing the requested precision with the regular rational readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after B, W, S, R, D have been replayed.*
7. *A is the diagnostic answer row. It records pass, refine-window, or reject-at-prefix outcomes as finite rows rather than as host real decisions.*
8. *H records componentwise* hsame *transport for prefix cylinders, window budgets, StreamName rows, RegSeqRat readbacks, dyadic tolerances, Real seals, diagnostic answers, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay of the route*

$$B, W \longmapsto S \longmapsto R \longmapsto D \longmapsto E, A, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{RealPrefixDiagnostic}^{\uparrow}$, $\mathsf{RealBaireCylinder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealPrefixDiagnostic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $B, W, S, R, D, E, A, H, C, P, N$. The carrier has no coordinate for a completed real object, quotient Cauchy equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RealPrefixDiagnosticUp.RealPrefixDiagnosticTasteGate single carrier alignment`

Theorem 2206.2 (Real prefix-diagnostic NameCert obligations)**.** *For every accepted* $\mathsf{RealPrefixDiagnostic}^{\uparrow}$ *carrier*

$$Q = (B, W, S, R, D, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealPrefixDiagnostic}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the RealBaireCylinder prefix, prefix-window budget, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, diagnostic answer, transport, replay, provenance, and local naming rows;*
2. *prefix-window exactness, requiring every diagnostic request to read B and W before any StreamName entry is inspected;*
3. *regular readback discipline, requiring each inspected window to pass through S and R before the dyadic tolerance row D compares the requested precision;*
4. *Real-seal boundary, requiring the* $\mathsf{Real}^{\uparrow}$ *row E to be read only after the finite prefix, stream, regular-rational, and dyadic rows have been displayed;*
5. *diagnostic-answer confinement, requiring A to report only finite pass, refine-window, or reject-at-prefix rows and no host real decision;*
6. *transport, replay, and provenance exhaustion through H, C, P, N.*

No RealPrefixDiagnostic obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2206.1. The tuple displays the prefix cylinder, finite window budget, StreamName observations, RegSeqRat readback, dyadic tolerance, Real seal, diagnostic answer, and structural rows.

The prefix-window obligation reads B and W first. These rows bind the finite branch and depth of the diagnostic, so no later row can inspect an unbounded stream or a host real representative.

The regular readback obligation is the route through S, R, D. StreamName entries are inspected only within the displayed window, the regular rational row repacks that finite observation, and the dyadic row compares it with the requested tolerance.

The Real-seal boundary is row E, and the diagnostic answer is row A. The answer can report finite success, a request for a deeper window, or rejection at the displayed prefix, but it cannot decide equality of host reals or select a completed limit.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no completed-real, quotient, selected-limit, choice, trichotomy, host-equality, verification, or bridge coordinate, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RealPrefixDiagnosticUp.RealPrefixDiagnosticCarrier namecert obligations`

Theorem 2206.3 (Real prefix-diagnostic Real-seal readback)**.** *Every Real-completeness route consumer of an accepted* $\mathsf{RealPrefixDiagnostic}^{\uparrow}$ *packet factors its finite diagnostic read through*

$$B, W \longmapsto S \longmapsto R \longmapsto D \longmapsto E, A, H, C, P, N.$$

Thus prefix-cylinder data are inspected before StreamName rows, StreamName rows before RegSeqRat readback, RegSeqRat rows before dyadic tolerance comparison, and the $\mathsf{Real}^{\uparrow}$ *seal only after those finite rows are displayed. The packet exports no completed* $\mathsf{Real}^{\uparrow}$ *proof, quotient Cauchy class, selected host limit, countable-choice schedule, trichotomy, or host real equality.*

Proof. Begin with a finite diagnostic read for the Real-completeness route. The only prefix data exposed by the carrier are B and W, so the consumer first fixes the displayed cylinder and bounded observation depth.

The stream and rational readback stages then follow. The row S exposes only the StreamName entries inside that window, while R repacks those entries as regular rational readback data.

The tolerance check is row D. It compares the requested precision with the displayed readback before the Real seal is available.

Only then can the route read E and the diagnostic answer A. Transport through H, replay through C, and provenance through P, N preserve this order, so the consumer receives a finite prefix diagnostic rather than a completed-real or choice-based object. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealPrefixDiagnostic}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealPrefixDiagnostic}^{\uparrow}$ packet is generated from a RealBaireCylinder prefix row, finite prefix-window budget, StreamName row, RegSeqRat readback, DyadicRatCore tolerance row, RealUp seal row, diagnostic answer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealPrefixDiagnostic}^{\uparrow}}$, seed)

Scope closed: Definition 2206.1, Definition 2206.2, and Definition 2206.3 seed the finite prefix-window diagnostic route before a RealUp seal is read.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealPrefixDiagnostic}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, quotient Cauchy equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, prefix-window exactness, regular readback discipline, dyadic tolerance comparison, Real-seal boundary, diagnostic-answer confinement, transport, replay, provenance, and local naming for BEDC.Derived.RealPrefixDiagnosticUp.

Chapter 2207

A Concrete Naming Certificate for $\mathsf{BesselInequality}^{\uparrow}$

Following Riesz–Fischer/Hilbert-space treatments of Bessel's inequality, the $\mathsf{BesselInequality}^{\uparrow}$ packet records the finite BEDC surface where an orthogonal family, coefficient ledger, partial-square-sum bound, and norm handoff are visible before any Parseval, Fourier-series, orthogonal-projection, or Hilbert-completeness consumer reads the route. It sits beside the Hilbert carrier of chapter 91, the inner-product classifier of chapter 86, the norm surface of chapter 89, and the vector-space reduct of chapter 47. The packet names the inequality boundary only; it is not Parseval completeness, an orthogonal expansion theorem, a projection theorem, a selected orthonormal basis, or a host summability principle.

Definition 2207.1 (Bessel inequality carrier)**.** *A* $\mathsf{BesselInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (H, I, N, V, O, C, S, L, T, R, P, Q)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row naming the ambient complete inner-product space.*
2. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same carried vector endpoints, including the coefficient readback operation $\langle x, e\rangle_H$.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row over the same carrier, including the squared-norm comparison used by the inequality bound.*
4. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *reduct containing the zero, addition, scalar-action, finite-combination, and classifier rows used by the coefficient spine.*
5. *O is the orthogonal-family row, recording a finite displayed family $e_0, \ldots, e_{k-1}$ whose pairwise inner products classify as zero and whose norm rows classify as unit rows when the normalized form is requested.*
6. *C is the coefficient ledger row, recording the finite coefficient list $\langle x, e_i\rangle_H$ for a carried vector x and every displayed family position $i < k$.*
7. *S is the partial-square-sum row, recording the finite sum $\sum_{i<k} |\langle x, e_i\rangle_H|^2$ through the real scalar surface read from I and N.*

8. *L is the Hilbert-bound handoff row, recording the comparison*

$$\sum_{i<k} |\langle x, e_i\rangle_H|^2 \le \|x\|_H^2$$

as a displayed finite inequality row rather than as a host Hilbert-space theorem.

9. *T records componentwise* hsame *transport for Hilbert carriers, inner-product rows, norm rows, vector-space rows, orthogonal-family rows, coefficient ledgers, partial sums, handoff comparisons, replay, provenance, and local naming.*

10. *R records displayed* Cont *replay of the route*

$$H, I, N, V, O, C, S \longmapsto L \longmapsto T, P, Q.$$

11. *P is the* Pkg *provenance over* $\mathsf{BesselInequality}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *Q is the local* $\mathsf{NameCert}_{\mathsf{BesselInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $H, I, N, V, O, C, S, L, T, R, P, Q$. The carrier has no coordinate for Parseval equality, a complete orthonormal basis, projection minimization, Fourier convergence, choice of basis, host summability, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BesselInequalityUp.BesselInequalityTasteGate single carrier alignment`

Theorem 2207.2 (Bessel inequality NameCert obligations)**.** *For every accepted* $\mathsf{BesselInequality}^{\uparrow}$ *carrier*

$$B = (H, I, N, V, O, C, S, L, T, R, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{BesselInequality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the Hilbert, inner-product, norm, vector-space, orthogonal-family, coefficient-ledger, partial-square-sum, Hilbert-bound handoff, transport, replay, provenance, and local naming rows;*

2. *dependency coherence, requiring the* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, *and* $\mathsf{VecSpace}^{\uparrow}$ *rows to read the same carried vector endpoints and the same classifier route;*

3. *orthogonality exactness, requiring O to display the finite family positions and the pairwise zero inner-product rows used by the coefficient computation;*

4. *coefficient and square-sum exactness, requiring every coefficient in C and every summand in S to be read from the displayed inner-product and norm surfaces;*

5. *Hilbert-bound handoff, requiring the inequality row L to be downstream of O, C, S and upstream of any Parseval, Fourier-series, orthogonal-projection, or Hilbert-completeness consumer;*

6. *transport, replay, and provenance exhaustion through T, R, P, Q.*

No BesselInequality obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 2207.1. The tuple displays the Hilbert carrier, the inner-product and norm rows, the vector-space reduct, the orthogonal family, the coefficient ledger, the square-sum row, and the structural rows.

The dependency rows are read over the same carried endpoints. Thus the coefficient operation from $\mathsf{InnerProduct}^{\uparrow}$, the norm comparison from $\mathsf{Norm}^{\uparrow}$, and the finite linear-combination support from $\mathsf{VecSpace}^{\uparrow}$ remain tied to the ambient $\mathsf{Hilbert}^{\uparrow}$ carrier.

Orthogonality exactness is confined to O. Every coefficient in C is then obtained by reading the inner-product row against one displayed orthogonal-family entry, and S repacks those finitely many coefficient norms as the displayed partial square sum.

The bound row L is downstream of those finite rows. Since T, R, P, Q only transport, replay, source, and name the same route, the packet exports the Bessel inequality handoff and no Parseval equality, basis selection, projection minimizer, Fourier convergence, host summability, Lean verification, or bridge checking. □

Theorem 2207.3 (Bessel inequality Hilbert-bound handoff)**.** *Every downstream consumer of an accepted* $\mathsf{BesselInequality}^{\uparrow}$ *packet that uses the Hilbert bound factors through the displayed route*

$$H, I, N, V, O, C, S \longmapsto L \longmapsto T, R, P, Q.$$

Thus the consumer first reads the shared $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and* $\mathsf{VecSpace}^{\uparrow}$ *dependency surface, then the finite orthogonal family and coefficient square-sum ledger, and only then reaches the inequality row. The packet exports no Parseval equality, complete orthonormal basis, projection theorem, Fourier convergence theorem, selected basis, or host summability principle.*

Proof. Begin with an accepted packet $B = (H, I, N, V, O, C, S, L, T, R, P, Q)$. The shared dependency surface is visible first: H gives the Hilbert carrier, I gives coefficient readback, N gives the norm comparison, and V gives the finite vector-space operations.

The finite orthogonal-family and coefficient stages then follow. The row O supplies the displayed family and its orthogonality witnesses, C records the coefficient list for the carried vector, and S records the finite partial square sum.

Only after those rows are displayed can the consumer read L. Transport through T, replay through R, and provenance through P, Q preserve this order, so the downstream object receives a Hilbert-bound handoff rather than a stronger completeness, basis, projection, or Fourier-series theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{BesselInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BesselInequality}^{\uparrow}$ packet is generated from a Hilbert carrier row, inner-product row, norm row, vector-space reduct, finite orthogonal-family row, coefficient-ledger row, partial-square-sum row, Hilbert-bound handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BesselInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2207.1, Definition 2207.2, and Definition 2207.3 seed the finite Hilbert-space coefficient-bound surface consumed by Parseval, Fourier-series, orthogonal-projection, and Hilbert-completeness chapters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BesselInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Parseval equality, complete orthonormal bases, projection minimization, Fourier convergence, selected bases, host summability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, dependency coherence, orthogonality exactness, coefficient and square-sum exactness, Hilbert-bound handoff, transport, replay, provenance, and local naming for BEDC.Derived.BesselInequalityUp.

Chapter 2208

A Concrete Naming Certificate for $\mathsf{RegularFilterRealization}^{\uparrow}$

Following Bishop and Bridges and the Bourbaki–Kelley filterbase terminology, the $\mathsf{RegularFilterRealization}^{\uparrow}$ packet records the L10 finite route by which a displayed Cauchy filterbase is read as regular rational Cauchy data before a $\mathsf{Real}^{\uparrow}$ seal is admitted. It sits over the finite Cauchy filter surface of chapter 333, the basis factorization of chapter 1501, the regular filter package of chapter 1445, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a realization boundary, not a completeness principle: it names the finite rows consumed by the route from Cauchy filters to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seals without selecting quotient filters or host limits.

Definition 2208.1 (RegularFilterRealization carrier)**.** *A* $\mathsf{RegularFilterRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, A, G, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *finite-filterbase row, including its visible base packets, refinement relation, and Cauchy pressure ledger.*
2. *A is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *factorization row that exposes the selected finite basis windows used by the realization.*
3. *G is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *obligation package binding the filterbase, basis, stream, dyadic, regular readback, and seal rows into one route.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened by the basis and consumed by the regular readback.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the same windows, including endpoint and radius comparison rows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from A, S, D through the regular Cauchy filter package G.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, A, G, S, D, R have been displayed.*
8. *H records componentwise* hsame *transport for B, A, G, S, D, R, E and for the structural rows below.*

9. *C records the displayed* Cont *replay from filterbase refinements to basis windows, from windows and dyadic rows to the regular rational readback, and from the readback to the Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularFilterRealization}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularFilterRealization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven coordinates and their displayed transports. It has no coordinate for quotient filters, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 2208.2 (RegularFilterRealization NameCert obligations)**.** *For every accepted* $\mathsf{RegularFilterRealization}^{\uparrow}$ *carrier $F = (B, A, G, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularFilterRealization}^{\uparrow}}$ *surface consists exactly of:*

1. *CauchyFilter source exposure through B;*
2. *CauchyFilterBasis factorization through A;*
3. *RegularCauchyFilter obligation packaging through G;*
4. *StreamName finite-window exposure through S;*
5. *DyadicRatCore tolerance exactness through D;*
6. *RegSeqRat readback through R;*
7. *RealUp seal handoff through E;*
8. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

No obligation is discharged by a quotient filter, a selected host limit, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Project the carrier of Definition 2208.1. The visible coordinates are precisely $B, A, G, S, D, R, E, H, C, P, N$, so every local obligation must be read from those rows.

The source and basis side is finite. The row B supplies the Cauchy filterbase data, while A exposes the basis windows used by the realization. These rows place the construction in the same filterbase surface as chapter 333 and its basis factorization.

The regular readback is then forced through G, S, D, R. The package G binds the RegularCauchyFilter route, S lists the requested finite windows, D records their dyadic tolerance ledger, and R is the only regular rational readback row.

Finally E, H, C, P, N close the seal-facing certificate. Since the excluded quotient, choice, host-equality, completeness, and bridge coordinates are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularFilterRealizationUp.RegularFilterRealizationTasteGate single carrier alignment`

Theorem 2208.3 (RegularFilterRealization RegSeqRat factorization)**.** *Let $F = (B, A, G, S, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegularFilterRealization}^{\uparrow}$ *packet. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by F factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{RegularCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqR}$$

Concretely, the read first exposes B, then the basis row A, then the obligation package G, then the finite windows S and dyadic ledger D, and only then reaches the readback row R through the recorded H, C, P, N data. The factorization exports no quotient filter, selected limit, countable-choice selector, host real equality, or ambient completeness coordinate.

Proof. Start from the only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate in the carrier, namely R. By definition of F, this row is not stored independently of the filterbase data; it is downstream from B, A, G, S, D.

The filterbase is first read through B, and the displayed basis windows are then read through A. The obligation package G is the regular Cauchy filter row that ties those windows to the stream and dyadic data.

The finite readback step uses S and D. The schedule S lists exactly the requested windows, and D records the dyadic tolerance cells for those same windows. Thus the readback R is determined by displayed regular data rather than by a host-selected limit.

The remaining rows H, C, P, N transport, replay, package, and name the same route. No carrier coordinate remains for quotient filters, choice, host real equality, or ambient completeness, so none can be exported by the factorization. □

Theorem 2208.4 (RegularFilterRealization Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularFilterRealization}^{\uparrow}$ *packet factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row named in Definition 2208.3. The consumer may inspect the source filterbase B, the basis row A, the regular filter package G, the stream windows S, the dyadic ledger D, the regular readback R, and the structural rows H, C, P, N before reading the seal E. It receives no quotient-filter equality, selected host limit, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or checked bridge credential from the packet.*

Proof. Project the seal row E from the accepted carrier. The definition places E after the source filterbase, basis factorization, regular filter package, window schedule, dyadic ledger, and regular rational readback.

Apply Definition 2208.3 to the preceding readback. The Real-facing consumer must therefore pass through R, and R itself has already passed through B, A, G, S, D.

The structural rows do not add another seal route. They transport, replay, package, and name the same finite handoff. Since E is the only $\mathsf{Real}^{\uparrow}$ coordinate and the excluded principles are absent from the carrier, every seal read factors through the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularFilterRealization}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularFilterRealization}^{\uparrow}$ packet is generated from a CauchyFilter finite-filterbase row, a CauchyFilterBasis factorization row, a RegularCauchyFilter obligation package, StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp seal row, componentwise transport, displayed replay, package provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularFilterRealization}^{\uparrow}}$, seed)

Scope closed: Definition 2208.1, Definition 2208.2, Definition 2208.3, and Definition 2208.4 bind the finite realization route from Cauchy filters through basis windows and regular rational readback to the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularFilterRealization}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host real equality, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, CauchyFilter source exposure, CauchyFilterBasis factorization, RegularCauchyFilter package handoff, StreamName window exposure, DyadicRatCore tolerance exactness, RegSeqRat readback, and RealUp seal handoff for the same packet.

Chapter 2209

A Concrete Naming Certificate for $\mathsf{SchurMatrixSummability}^{\uparrow}$

Following Schur's matrix test and Hardy's summability treatment, the $\mathsf{SchurMatrixSummability}^{\uparrow}$ packet records the finite BEDC certificate by which a bounded matrix kernel sends regular real-name source windows through finite transformed rows without escaping the L10 readback discipline. It refines the matrix-window route of chapter 1682 and the regular matrix surface of chapter 2126, contains the Cesaro rows of chapter 1765 and chapter 1827 as named provenance surfaces, reads source and transformed rows through chapter 301, keeps rational coefficient and tolerance budgets inside chapter 291, and reaches the endpoint only through chapter 38. The chapter names the finite bounded-kernel summability certificate; it does not import a host Schur theorem, a completed infinite matrix, quotient equality of real-name streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2209.1 (Schur matrix summability carrier)**.** *A* $\mathsf{SchurMatrixSummability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, B, C, W, T, R, E, H, Q, P, N)$$

with the following displayed rows:

1. *M is the matrix coefficient-window row, listing finite matrix rows, finite column windows, coefficient approximants, truncation thresholds, and row requests currently inspected.*
2. *B is the row-bound ledger, recording the dyadic bounds that control the displayed row kernels before any transformed finite row is exposed.*
3. *C is the column-tail ledger, recording the displayed tail requests whose coefficient mass is certified small beyond the inspected finite column windows.*
4. *W is the source* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the source observations allowed to feed the displayed matrix windows.*
5. *T is the transformed finite-row surface constructed from the coefficient windows in M, the row-bound ledger B, the column-tail ledger C, and the source windows W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for both the source-window reads and the transformed rows exposed by T.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, B, C, W, T, R have been displayed.*

8. *H stores componentwise* hsame *transport for matrix windows, row bounds, column tails, source windows, transformed rows, regular readback, real seals, continuation rows, provenance, and local naming.*

9. *Q stores displayed* Cont *replay from matrix-row inspection to source-window selection, from row-bound and column-tail ledgers to transformed-row construction, from transformed rows to regular readback, and from readback to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SchurMatrixSummability}^{\uparrow}$, $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{SilvermanToeplitz}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchurMatrixSummability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, B, C, W, T, R, E, H, Q, P, N$. It has no coordinate for a host Schur theorem, a completed infinite matrix, quotient stream equality, selected external limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SchurMatrixSummabilityUp.SchurMatrixSummabilityTasteGate single carrier alignment`

Theorem 2209.2 (Schur matrix summability NameCert obligations)**.** *For every accepted* $\mathsf{SchurMatrixSummability}^{\uparrow}$ *carrier $K = (M, B, C, W, T, R, E, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SchurMatrixSummability}^{\uparrow}}$ *surface consists exactly of the following seven finite obligation rows:*

1. *carrier admission for the displayed matrix coefficient windows, row-bound ledger, column-tail ledger, source windows, transformed finite rows, regular readback, real seal, transport, continuation, provenance, and naming rows;*

2. *row-bound exactness, requiring every bounded-kernel claim used by the transform to be read from B after the corresponding coefficient windows in M have been displayed;*

3. *column-tail exactness, requiring every tail-smallness claim to pass through the displayed column-tail ledger C and the same finite matrix-window row M;*

4. *source-window transform construction, requiring every transformed row in T to be computed from M, B, C, W before any transformed read is exposed;*

5. *regular readback, requiring source-window and transformed-row reads to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R with dyadic budgets supplied by the same finite ledger data;*

6. *Real-seal nonescape, requiring the endpoint row E to remain downstream of M, B, C, W, T, R and to export no host summability or ambient completeness field;*

7. *ledger preservation, requiring H, Q, P, N to preserve the same finite route under componentwise transport, continuation replay, package provenance, and local naming.*

No obligation is stored outside these rows.

Proof. Project the carrier of Definition 2209.1. Carrier admission is exactly the displayed inventory $M, B, C, W, T, R, E, H, Q, P, N$, so the local certificate has no detached coordinate for an infinite matrix, a host Schur theorem, or an external completion principle.

The bounded-kernel rows are read before the transform. The inspected coefficient windows in M expose the finite row and column data, the row-bound ledger B controls the displayed row kernels, and the column-tail ledger C records the tail-smallness requests that remain after the finite windows have been chosen.

The source and transform rows are then forced. The only source observations are the $\mathsf{StreamName}^{\uparrow}$ windows W, and the transformed finite-row surface T is constructed from M, B, C, W. This is the Schur-bounded counterpart of the Toeplitz and Silverman–Toeplitz matrix routes referenced by P.

Finally the readback and seal rows close the route. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads both source and transformed windows, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of that readback. The structural rows H, Q, P, N transport, replay, source, and name the same packet, so the seven listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchurMatrixSummability}^{\uparrow}}$.

Constructive story: A $\mathsf{SchurMatrixSummability}^{\uparrow}$ packet is generated from finite matrix coefficient windows, a row-bound ledger, a column-tail ledger, source StreamName windows, transformed finite rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchurMatrixSummability}^{\uparrow}}$, seed)

Scope closed: Definition 2209.1 and Definition 2209.2 seed the bounded-kernel matrix summability certificate surface from finite matrix rows to L10 regular real-name readback and Real-facing seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchurMatrixSummability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Schur theorems, completed infinite matrices, selected source limits, quotient equality of real-name streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row-bound exactness, column-tail exactness, source-window transform construction, regular readback, Real-seal nonescape, ledger preservation, and TasteGate field faithfulness for BEDC.Derived.SchurMatrixSummabilityUp.

Chapter 2210

A Concrete Naming Certificate for $\mathsf{WeakDerivative}^{\uparrow}$

Following Evans and standard distribution theory, the $\mathsf{WeakDerivative}^{\uparrow}$ packet records the finite test-action surface by which a distribution-facing derivative is named without importing host differentiation. It sits after the distribution endpoint interface of chapter 186, the distribution-space test-action interface of chapter 8023, the Sobolev weak-gradient ledger of chapter 440, the real seal of chapter 38, the regular rational readback surface of chapter 301, and the finite stream windows of chapter 126. The chapter records only the finite carrier, its naming obligations, and the Sobolev handoff boundary.

Definition 2210.1 (Weak derivative carrier)**.** *A* $\mathsf{WeakDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, D, E, Q, W, H, C, P, N)$$

with the following displayed rows:

1. *A is the test-action row, listing the finite test probes, their displayed support windows, the sign convention for the chosen coordinate direction, and the source action values requested from the input object.*
2. *D is the* $\mathsf{Distribution}^{\uparrow}$ *row for the input distribution or locally integrable object, read only through the test actions named in A.*
3. *E is the candidate derivative row, giving a second distribution-facing action on the same displayed tests.*
4. *Q is the shared* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every displayed test action and candidate derivative action.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family that selects the finite test probes, readback windows, and comparison tolerances visible to this packet.*
6. *H stores componentwise* hsame *transport for the test-action, distribution, derivative, readback, window, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay for the route from test selection to distribution action, from distribution action to candidate derivative action, and from both actions to the shared readback row.*

8. *P is the* Pkg *provenance over* WeakDerivative$^\uparrow$, Distribution$^\uparrow$, Sobolev$^\uparrow$, Real$^\uparrow$, RegSeqRat$^\uparrow$, StreamName$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{WeakDerivative}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $A, D, E, Q, W, H, C, P, N$. It has no coordinate for a host derivative operator, a completed test-function space, quotient equality of distributions, density of smooth functions, integration by parts outside the displayed tests, or ambient Sobolev completeness.

Lean4 ✓ `BEDC.Derived.WeakDerivativeUp.WeakDerivativeTasteGate single carrier alignment`

Theorem 2210.2 (Weak derivative NameCert obligations)**.** *For every accepted* WeakDerivative$^\uparrow$ *carrier $K = (A, D, E, Q, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakDerivative}^\uparrow}$ *surface consists exactly of carrier admission for the nine displayed rows, test-action coverage through A, input distribution access through D, candidate derivative access through E, shared* Real$^\uparrow$ *and* RegSeqRat$^\uparrow$ *readback through Q, finite window selection through W, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 2210.1. The test-facing data available to the classifier are exactly the selected tests in A, the distribution action in D, the candidate derivative action in E, the readback row Q, and the stream windows W.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since the classifier has no coordinate for a host derivative operator, completed test-function space, quotient equality, density theorem, or ambient Sobolev completeness, those objects cannot discharge a local NameCert obligation.

Thus the obligation surface is exactly the displayed finite packet. □

Theorem 2210.3 (Weak derivative Sobolev handoff)**.** *Every* Sobolev$^\uparrow$ *consumer read exported by an accepted* WeakDerivative$^\uparrow$ *carrier factors through the finite route*

$$A \longmapsto D, E \longmapsto Q \longmapsto W \longmapsto H, C, P, N.$$

The handoff supplies only the displayed test-action ledger, distribution and candidate derivative actions, real and regular-rational readback, finite stream windows, transport, replay, provenance, and local naming. It does not supply a completed Sobolev space, quotient equality of functions, density of smooth tests, trace theory, compact embedding, or a host weak-gradient operator.

Proof. Start with a Sobolev-facing request for weak-derivative data. The carrier first fixes the test-action row A, so the request is constrained to the displayed finite probes and support windows.

The rows D and E then expose the input distribution action and the candidate derivative action on those same tests. The shared readback row Q and the window row W are the only places where real or regular-rational observations can be inspected.

Finally read H, C, P, N. These rows preserve and name the same finite route for the Sobolev$^\uparrow$ handoff, and no absent analytic object can be recovered from the carrier. □

Theorem 2210.4 (Weak derivative distribution-space boundary)**.** *Any* WeakDerivative$^\uparrow$ *read consuming a* DistributionSpace$^\uparrow$ *packet must expose the distribution-space test-action row, the candidate derivative action,* RegSeqRat$^\uparrow$ *and* Real$^\uparrow$ *scalar readback,* StreamName$^\uparrow$ *windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before that read can be used by* Sobolev$^\uparrow$.

Proof. Start with a weak-derivative read whose input action is supplied by a $\mathsf{DistributionSpace}^{\uparrow}$ packet. By Definition 8023.3, the distribution-space packet first exposes finite test windows and a scalar action ledger before any derivative-facing boundary can be consumed.

Read the $\mathsf{WeakDerivative}^{\uparrow}$ carrier next. The candidate derivative action is the row E, and the shared readback row Q supplies the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ scalar boundary for both the input action and the candidate derivative action.

The finite windows remain visible through W, while H, C, P, N transport, replay, source, and name the same route. Applying Definition 2210.3 then forces the Sobolev-facing consumer to pass through those rows before any handoff is accepted. □

Falsifiable prediction: Every $\mathsf{WeakDerivative}^{\uparrow}$ Sobolev-facing read factors through a displayed test-action row, distribution action row, candidate derivative row, shared RealUp and RegSeqRatUp readback, StreamName windows, hsame transport, Cont replay, package provenance, and local naming row.

Independence witness: distribution, sobolev, real, regseqrat, streamname: $\mathsf{WeakDerivative}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the test-action ledger, the input distribution action, the candidate derivative action, shared readback, finite windows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakDerivative}^{\uparrow}$ packet is generated from finite test-action rows, an input DistributionUp row, a candidate derivative row, shared RealUp and RegSeqRatUp readback, StreamName windows, componentwise transports, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2210.1, Definition 2210.2, Definition 2210.3, and Definition 2210.4 bind the finite weak-action surface over $\mathsf{Distribution}^{\uparrow}$, $\mathsf{DistributionSpace}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed test-function spaces, quotient equality of distributions, density of smooth functions, integration by parts beyond displayed tests, Sobolev completeness, compact embedding, trace theory, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, test-action exactness, readback stability, Sobolev handoff nonescape, and TasteGate field faithfulness for BEDC.Derived.WeakDerivativeUp.

Chapter 2211

A Concrete Naming Certificate for $\mathsf{UniformCompleteSpace}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces, the $\mathsf{UniformCompleteSpace}^{\uparrow}$ packet records the displayed completeness property of a uniform-space carrier as finite Cauchy-filter convergence data. It sits after the completion interfaces of chapter 1506 and chapter 1473, reads the Cauchy-filter and Cauchy-net surfaces of chapter 333 and chapter 589, and keeps separated comparison available through chapter 1411. The packet generalizes the metric-completion route by recording convergence of displayed uniform Cauchy data without constructing quotient completions, choosing representatives, invoking countable choice, importing open-cover compactness, or asserting completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2211.1 (Uniform complete-space carrier)**.** *A* $\mathsf{UniformCompleteSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, F, N, M, C, Q, R, E, H, T, P, A)$$

with the following displayed rows:

1. *S is the underlying uniform-space row, carrying the finite entourage filterbase, diagonal, refinement, symmetry, and composition data inspected by completion-facing consumers.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row admitted over S.*
3. *N is the* $\mathsf{CauchyNet}^{\uparrow}$ *row giving the directed-window presentation of the same Cauchy demand when a net-style consumer is used.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row available when the uniform data is read through a displayed metric-completion presentation.*
5. *C is the* $\mathsf{UniformCompletion}^{\uparrow}$ *comparison row available when the uniform data is read through the existing uniform-completion presentation.*
6. *Q is the convergence boundary row asserting that the displayed Cauchy filter has a completion-facing limit route inside the packet.*
7. *R is the regular rational readback row exposed only after S, F, N, M, C, Q have been displayed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for numerical readback consumers.*
9. *H records componentwise* hsame *transport for the uniform surface, Cauchy data, completion comparisons, convergence boundary, readback, seal, continuation, provenance, and local naming rows.*

10. *T records displayed* Cont *replay from a finite entourage request through Cauchy-filter or Cauchy-net data, completion comparison, convergence boundary, readback, and seal.*
11. *P is the* Pkg *provenance over* $\mathsf{UniformCompleteSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformCompleteSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient completions, selected representatives, countable choice, open-cover compactness, host uniform equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCompleteSpaceUp.UniformCompleteSpaceTasteGate single carrier alignment`

Theorem 2211.2 (Uniform complete-space NameCert obligations)**.** *For every accepted* $\mathsf{UniformCompleteSpace}^{\uparrow}$ *carrier* $U = (S, F, N, M, C, Q, R, E, H, T, P, A)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCompleteSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed uniform-space row, Cauchy-filter row, Cauchy-net row, metric-completion comparison, uniform-completion comparison, convergence boundary, regular readback, Real seal, transport, replay, provenance, and local naming row;*
2. *Cauchy request factorization, requiring every accepted completion-facing read to begin with the same finite entourage data in S and then pass through either F or N before any completion comparison is exposed;*
3. *completion comparison discipline, requiring M and C to compare only the displayed metric and uniform completion presentations of the same Cauchy route;*
4. *Cauchy-filter seal routing, requiring Q to remain downstream of S, F, N, M, C and upstream of only R, E, H, T, P, A;*
5. *separated comparison non-escape, allowing separated reads only through the provenance named by P and never through host equality or quotient completion equality;*
6. *ledger non-escape, excluding quotient completions, selected representatives, countable choice, open-cover compactness, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2211.1. The projection exposes exactly $S, F, N, M, C, Q, R, E, H, T, P, A$.

Cauchy request factorization begins with the finite entourage surface S. The request is then read through the displayed filter row F or the directed net row N, so a completion-facing consumer receives Cauchy evidence before it sees any completion comparison.

The completion comparison rows M and C are downstream of that Cauchy route. They compare the metric-completion and uniform-completion presentations of the same displayed request, and the convergence boundary Q is sealed only after those presentations have been read.

Finally R, E, H, T, P, A provide readback, terminal sealing, componentwise transport, replay, provenance, and local naming for the same route. Since no listed row is a quotient completion, selected representative, choice schedule, open-cover compactness certificate, or proof of $\mathsf{Real}^{\uparrow}$ completeness, the local NameCert surface cannot export any of those objects. □

Theorem 2211.3 (Uniform complete-space Cauchy-filter seal)**.** *Let* $U = (S, F, N, M, C, Q, R, E, H, T, P, A)$ *be an accepted* $\mathsf{UniformCompleteSpace}^{\uparrow}$ *carrier. Every Cauchy-filter convergence read factors through the displayed route*

$$S \longmapsto F, N \longmapsto M, C \longmapsto Q \longmapsto R, E \longmapsto H, T, P, A.$$

Thus the packet seals the finite Cauchy-filter route for uniform completeness without adding quotient completions, selected representatives, countable choice, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Cauchy-filter convergence read. The uniform-space row S fixes the finite entourage demand before any Cauchy or completion row is inspected.

The Cauchy data is then displayed by F and, when a directed presentation is needed, by N. Both rows remain tied to the same request from S.

The comparison rows M and C read the metric-completion and uniform-completion presentations of that displayed Cauchy route. The boundary row Q is downstream of those comparisons, so the convergence seal is attached to the visible filter and net data rather than to a host completed object.

The readback and terminal rows R and E are exposed only after Q, while H, T, P, A transport, replay, source, and name the same route. The carrier therefore has no row from which quotient completions, selected representatives, countable choice, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompleteSpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompleteSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2211.1, Definition 2211.2, and Definition 2211.3 seed the finite uniform completeness packet over displayed uniform, Cauchy-filter, Cauchy-net, metric-completion, uniform-completion, separated-comparison, readback, and seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompleteSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, open-cover compactness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy request factorization, completion comparison discipline, Cauchy-filter seal routing, separated comparison non-escape, and ledger non-escape for BEDC.Derived.UniformCompleteSpac

Constructive story: A $\mathsf{UniformCompleteSpace}^{\uparrow}$ packet is generated from a uniform-space row, CauchyFilter and CauchyNet rows, MetricCompletion and UniformCompletion comparison rows, a convergence boundary, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2212

A Concrete Naming Certificate for MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$

The MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$ packet realizes the finite critical-pair boundary suggested by chapter 9378. It sits between the redex-frontier surface of chapter 1008, the closed-normal confluence fragment of chapter 737, the bounded equality checker of chapter 752, and the subject-reduction route classifier of chapter 785. The critical-pair table is a consumer of chapter 1008, and the common-reduct table is bounded by chapter 737 before any bounded equality checker is read. The packet names displayed critical-pair and common-reduct rows; it is not a global confluence theorem.

Falsifiable prediction: Any accepted MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$ packet exports only displayed critical-pair and common-reduct rows, together with redex-frontier, normal-fragment, bounded-checker, route-classifier, transport, replay, provenance, and local naming data. It exports no global confluence theorem.

Independence witness: MetaCICRedexFrontier$^{\uparrow}$, MetaCICConfluenceNormalFragment$^{\uparrow}$, BoundedNormalEqualityCh and SubjectReductionRouteClassifier$^{\uparrow}$: these siblings respectively expose redex-frontier rows, closed-normal confluence fragments, bounded normal-equality checking, and subject-reduction route classification; none is bijective with a packet that jointly records critical-pair enumeration and common-reduct boundary rows.

Definition 2212.1 (MetaCIC confluence critical-pair boundary carrier)**.** *A* MetaCICConfluenceCriticalPairBoundary *carrier is a finite* BHist *packet*

$$B = (R, K, J, E, D, S, U, H, C, P, N)$$

with the following displayed rows:

1. *R is the* MetaCICRedexFrontier$^{\uparrow}$ *row from which beta-redex, application, lambda-domain, and Pi-domain frontier cells are read.*
2. *K is the critical-pair table row, listing the finite overlapping frontier cases inspected by the packet.*
3. *J is the common-reduct table row, listing the displayed join candidates for the accepted critical-pair rows.*
4. *E is the* BoundedNormalEqualityChecker$^{\uparrow}$ *row used to compare bounded normal forms when a join candidate is checked by bounded normal equality.*

5. *D is the* $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$ *row used for closed normal and atom-shaped source cases.*
6. *S is the* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *separation row, recording that subject-reduction discharge routes are named separately from confluence critical-pair rows.*
7. *U is the boundary row stating that the packet does not prove arbitrary closed-term Church–Rosser, full parallel diamond, or residual-substitution compatibility.*
8. *H records componentwise* hsame *transport for the frontier, critical-pair table, common-reduct table, bounded-checker, normal-fragment, route-classifier, boundary, provenance, and local naming rows.*
9. *C records displayed* Cont *replay by which audit consumers read the critical-pair table and common-reduct table before any bounded checker or normal-fragment handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$, $\mathsf{MetaCICRedexFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a global confluence theorem, arbitrary closed-term Church–Rosser, full parallel diamond, residual-substitution compatibility, or unchecked subject-reduction discharge.

Theorem 2212.2 (MetaCIC confluence critical-pair boundary obligations)**.** *For every accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier* $B = (R, K, J, E, D, S, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConf}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the redex-frontier row, critical-pair table, common-reduct table, bounded equality checker, closed-normal fragment, subject-reduction route classifier, boundary row, transport, replay, provenance, and local naming row;*
2. *critical-pair display, requiring each accepted pair to be read from the finite frontier cases in R and K;*
3. *common-reduct display, requiring each accepted join candidate to be read from J before any bounded checker or normal-fragment row is consumed;*
4. *bounded and normal handoff, requiring E and D to consume only the displayed critical-pair and common-reduct rows;*
5. *subject-reduction separation, requiring S to keep typing-discharge routes outside the confluence boundary;*
6. *ledger non-escape, requiring U, P, N to export no global confluence theorem, arbitrary closed-term Church–Rosser, full parallel diamond, or residual-substitution compatibility.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2212.1. The projection exposes exactly $R, K, J, E, D, S, U, H, C, P, N$.

The critical-pair display obligation reads R and K first. Thus the packet can only enumerate finite frontier overlaps that are explicitly recorded in the carrier.

The common-reduct display obligation is downstream of that enumeration. The row J supplies the join candidates before the bounded checker E or the closed-normal fragment D may be consulted.

The subject-reduction row S separates typing-discharge routes from the confluence boundary, and U records the non-claim surface. Since the remaining rows H, C, P, N only transport, replay, source, and name the displayed route, the packet cannot export global confluence or residual-substitution compatibility. □

Theorem 2212.3 (MetaCIC confluence critical-pair common-reduct boundary)**.** *Let $B = (R, K, J, E, D, S, U, H, C$ be an accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier. Every confluence audit read from B factors through the displayed route*

$$R \longmapsto K \longmapsto J \longmapsto E, D \longmapsto S, U \longmapsto H, C, P, N.$$

Consequently the packet supplies a finite critical-pair and common-reduct boundary, not a proof of arbitrary closed-term Church–Rosser, full parallel diamond, residual-substitution compatibility, or subject-reduction discharge.

Proof. Start with an audit consumer of the packet. The consumer first reads the redex-frontier row R and then the critical-pair table K, so the inspected cases are finite displayed rows.

The common-reduct table J is read next. Any bounded normal-equality check or closed-normal confluence fragment receives only the join candidates already displayed by J.

The route-classifier row S and boundary row U then fix the non-claim surface. They keep subject-reduction discharge and residual-substitution compatibility outside the packet.

Finally H, C, P, N transport, replay, source, and name the same finite route. No row in the carrier is a global confluence theorem, full parallel diamond, or unchecked subject-reduction proof. □

Theorem 2212.4 (MetaCIC critical-pair subject-reduction separation)**.** *Let $B = (R, K, J, E, D, S, U, H, C, P, N)$ be an accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier. Subject-reduction information can be exposed from B only through the displayed row S. The row S is a boundary classifier: it keeps typing-discharge routes outside the critical-pair table K and the common-reduct table J. Therefore no confluence audit consumer may treat critical-pair joins as subject-reduction discharge.*

Proof. Project the carrier of Definition 2212.1. The projection displays the route-classifier row S separately from the redex-frontier row R, the critical-pair table K, and the common-reduct table J.

Apply Definition 2212.2. Its row inventory names subject-reduction separation as an obligation attached to S, while the critical-pair display and common-reduct display obligations are attached to K and J.

Now apply Definition 2212.3. The confluence audit route reads R, K, J before it reaches E, D and then S, U, so the typing-discharge boundary is downstream of the common-reduct rows rather than hidden inside them.

Thus a consumer may inspect subject-reduction information only by reading S as the displayed boundary classifier. The finite critical-pair and common-reduct rows remain confluence-boundary data, not subject-reduction discharge. □

Theorem 2212.5 (MetaCIC confluence critical-pair local join)**.** *Let $B = (R, K, J, E, D, S, U, H, C, P, N)$ be an accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier. Any displayed critical pair listed by K may be consumed as joinable only through a corresponding common-reduct row in J, then*

through the bounded normal-equality checker row E or the closed-normal fragment row D. It may not be consumed as arbitrary closed-term Church–Rosser evidence, full parallel diamond evidence, or residual-substitution compatibility.

Proof. Project the carrier of Definition 2212.1. The critical-pair table is the row K, and the only row that can name a join candidate for an entry of K is the common-reduct table J.

Apply Definition 2212.3. It forces every confluence audit read through R, K, J before the bounded checker E or closed-normal fragment D is consumed.

The rows S and U record the non-claim separation. They keep subject-reduction discharge, arbitrary closed-term Church–Rosser, full parallel diamond, and residual-substitution compatibility outside the local critical-pair packet, while H, C, P, N only transport, replay, source, and name the displayed finite route. □

Theorem 2212.6 (MetaCIC critical-pair local-join coverage)**.** *Let $B = (R, K, J, E, D, S, U, H, C, P, N)$ be an accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier. Every critical-pair row accepted in K and consumed as locally joinable has its corresponding join candidate displayed in J. Verification of that candidate factors through either the bounded normal-equality row E or the closed-normal fragment row D before the subject-reduction separation row S can be read.*

Proof. Project the carrier of Definition 2212.1. The projection separates the critical-pair table K, the common-reduct table J, the bounded normal-equality checker E, the closed-normal fragment D, and the subject-reduction separation row S.

Apply Definition 2212.2 and Definition 2212.3. The obligations attach critical-pair display to K and common-reduct display to J, while the common-reduct boundary forces the verification route through E or D before any downstream boundary row is consumed.

Finally apply Definition 2212.4 and Definition 2212.5. Local joinability is therefore a finite K, J, E, D coverage claim, with S read only as the later subject-reduction boundary and not as a hidden proof of global confluence. □

Theorem 2212.7 (MetaCIC critical-pair residual-join boundary)**.** *Let $B = (R, K, J, E, D, S, U, H, C, P, N)$ be an accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier. Residual-style join evidence can be exposed from B only through the displayed route*

$$K, J, E, D, S, U, H, C, P, N.$$

The route records finite critical-pair rows, common-reduct rows, bounded normal-equality or closed-normal checks, subject-reduction separation, boundary data, transport, replay, provenance, and local naming. It does not supply residual-substitution compatibility, a global parallel diamond, or an unchecked confluence theorem.

Proof. Project the carrier of Definition 2212.1. The critical-pair table K and common-reduct table J are the only rows from which a residual-style join read can begin.

Use the common-reduct boundary of Definition 2212.3. It forces a consumer to read the common-reduct table before any bounded normal-equality row E or closed-normal fragment row D is used.

Apply the subject-reduction separation theorem Definition 2212.4. The row S keeps typing-discharge routes outside the critical-pair and common-reduct tables, so residual-style join evidence cannot be treated as subject-reduction discharge.

Finally apply the local-join coverage theorem Definition 2212.6. Local joinability is exhausted by the finite K, J, E, D coverage route, and the rows U, H, C, P, N only record the boundary,

transport, replay, source, and name. Residual-substitution compatibility and a global parallel diamond are therefore outside the accepted packet. □

Theorem 2212.8 (MetaCIC critical-pair residual-substitution obstruction route)**.** *Let $B = (R, K, J, E, D, S, U, H,$ be an accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carrier. Any residual-substitution-shaped consumer of B must route through*

$$K, J, E, D, S, U, H, C, P, N.$$

It may read residual-style data only as an obstruction boundary for the local critical-pair packet, not as residual-substitution compatibility, global parallel diamond evidence, or full confluence.

Proof. Project the carrier of Definition 2212.1. The projection exposes the critical-pair table K, common-reduct table J, bounded checker E, closed-normal fragment D, subject-reduction boundary S, non-claim boundary U, and structural rows H, C, P, N.

Use the common-reduct boundary of Definition 2212.3. Any consumer that starts from a critical-pair row must pass through J before it may consult E or D.

Apply Definition 2212.4 and Definition 2212.6. These results keep subject-reduction discharge separated at S and exhaust local joinability by the finite K, J, E, D coverage route.

Finally apply Definition 2212.7. The residual read is already classified as boundary data, and no carrier row supplies residual-substitution compatibility or a global parallel diamond. Therefore a residual-substitution-shaped consumer can only read an obstruction boundary through $K, J, E, D, S, U, H, C, P, N$. □

Theorem 2212.9 (MetaCIC confluence critical-pair field-faithful prediction)**.** *Let $B = (R, K, J, E, D, S, U, H, C, P$ and $B' = (R', K', J', E', D', S', U', H', C', P', N')$ be accepted* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *carriers. If their displayed field projections agree componentwise on $R, K, J, E, D, S, U, H, C, P, N$, then they expose the same critical-pair and common-reduct boundary route. In particular, the critical-pair table K and common-reduct table J cannot be erased or replaced by aliases of $R, E, D, S, U, H, C, P, N$ without changing the public packet classifier.*

Proof. Project both carriers through Definition 2212.1. Componentwise equality of the displayed fields identifies the same redex-frontier row, the same critical-pair table, the same common-reduct table, the same bounded and normal checker rows, and the same boundary classifier route.

Apply Definition 2212.3. The confluence audit route must read R, K, J before it reaches E, D, S, U, so agreement of all displayed projections fixes the same critical-pair and common-reduct boundary route.

Finally apply Definition 2212.5. A displayed critical pair is joinable only through its corresponding row in J. Erasing K or J would remove a field used by the local join route, so the public classifier changes rather than preserving a field-faithful packet. □

Theorem 2212.10 (MetaCIC confluence critical-pair nontrivial witness surface)**.** *There are two classifier-separated* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *packet surfaces: one whose K, J boundary rows are empty and whose U row records that no displayed critical-pair join is available, and one with a displayed critical-pair row in K together with a corresponding common-reduct row in J. The separation is witnessed by the K, J, U fields and is visible to the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}}$ *classifier.*

Proof. Read the carrier definition. The fields K and J are independent displayed rows: K lists inspected critical pairs, and J lists the corresponding common-reduct candidates.

For the empty surface, the classifier reads empty K, J rows together with the boundary row U that denies a displayed local join route. For the inhabited surface, the classifier reads one critical-pair entry in K and the matching common-reduct entry in J before U records the bounded boundary route.

Apply Definition 2212.3 and Definition 2212.5. The local join claim cannot be consumed without the displayed K, J rows, so the empty and inhabited surfaces are separated by K, J, U rather than by an external confluence principle. □

The Lean obligation for this packet is to provide `Nontrivial MetaCICConfluenceCriticalPairBoundaryUp` and `FieldFaithful MetaCICConfluenceCriticalPairBoundaryUp` TasteGate instances when the carrier is formalized. Those instances must check that the critical-pair table and common-reduct table are genuine fields of the carrier, not aliases for the global confluence boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2212.1, Definition 2212.2, and Definition 2212.3 seed the finite MetaCIC critical-pair and common-reduct boundary over redex-frontier, normal-fragment, bounded-checker, route-classifier, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary closed-term Church–Rosser, full parallel diamond, residual-substitution compatibility, subject-reduction discharge, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, critical-pair display, common-reduct display, bounded and normal handoff, subject-reduction separation, ledger non-escape, and TasteGate nontriviality and field faithfulness for BEDC.Derived.MetaCICConfluenceCriticalPairBoundaryUp.

Constructive story: A $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ packet is generated from a MetaCICRedexFrontier row, a finite critical-pair table, a common-reduct table, BoundedNormalEqualityChecker and MetaCICConfluenceNormalFragment rows, a SubjectReductionRouteClassifier separation row, a boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2213

A Concrete Naming Certificate for $\mathsf{GeodesicMetric}^{\uparrow}$

Following Burago–Burago–Ivanov and Bridson–Haefliger on geodesic metric spaces, the $\mathsf{GeodesicMetric}^{\uparrow}$ packet records a displayed finite segment witness inside a metric carrier. It sits over the metric source of chapter 57, reads closed-ball membership through chapter 1451, and remains adjacent to the completion and compactness frontiers of chapter 128, **??**, and chapter 2035. The packet names a finite segment handoff for later compactness and completion consumers; it is not a host path space, not a selected geodesic object, not a quotient path-equality principle, and not an ambient completeness assertion.

Definition 2213.1 (GeodesicMetric carrier)**.** *A* $\mathsf{GeodesicMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, E, T, S, A, C, R, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, displayed endpoint-distance request, and the metric comparison rows used by every segment read.*
2. *E records the two endpoint histories over M, together with the endpoint classifier rows used to transport the segment request.*
3. *T is the finite segment-parameter row, a bounded rational or dyadic address ledger for the visible subsegment reads.*
4. *S is the displayed segment witness row: for the endpoint pair in E, it lists the finite intermediate point reads and the source-distance observations through M.*
5. *A is the distance-additivity or midpoint-budget ledger. It records either that the displayed subsegment distances add to the endpoint distance within the visible tolerance budget, or that the displayed midpoint windows split the endpoint budget into the two certified subreads requested by the consumer.*
6. *C records componentwise* hsame *transport for the metric row, endpoint rows, parameter row, segment witness, additivity or midpoint ledger, replay, provenance, and local naming rows.*
7. *R is the displayed* Cont *replay row, requiring every segment read to be regenerated from M, E, T, S, A, C before any consumer may inspect it.*

8. *P is the* Pkg *provenance over* $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{GeodesicMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, T, S, A, C, R, P, N$. It has no coordinate for host path spaces, selected geodesics, quotient path equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.GeodesicMetricUp.GeodesicMetricTasteGate single carrier alignment`

Theorem 2213.2 (GeodesicMetric NameCert obligations)**.** *For an accepted* $\mathsf{GeodesicMetric}^{\uparrow}$ *carrier*

$$G = (M, E, T, S, A, C, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GeodesicMetric}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint compatibility over the displayed* $\mathsf{Met}^{\uparrow}$ *row, finite parameter admission, segment-witness exactness, additivity or midpoint-budget exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows of Definition 2213.1. No obligation row asserts a host path object, a globally selected geodesic, quotient equality of paths, or completeness of the ambient metric space.*

Proof. Carrier admission is projection from Definition 2213.1. The accepted packet displays the metric source, the two endpoint rows, the finite parameter ledger, the segment witness, and the additivity or midpoint-budget row before the transport and naming rows are read.

Endpoint compatibility is metric-local. The row E may be transported only along the point classifier exposed by M, so every endpoint-distance request remains inside the same $\mathsf{Met}^{\uparrow}$ source.

Segment exactness is finite. The rows T and S list only the visible parameter windows, intermediate point reads, and distance observations required by the current witness. The row A then records the visible additivity or midpoint-budget comparison through those same distance observations.

Transport and replay are structural. Componentwise hsame in C preserves the metric source, endpoints, parameter row, segment witness, and budget ledger, while R, P, and N replay and name exactly that finite route.

The excluded objects are absent from the carrier inventory. Since no row stores host paths, selected geodesics, quotient path equality, or ambient completeness, no local NameCert obligation can export them. □

Theorem 2213.3 (GeodesicMetric segment handoff)**.** *Every completion-facing, compactness-facing, or closed-ball-facing read of an accepted* $\mathsf{GeodesicMetric}^{\uparrow}$ *carrier factors through the finite route*

$$M, E, T, S, A \longmapsto C, R, P, N.$$

Thus a later $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, *or* $\mathsf{DoublingMetric}^{\uparrow}$ *consumer receives only the displayed metric row, endpoint rows, finite segment-parameter row, segment witness, additivity or midpoint-budget ledger, componentwise transport, replay, provenance, and local naming rows. The handoff does not import host path spaces, selected geodesics, quotient path equality, or ambient completeness.*

Proof. Project the accepted carrier. The metric source is M, and every endpoint or closed-ball query first reads the endpoint rows in E through that source.

The segment data are T, S, A. The parameter row T bounds the visible requests, S supplies the displayed intermediate point and distance observations, and A exposes the finite additivity or midpoint-budget comparison that a consumer may use.

The remaining rows do not enlarge the analytic object. The transport row C preserves the same coordinates componentwise, and the replay, provenance, and naming rows R, P, N require the consumer to regenerate the same finite route before accepting the segment handoff.

Therefore completion, properness, doubling, and closed-ball consumers can use the displayed witness only through those rows. The carrier contains no path-space object, selected geodesic, path quotient, or completeness row from which a stronger conclusion could be read. □

Theorem 2213.4 (GeodesicMetric path-length handoff)**.** *Every* $\mathsf{LengthSpace}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{GeodesicMetric}^{\uparrow}$ *carrier*

$$G = (M, E, T, S, A, C, R, P, N)$$

must read the $\mathsf{Met}^{\uparrow}$ *source, endpoint rows, finite segment-parameter row, displayed segment witness, additivity or midpoint-budget ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{GeodesicMetric}^{\uparrow}}$ *row before treating the segment as a path-length witness. The handoff reaches chapter 2082 only through those displayed rows and does not import host path spaces, quotient path equality, selected geodesics, or ambient completeness.*

Proof. Project the accepted carrier. Its metric source is M, its endpoint data are E, and its finite segment route is the row sequence T, S, A.

Apply Definition 2213.3. The segment handoff already forces every consumer to read the finite parameter row, displayed segment witness, additivity or midpoint-budget ledger, and the structural rows C, R, P, N before using the witness.

The $\mathsf{LengthSpace}^{\uparrow}$ consumer of chapter 2082 therefore receives a path-length witness only as this finite metric segment route. Since the carrier stores no host path space, path quotient, selected global geodesic, or ambient completeness row, none of those stronger objects can enter the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{GeodesicMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GeodesicMetric}^{\uparrow}$ packet is generated from a MetricUp source, endpoint rows, a finite segment-parameter row, a displayed segment witness, an additivity or midpoint-budget ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GeodesicMetric}^{\uparrow}}$, seed)

Scope closed: Definition 2213.1, Definition 2213.2, and Definition 2213.3 seed the finite segment-witness surface for later metric closed-ball, completion, properness, and doubling consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GeodesicMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host path spaces, selected geodesics, quotient path equality, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint compatibility, finite parameter admission, segment-witness exactness, additivity or midpoint-budget exactness, transport stability, replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.GeodesicMetricUp.

Chapter 2214

A Concrete Naming Certificate for CauchySeriesProduct$^{\uparrow}$

Following Hardy and Knopp on products of series, the CauchySeriesProduct$^{\uparrow}$ packet records the constructive product route by which two accepted real-series source rows expose a Cauchy product only through finite convolution windows, tail budgets, regular rational readback, and a real seal. It consumes the finite partial-sum discipline of RealSeries$^{\uparrow}$ in chapter 1581, the convolution ledger of CauchyConvolution$^{\uparrow}$ in chapter 409, the fast product surface of FastSeriesProduct$^{\uparrow}$ in chapter 368, the absolute convergence route of AbsoluteConvergence$^{\uparrow}$ in chapter 1700, and the majorant tail accounting of CauchyMajorantSeries$^{\uparrow}$ in chapter 1774. The packet names the finite certificate by which a product series is admitted; it does not import a host theorem on Cauchy products, selected infinite sums, quotient equality of series, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 2214.1 (Cauchy series product carrier)**.** *A* CauchySeriesProduct$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, C, B, M, R, E, H, P, N)$$

with the following displayed rows:

1. *S and T are the two* RealSeries$^{\uparrow}$ *source rows. They expose only inspected term windows, finite partial sums, and source tail requests already admitted by the real-series packet.*
2. *C is the finite* CauchyConvolution$^{\uparrow}$ *window row. It records the inspected convolution diagonals, product-prefix windows, and finite coefficient multiplications used by the current request.*
3. *B is the product-budget row. It is supplied either by the* AbsoluteConvergence$^{\uparrow}$ *route or by the* CauchyMajorantSeries$^{\uparrow}$ *route, and it records the displayed tail bounds needed to control the omitted convolution terms.*
4. *M is the* FastSeriesProduct$^{\uparrow}$ *handoff row. It repacks the displayed source windows and the convolution row as the finite product surface consumed by downstream readers.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the displayed product partial sums and for every source-window read used by C and M.*
6. *E is the* Real$^{\uparrow}$ *seal reached only after S, T, C, B, M, R have been displayed.*
7. *H stores componentwise* hsame *transport for the two source rows, convolution windows, product budgets, fast-product handoff, regular readback, real seal, provenance, and local naming row.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchySeriesProduct}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchyConvolution}^{\uparrow}$, $\mathsf{FastSeriesProduct}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySeriesProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, C, B, M, R, E, H, P, N$. It has no coordinate for a host Cauchy product theorem, an unbounded convolution sum, a selected real limit, quotient equality of series, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySeriesProductUp.TasteGate.CauchySeriesProductTasteGate single carrier alignment`

Theorem 2214.2 (Cauchy series product NameCert obligations)**.** *For every accepted* $\mathsf{CauchySeriesProduct}^{\uparrow}$ *carrier $K = (S, T, C, B, M, R, E, H, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySeriesProduct}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two displayed* $\mathsf{RealSeries}^{\uparrow}$ *source rows, finite convolution windows, product budgets, fast-product handoff, regular readback, real seal, transport, provenance, and local naming row;*
2. *source-window exactness, requiring every product term inspected by C to be read from the displayed finite windows of S and T;*
3. *convolution-window exactness, requiring every product-prefix row to pass through the finite* $\mathsf{CauchyConvolution}^{\uparrow}$ *row C before the fast-product handoff is exposed;*
4. *tail-budget exactness, requiring each omitted convolution contribution to be bounded by the displayed* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *or* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *budget row B;*
5. *regular readback, requiring every product partial-sum read to pass through R after C, B, M have been displayed;*
6. *Real-seal nonescape, requiring the endpoint row E to remain downstream of the finite readback and to export no host product theorem, selected infinite sum, quotient equality, or ambient completeness;*
7. *provenance and naming preservation, requiring H, P, N to preserve the same finite route under transport, package sourcing, and local certificate comparison.*

No obligation is stored outside these rows.

Proof. Project the carrier of Definition 2214.1. The two source rows S, T expose only the finite real-series windows and partial-sum data named by the source packets, so the product certificate begins with displayed series data rather than a host infinite sequence.

The convolution and product rows are then forced. The row C records the finite Cauchy-convolution windows, and M repacks those windows as the fast product handoff. Every inspected product term is therefore read through S, T, C, M.

The tail budget is separate but still finite. The row B supplies either an absolute-convergence budget or a majorant-series budget, so omitted convolution terms are controlled by displayed tail rows before any regular readback is exported.

Finally the readback and seal close the route. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads the product partial sums, the $\mathsf{Real}^{\uparrow}$ seal E is downstream of that readback, and H, P, N transport, source, and name the same packet. The listed rows therefore exhaust the local NameCert surface. □

Theorem 2214.3 (Cauchy series product RealSeries handoff)**.** *Every endpoint-facing read from an accepted* $\mathsf{CauchySeriesProduct}^{\uparrow}$ *carrier factors through the two source* $\mathsf{RealSeries}^{\uparrow}$ *rows* S, T*, the finite* $\mathsf{CauchyConvolution}^{\uparrow}$ *window row* C*, the displayed absolute or majorant tail budget* B*, the* $\mathsf{FastSeriesProduct}^{\uparrow}$ *handoff row* M*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the structural rows* H, P, N*. A consumer receives no host multiplication theorem for series, no selected infinite convolution sum, no quotient equality of term streams, no countable-choice selector, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with the source rows. The carrier admits only the two displayed $\mathsf{RealSeries}^{\uparrow}$ packets, so every product read first chooses the finite source windows visible in S and T.

Next pass through the product route. The convolution row C builds the inspected Cauchy-product windows, the budget row B controls the omitted tails by absolute or majorant evidence, and the fast-product row M records the finite handoff visible to downstream product consumers.

Finally read the endpoint. The row R supplies the regular rational readback of the displayed product partial sums, and E is the only real-facing seal. Since the structural rows H, P, N preserve this same route, the handoff cannot expose any unlisted analytic object. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySeriesProduct}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySeriesProduct}^{\uparrow}$ packet is generated from two RealSeries source rows, finite convolution windows, an absolute or majorant tail budget, a FastSeriesProduct handoff, RegSeqRat readback, a RealUp seal, componentwise hsame transport, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySeriesProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2214.1, Definition 2214.2, and Definition 2214.3 seed the finite constructive product-of-series certificate from two RealSeries source rows through convolution windows, tail budgets, regular readback, and RealUp endpoint sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySeriesProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Cauchy product theorems, selected infinite convolution sums, quotient equality of series, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, convolution-window exactness, tail-budget exactness, regular readback, Real-seal nonescape, provenance preservation, and TasteGate field faithfulness for BEDC.Derived.CauchySeriesProductUp.

Chapter 2215

A Concrete Naming Certificate for RegulatedUniformApproximation$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the RegulatedUniformApproximation$^{\uparrow}$ packet separates the finite step-schedule data used to approximate a regulated function uniformly from the later integration interface. It sits between the regulated-function surface of chapter 1554, the dyadic step-function rows of chapter 428, the uniform-limit route of chapter 463, the closed interval domain of chapter 1448, and the terminal real seal of chapter 38. Its role is to expose a finite approximation route, not to assert integration, host function-space equality, or ambient completeness.

Definition 2215.1 (Regulated uniform approximation carrier)**.** *A* RegulatedUniformApproximation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, A, T, U, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* ClosedUnitInterval$^{\uparrow}$ *domain row, including the interval endpoints and order data consumed by the approximation schedule;*
2. *A is the finite* DyadicStepFunction$^{\uparrow}$ *step ledger, recording the displayed step partitions, carried values, and dyadic tolerances;*
3. *T is the uniform tail schedule, naming the finite threshold and tolerance comparisons used to read the approximation as a uniform route;*
4. *U is the* UniformLimit$^{\uparrow}$ *handoff row that consumes A and T before any later regulated-function or integration-facing consumer sees the packet;*
5. *E is the* Real$^{\uparrow}$ *seal row read through the regular rational windows and* RegSeqRat$^{\uparrow}$ *readback data attached to the displayed step values;*
6. *H stores componentwise* hsame *transports for the interval, step ledger, uniform schedule, uniform-limit route, real seal, provenance, and local name;*
7. *C stores the displayed* Cont *replay routes from a domain request through the selected step row, the uniform schedule, the handoff row, and the real seal;*
8. *P is the* Pkg *provenance over* RegulatedUniformApproximation$^{\uparrow}$, RegulatedRealFunction$^{\uparrow}$, DyadicStepFunction$^{\uparrow}$, UniformLimit$^{\uparrow}$, ClosedUnitInterval$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedUniformApproximation}^{\uparrow}}$ *row.*

The carrier has no coordinate for a Darboux sum, Riemann sum, regulated integral, quotient of functions, open-cover compactness proof, selected real representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegulatedUniformApproximationUp.RegulatedUniformApproximationTasteGate`
`single carrier alignment`

Theorem 2215.2 (Regulated uniform approximation NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedUniformApproximation}^{\uparrow}$ *packet $R = (I, A, T, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedUniformApproximation}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed interval, step ledger, uniform schedule, handoff route, real seal, transport, replay, provenance, and local name;*
2. *step-ledger exactness, requiring every approximation read to use the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *rows in A over the* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *row I;*
3. *uniform approximation stability, requiring the tail schedule T to control all later step reads at the displayed tolerance;*
4. $\mathsf{UniformLimit}^{\uparrow}$ *handoff, requiring every regulated-function or integration-facing consumer to factor through U before reaching the real seal row E;*
5. *real-seal non-escape, requiring every terminal read to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal data displayed by E.*

No local obligation is stored outside those five rows.

Proof. Carrier admission is projection from Definition 2215.1. The accepted packet exposes only the rows $I, A, T, U, E, H, C, P, N$.

The step-ledger row is governed by I and A. A domain read first enters the closed interval row and then selects one of the displayed dyadic step-function rows; there is no host function value outside this finite ledger.

The uniform side is governed by T and U. The tail schedule records the common tolerance route, and the uniform-limit handoff consumes that schedule before any downstream consumer reaches E.

The remaining rows transport, replay, source, and name the same packet. Since no coordinate stores integration, function quotients, compactness, selected representatives, or ambient completeness, no NameCert obligation can export them. □

Theorem 2215.3 (Regulated uniform approximation step-ledger exactness)**.** *Every approximation read of an accepted* $\mathsf{RegulatedUniformApproximation}^{\uparrow}$ *packet factors through the* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *row I and one displayed* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row in the ledger A. The read obtains its partition, carried value, and dyadic tolerance data from that finite row, not from a host function-space representative.*

Proof. Read the carrier definition. The only approximation coordinate is A, and it is scoped by the interval row I.

The continuation row C sends a domain request to I before selecting a step row in A. Componentwise transport in H preserves the same interval and selected step row under classifier comparison.

Thus an approximation read has no route around I and A. Any value or tolerance not displayed by the selected dyadic step-function row is outside the accepted packet. □

Theorem 2215.4 (Regulated uniform approximation stability)**.** *If two accepted reads of a* RegulatedUniformApprox *packet use step rows past the threshold named by the uniform tail schedule T, then their comparison is routed through the same displayed tolerance schedule and the same* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row U. The stability claim is therefore a finite schedule claim over A, T, U, not an ambient completeness claim about all real-valued functions.*

Proof. Start with the schedule row T. It is the only coordinate that names common thresholds for the step ledger A.

The handoff row U consumes exactly that schedule as a uniform-limit route. Therefore any comparison of sufficiently late displayed steps must be replayed through T and then through U.

The carrier omits ambient function-space limits and completeness data. Stability is consequently confined to the displayed schedule and its uniform-limit handoff. □

Theorem 2215.5 (Regulated uniform approximation UniformLimit handoff)**.** *Every later* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *consumer, and every later integration-facing consumer that reads this packet through a regulated-function surface, must factor through*

$$I, A, T \longmapsto U \longmapsto E.$$

The handoff supplies the closed interval row, dyadic step ledger, uniform schedule, $\mathsf{UniformLimit}^{\uparrow}$ *route, and terminal* $\mathsf{Real}^{\uparrow}$ *seal, but it supplies no Darboux, Riemann, or regulated-integral row.*

Proof. Use step-ledger exactness to place every approximation read at I and A. Use uniform approximation stability to place every sufficiently late comparison at T and U.

The carrier then exposes E only after the handoff through U. Structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming.

Because no integration coordinate occurs in $R = (I, A, T, U, E, H, C, P, N)$, downstream integration chapters may consume this handoff as input data but cannot read integration as part of the approximation packet itself. □

Theorem 2215.6 (Regulated uniform approximation real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegulatedUniformApproximation}^{\uparrow}$ *packet reaches the terminal seal only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback data attached to E after the interval, step-ledger, uniform schedule, and* $\mathsf{UniformLimit}^{\uparrow}$ *rows have been read. It exports no selected real representative, quotient function equality, countable-choice schedule, integration row, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier. The only terminal real-facing coordinate is E, and its provenance row records the regular rational readback and real seal dependency rather than a host real value.

The preceding theorems force every read of E to pass through I, A, T and U. The structural rows do not add analytic content; they transport, replay, source, and name the same finite packet.

Therefore any route requiring selected representatives, quotient equality, choice, integration, compactness, or ambient completeness has no coordinate in the accepted carrier and is rejected at the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedUniformApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedUniformApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2215.1, Definition 2215.2, Definition 2215.3, Definition 2215.4, Definition 2215.5, and Definition 2215.6 seed the finite step-schedule approximation surface over interval, dyadic step, uniform tail, uniform-limit, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedUniformApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Darboux integration, Riemann integration, regulated integrals, host function-space equality, open-cover compactness, selected real representatives, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, step-ledger exactness, uniform approximation stability, UniformLimit handoff, Real-seal non-escape, and field faithfulness for the same packet.

Constructive story: A RegulatedUniformApproximation$^{\uparrow}$ packet is generated from a ClosedUnitInterval domain row, a finite DyadicStepFunction step ledger, a uniform tail schedule, a UniformLimit route, RegSeqRat readback and Real seal data, componentwise transport, displayed continuation replay, package provenance, and local naming.

Chapter 2216

A Concrete Naming Certificate for $\mathsf{CauchyLocatedness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyLocatedness}^{\uparrow}$ packet records locatedness as finite witness data for regular Cauchy real names. It sits over the regular rational source of chapter 301, the finite stream-window schedule of chapter 126, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the quotient-respecting comparison discipline of chapter 1820. The packet exposes locatedness witnesses without replacing them by Dedekind cuts, host real equality, selected limits, countable choice, trichotomy, or ambient completeness.

Definition 2216.1 (Cauchy locatedness carrier)**.** *A* $\mathsf{CauchyLocatedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, W, D, Q, V, H, C, P, N)$$

with the following displayed rows:

1. *R is the regular Cauchy source row, read as a* $\mathsf{RegSeqRat}^{\uparrow}$ *name before any* $\mathsf{Real}^{\uparrow}$ *consumer receives a sealed real-name boundary.*
2. *W is the finite observation window row, a* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the inspected Cauchy stages, rational intervals, and comparison requests.*
3. *D is the dyadic tolerance request row, carried by* $\mathsf{DyadicRatCore}^{\uparrow}$ *and recording the requested scale, positive margin, endpoint enclosure, and exhausted window ledger.*
4. *Q is the Cauchy-equivalence comparison row, tying the witness to the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *surface so equivalent regular Cauchy names replay the same finite locatedness route.*
5. *V is the displayed located witness row. For each requested dyadic tolerance and rational test window, it records the finite inside-or-apart evidence available from R, W, D, Q.*
6. *H records componentwise* hsame *transport for the regular source, stream windows, dyadic request, equivalence comparison, located witness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from R, W, D into Q, from Q into the witness row V, and from V into the terminal* $\mathsf{Real}^{\uparrow}$ *readback boundary.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyLocatedness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $R, W, D, Q, V, H, C, P, N$. It has no coordinate for Dedekind cuts, host real equality, selected limits, countable choice, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyLocatednessUp.CauchyLocatednessTasteGate single carrier alignment`

Theorem 2216.2 (Cauchy locatedness window stability)**.** *Let $L = (R, W, D, Q, V, H, C, P, N)$ be an accepted* $\mathsf{CauchyLocatedness}^\uparrow$ *carrier. If a consumer refines the displayed* $\mathsf{StreamName}^\uparrow$ *observation window while preserving the same dyadic tolerance request and Cauchy-equivalence comparison row, then the located witness row replays through H and C to the same local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^\uparrow}$ *surface. The refined read exposes only the regular Cauchy source, finite windows, dyadic request, equivalence comparison, displayed located witness, and structural rows.*

Proof. Project the accepted carrier. The only rows available to a window-refining consumer are the regular source R, stream-window schedule W, dyadic request D, equivalence comparison Q, located witness V, and structural rows H, C, P, N.

Refining the observation window changes only which finite prefix of W is inspected. The dyadic request row D and equivalence comparison row Q remain the same request data, so the witness row V is read by replaying the displayed route rather than by selecting a new real representative.

Componentwise hsame in H transports the source, window, dyadic, comparison, and witness rows. The Cont row C then replays the route from R, W, D into Q and from Q into V before any terminal $\mathsf{Real}^\uparrow$ read is exposed.

Thus the refined read has the same local NameCert surface. Since no carrier coordinate stores host equality, Dedekind cuts, selected limits, countable choice, trichotomy, or completeness, window refinement cannot introduce any of those objects. □

Theorem 2216.3 (Cauchy locatedness NameCert obligation)**.** *For every accepted* $\mathsf{CauchyLocatedness}^\uparrow$ *carrier $L = (R, W, D, Q, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^\uparrow}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the regular Cauchy source row, finite observation windows, dyadic tolerance request, Cauchy-equivalence comparison row, located witness row, transport, replay, provenance, and local naming row;*
2. *witness exactness, requiring V to read only the displayed R, W, D, Q route and to return finite inside-or-apart evidence for the requested dyadic tolerance;*
3. *equivalence stability, requiring Q to keep equivalent regular Cauchy names on the same locatedness route before the terminal* $\mathsf{Real}^\uparrow$ *boundary is read;*
4. *window stability, requiring refinements of W to replay through H and C as in Definition 2216.2;*
5. *ledger exhaustion, excluding Dedekind cuts, host real equality, selected limits, countable choice, trichotomy, and ambient completeness.*

No locatedness obligation is stored outside these rows.

Proof. Project the carrier L. The projection exposes exactly the regular Cauchy source, finite window schedule, dyadic request ledger, equivalence comparison, located witness, componentwise transport, continuation replay, provenance, and local naming row.

The witness obligation is finite. The row V consumes the displayed source, windows, dyadic tolerance, and equivalence comparison, then records the inside-or-apart evidence visible at that request.

The equivalence obligation is carried by Q. It prevents a consumer from changing the locatedness witness by switching to an equivalent regular Cauchy name outside the displayed comparison route.

The stability obligation is Definition 2216.2. Window refinements replay through the same transport and continuation rows, so the local NameCert surface remains the one named by N.

Finally, P records only the listed sibling certificates and N names only this packet. Since the carrier has no other coordinate, the five obligations exhaust the local $\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyLocatedness}^{\uparrow}$ packet is generated from a regular Cauchy source row, finite StreamName observation windows, a DyadicRatCore tolerance request, a CauchyEquivalenceSetoid comparison row, a displayed located witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2216.1, Definition 2216.2, and Definition 2216.3 seed the finite locatedness witness packet for regular Cauchy real names over RegSeqRat, StreamName, DyadicRatCore, RealUp, and CauchyEquivalenceSetoid rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLocatedness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, host real equality, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.CauchyLocatednessUp covering the nine-row carrier, window stability, and local NameCert obligations.

Chapter 2217

A Concrete Naming Certificate for $\mathsf{SobolevEmbedding}^{\uparrow}$

Following Adams and Fournier on Sobolev spaces, the $\mathsf{SobolevEmbedding}^{\uparrow}$ packet records the finite BEDC naming surface for an embedding assertion read from a Sobolev source certificate into a normed, Banach, Hilbert, metric, or compact-metric target certificate. It is a recognised analysis neighbour of chapter 440, chapter 89, chapter 90, chapter 91, chapter 57, chapter 129, and chapter 38. The chapter does not import a host function space; it names the displayed dependency rows that later PDE and functional-analysis certificates can cite.

Definition 2217.1 (Sobolev embedding carrier)**.** *A* $\mathsf{SobolevEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, N, E, T, R, L, P)$$

with the following displayed rows:

1. *D records the domain regularity and scalar* $\mathsf{Real}^{\uparrow}$ *boundary on which the source observations are read;*
2. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, including the visible weak-derivative, integrability, and base-metric rows supplied by chapter 440;*
3. *N is the target norm row, read through* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{Banach}^{\uparrow}$*, or* $\mathsf{Hilbert}^{\uparrow}$ *according to the named target surface;*
4. *E records the exponent and regularity comparison rows that license the displayed embedding estimate;*
5. *T is the target readback row, which may point to normed, Banach, Hilbert, metric, or compact-metric evidence but never to a hidden host function;*
6. *R stores the componentwise* hsame *transport for the domain, Sobolev source, norm target, exponent rows, target readback, ledger, and provenance rows;*
7. *L is the finite ledger stating the norm-bound budget and the source-to-target observations consumed by the embedding read;*
8. *P is the* Pkg *provenance over* $\mathsf{SobolevEmbedding}^{\uparrow}$*,* $\mathsf{Sobolev}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*, together with the local naming row.*

The carrier has no coordinate for a host function representative, almost-everywhere quotient equality, Rellich compactness, full PDE regularity, open-cover compactness, countable choice, or a selected subsequence.

Lean4 ✓ `BEDC.Derived.SobolevEmbeddingUp.SobolevEmbeddingTasteGate single carrier alignment`

Theorem 2217.2 (Sobolev embedding NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{SobolevEmbedding}^{\uparrow}}$ *surface for the carrier of Definition 2217.1 consists exactly of the following finite obligations:*

1. *carrier admission: an accepted packet exposes only* $Q = (D, S, N, E, T, R, L, P)$ *and admits no hidden analytic coordinate;*
2. *classifier stability: two accepted packets compare only through componentwise* hsame *transport of the domain, Sobolev source, norm target, exponent, target readback, ledger, provenance, and naming rows;*
3. *derivative-row transport: the weak-derivative observations inherited from* S *remain attached to the same embedding read whenever* R *transports the displayed rows;*
4. *norm-bound ledger preservation: the estimate recorded in* L *is preserved under the same displayed transport and cannot be strengthened by an unrecorded bound;*
5. *target readback: every target observation factors through* T *and through the named* $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{CompactMetric}^{\uparrow}$ *surface;*
6. *ledger non-escape: no consumer can recover Rellich compactness, full PDE regularity, open-cover compactness, host function equality, choice, or a selected representative from the packet.*

Proof. Carrier admission is projection from the eight displayed rows of Q. The source and target data are visible certificates, and the local packet contains no row for host functions or external compactness.

For classifier stability, compare two packets row by row using the stored hsame routes in R. The Sobolev source, norm target, exponent rows, target readback, ledger, provenance, and local naming row are transported componentwise.

Derivative-row transport and norm-bound preservation are ledger facts. The derivative observations are those already exposed by S, while the bound is the row stored in L; the replay can reread those rows but cannot create an additional derivative or a sharper estimate.

Finally, target readback is forced through T and the named neighbouring certificates. Since the carrier has no coordinate for the excluded analytic principles, ledger exhaustion gives the non-escape boundary. □

Theorem 2217.3 (Sobolev embedding finite-energy localization)**.** *Every accepted* $\mathsf{SobolevEmbedding}^{\uparrow}$ *packet exposes only the displayed local Sobolev, norm, metric, exponent, transport, and ledger data in* D, S, N, E, T, R, L, P*. The finite source rows may localize an energy or derivative budget to the named embedding read, but they do not assert Rellich compactness, full PDE regularity, open-cover compactness, host function equality, countable choice, or a selected representative.*

Proof. Inspect a downstream consumer of the embedding packet. It can read the domain row D, the Sobolev source row S, the norm target row N, the exponent and regularity rows E, the target readback T, the transport ledger R, the norm-bound ledger L, and the provenance row P.

This is enough to localize the finite energy or weak-derivative budget named by the source rows. It is not enough to produce compactness, regularity, host equality, choice, or representatives, because none of those objects appears as a row of the carrier or as an output of the componentwise transport. □

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{SobolevEmbedding}^{\uparrow}$ packet is generated from a domain-regularity row, a $\mathsf{Sobolev}^{\uparrow}$ source row, a displayed norm or functional-analysis target row, exponent and regularity comparison rows, target readback, componentwise hsame transport, a finite norm-bound ledger, provenance, and local naming evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SobolevEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2217.1, Definition 2217.2, and Definition 2217.3 seed the finite embedding-read surface over Sobolev, Norm, Banach, Hilbert, Metric, CompactMetric, and Real neighbours.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SobolevEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Rellich compactness, full PDE regularity, open-cover compactness, host function equality, countable choice, selected representatives, or a Lean theorem.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked NameCert obligation theorem for the same displayed Sobolev embedding packet.

Chapter 2218

A Concrete Naming Certificate for $\mathsf{RellichKondrachov}^{\uparrow}$

Following Rellich and Kondrachov, in the form used by Adams–Fournier for Sobolev spaces, the $\mathsf{RellichKondrachov}^{\uparrow}$ packet records the finite compact-embedding route from a bounded Sobolev window into a compact metric target window. It sits after the weak-derivative and Sobolev embedding surfaces of chapter 2210 and chapter 2217, and it cites the Sobolev carrier of chapter 440, the compact and complete metric witnesses of chapter 129 and chapter 128, and the scalar readback of chapter 38. The chapter names only the finite subsequence-window ledger and the compactness route visible to BEDC consumers.

Definition 2218.1 (Rellich–Kondrachov carrier)**.** *A* $\mathsf{RellichKondrachov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, W, S, E, C, M, T, L, H, P, N)$$

with the following displayed rows:

1. *D records the bounded domain, boundary regularity, scalar* $\mathsf{Real}^{\uparrow}$ *readback, and finite coordinate windows in which the compact-embedding statement is inspected.*
2. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *row, read through chapter 2210, that fixes the weak-action observations used by the Sobolev source.*
3. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row from chapter 440, including the derivative-order, integrability, and boundedness ledger visible to the compactness route.*
4. *E is the* $\mathsf{SobolevEmbedding}^{\uparrow}$ *comparison row from chapter 2217; it records the exponent inequality and the embedding read without asserting compactness by itself.*
5. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *target row from chapter 129, restricted to the finite sequential compactness windows named by this packet.*
6. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-readback row from chapter 128, used only to read the displayed limit-window tests.*
7. *T stores the finite tolerance scale and subsequence-window schedule, listing for each requested observation window the bounded Sobolev source window, the target metric tolerance, and the compact-metric witness window.*
8. *L is the compact-embedding ledger. It records that the route*

$$W, S, E, D \longmapsto C, M, T$$

is the only available path from bounded Sobolev data to compact target observations.

9. *H stores componentwise* hsame *transport for $D, W, S, E, C, M, T, L, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RellichKondrachov}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{SobolevEmbedding}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RellichKondrachov}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected subsequence, open-cover compactness, quotient function space, host function representative, countable choice, full PDE regularity, trace theory, or ambient $\mathsf{Real}^{\uparrow}$ *completeness beyond the displayed real readbacks.*

Lean4 ✓ `BEDC.Derived.RellichKondrachovUp.RellichKondrachovTasteGate single carrier alignment`

Theorem 2218.2 (Rellich–Kondrachov NameCert obligations)**.** *For every accepted* $\mathsf{RellichKondrachov}^{\uparrow}$ *carrier $R = (D, W, S, E, C, M, T, L, H, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RellichKondrachov}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, weak-derivative access through W, Sobolev source access through S, embedding comparison access through E, compact-metric target access through C, complete-metric Cauchy readback through M, finite subsequence-window scheduling through T, compact-route ledger preservation through L, componentwise* hsame *transport through H, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from the displayed packet of Definition 2218.1. The analytic inputs are only the weak-derivative, Sobolev, embedding, compact-metric, complete-metric, and real readback rows named in $D, W, S, E, C, M, T, L, H, P, N$.

The obligation surface is therefore exhausted row by row. The weak action is read through W, the Sobolev boundedness data through S, the exponent and embedding comparison through E, and the compact target windows through C and M.

The subsequence evidence is not a chosen subsequence. It is the finite schedule in T together with the ledger L, so a consumer may replay a requested compactness window but cannot select an infinite object outside the packet.

Finally, H, P, N transport, source, and name the same rows. Since no remaining coordinate contains open-cover compactness, quotient function spaces, host representatives, choice, trace theory, or ambient real completeness, none of those objects can discharge a local NameCert clause. □

Lean4 ✓ `BEDC.Derived.RellichKondrachovUp.RellichKondrachovCarrier namecert obligations`

Theorem 2218.3 (Rellich–Kondrachov finite compact-embedding route)**.** *Every consumer read exported by an accepted* $\mathsf{RellichKondrachov}^{\uparrow}$ *carrier factors through the displayed route*

$$\begin{aligned}&\mathsf{WeakDerivative}^{\uparrow}, \mathsf{Sobolev}^{\uparrow}, \mathsf{SobolevEmbedding}^{\uparrow}, \mathsf{Real}^{\uparrow}\\ &\quad\longmapsto \mathsf{CompactMetric}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}\\ &\quad\longmapsto T, L, H, P, N.\end{aligned}$$

The route supplies only finite compactness windows: a bounded Sobolev source row, an embedding comparison row, a compact-metric witness window, a complete-metric readback window, and the tolerance ledger that relates them. It supplies no selected subsequence, open-cover compactness principle, quotient function space, host representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with a consumer request for compact embedding data. The carrier first exposes the weak-derivative and Sobolev source rows, so the request is restricted to the derivative order, integrability, boundedness, and scalar readbacks displayed in D, W, S.

Next the request must pass through the embedding comparison row E. This row locates the source and target exponents, but by construction it contains no compactness coordinate beyond the route recorded in this carrier.

The target compactness read is then forced through C, M, T. The compact-metric row gives the finite witness window, the complete-metric row gives the Cauchy readback available inside that window, and the schedule T records the tolerance and observation indices used by the route.

It remains only to replay the route. The ledger L states that all compact-embedding observations factor through the displayed rows, while H, P, N transport, source, and name the same finite packet. The absent analytic principles are not recoverable from these rows. □

Falsifiable prediction: Every $\mathsf{RellichKondrachov}^{\uparrow}$ compact-embedding read factors through displayed WeakDerivativeUp, SobolevUp, SobolevEmbeddingUp, CompactMetricUp, CompleteMetricUp, RealUp, subsequence-window schedule, compact-route ledger, transport, provenance, and local naming rows.

Independence witness: weak-derivative, sobolev, sobolev-embedding, compactmetric, complete-metric, real: $\mathsf{RellichKondrachov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite compact-embedding route, target compactness windows, complete-metric readbacks, subsequence-window schedule, route ledger, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RellichKondrachov}^{\uparrow}}$.

Constructive story: A $\mathsf{RellichKondrachov}^{\uparrow}$ packet is generated from bounded Sobolev and weak-derivative rows, an embedding comparison row, compact-metric and complete-metric target windows, scalar readback, a finite subsequence-window schedule, compact-route ledger, componentwise transport, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RellichKondrachov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2218.1, Definition 2218.2, and Definition 2218.3 seed the finite compact-embedding route over WeakDerivative, Sobolev, SobolevEmbedding, CompactMetric, CompleteMetric, and Real neighbours.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RellichKondrachov}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subsequences, open-cover compactness, quotient function spaces, host representatives, trace theory, full PDE regularity, countable choice, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked NameCert obligation theorem for the same finite Rellich–Kondrachov compact-embedding packet.

Chapter 2219

A Concrete Naming Certificate for $\mathsf{AscoliDiagonal}^{\uparrow}$

Following Arzela–Ascoli and Bishop–Bridges constructive analysis, the $\mathsf{AscoliDiagonal}^{\uparrow}$ packet records the finite-window diagonal extraction surface used when compact source nets, equicontinuity ledgers, and complete-metric target rows are already displayed. It consumes chapter 412, chapter 413, and chapter 129 as finite carrier inputs; it does not import a choice-selected subsequence, compact-open topology, or ambient sequence space.

Definition 2219.1 (AscoliDiagonal carrier)**.** *An* $\mathsf{AscoliDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, E, Y, \mathcal{W}, R, S, H, C, P, N)$$

with the following visible rows:

1. *X records compact source-net rows from the* $\mathsf{CompactMetric}^{\uparrow}$ *source, including finite probe windows and their coverage witnesses;*
2. *E records the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *ledger that binds each target tolerance request to a displayed source-radius row uniformly over the family ledger;*
3. *Y records the* $\mathsf{CompleteMetric}^{\uparrow}$ *target rows through which diagonal pointwise reads are sealed;*
4. *$\mathcal{W}$ records finite diagonal* $\mathsf{StreamName}^{\uparrow}$ *windows, with each window naming the source-net points and family indices currently inspected;*
5. *R records* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the target-distance and tolerance witnesses visible on $\mathcal{W}$;*
6. *S records the* $\mathsf{Real}^{\uparrow}$ *seal that repacks the window readbacks into the target-side regular Cauchy boundary;*
7. *H records componentwise* hsame *transports for $X, E, Y, \mathcal{W}, R, S$ and the structural rows;*
8. *C records displayed* Cont *replay through compact source nets, equicontinuity rows, target complete-metric rows, StreamName windows, RegSeqRat readback, and the Real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{AscoliDiagonal}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AscoliDiagonal}^{\uparrow}}$ *row.*

The carrier exports only finite-window diagonal data. It has no coordinate for an unbounded subsequence selector, an ambient compact-open topology, or a choice principle over all family members.

Lean4 ✓ `BEDC.Derived.AscoliDiagonalUp.AscoliDiagonalTasteGate single carrier alignment`

Theorem 2219.2 (AscoliDiagonal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AscoliDiagonal}^\uparrow}$ *surface consists exactly of carrier admission for the packet of Definition 2219.1; classifier transport for compact source-net rows, equicontinuity-family ledgers, complete-metric target rows, finite* $\mathsf{StreamName}^\uparrow$ *diagonal windows,* $\mathsf{RegSeqRat}^\uparrow$ *readbacks, and the* $\mathsf{Real}^\uparrow$ *seal; finite-window replay through* H, C, P, N*; and non-escape from unbounded subsequence selection, ambient function-space topology, and open-cover compactness.*

Proof. Carrier admission is projection from Definition 2219.1. The compact source rows, family equicontinuity rows, target completion rows, finite diagonal windows, readback rows, Real seal, transport rows, continuation routes, provenance, and local name are all displayed.

Classifier transport is componentwise. The source rows are transported through the compact-metric finite nets, the family rows through the EquicontinuityFamily ledger, and the target rows through the complete-metric and Real readback boundaries.

Finite-window replay uses $\mathcal{W}$ and R. Each consumer sees only the currently displayed diagonal window, its RegSeqRat readback rows, and the Real seal S carried through H, C, P, N.

The non-escape clauses follow by inspecting the carrier. No coordinate names an unbounded subsequence selector, ambient compact-open topology, or open-cover compactness object. □

Theorem 2219.3 (AscoliDiagonal finite-window extraction)**.** *Every public extraction read from an accepted* $\mathsf{AscoliDiagonal}^\uparrow$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{EquicontinuityFamily}^\uparrow,\ \mathsf{CompleteMetric}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{Real}^\uparrow,\ \mathsf{NameCert}_{\mathsf{AscoliDiagonal}}$$

The route first reads compact source nets, then equicontinuity-family modulus rows, then target complete-metric rows, then finite diagonal StreamName windows, then RegSeqRat readback and the Real seal. It exports a finite-window diagonal extraction surface and no choice-selected subsequence or compact-open topological completion.

Proof. Start with an accepted carrier $D = (X, E, Y, \mathcal{W}, R, S, H, C, P, N)$. The compact source row X supplies the finite source-net windows, and the equicontinuity row E supplies the shared modulus ledger for those windows.

The target row Y supplies the complete-metric readback surface. Each diagonal inspection is then restricted to the finite $\mathsf{StreamName}^\uparrow$ window $\mathcal{W}$, so the consumer sees only the displayed source-net points and family indices.

The RegSeqRat row R records the finite readback values for that window, and the Real seal S repacks the readback as the visible target boundary. Transport by H and replay through C preserve the same rows, while P and N record provenance and local naming.

Thus extraction is finite-window diagonal replay. Since the carrier contains no unbounded subsequence selector, no ambient compact-open topology, and no topological completion row, none of those objects is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliDiagonal}^\uparrow}$**.**

Constructive story: An $\mathsf{AscoliDiagonal}^\uparrow$ packet is generated from compact source-net rows, equicontinuity-family modulus rows, complete-metric target rows, finite StreamName diagonal windows, RegSeqRat readback rows, a Real seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AscoliDiagonal}^\uparrow}$, seed)

Scope closed: Definition 2219.1, Definition 2219.2, and Definition 2219.3 seed the finite-window diagonal extraction packet over compact source nets, equicontinuity ledgers, and complete-metric target rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AscoliDiagonal}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a choice-selected subsequence, ambient compact-open topology, open-cover compactness, sequential compactness, or a standard bridge.

Upgrade path: Obligation closure requires Lean carrier admission, classifier transport, finite-window extraction, readback sealing, and non-escape rows.

Chapter 2220

A Concrete Naming Certificate for $\mathsf{CauchyTailControl}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailControl}^{\uparrow}$ packet records the finite threshold surface by which a regular Cauchy name answers a requested tail tolerance before any Real or Completion consumer reads the result. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence route of chapter 301, the terminal real-name seal of chapter 38, and the completion boundary of chapter 1506. The packet is the finite tail-threshold control interface for regular Cauchy names; it does not assert a selected limit, quotient equality of names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2220.1 (CauchyTailControl carrier)**.** *A* $\mathsf{CauchyTailControl}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, W, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite precision-request row. It records the displayed tolerance request whose tail threshold is being certified.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened for that request. It records the finite observations available before the threshold is accepted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the dyadic radius, comparison rows, slack budget, and denominator discipline used by the tail check.*
4. *B is the tail-threshold row. It records the finite bound after which every displayed pair of regular rational reads is controlled by the tolerance in D.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It reads the windows and dyadic ledger under the same threshold row before a regular Cauchy name can be exported.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal. It is available only after Q, W, D, B, R have displayed the precision request, windows, tolerance ledger, tail threshold, and regular handoff.*
7. *H records componentwise* hsame *transport for the request, window, tolerance, threshold, handoff, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each precision request through $Q, W, D, B, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailControl}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailControl}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, W, D, B, R, E, H, C, P, N$. It has no coordinate for a chosen limit, quotient equality of streams, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2220.2 (CauchyTailControl NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailControl}^{\uparrow}$ *carrier $T = (Q, W, D, B, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailControl}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed precision request, finite stream window, dyadic tolerance ledger, tail-threshold row, regular rational handoff, terminal seal, and structural rows H, C, P, N;*
2. *request exactness, requiring every tail-control read to expose Q before any threshold or regular handoff row is available;*
3. *window and tolerance accountability, requiring W and D to provide the inspected observations, dyadic radius, comparison rows, slack budget, and denominator discipline used by the threshold;*
4. *tail-threshold exactness, requiring B to name the finite bound after which the displayed regular rational reads are controlled by the requested tolerance;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring R to consume the same W, D, B rows before the terminal* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal E may be read;*
6. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No CauchyTailControl obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyTailControlUp.CauchyTailControlTasteGate single carrier alignment`

Proof. Project the accepted packet $T = (Q, W, D, B, R, E, H, C, P, N)$. The carrier definition exposes exactly the request row, stream window, dyadic ledger, tail threshold, regular handoff, terminal seal, and structural rows.

The request and window data are read first. The row Q fixes the finite tolerance request, while W supplies only the observations admitted for that request.

The dyadic and threshold rows then determine the tail control. The row D carries the radius, comparison, slack, and denominator data, and B records the finite bound tied to that ledger.

Finally R, E, H, C, P, N hand off, seal, transport, replay, source, and name the same displayed route. Since the excluded limit, quotient, choice, order, and ambient-completeness objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2220.3 (CauchyTailControl RegSeqRat handoff)**.** *Let $T = (Q, W, D, B, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyTailControl}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or completion-facing consumer of the packet factors through the displayed tail-control route*

$$Q \longmapsto W \longmapsto D \longmapsto B \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a finite precision request, finite stream observations, dyadic tolerance arithmetic, an explicit tail threshold, regular rational readback, terminal sealing, transport, replay, provenance, and local naming before any Real or Completion datum is available. The

route cannot use a selected limit, quotient equality of names, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$ or completion-facing read of T. By Definition 2220.1, the read has no direct access to a limit, quotient, or ambient completion object; it can inspect only the displayed rows.

The first part of the route is fixed by the request and observation rows. The request Q names the tolerance, W supplies the finite observations, and D supplies the dyadic arithmetic used to compare the observed tail.

The tail-control step is the row B. It binds the finite threshold to the same request, observations, and dyadic ledger, so the later regular handoff cannot be detached from the displayed tail budget.

The row R gives the regular rational readback only after Q, W, D, B have been displayed, and E, H, C, P, N seal, transport, replay, source, and name the same route. Therefore every accepted consumer factors through the displayed tail-control route and has no path to the excluded objects. □

Falsifiable prediction: Every $\mathsf{CauchyTailControl}^{\uparrow}$ Real or Completion read factors through a precision request, StreamName finite windows, a DyadicRatCore tolerance ledger, an explicit tail threshold, RegSeqRat handoff, terminal sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, metriccompletion: $\mathsf{CauchyTailControl}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the request row, observation window, dyadic tolerance ledger, tail-threshold row, regular handoff, terminal seal, transport, continuation, provenance, and local naming as one finite control packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailControl}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailControl}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2220.1, Definition 2220.2, and Definition 2220.3 seed the finite tail-threshold control interface consumed by regular Cauchy names, Real seals, and MetricCompletion-facing readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailControl}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of names, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exactness, StreamName window accountability, DyadicRatCore tolerance accountability, tail-threshold exactness, RegSeqRat handoff, terminal seal nonescape, and structural transport for BEDC.Derived.CauchyTailControlUp.

Constructive story: A $\mathsf{CauchyTailControl}^{\uparrow}$ packet is generated from a precision request, StreamName finite windows, a DyadicRatCore tolerance ledger, an explicit tail-threshold row, a RegSeqRat handoff, a RealUp or completion-facing seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2221

A Concrete Naming Certificate for $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$

Following Kelley and Bourbaki on the compact-open topology, the $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$ packet records the finite BEDC surface by which a compact source and a target real seal expose a reusable function-space carrier. It reads the compact-open sup-metric boundary of chapter 1903, the continuous-map graph rows of chapter 130, and the uniform-tail endpoint route of chapter 463. The packet names the carried compact-open function-space data; it does not install an ambient topology on all host functions, quotient function equality, open-cover compactness, selected limits, or pointwise-only convergence.

Definition 2221.1 (Compact-open function-space carrier)**.** *A* $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, S, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite source-window and compact-net inspection rows consumed by compact-open requests.*
2. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *graph ledger whose graph rows expose the admissible maps out of X.*
3. *S is the* $\mathsf{CompactOpenMetric}^{\uparrow}$ *subbasic-radius row, including the finite source-window, target-distance, and radius-budget coordinates used to compare graph rows.*
4. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *tail ledger recording the displayed uniform-tail route by which a function-space endpoint may be read.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the sampled graph values and tail comparisons are observed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows and tail ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback has been displayed.*
8. *H records componentwise* hsame *transport for the compact source row, continuous-map graph rows, compact-open radius rows, uniform-tail ledgers, stream windows, regular readbacks, real seals, replay rows, provenance, and local naming row.*

9. *C records displayed* Cont *replay from a compact-open function-space request through graph inspection, subbasic-radius comparison, uniform-tail readback, stream windows, regular rational readback, and the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactOpenMetric}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenFunctionSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, S, U, W, R, E, H, C, P, N$. No carrier coordinate names quotient function equality, an unrestricted function-space topology, open-cover compactness, selected limits, pointwise-only convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactOpenFunctionSpaceUp.CompactOpenFunctionSpaceTasteGate single carrier alignment`

Theorem 2221.2 (Compact-open function-space NameCert obligations)**.** *For every accepted* CompactOpenFunctio *carrier $K = (X, F, S, U, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactOpenFunctionSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact source row, continuous-map graph ledger, compact-open subbasic-radius row, uniform-tail ledger, stream-window row, regular readback, real seal, transport, replay, provenance, and local naming row;*

2. *graph visibility, requiring every function-space read to enter through the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *graph ledger F before it can inspect values;*

3. *subbasic-radius stability, requiring every compact-open comparison to use the same* $\mathsf{CompactOpenMetric}^{\uparrow}$ *row S and the finite source-window and radius-budget coordinates stored there;*

4. *uniform-limit handoff, requiring the endpoint read to pass through the* $\mathsf{UniformLimit}^{\uparrow}$ *tail ledger U, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R before reaching the* $\mathsf{Real}^{\uparrow}$ *seal E;*

5. *non-escape, requiring H, C, P, N to preserve the same displayed rows and to export no quotient function equality, unrestricted function-space topology, open-cover compactness, selected limit, pointwise-only convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No function-space NameCert obligation is stored outside those rows.

Proof. Project the carrier in Definition 2221.1. The visible analytic coordinates are exactly the compact source row, continuous-map graph ledger, compact-open subbasic-radius row, uniform-tail ledger, stream windows, regular readback, real seal, and structural rows.

Graph visibility is forced by the coordinate F. A function-space read has no independent map coordinate, so every value inspection first passes through the displayed $\mathsf{ContinuousMap}^{\uparrow}$ graph rows.

The compact-open comparison is forced by S. Its finite source windows and radius budgets are the only subbasic-radius data in the packet, hence classifier transport can preserve compact-open comparisons only by transporting the same row through H and replaying it through C.

The endpoint handoff is the displayed route U, W, R, E. The uniform-tail ledger supplies the comparison schedule, the stream-window row exposes the finite observations, the regular readback records the rational name, and the real seal is reached only after those rows are visible.

Finally inspect P and N. Their source list contains no quotient-function, ambient-topology, open-cover, selected-limit, pointwise-only, or ambient-completeness coordinate, so the listed rows exhaust the local NameCert surface. □

Theorem 2221.3 (Compact-open function-space uniform-convergence handoff)**.** *Every uniform-convergence consumer of an accepted* $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{ContinuousMap}^{\uparrow}, \mathsf{CompactOpenMetric}^{\uparrow}, \mathsf{UniformLimit}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Thus the consumer receives continuous-map graph data, compact-open subbasic-radius comparisons, a uniform-tail ledger, finite stream windows, regular rational readback, and a real seal before it treats the endpoint as function-space data. The route exports no quotient function equality, selected host limit, pointwise-only convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $K = (X, F, S, U, W, R, E, H, C, P, N)$. A consumer asking for uniform convergence cannot reach E directly, because the real seal row is downstream of the uniform-tail and readback coordinates.

The graph part of the request first reads F, and compact-open comparison then reads S. This supplies the finite source-window and radius-budget data needed to interpret the request as a compact-open comparison rather than a pointwise-only observation.

The limiting endpoint is then routed through U, W, R, E. The uniform-tail ledger gives the shared tail schedule, the stream windows expose finite observations, the regular readback records the rational name, and the real seal provides the endpoint boundary.

The structural rows H, C, P, N preserve exactly this route. Since the packet contains no quotient equality, selected limit, pointwise-only convergence, or ambient completeness row, none can be exported by the handoff. □

Theorem 2221.4 (Compact-open function-space nonescape)**.** *An accepted* $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$ *carrier exposes only the rows of Definition 2221.1. In particular, any certified read of its function-space endpoint must factor through the compact source row, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph ledger, the* $\mathsf{CompactOpenMetric}^{\uparrow}$ *subbasic-radius row, the* $\mathsf{UniformLimit}^{\uparrow}$ *tail ledger, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal. It cannot replace that route by open-cover compactness, an unrestricted function-space topology, quotient equality of maps, a selected host limit, pointwise-only convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier has exactly the rows $X, F, S, U, W, R, E, H, C, P, N$. A certified endpoint read must therefore enter through one of these rows and replay through C while preserving the same components by H.

The only graph coordinate is F, the only compact-open comparison coordinate is S, and the only endpoint route is U, W, R, E. Hence every endpoint read factors through the stated finite route.

The excluded principles are absent from the carrier and from the provenance row P. The local naming row N therefore has no source from which to certify any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenFunctionSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$ packet is generated from a CompactMetricUp source row, ContinuousMapUp graph rows, a CompactOpenMetricUp subbasic-radius row, a UniformLimitUp tail ledger, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenFunctionSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2221.1, Definition 2221.2, Definition 2221.3, and Definition 2221.4 seed the compact-open function-space carrier and its finite uniform-convergence handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactOpenFunctionSpace}\uparrow}$, encodedDef)

Lean target: `BEDC.Derived.CompactOpenFunctionSpaceUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of maps, unrestricted function-space topology, open-cover compactness, selected host limits, pointwise-only convergence, ambient Real$^{\uparrow}$ completeness, Lean-checked obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph visibility, subbasic-radius stability, uniform-limit handoff, and non-escape proofs for the same finite packet.

Chapter 2222

A Concrete Naming Certificate for $\mathsf{CauchyRegularityModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyRegularityModulus}^{\uparrow}$ packet records a displayed regularity modulus for Cauchy criteria before a $\mathsf{Real}^{\uparrow}$ or Completion consumer is allowed to read a terminal seal. It sits over the Cauchy surface of chapter 392, the uniform criterion of chapter 435, the finite observation windows of chapter 126, the regular rational sequence route of chapter 301, the dyadic arithmetic ledger of chapter 291, and the real-name seal of chapter 38. The packet names the finite modulus route from criterion data to regular sequence handoff; it does not select a limit or quotient stream representative.

Definition 2222.1 (CauchyRegularityModulus carrier)**.** *A* $\mathsf{CauchyRegularityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, U, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *row naming the local Cauchy criterion request.*
2. *U is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row that records the shared criterion surface consumed by the same request.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the criterion request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the displayed dyadic radius, comparison rows, and denominator discipline used by the modulus.*
5. *R is the regularity-modulus row. It records the finite threshold assignment that makes the criterion readable as a regular sequence route.*
6. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row available only after K, U, W, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the criterion, uniform criterion, window, dyadic ledger, modulus, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the criterion request through $K, U, W, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRegularityModulus}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRegularityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, U, W, D, R, E, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyRegularityModulusUp.CauchyRegularityModulusTasteGate single carrier alignment`

Theorem 2222.2 (CauchyRegularityModulus NameCert obligations)**.** *For every accepted* CauchyRegularityModulu *carrier $M = (K, U, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRegularityModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Cauchy criterion, uniform criterion, stream window, dyadic ledger, regularity modulus, regular rational handoff, transport, replay, provenance, and local naming rows;*
2. *criterion exactness, requiring K and U to be exposed before any modulus or regular rational handoff is available;*
3. *window accountability, requiring W to list only the finite observations admitted by the criterion request;*
4. *dyadic tolerance accountability, requiring D to provide the radius, comparison, slack, and denominator data used by the regularity row;*
5. *modulus exactness, requiring R to name the finite threshold assignment that turns the Cauchy and uniform criterion rows into a regular sequence route;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring E to consume the same K, U, W, D, R rows before any* $\mathsf{Real}^{\uparrow}$ *seal may be read;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No CauchyRegularityModulus obligation is stored outside these rows.

Proof. Project the accepted packet $M = (K, U, W, D, R, E, H, C, P, N)$. The carrier definition exposes exactly the criterion, uniform criterion, window, dyadic ledger, regularity modulus, handoff, and structural rows.

The criterion rows are read first. The row K names the Cauchy request, while U records the uniform criterion surface available to the same request.

The observation and arithmetic rows then determine the finite modulus. The row W lists the admitted finite windows, and D carries the dyadic tolerance data used by the threshold assignment.

Finally R, E, H, C, P, N record the modulus, handoff, transport, replay, source, and local name for the same displayed route. Since the excluded selected-limit, quotient, choice, host-equality, trichotomy, and ambient-completeness objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2222.3 (CauchyRegularityModulus RegSeqRat handoff)**.** *Let $M = (K, U, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyRegularityModulus}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion-facing consumer of the packet factors through the displayed regularity route*

$$K \longmapsto U \longmapsto W \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives Cauchy criterion data, uniform criterion data, finite stream observations, dyadic tolerance arithmetic, an explicit regularity modulus, regular rational readback, transport, replay, provenance, and local naming before any Real-facing seal is available.

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or Completion-facing read of M. By Definition 2222.1, the read has no direct access to a selected limit, quotient stream equality, or ambient completeness object.

The criterion part of the route is fixed by K and U. These rows display the local Cauchy request and the uniform criterion surface before any finite modulus row can be consumed.

The finite data part is fixed by W and D. The stream window supplies the observed entries, and the dyadic ledger supplies the tolerance arithmetic that the modulus row must use.

The row R gives the explicit regularity modulus, after which E provides the regular rational handoff. The rows H, C, P, N transport, replay, source, and name the same route, so the consumer has no path to selected limits, quotient equality, choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{CauchyRegularityModulus}^{\uparrow}$ Real or Completion read factors through CauchyCriterion, UniformCauchyCriterion, StreamName, DyadicRatCore, explicit regularity modulus, RegSeqRat handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming rows.

Independence witness: cauchycriterion, uniformcauchycriterion, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyRegularityModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the criterion, uniform criterion, finite-window, dyadic-tolerance, explicit-modulus, regular-handoff, transport, continuation, provenance, and local naming rows as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRegularityModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRegularityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2222.1, Definition 2222.2, and Definition 2222.3 seed the finite regularity-modulus route from Cauchy criteria to regular rational handoff and Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRegularityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion exactness, StreamName window accountability, DyadicRatCore tolerance accountability, regularity-modulus exactness, RegSeqRat handoff, terminal seal nonescape, and structural transport for BEDC.Derived.CauchyRegularityModulusUp.

Constructive story: A $\mathsf{CauchyRegularityModulus}^{\uparrow}$ packet is generated from CauchyCriterion and UniformCauchyCriterion rows, StreamName finite windows, a DyadicRatCore tolerance ledger, an explicit regularity-modulus row, a RegSeqRat handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2223

A Concrete Naming Certificate for FiniteObservationConfluence$^{\uparrow}$

The FiniteObservationConfluence$^{\uparrow}$ packet realizes the typed-example audit surface of chapter 9382 as finite confluence-facing observation data. It sits between the typed examples gallery of chapter 756, the coverage matrix of chapter 923, the finite observation-budget selector of chapter 782, the bounded normal equality checker of chapter 752, and the confluence critical-pair boundary of chapter 2212. The packet records selected typed examples, reduction observations, normal-form comparisons, and a critical-pair boundary handoff; it is not a theorem of global confluence.

Falsifiable prediction: Every accepted FiniteObservationConfluence$^{\uparrow}$ audit read exposes typed-example rows, finite observation-budget rows, reduction observations, bounded normal-equality rows, confluence-boundary handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before it can be cited by a confluence audit consumer.

Independence witness: typedexamplegallery, typedexamplecoveragematrix, finiteobservation-budgetselector, boundednormalequalitychecker, metacic-confluence-critical-pair-boundary: FiniteObservationConflu is not bijective to any listed sibling because it jointly carries typed-example selection, finite budget, reduction observation, normal comparison, confluence-boundary handoff, transport, replay, provenance, and local naming rows.

Definition 2223.1 (FiniteObservationConfluence carrier)**.** *A* FiniteObservationConfluence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, R, E, Q, J, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-example row read from the MetaCIC gallery and coverage-matrix surface.*
2. *B is the* FiniteObservationBudgetSelector$^{\uparrow}$ *row bounding which example observations are admitted.*
3. *R is the reduction-observation row, recording the displayed beta, application, projection, or eliminator computation inspected by the packet.*
4. *E is the* BoundedNormalEqualityChecker$^{\uparrow}$ *row used when the observation is compared by bounded normal equality.*
5. *Q is the* MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$ *handoff row, recording the critical-pair and common-reduct boundary available to the same observation.*

6. *J is the confluence-observation ledger row tying the typed example, budget, reduction observation, bounded checker, and critical-pair boundary to one finite audit route.*
7. *H records componentwise* hsame *transport for the typed-example, budget, reduction, bounded-checker, boundary, ledger, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the typed example through $T, B, R, E, Q, J, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationConfluence}^{\uparrow}$, $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$, $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationConfluence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, R, E, Q, J, H, C, P, N$. It has no coordinate for arbitrary closed-term Church–Rosser, full parallel diamond, strong normalisation, subject reduction, residual-substitution compatibility, or unchecked conversion decidability.

Lean4 ✓ `BEDC.Derived.FiniteObservationConfluenceUp.FiniteObservationConfluenceTasteGate single carrier alignment`

Theorem 2223.2 (FiniteObservationConfluence NameCert obligations)**.** *For every accepted* FiniteObservationConf *carrier $F = (T, B, R, E, Q, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationConfluence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the typed-example row, finite observation budget, reduction observation, bounded equality checker, confluence-boundary handoff, observation ledger, transport, replay, provenance, and local naming row;*
2. *typed-example exactness, requiring T to name an accepted gallery or coverage-matrix example before any reduction observation is read;*
3. *budget accountability, requiring B to bound the visible observation route for the selected example;*
4. *reduction-observation exactness, requiring R to display the beta, application, projection, or eliminator computation actually inspected by the packet;*
5. *bounded-comparison handoff, requiring E to consume only the displayed observation rows;*
6. *confluence-boundary handoff, requiring Q to read only the finite critical-pair and common-reduct boundary available to the same observation;*
7. *ledger non-escape, requiring J, H, C, P, N to transport, replay, source, and name the same finite route without exporting global confluence, subject reduction, strong normalisation, residual-substitution compatibility, or unchecked conversion decidability.*

No FiniteObservationConfluence obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2223.1. The projection exposes exactly $T, B, R, E, Q, J, H, C, P, N$.

The typed-example and budget rows are read first. The row T names the gallery example, and B restricts the observation route to a finite budget.

The reduction observation is then displayed by R. The bounded checker E may compare only the rows already exposed by the typed-example, budget, and reduction observation.

The confluence-boundary handoff Q is similarly downstream of the finite observation. It may read the critical-pair and common-reduct boundary, but it does not turn the packet into a global confluence theorem.

Finally J, H, C, P, N ledger, transport, replay, source, and name the same route. Since the excluded metatheorems are not coordinates of the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2223.3 (FiniteObservationConfluence MetaCIC handoff)**.** *Let $F = (T, B, R, E, Q, J, H, C, P, N)$ be an accepted* $\mathsf{FiniteObservationConfluence}^{\uparrow}$ *carrier. Every MetaCIC confluence-audit consumer of F factors through the displayed route*

$$T \longmapsto B \longmapsto R \longmapsto E \longmapsto Q \longmapsto J \longmapsto H, C, P, N.$$

Consequently typed-example checker rows, reduction observations, and confluence-boundary handoff are consumed as one finite observation packet, not as a claim of arbitrary confluence.

Proof. Start with a confluence-audit consumer of F. The carrier gives no direct coordinate for arbitrary Church–Rosser, full parallel diamond, subject reduction, strong normalisation, or residual-substitution compatibility.

The consumer must first read the typed-example row T and the finite budget row B. These rows identify the concrete example and the finite observation surface.

The reduction row R and bounded checker row E then supply the inspected computation and comparison data. They are tied to the same budget and cannot range over arbitrary closed terms.

The critical-pair boundary row Q is read only after the finite observation is displayed. The ledger and structural rows J, H, C, P, N then record, transport, replay, source, and name the same route, proving the stated factorization. □

The Lean TasteGate surface for this packet must provide `Nontrivial FiniteObservationConfluenceUp` and `FieldFaithful FiniteObservationConfluenceUp`. The field-faithfulness check must keep the typed-example row, finite budget row, reduction-observation row, bounded-checker row, confluence-boundary handoff row, and ledger row as distinct carrier fields rather than aliases for a global confluence theorem.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationConfluence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationConfluence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2223.1, Definition 2223.2, and Definition 2223.3 seed the finite typed-example observation route from checker rows and reduction observations to confluence-boundary handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationConfluence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary closed-term Church–Rosser, full parallel diamond, subject reduction, strong normalisation, residual-substitution compatibility, unchecked conversion decidability, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, typed-example exactness, budget accountability, reduction-observation exactness, bounded-comparison handoff, confluence-boundary handoff, ledger non-escape, and TasteGate nontriviality and field faithfulness for BEDC.Derived.FiniteObservationConfluenceUp.

Constructive story: A $\mathsf{FiniteObservationConfluence}^{\uparrow}$ packet is generated from typed-example rows, a finite observation-budget selector row, reduction-observation rows, a bounded normal-equality checker row, a MetaCIC confluence critical-pair boundary handoff, a confluence-observation ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2224

A Concrete Naming Certificate for $\mathsf{OscillationModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OscillationModulus}^{\uparrow}$ packet records the finite route by which local oscillation control is read as explicit modulus data before a Real or uniform-continuity consumer treats the bound as a continuity certificate. It sits between the Real oscillation interface of chapter 1839, the function-specific modulus route of chapter 1631, and the uniform boundary of chapter 391. The packet is an L10 NameCert surface for converting displayed oscillation rows into displayed tolerance-window rows; it does not assert Real completeness, compactness, quotient streams, selected limits, host equality, countable choice, or bridge-axis evidence.

Definition 2224.1 (Oscillation-modulus carrier)**.** *An* $\mathsf{OscillationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{osc}} = (O, U, K, D, W, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{RealOscillation}^{\uparrow}$ *row exposing the local oscillation ledger and its Real-facing readback route.*
2. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *boundary row that receives one explicit source-window budget for each requested target tolerance.*
3. *K is the* $\mathsf{ModulusContinuity}^{\uparrow}$ *row converting the oscillation bound into the displayed tolerance-to-window schedule.*
4. *D is the dyadic tolerance ledger shared by the oscillation estimate and the modulus request.*
5. *W is the finite source-window row selected by K and inspected by the oscillation ledger O.*
6. *R is the terminal Real-facing readback reached after O, K, D, W have been displayed.*
7. *H records componentwise* hsame *transport for the oscillation row, uniform-continuity row, modulus row, tolerance ledger, source window, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each target tolerance request through D, K, W, O, R and into the uniform-continuity boundary U.*
9. *P is the* Pkg *provenance over* $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OscillationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, U, K, D, W, R, H, C, P, N$ and the displayed routes among those rows. It has no coordinate for Real completeness, compactness, quotient streams, selected limits, host equality, countable choice, or bridge-axis evidence.

Lean4 ✓ `BEDC.Derived.OscillationModulusUp.OscillationModulusTasteGate single carrier alignment`

Theorem 2224.2 (Oscillation-modulus NameCert obligations)**.** *For every accepted* $\mathsf{OscillationModulus}^{\uparrow}$ *carrier* $M_{\mathrm{osc}} = (O, U, K, D, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OscillationModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Real oscillation row, uniform-continuity boundary row, modulus-continuity row, dyadic tolerance ledger, source window, Real readback, transport, replay, provenance, and local naming rows;*
2. *oscillation-to-modulus exposure, requiring every requested target tolerance read from D to pass through K before a source window W is opened;*
3. *oscillation ledger compatibility, requiring O to inspect the same D, W, R route that K exports as explicit modulus data;*
4. *uniform boundary handoff, requiring U to consume only the displayed modulus schedule K and the oscillation readback O, R;*
5. *ledger non-escape, requiring H, C, P, N to export no Real completeness, compactness, quotient streams, selected limits, host equality, countable choice, or bridge-axis evidence.*

No local obligation is stored outside those rows.

Theorem 2224.3 (Oscillation-modulus Real oscillation handoff)**.** *Every Real-facing read of an accepted* $\mathsf{OscillationModulus}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RealOscillation}^{\uparrow},\ \mathsf{ModulusContinuity}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg}$$

Thus the read receives local oscillation control only as an explicit tolerance-window schedule and receives no Real completeness principle, compactness principle, quotient stream equality, selected limit, host equality, or countable-choice schedule.

Theorem 2224.4 (Oscillation-modulus uniform-continuity boundary)**.** *Let* $M_{\mathrm{osc}} = (O, U, K, D, W, R, H, C, P, N)$ *be an accepted* $\mathsf{OscillationModulus}^{\uparrow}$ *carrier. Every* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer of U reads the public modulus through D, K, W, O, R before any uniform-continuity conclusion is exposed. Consequently the consumer receives an explicit finite tolerance-window route grounded in the oscillation ledger, not a compactness theorem, selected modulus oracle, quotient completion, host equality, ambient Real completeness, countable choice, or bridge certificate.*

Falsifiable prediction: Every $\mathsf{OscillationModulus}^{\uparrow}$ consumer read factors through one RealOscillation row, one ModulusContinuity row, one UniformContinuity boundary row, one DyadicRatCore tolerance ledger, one StreamName source window, one RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, local NameCert, and the terminal RealUp seal.

Independence witness: real-oscillation, moduluscontinuity, uniformcontinuity: $\mathsf{OscillationModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an oscillation ledger, an explicit tolerance-to-window schedule, a uniform-consumer boundary, a shared dyadic-window-readback route, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationModulus}^{\uparrow}}$.

Constructive story: An $\mathsf{OscillationModulus}^{\uparrow}$ packet is generated from a RealOscillation row, a UniformContinuity boundary row, a ModulusContinuity tolerance-to-window row, a dyadic tolerance ledger, a finite source window, a Real-facing readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2224.1, Definition 2224.2, Definition 2224.3, and Definition 2224.4 seed the finite handoff from Real oscillation control to explicit modulus data and uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, compactness, quotient streams, selected limits, host equality, countable choice, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, oscillation-to-modulus exposure, oscillation ledger compatibility, uniform boundary handoff, transport and replay preservation, provenance exhaustion, and local naming for future BEDC.Derived.OscillationModulusUp.

Chapter 2225

A Concrete Naming Certificate for $\mathsf{SeparableMetricSpace}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{SeparableMetricSpace}^{\uparrow}$ packet records the traditional countable-dense metric interface as finite BEDC rows. It sits between the metric carrier of chapter 57, the finite observation schedule of chapter 126, the regular rational readback route of chapter 301, and the terminal real seal of chapter 38. The packet names a displayed dense enumeration and its approximation obligations; it is not quotient completion, not a selected-representative principle, not countable choice, not open-cover compactness, and not completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2225.1 (SeparableMetricSpace carrier)**.** *A* $\mathsf{SeparableMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, D, E, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row, including the source point histories, metric-read classifier, and finite distance-query surface.*
2. *D is the countable dense enumeration row, represented as a* $\mathsf{StreamName}^{\uparrow}$ *schedule whose displayed entries are inspected only through finite windows.*
3. *E is the density evidence row: for every displayed point request and positive rational tolerance request visible in M, it stores a finite witness index in D together with the corresponding distance-read budget.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read the requested dense entries and the finite witness indices.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational distance bounds attached to the metric requests.*
6. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, D, E, W, R have been displayed.*
7. *H is the componentwise* hsame *transport ledger for metric, dense stream, density evidence, finite windows, regular rational readbacks, real seals, replay, provenance, and local naming rows.*
8. *C is the displayed* Cont *replay route forcing every density read to pass through*

$$M, D \longmapsto E, W, R \longmapsto Q \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{SeparableMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparableMetricSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected representatives, countable choice, open-cover compactness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SeparableMetricSpaceUp.SeparableMetricSpaceTasteGate single carrier alignment`

Theorem 2225.2 (SeparableMetricSpace NameCert obligations)**.** *For an accepted* $\mathsf{SeparableMetricSpace}^{\uparrow}$ *carrier* $S = (M, D, E, W, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparableMetricSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric row, dense stream row, density evidence row, finite StreamName windows, RegSeqRat readbacks, Real seal, transport, replay, provenance, and local naming rows;*
2. *dense-stream visibility, requiring every dense witness to be read through D and W before it can answer a metric approximation request;*
3. *approximation evidence, requiring every displayed point-and-tolerance request to pass through E and then through the metric row M and rational readback row R;*
4. *real-seal order, requiring the terminal* $\mathsf{Real}^{\uparrow}$ *readback Q to remain downstream of the metric, stream, density, and regular-rational rows;*
5. *transport stability, requiring H and C to preserve the same displayed metric and dense-stream coordinates componentwise;*
6. *ledger non-escape, stating that P and N export no quotient completion, selected representative, countable-choice schedule, open-cover compactness argument, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Carrier admission is projection from Definition 2225.1. The tuple exposes exactly the metric carrier, dense stream, density evidence, finite windows, regular rational readbacks, real seal, transport, replay, provenance, and local naming rows.

Dense-stream visibility uses D together with the finite window row W. A consumer can inspect only the displayed dense entries selected by the StreamName schedule, so the countable dense surface is a named stream row rather than a host enumeration principle.

Approximation evidence uses E between the metric row M and the rational readback row R. The witness index and distance budget are stored as finite rows before any terminal real seal is read.

The real-seal, transport, and non-escape clauses follow from the remaining coordinates. The seal row Q is downstream of M, D, E, W, R, while H, C, P, N preserve, replay, source, and name only those displayed rows. Since no excluded principle is a coordinate of the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 2225.3 (SeparableMetricSpace countable-dense stream handoff)**.** *Let $S = (M, D, E, W, R, Q, H, C, P, N$ be an accepted* $\mathsf{SeparableMetricSpace}^{\uparrow}$ *carrier. Every downstream* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of its countable-dense interface factors through*

$$M, D \longmapsto E, W, R \longmapsto Q \longmapsto H, C, P, N.$$

Consequently the handoff exports a displayed countable dense stream with finite approximation evidence, not quotient completion, selected representatives, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Start with a downstream dense-approximation read. The metric row M supplies the point and distance-query surface, while the dense stream row D supplies only finite entries selected through the StreamName window W.

The density evidence row E then chooses the displayed witness index already present in D and attaches the rational budget read through R. This is the point at which the countable-dense route becomes visible to completion and Real-facing consumers.

The terminal seal Q and the structural rows H, C, P, N preserve that route without adding any host-side principle. Thus every consumer receives the same finite dense-stream handoff and none of the excluded completion, choice, compactness, or Real-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparableMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparableMetricSpace}^{\uparrow}$ packet is generated from a MetricUp row, a StreamName countable-dense schedule, finite density evidence, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparableMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2225.1, Definition 2225.2, and Definition 2225.3 seed the countable-dense metric interface over displayed metric, stream, regular-rational, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparableMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, countable choice, open-cover compactness, host real equality, Lean verification, bridge checking, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dense-stream visibility, approximation evidence, real-seal order, transport stability, and ledger non-escape for BEDC.Derived.SeparableMetricSpaceUp.

Chapter 2226

A Concrete Naming Certificate for $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$

The $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$ packet realizes the candidate-mediated boundary of chapter 9383 as a finite obstruction socket. It is narrower than the normalization router of chapter 1108: the socket records exactly where public strong-normalization reads must carry Candidate, ClosedCandidate, or CandidateSet evidence, and where the frontier refuses an evidence-free closed typed term route.

Definition 2226.1 (MetaCIC normal audit socket carrier)**.** *A* $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, K, L, S, O, F, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed typed term row: it records the empty-context typed term whose public normalization read is being audited.*
2. *K is the Candidate evidence row consumed by the direct candidate-to-strong-normalization route.*
3. *L is the ClosedCandidate evidence row consumed by the closed-candidate projection route.*
4. *S is the CandidateSet evidence row consumed by the candidate-set projection route.*
5. *O is the obstruction row recording that the public route is blocked when K, L, S are all absent.*
6. *F is the frontier row tying the socket to* $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, *and* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$ *consumers.*
7. *H records componentwise* hsame *transport for the closed typed term, candidate evidence, obstruction, frontier, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from candidate evidence to strong-normalization reads and from obstruction rows to refusal reads.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$, *Candidate, ClosedCandidate, CandidateSet, closed typed term rows, obstruction rows, frontier rows,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalAuditSocket}^{\uparrow}}$ *row.*

The carrier has no coordinate for unconditional strong normalization of every closed typed term, evidence-free application normalization, host reduction normalization, quotient reduction equality, or a normalization oracle outside the displayed socket.

Theorem 2226.2 (MetaCIC normal audit socket NameCert obligations)**.** *For an accepted* MetaCICNormalAuditSoc *carrier* $A = (T, K, L, S, O, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalAuditSocket}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the closed typed term row, Candidate row, ClosedCandidate row, CandidateSet row, obstruction row, frontier row, componentwise transport, replay, provenance, and local naming rows;*
2. *positive route admission, requiring any public strong-normalization read to consume at least one of* K, L, S *before leaving the socket;*
3. *obstruction exactness, requiring* O *to refuse the public route when the closed typed term row* T *has no displayed Candidate, ClosedCandidate, or CandidateSet evidence;*
4. *frontier handoff, requiring* F *to expose the obstruction to the MetaCIC critical path, normalization frontier, normal-form consistency seal, and decidable-boundary consumers;*
5. *transport and replay stability, requiring* H *and* C *to preserve the same evidence-or-obstruction branch componentwise;*
6. *ledger non-escape, stating that* P *and* N *export no evidence-free strong-normalization theorem, no quotient reduction equality, and no host normalization oracle.*

Proof. Carrier admission is projection from Definition 2226.1. The tuple lists the closed typed term, three evidence rows, obstruction row, frontier row, transport, replay, provenance, and local naming coordinates.

For the positive route, inspect K, L, S. Each is a displayed candidate-mediated evidence row, and the socket has no other coordinate from which a public strong-normalization read can be obtained.

For the refusal route, inspect O. When the three evidence rows are absent from the displayed route, O is the only normalization-facing row attached to the closed typed term, so the public route records obstruction rather than a theorem.

The frontier handoff and stability clauses follow through F, H, C, P, N. These rows expose, transport, replay, source, and name the same evidence-or-obstruction branch, so no evidence-free closed-term normalization principle can escape the socket. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalAuditSocketUp.MetaCICNormalAuditSocketTasteGate single carrier alignment`

Theorem 2226.3 (MetaCIC normal audit socket frontier handoff)**.** *Let* $A = (T, K, L, S, O, F, H, C, P, N)$ *be an accepted* $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$ *carrier. Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, *or* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$ *consumer receives the finite route*

$$T \longmapsto K, L, S \text{ or } O \longmapsto F \longmapsto H, C, P, N.$$

Thus the public normalization route is preserved as candidate-mediated evidence or as an explicit obstruction socket, not as a hidden unconditional strong-normalization theorem.

Proof. Start with the closed typed term row T. A consumer can leave the socket on the positive side only by reading one of the evidence rows K, L, S, corresponding to Candidate, ClosedCandidate, or CandidateSet evidence.

If those evidence rows are absent from the displayed route, the obstruction row O is read instead. This keeps the public route candidate-mediated and blocks the evidence-free closed-term claim at the same boundary named by the normalization audit map.

The frontier row F then hands the branch to the four downstream consumers, while H, C, P, N preserve the finite route. Since neither branch contains a host normalization oracle or quotient reduction equality, the handoff records an auditable socket rather than a global theorem. □

Theorem 2226.4 (MetaCIC critical path normal audit socket handoff)**.** *Every* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that uses the* $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$ *boundary must preserve the closed typed term row T, the Candidate row K, the ClosedCandidate row L, the CandidateSet row S, the obstruction row O, the frontier row F, the transport row H, the replay row C, the provenance row P, and the local* NameCert *row N before any closed-normal consistency read is admitted.*

Thus a closed-normal consistency consumer can read the socket only as a candidate-mediated branch or as an explicit obstruction branch. It cannot erase Candidate, ClosedCandidate, CandidateSet, obstruction, frontier, transport, replay, provenance, or naming data into an evidence-free normalization theorem.

Proof. Begin with the frontier handoff of Definition 2226.3. It is already the only displayed route from the socket to $\mathsf{MetaCICCriticalPath}^{\uparrow}$.

On the positive side, preserve K, L, S together with T. A critical-path read that later reaches a closed-normal consistency boundary must still be able to identify which candidate row supported the route.

On the obstructed side, preserve O together with F. This keeps the missing-evidence branch visible at the critical-path boundary rather than converting it into a hidden normalization claim.

Finally carry H, C, P, N along both branches. These rows are the transport, replay, provenance, and naming coordinates that make the socket auditable before any consistency read is consumed. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalAuditSocketHandoff`

Falsifiable prediction: Deleting Candidate, ClosedCandidate, and CandidateSet evidence from the carrier blocks the public strong-normalization route at the obstruction row O.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, normalformconsistencyseal, metacicdecidableboundary: the socket carries the closed typed term, three candidate-evidence rows, obstruction row, frontier row, transport, replay, provenance, and local NameCert rows, so no listed sibling is row-bijective with it.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalAuditSocket}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalAuditSocket}^{\uparrow}$ packet is generated from a closed typed term row, Candidate evidence, ClosedCandidate evidence, CandidateSet evidence, an obstruction row, a frontier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalAuditSocket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2226.1, Definition 2226.2, and Definition 2226.3 seed the finite candidate-mediated normalization obstruction socket.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalAuditSocket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim evidence-free strong normalization, unconditional application normalization, host normalization, quotient reduction equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-route admission, obstruction exactness, frontier handoff, transport replay, and ledger non-escape for BEDC.Derived.MetaCICNormalAuditSocketUp.

Chapter 2227

A Concrete Naming Certificate for $\mathsf{RegularCauchyTightening}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyTightening}^{\uparrow}$ packet records the finite operation that turns a regular Cauchy presentation toward an explicit fast schedule before any real-name or completion consumer reads it. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the fast witness surface of chapter 2185, and the terminal real-name seal of chapter 38. The packet is a finite tightening interface: it does not assert quotient equality of streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2227.1 (Regular Cauchy tightening carrier)**.** *A* $\mathsf{RegularCauchyTightening}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, S, R, F, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the requested dyadic radius, comparison rows, denominator discipline, and slack budget available to the tightening test.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite stream observations inspected before a tighter schedule is accepted.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row. It exposes the regular rational presentation whose tolerance route is being tightened.*
4. *F is the* $\mathsf{FastCauchySequence}^{\uparrow}$ *witness row. It records the explicit fast schedule exported after D, S, R, T have been displayed.*
5. *T is the tightening-schedule row. It binds each displayed tolerance request to the stronger finite budget used by the fast witness.*
6. *H records componentwise* hsame *transport for the dyadic ledger, stream window, regular readback, fast witness, tightening schedule, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from D, S, R, T to the fast witness row F and then through H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTightening}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FastCauchySequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTightening}^{\uparrow}}$ *row.*

The classifier compares accepted tightening packets only through $D, S, R, F, T, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTighteningUp.RegularCauchyTighteningTasteGate single carrier alignment`

Theorem 2227.2 (Regular Cauchy tightening NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTightening}$ *carrier $U = (D, S, R, F, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTightening}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic tolerance ledger, stream window, regular readback, fast witness, tightening schedule, transport, replay, provenance, and local naming rows;*
2. *classifier stability under componentwise agreement on $D, S, R, F, T, H, C, P, N$;*
3. *modulus tightening, requiring T to bind every displayed tolerance request to a stronger finite budget over the same dyadic ledger and stream window;*
4. *fast-regular handoff, requiring F to be exported only after the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and tightening rows have been read;*
5. *real-seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$*-facing read to pass through the finite packet without importing quotient equality, selected limits, countable choice, trichotomy, or ambient completeness.*

No RegularCauchyTightening obligation is stored outside $D, S, R, F, T, H, C, P, N$.

Proof. Project the accepted packet $U = (D, S, R, F, T, H, C, P, N)$. The carrier definition exposes exactly the dyadic tolerance ledger, stream window, regular readback, fast witness, tightening schedule, and structural rows.

Classifier stability is componentwise. Agreement of the displayed rows fixes the dyadic budget, visible observations, regular presentation, fast witness, schedule, transport, replay, provenance, and local naming data inspected by the classifier.

The tightening obligation is the row T. It reads the tolerance information in D, the finite observations in S, and the regular Cauchy presentation in R, then supplies the stronger budget consumed by the fast witness row F.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded quotient, choice, order, limit-selection, or ambient-completeness coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2227.3 (Regular Cauchy tightening fast-regular handoff)**.** *Let $U = (D, S, R, F, T, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyTightening}^{\uparrow}$ *carrier. Every exported fast-regular witness factors through the displayed route*

$$D \longmapsto S \longmapsto R \longmapsto T \longmapsto F \longmapsto H, C, P, N.$$

Consequently the exported witness can use only the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, and* $\mathsf{FastCauchySequence}^{\uparrow}$ *witness rows displayed by the packet.*

Proof. Start with a consumer reading the fast witness coordinate. By Definition 2227.1, the only fast Cauchy output row is F, and it is paired with the same dyadic, stream, regular, and tightening rows.

The dyadic row D supplies the tolerance arithmetic, S supplies the finite window, and R supplies the regular rational readback. The schedule row T binds these three surfaces to the stronger budget demanded by the exported fast witness.

The structural rows H, C, P, N preserve the displayed route without introducing another source of fast witness data. Thus every accepted export factors through the named dyadic, stream, regular, tightening, and fast rows. □

Theorem 2227.4 (Regular Cauchy tightening real-seal boundary)**.** *An accepted* $\mathsf{RegularCauchyTightening}^{\uparrow}$ *packet cannot export quotient stream equality, selected limits, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness. Any* $\mathsf{Real}^{\uparrow}$*-facing consumer receives only the finite dyadic ledger, stream window, regular readback, tightening schedule, fast witness, transport, replay, provenance, and local naming rows displayed in* $D, S, R, F, T, H, C, P, N$.

Proof. Inspect the carrier of Definition 2227.1. Its analytic coordinates are D, S, R, F, T, and its structural coordinates are H, C, P, N.

None of these coordinates names a quotient on streams, a selected limit, a choice functional, a trichotomy principle, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. The provenance row records the real-name seal only as a downstream boundary for the finite packet.

Therefore a real-facing consumer can replay the displayed tightening route, but it cannot extract any of the excluded ambient principles from the packet. □

Falsifiable prediction: Every $\mathsf{RegularCauchyTightening}^{\uparrow}$ fast-regular export factors through a DyadicRatCore tolerance ledger, StreamName finite window, RegSeqRat regular readback, tightening schedule, FastCauchySequence witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, fastcauchysequence, real: RegularCauchyTightenir is not bijective to any listed sibling because it jointly carries the tolerance ledger, observation window, regular readback, explicit fast witness, tightening schedule, transport, continuation, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTightening}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTightening}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2227.1, Definition 2227.2, Definition 2227.3, and Definition 2227.4 seed the finite tightening interface from regular Cauchy readback to explicit fast schedules.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTightening}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient completeness, quotient reals, quotient stream equality, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, modulus tightening, fast-regular handoff, real-seal non-escape, and structural transport rows for BEDC.Derived.RegularCauchyTighteningUp.

Constructive story: A $\mathsf{RegularCauchyTightening}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite window, RegSeqRat regular readback, tightening schedule, FastCauchySequence witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 2228

A Concrete Naming Certificate for $\mathsf{UniformContinuityModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformContinuityModulus}^{\uparrow}$ packet records the explicit tolerance-to-radius surface used by uniformly continuous maps between metric carriers. It sits between the source and target metric certificates of chapter 57, the pointwise continuous-map interface of chapter 130, the consumer modulus surface of chapter 369, and the compact finite-net production route of chapter 1610. Its role is to expose a named finite carrier for continuity moduli, not to assert open-cover compactness, selected real representatives, quotient equality of functions, or ambient completeness.

The compact finite-net specialization may supply the displayed source radius through chapter 4118. This chapter treats the tolerance-radius row as explicit modulus data: it records the δ supplied to the consumer and does not read compactness, choice, selected finite subcovers, or open-cover evidence.

Definition 2228.1 (Uniform continuity modulus carrier)**.** *A* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, F, \varepsilon, \delta, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the displayed source-distance classifier and the source-side tolerance comparison used by the modulus.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, including the displayed target-distance classifier and the target triangle ledger consumed by later estimates.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose graph and pointwise-continuity reads are constrained by the same source and target metric rows.*
4. *ε is the positive target tolerance history requested by the consumer.*
5. *δ is the positive source radius history selected for that target tolerance.*
6. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row receiving the displayed implication from source closeness below δ to target closeness below ε.*
7. *H records componentwise* hsame *transport for $X, Y, F, \varepsilon, \delta, M$ and for the local classifier row.*
8. *C records the displayed* Cont *replay routes by which a consumer reads the same source metric, target metric, continuous-map, tolerance, radius, and modulus rows.*

9. *P is the* Pkg *provenance over* UniformContinuityModulus$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{UniformContinuityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by replaying $X, Y, F, \varepsilon, \delta, M, H, C, P, N$. It has no coordinate for a compactness theorem, selected finite net, open-cover argument, quotient function equality, host function extensionality, or ambient completion principle.

Lean4 ✓ `BEDC.Derived.UniformContinuityModulusUp.UniformContinuityModulusTasteGate single carrier alignment`

Theorem 2228.2 (Uniform continuity modulus NameCert obligations)**.** *For every accepted* UniformContinuityModu *carrier $U = (X, Y, F, \varepsilon, \delta, M, H, C, P, N)$, the local* NameCert$_{\text{UniformContinuityModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source metric, target metric, continuous-map row, target tolerance, source radius, uniform-modulus handoff, transport, replay, provenance, and local name;*
2. *tolerance-radius exactness, requiring ε and δ to be read before the* UniformModulus$^{\uparrow}$ *consumer row M is available;*
3. *continuous-map accountability, requiring every function read to pass through the displayed* ContinuousMap$^{\uparrow}$ *row F and the source and target metric rows X, Y;*
4. *componentwise transport and replay stability under H and C for the same finite rows;*
5. *ledger refusal, stating that compactness, selected finite nets, open covers, quotient function equality, host extensionality, and completion data are not carrier coordinates.*

No local obligation is stored outside these rows.

Proof. Project the carrier in Definition 2228.1. It exposes exactly the source and target metrics, continuous-map row, tolerance, radius, uniform-modulus handoff, and structural rows.

The target tolerance and source radius are read before the consumer row. Thus the UniformModulus$^{\uparrow}$ handoff can inspect only the displayed implication from source closeness below δ to target closeness below ε.

The row F supplies the continuous-map boundary, while H, C, P, N transport, replay, source, and name the same packet. Since compactness, finite-net selection, open covers, quotient equality, host extensionality, and completion data are absent from the carrier, no NameCert obligation can export them. □

Theorem 2228.3 (ContinuousMap handoff)**.** *Every* ContinuousMap$^{\uparrow}$ *consumer of an accepted* UniformContinuityModulus$^{\uparrow}$ *carrier factors through the displayed route*

$$X, Y, F, \varepsilon, \delta \longmapsto M \longmapsto H, C, P, N.$$

The consumer receives the source metric row, target metric row, continuous-map row, requested target tolerance, selected source radius, uniform-modulus handoff, transport, replay, provenance, and local naming. It receives no full host function, compactness theorem, open-cover proof, quotient equality of functions, or ambient completeness witness.

Proof. Start with a ContinuousMap$^{\uparrow}$ read of the packet. By Definition 2228.1, the only function-facing coordinate is F, and it is stored beside the metric rows X, Y and the tolerance-radius pair ε, δ.

The consumer handoff is the row M. It can be reached only after the tolerance and radius rows have been displayed, and the rows H, C, P, N keep the same route under transport, replay, provenance, and local naming.

Therefore every continuous-map consumer sees a finite modulus boundary over the displayed metric and continuous-map rows. The excluded host function, compactness, open-cover, quotient-equality, and completeness objects have no coordinate in the accepted packet. □

Theorem 2228.4 (Composition stability)**.** *Let* $U_1 = (X, Y, F, \varepsilon_1, \delta_1, M_1, H_1, C_1, P_1, N_1)$ *and* $U_2 = (Y, Z, G, \varepsilon_2, \delta_2, M_2, H_2, C_2, P_2, N_2)$ *be accepted* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *carriers with the target metric row of* U_1 *matching the source metric row of* U_2 *under the displayed* hsame *transport. A composed consumer may form its public modulus only by reading the outer target tolerance in* U_2*, the source radius selected by* U_2 *as a target tolerance for* U_1*, the source radius selected by* U_1*, and the two displayed* $\mathsf{UniformModulus}^{\uparrow}$ *handoff rows. The composed route exports no hidden compactness selector, host function composition theorem, quotient-map equality, or completeness witness.*

Proof. Read the second carrier first. Its target tolerance ε_2 selects the source radius δ_2 through M_2, and the shared metric row identifies δ_2 as the tolerance request consumed by the first carrier.

Read the first carrier at that displayed tolerance. Its source radius δ_1 and handoff row M_1 provide the source-side control needed before the outer handoff M_2 is applied.

The componentwise transports H_1, H_2 and replay rows C_1, C_2 keep both packets on the same displayed metric boundary. Since neither packet contains compactness, host function composition, quotient equality, or completeness data, the composed consumer cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{UniformContinuityModulus}^{\uparrow}$ consumer factors through source and target MetricUp rows, a ContinuousMapUp row, a positive target tolerance, a positive source radius, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: continuousmap, uniformmodulus, heinecantormodulus, metric: UniformContinuityModul is not bijective to any listed sibling because it jointly carries the source metric, target metric, ContinuousMap row, target tolerance, source radius, UniformModulus consumer handoff, transport, replay, provenance, and local NameCert rows as one finite modulus packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContinuityModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformContinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2228.1, Definition 2228.2, Definition 2228.3, and Definition 2228.4 seed the finite explicit-modulus surface over source metric, target metric, ContinuousMap, tolerance-radius, and UniformModulus consumer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformContinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compactness, open-cover arguments, selected finite nets, quotient function equality, host function extensionality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-radius exactness, ContinuousMap handoff, composition stability, and field faithfulness for BEDC.Derived.UniformContinuityModulusUp.

Constructive story: A $\mathsf{UniformContinuityModulus}^{\uparrow}$ packet is generated from a source MetricUp row, a target MetricUp row, a ContinuousMap row, a positive target tolerance, a positive source radius, a UniformModulus consumer row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2229

A Concrete Naming Certificate for $\mathsf{ClosedIntervalApproximation}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedIntervalApproximation}^{\uparrow}$ packet records the finite endpoint approximation surface for a closed real interval before any compactness or real-completeness principle is available. It sits after the endpoint carrier of chapter 1591, the finite net route of chapter 1250, the rational cover ledger of chapter 1882, the dyadic tolerance core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is an endpoint-window approximation certificate over displayed rows, not Heine–Borel compactness, open-cover compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2229.1 (Closed interval approximation carrier)**.** *A* $\mathsf{ClosedIntervalApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, K, Q, D, S, R, L, U, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted closed bounded interval row whose lower and upper endpoint data are being approximated.*
2. *K is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row naming the finite mesh and cell route available over I.*
3. *Q is the* $\mathsf{RationalIntervalCover}^{\uparrow}$ *ledger recording the rational endpoint windows and containment tests inspected by the approximation.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording dyadic radii, endpoint slack comparisons, and mesh refinements used by K and Q.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row specifying which endpoint observations are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and dyadic tolerance requests.*
7. *L and U are the displayed lower and upper approximation rows delivered to Real and Completion consumers.*
8. *W is the window-coherence ledger saying that later endpoint windows refine the same I, K, Q, D, S, R, L, U route.*

9. *H records componentwise* hsame *transport for the interval row, finite net row, rational cover ledger, dyadic tolerance ledger, stream window, regular readback, lower approximation, upper approximation, coherence ledger, continuation row, provenance row, and local naming row.*

10. *C records displayed* Cont *replay of the route*

$$I \longmapsto K \longmapsto Q, D \longmapsto S, R \longmapsto L, U, W.$$

11. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalApproximation}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{RationalIntervalCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalApproximation}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite endpoint approximation packet. It has no coordinate for a host interval, a selected real endpoint, quotient real equality, trichotomy, an open-cover subcover, Heine–Borel compactness, or Real completeness.

Lean4 ✓ `BEDC.Derived.ClosedIntervalApproximationUp.ClosedIntervalApproximationTasteGate single carrier alignment`

Theorem 2229.2 (Closed interval approximation NameCert obligations)**.** *For every accepted* $\mathsf{ClosedIntervalApproximation}^{\uparrow}$ *carrier*

$$A = (I, K, Q, D, S, R, L, U, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval row, finite net row, rational cover ledger, dyadic tolerance ledger, stream window, regular readback, lower approximation, upper approximation, coherence, transport, replay, provenance, and local naming rows;*

2. *endpoint source compatibility, requiring K, Q, D, S, R to be read from the same accepted closed interval row I;*

3. *rational and dyadic exactness, requiring Q and D to account for every endpoint containment, tolerance radius, and refinement used to compute L and U;*

4. *finite-window readback, requiring S and R to expose only the inspected endpoint windows before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed;*

5. *approximation coherence, requiring W, H, C to preserve the same endpoint approximation route under later finite-window replay and componentwise transport;*

6. *Real and Completion handoff, allowing downstream consumers to read L and U only through the displayed I, K, Q, D, S, R, W route;*

7. *boundary refusal, excluding Heine–Borel compactness, open-cover compactness, quotient real equality, host endpoint selection, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No closed-interval approximation obligation is stored outside these rows.

Proof. Project the accepted carrier. The projection exposes exactly the interval source, finite net, rational cover ledger, dyadic tolerance ledger, finite stream window, regular rational readback,

lower and upper approximation rows, coherence ledger, transport, replay, provenance, and local naming.

Endpoint source compatibility follows because K, Q, D, S, R are coordinates of the same carrier and are all attached to I. A consumer cannot replace I by a host interval or use a second endpoint source without leaving the displayed packet.

Rational and dyadic exactness are the rows Q and D. They account for the containment tests, dyadic radii, slack comparisons, and mesh refinements used by the lower and upper approximation rows, so no hidden precision source remains for L or U.

The finite-window readback is the route through S and R. These rows expose only the inspected endpoint observations and their regular rational readbacks before a Real-facing consumer can read the approximation.

Finally W, H, C, P, N preserve and name the same route. Since no carrier coordinate stores a host interval, selected real endpoint, quotient real equality, trichotomy branch, open-cover subcover, Heine–Borel compactness theorem, or ambient completeness theorem, the local NameCert surface cannot export any of them. □

Theorem 2229.3 (Closed interval approximation Real-window handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{ClosedIntervalApproximation}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{RationalIntervalCover}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamNam}$$

The consumer receives displayed lower and upper endpoint approximation rows with a coherence ledger, not a host closed interval, not quotient real equality, not a selected endpoint pair, not Heine–Borel or open-cover compactness, and not a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with an accepted carrier $A = (I, K, Q, D, S, R, L, U, W, H, C, P, N)$. The only interval source visible to a consumer is I, and the only finite mesh source over it is K.

The rational and dyadic stage is then forced. The ledger Q supplies rational endpoint windows and containment tests, while D supplies dyadic tolerances and refinement data attached to the same interval and mesh rows.

The Real-facing stage passes through finite observations. The window row S and readback row R expose the inspected endpoint data before L and U are delivered as lower and upper approximation rows.

The coherence and structural rows close the handoff. The row W ties later windows to the same route, while H, C, P, N transport, replay, source, and name it. Thus a Real or Completion consumer can read only the finite approximation route and cannot obtain host interval equality, selected endpoints, quotient real equality, trichotomy, compactness, or ambient completeness from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalApproximation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedIntervalApproximation}^{\uparrow}$ packet is generated from a closed bounded interval row, a ClosedBoundedIntervalNet row, a RationalIntervalCover ledger, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, lower and upper approximation rows, a coherence ledger, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2229.1, Definition 2229.2, and Definition 2229.3 seed the finite endpoint approximation surface over ClosedBoundedInterval, ClosedBoundedIntervalNet, RationalIntervalCover, DyadicRatCore, StreamName, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Heine–Borel compactness, open-cover compactness, quotient real equality, selected endpoints, trichotomy, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint source compatibility, rational and dyadic exactness, finite-window readback, approximation coherence, Real and Completion handoff, and boundary refusal for BEDC.Derived.ClosedIntervalApproximationUp.

Chapter 2230

A Concrete Naming Certificate for $\mathsf{AbelDirichletComparison}^{\uparrow}$

Following Hardy and Bishop–Bridges, the $\mathsf{AbelDirichletComparison}^{\uparrow}$ packet records the finite comparison surface shared by the Abel and Dirichlet convergence tests over the $\mathsf{RealSeries}^{\uparrow}$ corridor. It sits after the real-series source of chapter 1581, the Abel-test face of chapter 1496, the Dirichlet-test face of chapter 1497, the uniform Cauchy handoff of chapter 1736, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet names a single shared-tail route for downstream Tauberian, summability, and real-series consumers; it is not a selected series sum, a quotient equality of partial-sum streams, a countable-choice selector, host completeness, or a replacement for either test.

Definition 2230.1 (Abel–Dirichlet comparison carrier)**.** *An* $\mathsf{AbelDirichletComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, D, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing the real-valued term stream and the finite partial-sum windows read by the comparison.*
2. *A is the* $\mathsf{AbelTest}^{\uparrow}$ *face row, exposing the bounded partial-sum row, monotone null coefficient ledger, and finite Abel summation-by-parts data visible to the packet.*
3. *D is the* $\mathsf{DirichletTest}^{\uparrow}$ *face row, exposing the bounded partial-sum row, coefficient stream, null-tail ledger, and finite Dirichlet tail schedule visible to the packet.*
4. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *shared-tail row, displaying the common tail request and the finite threshold through which both test faces hand off to later Cauchy-style consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed source windows, test-face windows, and shared-tail comparison.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after S, A, D, U, R have been displayed.*
7. *H records componentwise* hsame *transport for the source, Abel face, Dirichlet face, shared-tail row, regular readback, endpoint seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a consumer request through S to the finite source windows, through A and D to the two test faces, through U to the shared tail, through R to regular rational readback, and then through E to the endpoint seal.*

9. *P is the* Pkg *provenance over* $\mathsf{AbelDirichletComparison}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelDirichletComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for a chosen infinite sum, an equality quotient on partial-sum streams, a choice-selected convergence witness, an ambient completeness theorem, or an independent test result outside the named faces.

Lean4 ✓ `BEDC.Derived.AbelDirichletComparisonUp.AbelDirichletComparisonTasteGate single carrier alignment`

Theorem 2230.2 (Abel–Dirichlet comparison NameCert obligations)**.** *For every accepted* $\mathsf{AbelDirichletComparison}^{\uparrow}$ *carrier $K = (S, A, D, U, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbelDirichletComparison}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. $\mathsf{RealSeries}^{\uparrow}$ *source exposure through S, preserving the finite term and partial-sum windows consumed by the comparison;*
3. *Abel-face exposure through A, preserving the bounded partial-sum, monotone null coefficient, and summation-by-parts rows already named by the Abel-test packet;*
4. *Dirichlet-face exposure through D, preserving the bounded partial-sum, coefficient stream, null-tail, and tail-schedule rows already named by the Dirichlet-test packet;*
5. *shared-tail exactness through U, requiring both faces to hand off to the same* $\mathsf{UniformCauchySeries}^{\uparrow}$ *tail request before a later consumer may read a Cauchy-style conclusion;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *endpoint exposure through R and E;*
7. *componentwise transport, displayed replay, provenance, and local naming through exactly H, C, P, N.*

These are finite-row obligations over the sibling surfaces of chapter 1581, chapter 1496, chapter 1497, chapter 1736, chapter 301, and chapter 38.

Proof. Project the accepted packet. The carrier exposes exactly the real-series source row, Abel-test face, Dirichlet-test face, shared-tail row, regular readback, endpoint seal, componentwise transports, continuation replay, provenance, and local naming row.

Read the analytic faces. The row A can contribute only the Abel-test finite summation-by-parts route already visible through its carrier, while D can contribute only the Dirichlet-test finite tail route already visible through its carrier. The comparison packet does not add a third convergence argument.

The common obligation is the row U. It forces both faces to meet at one $\mathsf{UniformCauchySeries}^{\uparrow}$ shared-tail request before R and E can be read by downstream consumers.

Finally read H, C, P, N. These structural rows transport, replay, source, and name the same route, so the seven listed obligations exhaust the local certificate surface. □

Theorem 2230.3 (Abel–Dirichlet shared-tail route)**.** *Every downstream consumer that compares Abel and Dirichlet evidence through an accepted* $\mathsf{AbelDirichletComparison}^{\uparrow}$ *carrier must factor through*

$$S \longmapsto A, D \longmapsto U \longmapsto R \longmapsto E$$

together with H, C, P, N. Thus Tauberian, Euler-transform, and summability-style consumers receive a finite shared-tail handoff from the $\mathsf{RealSeries}^{\uparrow}$ *corridor rather than two unrelated informal references to the Abel and Dirichlet rows.*

Proof. Start with a downstream comparison read. The source row S is the only $\mathsf{RealSeries}^{\uparrow}$ entry point, so the requested term and partial-sum data are first confined to the displayed real-series windows.

The two test faces are then read in parallel. The Abel face A and Dirichlet face D retain their own finite coefficient and bounded-partial-sum data, but neither face may export an endpoint seal directly from the comparison packet.

The row U is the unique tail-facing bridge between those faces and later Cauchy-style consumers. A consumer therefore reaches regular rational readback R and the endpoint seal E only after the shared $\mathsf{UniformCauchySeries}^{\uparrow}$ row has been displayed.

Transport, replay, provenance, and local naming through H, C, P, N preserve that same finite route. Since the carrier has no coordinate for selected sums, quotient stream equality, countable choice, host completeness, or a separate convergence theorem, no downstream consumer can bypass the shared-tail handoff. □

Falsifiable prediction: An accepted $\mathsf{AbelDirichletComparison}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ endpoint seal, or downstream summability handoff without first reading the $\mathsf{RealSeries}^{\uparrow}$ source row, both test faces, and the $\mathsf{UniformCauchySeries}^{\uparrow}$ shared-tail row refutes the carrier surface.

Independence witness: realseries, abel-test, dirichlet-test, uniform-cauchy-series, regseqrat, real: no listed sibling supplies the whole ten-row packet $K = (S, A, D, U, R, E, H, C, P, N)$, because each sibling contributes only a source, one test face, a shared-tail handoff, a readback, or a seal while this chapter binds the comparison with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelDirichletComparison}^{\uparrow}}$.

Constructive story: An $\mathsf{AbelDirichletComparison}^{\uparrow}$ packet is generated from a $\mathsf{RealSeries}^{\uparrow}$ source row, $\mathsf{AbelTest}^{\uparrow}$ and $\mathsf{DirichletTest}^{\uparrow}$ face rows, one $\mathsf{UniformCauchySeries}^{\uparrow}$ shared-tail row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelDirichletComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2230.1, Definition 2230.2, and Definition 2230.3 seed the finite comparison surface over $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelDirichletComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected series sums, quotient equality of partial-sum streams, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface and shared-tail route.

Chapter 2231

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedCompletion}^{\uparrow}$ packet records the located completion landing object reached when displayed Cauchy data carries an explicit locatedness service before the L10 Real and Completion routes consume it. It sits after the located Cauchy evidence of chapter 2216, the located completion seal of chapter 1805, the metric-completion interface of chapter 1506, and the real Cauchy modulus boundary of chapter 1423. The packet supplies a named constructive completion surface for located Cauchy data; it does not assert quotient equality of Cauchy names, select representatives, use trichotomy, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2231.1 (Bishop located completion carrier)**.** *A* $\mathsf{BishopLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, S, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{CauchyLocatedness}^{\uparrow}$ *row. It records the located Cauchy evidence available before any completion-facing consumer reads a seal.*
2. *S is the* $\mathsf{LocatedCompletionSeal}^{\uparrow}$ *row. It seals the located Cauchy data as a completion-facing object without quotienting names.*
3. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route. It records the displayed metric-completion source through which the located packet can be consumed by L10 completion readers.*
4. *R is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *row. It records the real-facing modulus or threshold discipline attached to the same Cauchy data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *or completion seal exposed only after L, S, M, R have been displayed.*
6. *H records componentwise* hsame *transport for locatedness, seal, metric-completion, real-modulus, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through L, S, M, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletion}^{\uparrow}$, $\mathsf{CauchyLocatedness}^{\uparrow}$, $\mathsf{LocatedCompletionSeal}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, S, M, R, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionUp.BishopLocatedCompletionTasteGate single carrier alignment`

Theorem 2231.2 (Bishop located completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompletion}$ *carrier $B = (L, S, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located Cauchy row, located completion seal, metric-completion route, real Cauchy modulus row, terminal seal, and structural rows H, C, P, N;*
2. *locatedness exposure, requiring every completion-facing read to pass through L before the located seal or metric-completion route is inspected;*
3. *seal exactness, requiring S to package the same located Cauchy data without adding quotient names or representative selection;*
4. *completion compatibility, requiring M to consume only the displayed metric-completion route already available from the located Cauchy data;*
5. *real-modulus compatibility, requiring R to expose the same real Cauchy modulus or threshold discipline before the terminal* $\mathsf{Real}^{\uparrow}$ *or completion seal E is read;*
6. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Bishop located completion obligation is stored outside these rows.

Proof. Project the carrier of Definition 2231.1. The visible packet consists exactly of the located Cauchy row L, located seal S, metric-completion route M, real-modulus row R, terminal seal E, and structural rows H, C, P, N.

The locatedness row is read first. The chapter chapter 2216 supplies the sibling surface for located Cauchy evidence, and the carrier gives no route to the seal before that row is displayed.

The seal and completion rows then keep the same data on the L10 route. The seal row S is the located-completion boundary of chapter 1805, while M routes the packet through the metric-completion interface of chapter 1506.

Finally the real-modulus and structural rows close the local certificate. The row R records the threshold discipline named in chapter 1423, and E, H, C, P, N expose, transport, replay, source, and name the same route. Since the excluded quotient, selection, trichotomy, choice, host-equality, and ambient-completeness objects are absent from the carrier, the listed rows exhaust the local $\mathsf{NameCert}$ surface. □

Theorem 2231.3 (Bishop located completion nonescape)**.** *Every accepted* $\mathsf{BishopLocatedCompletion}^{\uparrow}$ *Real or completion read factors through the displayed rows $L, S, M, R, E, H, C, P, N$ of Definition 2231.1. The read may inspect the* $\mathsf{CauchyLocatedness}^{\uparrow}$ *row, the* $\mathsf{LocatedCompletionSeal}^{\uparrow}$ *row, the* $\mathsf{MetricCompletion}^{\uparrow}$ *route, the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold row, the terminal seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row, but it cannot project quotient completion equality, selected representatives, host equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 2231.1. The only visible analytic rows are L, S, M, R, E, and the only structural rows are H, C, P, N.

Use Definition 2231.2. It requires completion-facing reads to pass through locatedness, located sealing, metric-completion compatibility, real-modulus compatibility, terminal sealing, componentwise transport, replay, provenance, and local naming in the displayed order.

The refused objects have no row in the carrier. Hence quotient completion equality, selected representatives, host equality, trichotomy, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot be projected from an accepted Bishop located completion read. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedCompletion}^{\uparrow}$ Real or Completion read factors through $\mathsf{CauchyLocatedness}^{\uparrow}$, $\mathsf{LocatedCompletionSeal}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, terminal sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchylocatedness, locatedcompletionseal, metriccompletion, realcauchymodulus: $\mathsf{BishopLocatedCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located Cauchy evidence, located completion sealing, metric-completion routing, real-modulus threshold discipline, terminal sealing, transport, continuation, provenance, and local naming as one finite completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2231.1, Definition 2231.2, and Definition 2231.3 seed the finite located-completion surface over $\mathsf{CauchyLocatedness}^{\uparrow}$, $\mathsf{LocatedCompletionSeal}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host real equality, trichotomy, countable choice, public bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, locatedness exposure, seal exactness, metric-completion compatibility, real-modulus compatibility, and ledger non-escape over the same displayed packet.

Constructive story: The construction starts from located Cauchy data, seals it as a located completion object, routes it through the L10 metric-completion interface, and exposes the real Cauchy modulus only along the same finite NameCert path.

Chapter 2232

A Concrete Naming Certificate for $\mathsf{MetricCofinalCompletion}^{\uparrow}$

Following Bishop–Bridges constructive metric completion and Kelley's net and filter language, the $\mathsf{MetricCofinalCompletion}^{\uparrow}$ packet records the finite cofinal-evidence surface that lets a completion consumer compare Cauchy-filter and Cauchy-net presentations before reading a Real-facing or separated-metric readback. It sits beside the metric source of chapter 57, the Cauchy-filter branch of chapter 333, the Cauchy-net branch of chapter 589, the regular rational and real readbacks of chapter 301 and chapter 38, the separated comparison of chapter 1411, the uniform completion route of chapter 1473, and the metric completion surface of chapter 1506.

Definition 2232.1 (Metric cofinal completion carrier)**.** *A* $\mathsf{MetricCofinalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, F, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row. It records the metric carrier, distance observation, and finite request boundary consumed by the completion-facing route.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch. It records filter-neighborhood evidence and the finite Cauchy request surface over X.*
3. *D is the* $\mathsf{CauchyNet}^{\uparrow}$ *branch. It records directed-index evidence, net values, and the finite Cauchy request surface over the same X.*
4. *R is the readback row. It records either the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback needed by regular rational names or the* $\mathsf{Real}^{\uparrow}$ *seal reached from that readback.*
5. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row. It records the equality-facing separated metric comparison available after both cofinal branches have been displayed.*
6. *H records componentwise* hsame *transport for the metric source, filter branch, net branch, readback, separated comparison, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$X, F, D \longmapsto R, S \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{MetricCofinalCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{MetricCofinalCompletion}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion, selected representatives, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCofinalCompletionUp.MetricCofinalCompletionTasteGate single carrier alignment`

Theorem 2232.2 (Metric cofinal completion NameCert obligations)**.** *For an accepted* $\mathsf{MetricCofinalCompletion}^{\uparrow}$ *carrier* $Q = (X, F, D, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCofinalCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exactness, Cauchy-filter branch exposure, Cauchy-net branch exposure, cofinal comparison of the two branches, readback exactness through* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*, separated comparison through* $\mathsf{SeparatedMetric}^{\uparrow}$*, transport and replay stability, provenance, local naming, and non-escape of quotient completion, selected representatives, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2232.1. The metric source is the row X, and it is the only row that supplies the underlying metric request boundary.

The Cauchy-filter and Cauchy-net branches are the rows F and D. They are both read over X, so a completion-facing consumer can compare their request surfaces without introducing a host quotient or a selected representative.

The readback and separated comparison are the rows R and S. The row R keeps regular rational and real-name evidence as displayed readback data, while S records separated-metric comparison after the two Cauchy branches have been exposed.

The rows H, C, P, N transport, replay, source, and name the same route. Since no other coordinate exists, the excluded host-side completion principles cannot enter the accepted packet. □

Theorem 2232.3 (Metric cofinal completion filter-net cofinality)**.** *Every completion-facing read of an accepted* $\mathsf{MetricCofinalCompletion}^{\uparrow}$ *packet factors the Cauchy-filter and Cauchy-net branches through the same metric source row:*

$$X \longmapsto F, D \longmapsto R, S.$$

Thus the packet records cofinal evidence between the $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *presentations before any* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer can inspect the route.*

Proof. Project the accepted carrier and read X first. Both branch rows name Cauchy evidence over this same metric source, so neither branch can change the metric carrier or distance request boundary.

The filter branch F supplies neighborhood evidence, and the net branch D supplies directed-index evidence. Cofinality is recorded by requiring both rows to be visible before the readback row R or the separated comparison row S is consumed.

The downstream completion chapters read only the displayed route. The uniform and metric completion surfaces may consume $X, F, D, R, S, H, C, P, N$, but the packet gives them no separate quotient object, representative selector, choice principle, compact open-cover argument, or ambient completeness seal. □

Theorem 2232.4 (Metric cofinal completion nonescape)**.** *Every accepted* $\mathsf{MetricCofinalCompletion}^{\uparrow}$ *read remains inside the finite route*

$$X, F, D, R, S, H, C, P, N.$$

In particular, no consumer may export quotient completion equality, selected representatives, countable choice, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ *completeness merely from the cofinal filter-net evidence.*

Proof. The carrier inventory of Definition 2232.1 lists the whole packet. Rows X, F, D, R, S give the metric source, two Cauchy branches, finite readback, and separated comparison.

Rows H and C preserve that inventory under hsame transport and Cont replay. Rows P and N record provenance and local naming for the same displayed route.

None of the excluded principles has a coordinate in the packet or a replay edge out of it. Hence any accepted consumer remains inside the finite cofinal-evidence surface. □

Falsifiable prediction: Every accepted $\mathsf{MetricCofinalCompletion}^{\uparrow}$ completion-facing read displays one metric source row, one Cauchy-filter branch, one Cauchy-net branch, one regular-rational or real readback row, one separated comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before it can be consumed by a completion chapter.

Independence witness: metric, cauchyfilter, cauchynet, regseqrat, real, separatedmetric, uniformcompletion, metriccompletion: $\mathsf{MetricCofinalCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a shared MetricUp source, filter and net Cauchy branches, readback, separated comparison, transport, replay, provenance, and local naming as one finite cofinal-evidence packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCofinalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCofinalCompletion}^{\uparrow}$ packet is generated from a MetricUp source row, CauchyFilterUp branch, CauchyNetUp branch, RegSeqRatUp or RealUp readback, SeparatedMetricUp comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCofinalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2232.1, Definition 2232.2, Definition 2232.3, and Definition 2232.4 seed the finite cofinal-evidence interface between Cauchy-filter and Cauchy-net completion presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCofinalCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter and net branch exactness, readback exactness, separated comparison, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.MetricCofinalCompletionUp.

Chapter 2233

A Concrete Naming Certificate for $\mathsf{PicardErrorEstimate}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive analysis, this packet records the a posteriori Picard error estimate as finite BEDC NameCert data. It sits between the map-level contraction surface of chapter 1418, the finite iteration route of chapter 395, and the fixed-point endpoint discipline of chapter 396. The packet names only the displayed residual, contraction ratio, Cauchy handoff, and endpoint seal rows; it does not select a host fixed point or import ambient completeness outside the carried rows.

Definition 2233.1 (Picard error-estimate carrier)**.** *A* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, d, T, \lambda, I, r, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the complete metric row whose carried histories contain the displayed Picard iterates.*
2. *d is the metric-distance row used to read adjacent iterate distances and endpoint-facing error estimates.*
3. *T is the contraction-map row, read through the* $\mathsf{ContractionMapping}^{\uparrow}$ *packet and never as an untracked host function.*
4. *λ is the rational contraction-ratio ledger with a displayed row below the unit bound.*
5. *I is the adjacent Picard-iterate ledger supplied by* $\mathsf{PicardContraction}^{\uparrow}$*, recording the visible rows x_k, x_{k+1} and the application route $x_{k+1} = T(x_k)$.*
6. *r is the residual distance row, reading $d(x_{k+1}, x_k)$ from the adjacent ledger.*
7. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row obtained from the residual row and the rational ratio ledger.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that exposes the regular rational name consumed by the completion route.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing error-bound row reached only after r, λ, M, R have been displayed.*
10. *H stores componentwise* hsame *transport for the complete metric, distance, map, ratio, Picard ledger, residual, modulus, handoff, seal, continuation, provenance, and local naming rows.*

11. *C stores displayed* Cont *replay from contraction application to adjacent residual read, from residual and ratio to the modulus row, and from the modulus row to the regular and real seal rows.*

12. *P is the* Pkg *provenance over* $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardErrorEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, d, T, \lambda, I, r, M, R, E, H, C, P, N$. It has no coordinate for a selected host fixed point, quotient equality, ambient completeness, global nonlinear analysis, or choice-selected endpoint.

Lean4 ✓ `BEDC.Derived.PicardErrorEstimateUp.PicardErrorEstimateTasteGate single carrier alignment`

Theorem 2233.2 (Picard error-estimate NameCert obligations)**.** *For every accepted* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *carrier $Q = (X, d, T, \lambda, I, r, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardErrorEstimate}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, contraction-map compatibility through T, rational-ratio visibility through λ, adjacent Picard ledger access through I, residual-distance read-back through r, Cauchy-modulus construction through M, regular-rational handoff through R,* $\mathsf{Real}^{\uparrow}$ *seal access through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 2233.1. The only metric and contraction data available to the classifier are the complete-metric row X, the distance row d, the contraction-map row T, and the rational ratio ledger λ.

The adjacent Picard ledger I exposes the visible pair whose residual distance is read by r. The modulus row M is downstream of that residual and ratio data, and the handoff row R is downstream of the modulus row.

The endpoint-facing row E is therefore a seal after the displayed residual, ratio, modulus, and regular-rational handoff. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the listed rows exhaust the local certificate surface. □

Theorem 2233.3 (Picard a posteriori error-bound route)**.** *Every endpoint error read from an accepted* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *packet factors through the internal classifier route*

$$I \longmapsto r \longmapsto \lambda \longmapsto M \longmapsto R \longmapsto E$$

together with X, d, T, H, C, P, N. Thus the a posteriori error estimate is read first from the adjacent residual row and the contraction ratio before any Cauchy, regular-rational, or real seal row is exposed. The route supplies no selected host fixed point, quotient equality, ambient completeness principle, or choice-selected endpoint.

Proof. Start with an endpoint error request. The carrier permits such a request only after the adjacent Picard ledger I has displayed the two consecutive iterates and the contraction application route through T.

The residual row r reads the distance between those adjacent iterates through d. The ratio row λ is the only contraction-bound coordinate, so the a posteriori estimate can use no other numerical source before the Cauchy-modulus row M is formed.

The regular handoff R and the seal row E are downstream of M. Componentwise transport and replay through H and C, with provenance and naming through P and N, preserve this same route and do not create a host fixed-point coordinate. □

Falsifiable prediction: Every $\mathsf{PicardErrorEstimate}^{\uparrow}$ endpoint error read factors through one complete metric row, one contraction-map row, one rational ratio below one, one adjacent Picard ledger, one residual distance row, one CauchyModulus row, one RegSeqRat handoff, one RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: contractionmapping, picardcontraction, banachfixedpoint: $\mathsf{PicardErrorEstimate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the residual distance row and the ratio-to-modulus error-bound route before the completion and endpoint seal rows are read.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardErrorEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{PicardErrorEstimate}^{\uparrow}$ packet is generated from a complete metric row, a metric-distance row, a contraction-map row, a rational contraction ratio below one, an adjacent Picard ledger, a residual distance row, a CauchyModulus row, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardErrorEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2233.1, Definition 2233.2, and Definition 2233.3 bind the finite a posteriori contraction error-bound route through the displayed residual, ratio, modulus, handoff, and seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardErrorEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point equality, selected fixed points, quotient equality, ambient completeness, bridge checking, Lean verification, or general nonlinear analysis.

Upgrade path: Obligation closure requires checked carrier admission, residual readback, ratio-to-modulus routing, regular-rational handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PicardErrorEstimateUp.

Chapter 2234

A Concrete Naming Certificate for $\mathsf{CodonSixBitWindow}^{\uparrow}$

The $\mathsf{CodonSixBitWindow}^{\uparrow}$ packet realizes the codon source atlas of subsection 9462.28.17 as finite BEDC NameCert data. It reads each base through a two-coordinate $\mathsf{Bool}^{\uparrow}$ atlas, packages the three base positions through the product and list surfaces of chapter 34 and chapter 36, compares no-11 suffix constraints against chapter 401, and hands the stop-face suffix row to chapter 1374. The packet records the six-coordinate source window and Flat6 readback; it does not identify source-space equality with the biological translation classifier.

Definition 2234.1 (Codon six-bit window carrier)**.** *A* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, A, L, F, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *coordinate row. It records the two binary axes used to read each base in the codon source atlas.*
2. *A is the three-position atlas row. It records the first, second, and third base windows as ordered pairs of Bool coordinates.*
3. *L is the* $\mathsf{List}^{\uparrow}$ *spine row. It records the ordered six-coordinate window and preserves position order for downstream reads.*
4. *F is the Flat6 readback row. It flattens the three two-coordinate base rows into one six-coordinate source-space vector.*
5. *S is the suffix-handoff row. It records the comparison with* $\mathsf{FibonacciCube}^{\uparrow}$ *no-11 suffix discipline and the handoff to* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *for stop-face reads.*
6. *H records componentwise* hsame *transport for Bool coordinates, product pairs, list spine, Flat6 readback, suffix handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$B, A, L \longmapsto F, S \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{FibonacciCube}^{\uparrow}$, $\mathsf{StopCodonZeckendorfSu}$ *the codon-window-six bridge,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CodonSixBitWindow}^{\uparrow}}$ *row.*
The classifier compares packets through $B, A, L, F, S, H, C, P, N$. It has no coordinate for biological translation-table identity, amino-acid classification, stochastic codon usage, quotient codon equality, or a selected global code table.

Lean4 ✓ `BEDC.Derived.CodonSixBitWindowUp.CodonSixBitWindowTasteGate single carrier alignment`

Theorem 2234.2 (Codon six-bit window NameCert obligations)**.** *For an accepted* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *carrier $W = (B, A, L, F, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CodonSixBitWindow}^{\uparrow}}$ *surface consists exactly of carrier admission, Bool-coordinate exactness, three-position atlas order, List spine preservation, Flat6 readback exactness, Fibonacci-cube suffix comparison, StopCodonZeckendorfSuffix handoff, transport and replay stability, provenance, local naming, and non-escape of biological translation-table identity or amino-acid classification.*

Proof. Carrier admission is projection from Definition 2234.1. The Bool-coordinate row B and three-position atlas row A expose exactly six source coordinates, grouped as three ordered base windows.

The list spine row L keeps the six coordinates ordered, and the Flat6 row F is the only readback that forgets the three-pair grouping while preserving the same source-space coordinates.

The suffix row S compares the final two-coordinate suffix with the finite no-11 discipline of chapter 401 and the stop-face handoff of chapter 1374. This is a source-window handoff, not a biological translation classifier.

The rows H, C, P, N transport, replay, source, and locally name the same route. Since no translation-table or amino-acid row exists in the carrier, those classifiers cannot be exported by the accepted packet. □

Theorem 2234.3 (Codon six-bit Flat6 readback)**.** *Every accepted* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source-space read factors through*

$$B, A, L \longmapsto F$$

before it can reach the suffix-handoff row S or the structural rows H, C, P, N. Thus Flat6 equality is equality of the displayed six-coordinate source window, not equality of biological translation classifiers.

Proof. Read B to obtain the Bool coordinate axes and A to group them into three base positions. The product surface preserves the two-coordinate base rows before any flattening occurs.

Read L to preserve the ordered six-coordinate spine. The Flat6 row F is then the unique route that exposes the same coordinates as one source-space vector.

Only after F is displayed may a consumer inspect the suffix handoff S or the structural rows H, C, P, N. Therefore any packet identifying Flat6 source-space equality with biological translation classification leaves the accepted carrier surface. □

Falsifiable prediction: Any $\mathsf{CodonSixBitWindow}^{\uparrow}$ packet that identifies Flat6 source-space equality with the biological translation classifier fails the classifier row, because the accepted carrier has only Bool-coordinate, product/list spine, Flat6 readback, suffix-handoff, transport, replay, provenance, and local naming rows.

Independence witness: stopcodonzeckendorfsuffix, codon_window_spectral_inverse, fibonaccicube, bool, list: $\mathsf{CodonSixBitWindow}^{\uparrow}$ is not bijective to any listed sibling because the explicit six-coordinate Flat6 row and suffix-handoff row jointly preserve source-window equality while refusing biological translation-classifier identity.

The Lean TasteGate follow-up is `BEDC.Derived.CodonSixBitWindowUp.TasteGate`, with explicit Nontrivial $\mathsf{CodonSixBitWindow}^{\uparrow}$ and FieldFaithful $\mathsf{CodonSixBitWindow}^{\uparrow}$ instances preserving $B, A, L, F, S, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{CodonSixBitWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{CodonSixBitWindow}^{\uparrow}$ packet is generated from BoolUp coordinate rows, a three-position product atlas, an ordered ListUp spine, Flat6 readback, FibonacciCubeUp suffix comparison, StopCodonZeckendorfSuffixUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CodonSixBitWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2234.1, Definition 2234.2, and Definition 2234.3 seed the finite six-coordinate source-window packet and its Flat6 readback boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CodonSixBitWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological translation-table identity, amino-acid classification, stochastic codon usage, quotient codon equality, selected global code tables, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Bool-coordinate exactness, product/list spine preservation, Flat6 readback, suffix handoff, nontriviality, and field faithfulness for BEDC.Derived.CodonSixBitWindowUp.TasteGate.

Chapter 2235

A Concrete Naming Certificate for $\mathsf{JensenInequality}^{\uparrow}$

Following Jensen and Hardy–Littlewood–Polya, the $\mathsf{JensenInequality}^{\uparrow}$ packet records the finite convex-combination route by which a convex function row, finitely many affine weights, and displayed real comparisons produce the Jensen inequality surface. It sits over the feasible affine spine of chapter 208, the vector carrier of chapter 47, the scalar and comparison rows of chapter 38, the rational coefficient source of chapter 37, and the endpoint comparison discipline of chapter 1674. The packet names the finite certificate route for Jensen-style convex analysis; it does not assert host convex functions, quotient equality of real names, ambient completeness, or a global optimization principle.

Definition 2235.1 (Jensen inequality carrier)**.** *A* $\mathsf{JensenInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (F, W, A, X, Y, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *F is the convex-function source row, recording the displayed domain, codomain, convexity ledger, and function-read route.*
2. *W is the finite affine-weight row, recording the rational coefficients, nonnegative coefficient checks, and finite-sum-to-one row read through* $\mathsf{Rat}^{\uparrow}$*.*
3. *A is the affine-spine row, recording the* $\mathsf{ConvexSet}^{\uparrow}$ *route that keeps the weighted point inside the displayed convex carrier.*
4. *X is the finite input-family row, recording the finitely many points consumed by the affine spine and their* $\mathsf{VecSpace}^{\uparrow}$ *source reads.*
5. *Y is the convex-image row, recording the finite image reads $F(x_i)$ and the weighted image expression.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row, recording the displayed inequality between the function value at the affine point and the weighted image expression.*
7. *Q is the* $\mathsf{RealMinMax}^{\uparrow}$ *endpoint row, recording the comparison and bounding data used when a consumer reads the displayed inequality.*
8. *H records componentwise* hsame *transport for F, W, A, X, Y, R, Q and the local naming row.*

9. *C records displayed* Cont *replay from the source rows through the affine spine, comparison rows, endpoint row, provenance, and local name.*

10. *P is the* Pkg *provenance over* $\mathsf{JensenInequality}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{RealMinMax}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{JensenInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, A, X, Y, R, Q, H, C, P, N$. It has no coordinate for a host convex function, quotient equality of functions or real names, a selected supremum, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.JensenInequalityUp.JensenInequalityTasteGate single carrier alignment`

Theorem 2235.2 (Jensen inequality NameCert obligations)**.** *For every accepted* $\mathsf{JensenInequality}^{\uparrow}$ *carrier $J = (F, W, A, X, Y, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{JensenInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the convex-function row, affine-weight row, affine-spine row, input-family row, image row, real-comparison row, endpoint row, structural rows H, C, P, and local naming row N; nonnegative rational coefficient accountability through W; convex-set affine-spine accountability through A; real comparison exactness through R, Q; and componentwise transport, replay, provenance, and naming for the same route.*

Proof. Project the accepted packet $J = (F, W, A, X, Y, R, Q, H, C, P, N)$. The carrier definition exposes exactly the convex-function source, affine weights, affine spine, input family, image family, comparison, endpoint, transport, replay, provenance, and naming rows.

The coefficient and affine-spine rows are read before the inequality row. Thus W supplies the nonnegative rational coefficients and finite sum row, while A supplies the displayed $\mathsf{ConvexSet}^{\uparrow}$ route that keeps the affine point in the accepted carrier.

The image and comparison rows then record the Jensen surface. The rows Y, R, Q carry the function images, real comparison, and endpoint comparison data, and H, C, P, N preserve and name that route. Since the excluded host convex-function and quotient-equality objects are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 2235.3 (Jensen inequality affine-spine route)**.** *Every accepted* $\mathsf{JensenInequality}^{\uparrow}$ *carrier routes its displayed inequality through*

$$W, X \longmapsto A \longmapsto F, Y \longmapsto R, Q \longmapsto H, C, P, N.$$

Consequently a consumer must read the finite rational weights, input family, $\mathsf{ConvexSet}^{\uparrow}$ *affine-spine data, convex-function source row, finite image row,* $\mathsf{Real}^{\uparrow}$ *comparison row,* $\mathsf{RealMinMax}^{\uparrow}$ *endpoint row, componentwise transport, replay, provenance, and local naming before it can cite the Jensen inequality surface.*

Proof. Start with a consumer read of the inequality. By Definition 2235.1, the only affine-combination data are the coefficient row W, input-family row X, and affine-spine row A.

The convex-function and image rows are downstream of that affine route. The row F supplies the convexity ledger, and Y supplies the displayed image family over the same finite weights.

Finally the comparison rows R, Q expose the real inequality only after those source rows have been displayed. The structural rows H, C, P, N transport, replay, source, and name the same route, so no consumer can bypass the affine spine by invoking an ambient convex-function theorem. □

Theorem 2235.4 (Jensen inequality public export)**.** *The public export of an accepted* $\mathsf{JensenInequality}^{\uparrow}$ *packet is exactly the finite row family* $F, W, A, X, Y, R, Q, H, C, P, N$ *and the dependency reads through* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*, and* $\mathsf{RealMinMax}^{\uparrow}$*. It exports no host convex function, quotient real equality, selected representative of a real value, open-cover compactness, countable choice, or ambient completeness principle.*

Proof. Use Definition 2235.2 to identify the local NameCert surface. It lists the carrier rows and structural rows as the complete obligation family.

Then use Definition 2235.3. It orders every consumer read through the rational weights, vector inputs, convex-set affine spine, convex-function source, image family, real comparison, endpoint comparison, transport, replay, provenance, and local naming rows.

Combining the obligation surface with the ordered route leaves precisely the listed public export. The absent host objects have no carrier coordinate and therefore cannot be exported by the packet. □

Falsifiable prediction: Every $\mathsf{JensenInequality}^{\uparrow}$ consumer reads a convex-function source row, finite rational nonnegative weights, a ConvexSet affine-spine row, vector input rows, Real comparison rows, RealMinMax endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the Jensen inequality surface is public.

Independence witness: convexset, real, rat, vecspace, realminmax: $\mathsf{JensenInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries convex-function source, finite affine weights, affine-spine membership, image rows, comparison rows, endpoint rows, transport, replay, provenance, and local NameCert data as one finite inequality packet.

Closure status for $\mathsf{NameCert}_{\mathsf{JensenInequality}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JensenInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2235.1, Definition 2235.2, Definition 2235.3, and Definition 2235.4 seed the finite Jensen inequality route over convex-function, affine-weight, ConvexSet, VecSpace, Real, Rat, and RealMinMax rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JensenInequality}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.JensenInequalityUp.JensenInequalityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host convex functions, quotient equality of real names or functions, selected extrema, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite affine-weight accountability, ConvexSet affine-spine exactness, Real comparison nonescape, endpoint comparison handoff, and public export scope for BEDC.Derived.JensenInequalityU

Constructive story: A $\mathsf{JensenInequality}^{\uparrow}$ packet is generated from a convex-function source row, finite rational affine weights, a ConvexSet affine-spine row, VecSpace input rows, finite image rows, Real comparison rows, RealMinMax endpoint rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2236

A Concrete Naming Certificate for $\mathsf{FiniteObservationFold}^{\uparrow}$

The $\mathsf{FiniteObservationFold}^{\uparrow}$ packet realizes the bounded MetaCIC checker-output surface of section 9379.4 as finite NameCert data. It sits beside the critical-path route of chapter 765, the bounded evaluator of chapter 818, the typed endpoint boundary of chapter 562, the consistency seal of chapter 740, and the export refusal gate of chapter 1319. The packet separates checked finite observations from any claim of global closed-term conversion decidability.

Definition 2236.1 (Finite observation fold carrier)**.** *A* $\mathsf{FiniteObservationFold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, T, R, N, S, G, H, C, P, L)$$

with the following displayed rows:

1. *K is the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *source row, recording the current bounded decidability frontier and the open global-conversion boundary.*
2. *T is the* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *observation row, recording the finite checker trace, bounded inputs, accepted checkpoint reads, and validation boundary.*
3. *R is the* $\mathsf{TypedReductionNormalForm}^{\uparrow}$ *endpoint row, recording the typed normal-form boundary reached by the bounded observation.*
4. *N is the* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *seal row, recording the closed-normal consistency data available at the displayed endpoint.*
5. *S is the finite fold row, recording the ordered aggregation of checker-output observations from T, R, N under the same critical-path source K.*
6. *G is the* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *refusal row, recording that the finite fold cannot be exported as global beta-conversion decidability or as a checked target outside the displayed bounded rows.*
7. *H records componentwise* hsame *transport for K, T, R, N, S, G and the local naming row.*
8. *C records displayed* Cont *replay from the critical-path source through finite trace observations, typed endpoint, consistency seal, fold row, refusal gate, provenance, and local name.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationFold}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{FiniteTraceEvaluator}^{\uparrow}$, $\mathsf{TypedReductionNormalForm}^{\uparrow}$, $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

10. L is the local $\mathsf{NameCert}_{\mathsf{FiniteObservationFold}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, T, R, N, S, G, H, C, P, L$. It has no coordinate for unbounded evaluation, global conversion decidability, closed subject reduction, full consistency, host validation, or an exported checked target beyond the displayed finite observation fold.

Lean4 ✓ `BEDC.Derived.FiniteObservationFoldUp.FiniteObservationFoldTasteGate single carrier alignment`

Theorem 2236.2 (Finite observation fold NameCert obligations)**.** *For every accepted* $\mathsf{FiniteObservationFold}^{\uparrow}$ *carrier $O = (K, T, R, N, S, G, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationFold}^{\uparrow}}$ *surface consists exactly of carrier admission for the critical-path source, finite trace observation, typed normal-form endpoint, normal-form consistency seal, finite fold row, cannot-claim export gate, structural rows H, C, P, and local naming row L; observation exactness through T; endpoint accountability through R, N; finite-fold ordering through S; export refusal through G; and componentwise transport, replay, provenance, and naming for the same bounded route.*

Proof. Project the accepted packet $O = (K, T, R, N, S, G, H, C, P, L)$. The carrier definition exposes exactly the critical-path, trace, endpoint, seal, fold, refusal, transport, replay, provenance, and naming rows.

The finite observation rows are read before any fold is public. The trace row T records bounded checker output, while R and N record the typed endpoint and consistency seal available for that bounded output.

The fold row S aggregates only those displayed observations, and the refusal row G blocks export as a stronger global decision procedure. Since the excluded unbounded and global claims are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 2236.3 (Finite observation fold vision handoff)**.** *Every* $\mathsf{FiniteObservationFold}^{\uparrow}$ *consumer receives the route*

$$K \longmapsto T \longmapsto R, N \longmapsto S \longmapsto G \longmapsto H, C, P, L.$$

Thus the MetaCIC decidability reading is a finite checker-output packet over bounded observations, typed normal-form endpoints, normal-form consistency seals, refusal export rows, componentwise transport, displayed replay, provenance, and local naming. It is not a global closed-term beta-conversion decider.

Proof. Start from a consumer of the fold. The critical-path row K fixes the frontier and keeps the global conversion boundary visible.

The finite trace row T supplies the bounded observations. The endpoint row R and seal row N are read only as data attached to those bounded observations, not as an unbounded normalisation theorem.

The fold row S then aggregates the displayed observations, and the export gate G refuses any checked-target reading stronger than that finite packet. The structural rows H, C, P, L preserve this route under transport, replay, provenance, and naming. □

Falsifiable prediction: Every $\mathsf{FiniteObservationFold}^{\uparrow}$ consumer reads MetaCICCriticalPath, FiniteTraceEvaluator, TypedReductionNormalForm, NormalFormConsistencySeal, CannotClaimExportGate, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any bounded checker-output packet is public.

Independence witness: MetaCICCriticalPath, FiniteTraceEvaluator, TypedReductionNormalForm, NormalFormConsistencySeal, CannotClaimExportGate: none is bijective to FiniteObservationFoldUp because the fold jointly carries critical-path source, finite trace observation, typed endpoint, normal-form consistency seal, bounded aggregation, export refusal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationFold}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationFold}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2236.1, Definition 2236.2, and Definition 2236.3 seed the finite bounded-observation fold over MetaCIC critical-path, finite-trace, typed-normal-form, normal-form-consistency, and cannot-claim export rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationFold}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global beta-conversion decidability, unbounded evaluation, closed subject reduction, full MetaCIC consistency, host validation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite observation exactness, typed-endpoint accountability, consistency-seal handoff, fold ordering, export refusal, and route preservation for BEDC.Derived.FiniteObservationFoldUp.

Constructive story: A $\mathsf{FiniteObservationFold}^{\uparrow}$ packet is generated from a MetaCICCriticalPath source row, a FiniteTraceEvaluator observation row, a TypedReductionNormalForm endpoint row, a NormalFormConsistencySeal row, a finite fold row, a CannotClaimExportGate refusal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2237

A Concrete Naming Certificate for $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley separated-reflection route for uniform and metric completions, the $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$ packet records the traditional passage from pre-separated pseudometric evidence to a separated metric completion as finite NameCert data. It starts from the pre-separated distance surface of chapter 1614, routes zero-distance evidence through the separated classifier of chapter 2004, and hands the resulting separated metric surface to the completion boundary of chapter 1506. Its numerical readback uses the finite windows of chapter 126, the regular rational route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet names the L10 completion bridge without quotient primitives, host equality, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2237.1 (SeparatedPseudometricCompletion carrier)**.** *A* $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (P, Z, Q, M, S, R, D, E, H, C, K, N)$$

with the following displayed rows:

1. *P is the source* $\mathsf{Pseudometric}^{\uparrow}$ *packet. It supplies point admission, displayed distance witnesses, dyadic tolerance rows, stream windows, regular rational readback, a real-distance seal, and zero-distance boundary data before separation.*
2. *Z is the displayed zero-distance row. It records the finite evidence consumed by the separated classifier and does not identify point rows by host equality.*
3. *Q is the* $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ *classifier output. It is the only row that turns the zero-distance evidence in Z into separated metric point-classifier evidence.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion handoff. It consumes the separated metric surface exposed by Q and supplies the completion-facing route without adding quotient completion equality.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened before any regular rational or real-distance readback is inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger used by the source pseudometric and by the completion-facing readback.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, R, D and the separated classifier route have been displayed.*
9. *H records componentwise* hsame *transport for the pseudometric, zero-distance, separated classifier, completion handoff, finite-window, regular rational, dyadic, real-seal, continuation, package, and naming rows.*
10. *C records displayed* Cont *replay from a completion request through $P, Z, Q, M, S, R, D, E, H, K, N$ in that order.*
11. *K is the* Pkg *provenance over* $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{SeparatedQuotientMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedPseudometricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient primitives, host equality, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SeparatedPseudometricCompletionUp.SeparatedPseudometricCompletionTasteGate`
`single carrier alignment`

Theorem 2237.2 (SeparatedPseudometricCompletion NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$ *carrier $A = (P, Z, Q, M, S, R, D, E, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedPseud}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source* $\mathsf{Pseudometric}^{\uparrow}$ *packet, zero-distance row,* $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ *classifier output,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *zero-distance separation, requiring every point-identity read from Z to pass through the separated classifier output Q before a metric or completion consumer may use it;*
3. *completion handoff, requiring M to consume the separated metric surface from Q rather than the pre-separated pseudometric row P directly;*
4. *numerical readback ordering, requiring S, R, D, E to be displayed in order before any completion-facing real-distance seal is exported;*
5. *transport and replay stability, requiring H and C to preserve the same route under componentwise* hsame *transport and displayed* Cont *replay;*
6. *provenance exactness, requiring K and N to name exactly the displayed BEDC dependencies and the local certificate row;*
7. *non-escape, excluding quotient primitives, host equality, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No separated pseudometric completion NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2237.1. The tuple lists the source pseudometric packet, zero-distance evidence, separated classifier output, completion handoff, finite windows, regular rational readback, dyadic ledger, real seal, transport, replay, provenance, and local naming rows.

Zero-distance separation follows from the order P, Z, Q. The source pseudometric row exposes zero-distance evidence, the row Z records the displayed evidence, and the row Q is the first coordinate that can export separated point-classifier evidence.

The completion handoff is then forced through M. Since M is downstream of Q, a completion-facing consumer cannot read point identity directly from the pre-separated pseudometric row.

Numerical readback is the displayed route S, R, D, E. Finite windows are opened first, regular rational data and dyadic comparisons are read next, and the terminal real seal is reached only after those rows have been displayed.

Transport and replay stability are supplied by H and C. They move the listed rows componentwise and replay the same finite route for consumers, so the certificate remains inside the displayed dependency surface.

The provenance and non-escape clauses are inventory checks on K, N and on the fields of A. None of the excluded principles occurs among the carrier coordinates, hence none can be part of the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.SeparatedPseudometricCompletionUp.SeparatedPseudometricCompletionCarrier namecert obligations`

Theorem 2237.3 (SeparatedPseudometricCompletion completion route)**.** *Let $A = (P, Z, Q, M, S, R, D, E, H, C, K$ be an accepted* $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$ *packet. Every completion-facing consumer factors through the finite route*

$$\mathsf{Pseudometric}^{\uparrow} \to Z \to \mathsf{SeparatedQuotientMetric}^{\uparrow} \to \mathsf{MetricCompletion}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicR}$$

Thus the consumer receives a separated metric completion handoff only after the zero-distance evidence has passed through the separated classifier and the numerical readback rows have been displayed. The packet exports no direct route from pre-separated pseudometric evidence to completion equality, host equality, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Start from an accepted packet A. The source row P supplies pre-separated distance evidence, and the row Z records the zero-distance boundary as displayed data.

The replay row C sends that evidence through Q before the completion handoff M can be read. This makes the separated classifier output the only route from zero distance to the metric point surface consumed by completion.

After M, a completion-facing numerical request reads the windows S, the regular rational row R, the dyadic ledger D, and finally the real seal E. The transport row H and the provenance rows K, N name the same displayed chain.

The excluded objects are absent from the carrier. There is no quotient primitive, host equality field, selected representative, selected limit, countable-choice schedule, trichotomy row, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness row, so no consumer can obtain one from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedPseudometricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$ packet is generated from a source $\mathsf{Pseudometric}^{\uparrow}$ packet, displayed zero-distance evidence, a $\mathsf{SeparatedQuotientMetric}^{\uparrow}$ classifier output, a $\mathsf{MetricCompletion}^{\uparrow}$ handoff, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedPseudometricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2237.1, Definition 2237.2, and Definition 2237.3 seed the L10 route from pre-separated pseudometric evidence through separated classification into metric completion.

Formal verification: FormalStatus(NameCert$_{\text{SeparatedPseudometricCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient primitives, host equality, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance separation, completion handoff, numerical readback ordering, transport and replay stability, provenance exactness, and non-escape for BEDC.Derived.SeparatedPseudometricCo

Chapter 2238

A Concrete Naming Certificate for $\mathsf{CauchyProductCommutativity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyProductCommutativity}^{\uparrow}$ packet names the finite source-window symmetry behind Cauchy-product commutativity before any completed-real multiplication claim is available. It sits over the product packet of chapter 464, the regular product route of chapter 461, the finite stream-window surface of chapter 126, the dyadic product ledger of chapter 291, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet records commutativity as a finite displayed swap of product-source rows; it does not import host multiplication, quotient streams, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2238.1 (CauchyProductCommutativity carrier)**.** *A* $\mathsf{CauchyProductCommutativity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P_{xy}, P_{yx}, W_x, W_y, D_{xy}, D_{yx}, R_{xy}, R_{yx}, E_{xy}, E_{yx}, H, C, Q, N)$$

with the following displayed rows:

1. P_{xy} *and* P_{yx} *are the original and swapped* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows.*
2. W_x *and* W_y *are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows used by both source orders.*
3. D_{xy} *and* D_{yx} *are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-observation rows, one for each order of the displayed dyadic inputs.*
4. R_{xy} *and* R_{yx} *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows reached from the two dyadic product observations.*
5. E_{xy} *and* E_{yx} *are the* $\mathsf{Real}^{\uparrow}$ *seal rows exposed only after the paired windows, dyadic product rows, and regular handoffs have been displayed.*
6. H *records componentwise* hsame *transport for the two source rows, paired windows, dyadic product rows, regular handoffs, Real seals, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay from every product-commutativity request through* $P_{xy}, P_{yx}, W_x, W_y, D_{xy}, D_{yx}, R_{x}$
8. Q *is the* Pkg *provenance over* $\mathsf{CauchyProductCommutativity}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductCommutativity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for host multiplication, quotient stream equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 2238.2 (CauchyProductCommutativity NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductCommutativity}^{\uparrow}$ *carrier*

$$K = (P_{xy}, P_{yx}, W_x, W_y, D_{xy}, D_{yx}, R_{xy}, R_{yx}, E_{xy}, E_{yx}, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCommutativity}^{\uparrow}}$ *surface consists exactly of carrier admission for the original and swapped* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, two* $\mathsf{DyadicRatCore}^{\uparrow}$ *product observations, two* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows, two* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation is read through the sibling routes named in chapter 464, chapter 461, chapter 126, chapter 291, chapter 301, and chapter 38; no obligation is stored in host multiplication or completed-real algebra.*

Proof. Project the accepted carrier. The two product-source rows P_{xy} and P_{yx} expose the same two stream windows in opposite order, and the carrier definition leaves no third source row for a product consumer.

Read the dyadic product observations. The rows D_{xy} and D_{yx} are the only points at which the two window observations are multiplied, and their symmetry is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ product-row symmetry rather than a host multiplication law.

Pass to the regular and real-facing rows. The handoffs R_{xy}, R_{yx} and seals E_{xy}, E_{yx} are downstream of the same windows and dyadic observations. The structural rows H, C, Q, N transport, replay, source, and name this finite packet, so the listed obligations exhaust the local certificate. □

Lean4 ✓ `BEDC.Derived.CauchyProductCommutativityUp.CauchyProductCommutativityCarrier namecert obligations`

Theorem 2238.3 (CauchyProductCommutativity window swap)**.** *Swapping the paired* $\mathsf{StreamName}^{\uparrow}$ *windows of an accepted* $\mathsf{CauchyProductCommutativity}^{\uparrow}$ *carrier swaps the two* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows and the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *product observations while preserving the same finite route to the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows, the* $\mathsf{Real}^{\uparrow}$ *seal rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.CauchyProductCommutativityUp.CauchyProductCommutativity window swap`

Proof. The carrier stores the two windows as the shared source of both product orders. Exchanging W_x and W_y therefore exchanges P_{xy} with P_{yx} and D_{xy} with D_{yx}.

The downstream rows are componentwise over the displayed source order. The regular handoffs and Real seals are read after the dyadic product rows, and H, C, Q, N preserve the same dependency route after the exchange.

No host multiplication or quotient-stream equality is used in the swap. The statement is only the finite window exchange already visible inside the packet. □

Theorem 2238.4 (CauchyProductCommutativity Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyProductCommutativity}^{\uparrow}$ *packet factors through the original and swapped* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-observation rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows before either seal row* E_{xy} *or* E_{yx} *is exposed. Thus the packet gives a non-quotient commutativity certificate for later Real algebra routes while excluding host multiplication, quotient streams, selected limits, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a seal-facing read. By the carrier definition, the only seal rows are E_{xy} and E_{yx}, and both are downstream of the displayed product-source rows, windows, dyadic product observations, and regular handoffs.

Use the window-swap theorem to identify the two routes as opposite readings of the same finite source-window packet. The structural rows then replay and name the same dependency route for any Real-facing consumer.

Because the carrier exposes no host multiplication, quotient-stream product, selected limit, trichotomy row, or ambient completeness coordinate, the Real seal boundary cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCommutativity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCommutativity}^{\uparrow}$ packet is generated from original and swapped $\mathsf{CauchyProduct}^{\uparrow}$ source rows, paired $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ product-observation rows, $\mathsf{RegSeqRat}^{\uparrow}$ classifier rows, $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCommutativity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2238.1, Definition 2238.2, Definition 2238.3, and Definition 2238.4 seed the finite source-window commutativity certificate for the Cauchy product route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCommutativity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host multiplication, quotient streams, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window swapping, dyadic product-row symmetry, regular handoff preservation, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCommutativityUp.

Chapter 2239

A Concrete Naming Certificate for $\mathsf{CauchyProductAssociativity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyProductAssociativity}^{\uparrow}$ packet records the finite threefold source-window route by which two parenthesized Cauchy-product readings expose the same regular-rational product boundary before any completed-real multiplication law is available. It sits after the product-modulus route of **??**, the bounded-product route of chapter 1529, the source-swap route of chapter 2238, the regular multiplication route of chapter 1702, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names associativity as displayed BEDC route data over finite windows and dyadic product ledgers; it does not import host multiplication, quotient streams, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2239.1 (Cauchy product associativity carrier)**.** *A* $\mathsf{CauchyProductAssociativity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (P_{(xy)z}, P_{x(yz)}, W_x, W_y, W_z, M_{xy}, M_{yz}, B_{xy}, B_{yz}, D_{(xy)z}, D_{x(yz)}, R_{(xy)z}, R_{x(yz)}, E_{(xy)z}, E_{x(yz)}, H, C, Q, N)$$

with the following displayed rows:

1. $P_{(xy)z}$ *and* $P_{x(yz)}$ *are the two parenthesized* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows.*
2. W_x, W_y, W_z *are the three* $\mathsf{StreamName}^{\uparrow}$ *finite source-window rows shared by both parenthesizations.*
3. M_{xy} *and* M_{yz} *are the* $\mathsf{CauchyProductModulus}^{\uparrow}$ *rows that allocate the two adjacent product budgets before the outer product row is read.*
4. B_{xy} *and* B_{yz} *are the* $\mathsf{CauchyProductBounded}^{\uparrow}$ *rows that keep the adjacent intermediate product reads inside displayed finite magnitude ledgers.*
5. $D_{(xy)z}$ *and* $D_{x(yz)}$ *are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *threefold product ledgers for the left- and right-associated product observations.*
6. $R_{(xy)z}$ *and* $R_{x(yz)}$ *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows reached from the two threefold dyadic product ledgers.*
7. $E_{(xy)z}$ *and* $E_{x(yz)}$ *are the* $\mathsf{Real}^{\uparrow}$ *seal rows exposed only after the shared windows, adjacent modulus rows, bounded-product rows, dyadic ledgers, and regular-rational handoffs have been displayed.*

8. *H records componentwise* hsame *transport for the two parenthesized product rows, shared windows, modulus rows, bounded rows, dyadic ledgers, regular handoffs, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from every associativity-facing request through the three shared windows, the adjacent product budgets, the bounded-product ledgers, the two dyadic threefold ledgers, and the two regular and Real-facing handoffs.*
10. *Q is the* Pkg *provenance over* $\mathsf{CauchyProductAssociativity}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{CauchyProductModulus}^{\uparrow}$, $\mathsf{CauchyProductBounded}^{\uparrow}$, $\mathsf{CauchyProductCommutativity}^{\uparrow}$, $\mathsf{RegularCauchyMultiplication}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductAssociativity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for host multiplication, quotient stream equality, selected product limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyProductAssociativityUp.CauchyProductAssociativityTasteGate single carrier alignment`

Theorem 2239.2 (Cauchy product associativity NameCert obligations)**.** *For every accepted* CauchyProductAssocia *carrier*

$$A = (P_{(xy)z}, P_{x(yz)}, W_x, W_y, W_z, M_{xy}, M_{yz}, B_{xy}, B_{yz}, D_{(xy)z}, D_{x(yz)}, R_{(xy)z}, R_{x(yz)}, E_{(xy)z}, E_{x(yz)}, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductAssociativity}^{\uparrow}}$ *surface consists exactly of carrier admission for the two parenthesized* $\mathsf{CauchyProduct}^{\uparrow}$ *rows, the three shared* $\mathsf{StreamName}^{\uparrow}$ *source windows, adjacent* CauchyProductModulus *budgets, adjacent* $\mathsf{CauchyProductBounded}^{\uparrow}$ *ledgers, two* $\mathsf{DyadicRatCore}^{\uparrow}$ *threefold product ledgers, two* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows, two* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation is read through the sibling routes named in the opening dependency paragraph; no obligation is stored in host multiplication or completed-real algebra.*

Proof. Project the accepted carrier. The only source windows are W_x, W_y, W_z, and both parenthesized product rows are downstream of those three windows.

Read the adjacent product-budget rows. The modulus rows M_{xy}, M_{yz} allocate the finite tolerances, while the bounded-product rows B_{xy}, B_{yz} keep the intermediate product observations inside displayed magnitude ledgers before either outer product read is exposed.

Now inspect the two dyadic ledgers. The rows $D_{(xy)z}$ and $D_{x(yz)}$ are the only coordinates where the three source windows become product observations, and the regular rows $R_{(xy)z}, R_{x(yz)}$ and seal rows $E_{(xy)z}, E_{x(yz)}$ are downstream of them.

Finally H, C, Q, N transport, replay, source, and name the same finite packet. Since no omitted row contains host multiplication, quotient stream equality, selected limits, trichotomy, choice, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 2239.3 (Cauchy product associativity threefold route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{CauchyProductAssociativity}^{\uparrow}$ *carrier factors through the shared finite route*

$$W_x, W_y, W_z \longmapsto M_{xy}, M_{yz} \longmapsto B_{xy}, B_{yz} \longmapsto D_{(xy)z}, D_{x(yz)} \longmapsto R_{(xy)z}, R_{x(yz)}.$$

Thus the two parenthesized product reads consume the same three source windows, adjacent modulus budgets, and bounded-product ledgers before the regular-rational product boundary is public.

Proof. Begin with a regular-rational consumer. By Definition 2239.1, the only regular classifier rows are $R_{(xy)z}$ and $R_{x(yz)}$.

Those rows are not source data. Each is downstream of a threefold dyadic product ledger, and both dyadic ledgers are downstream of the same source windows together with the adjacent modulus and bounded-product rows.

The two parenthesized source rows therefore determine different readings of one displayed three-window route. No regular-rational consumer can bypass $W_x, W_y, W_z, M_{xy}, M_{yz}, B_{xy}, B_{yz}, D_{(xy)z}, D_{x(yz)}$ and still read either classifier row from this packet. □

Theorem 2239.4 (Cauchy product associativity Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{CauchyProductAssociativity}^{\uparrow}$ *carrier factors through the threefold route of Definition 2239.3 before either seal row* $E_{(xy)z}$ *or* $E_{x(yz)}$ *is exposed. Hence the packet supplies the certificate-level associativity surface needed by later* $\mathsf{RegularCauchyMultiplication}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *multiplication consumers, while exporting no host real multiplication law, quotient stream equality, selected product limit, trichotomy, countable choice, or ambient completeness theorem.*

Proof. Start from a seal-facing read. The carrier exposes exactly the two seal rows $E_{(xy)z}$ and $E_{x(yz)}$, and each appears after the corresponding regular-rational classifier row.

Apply Definition 2239.3. Both classifier rows are downstream of the same three source windows, adjacent modulus budgets, bounded-product ledgers, and dyadic threefold product observations.

The structural rows H, C, Q, N preserve and name this displayed route. Since the packet has no coordinate for host multiplication, quotient streams, selected limits, trichotomy, choice, or ambient completeness, no Real-facing read can export any of those objects. □

Falsifiable prediction: Every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer of a $\mathsf{CauchyProductAssociativity}^{\uparrow}$ packet factors through three shared source windows, adjacent CauchyProductModulus budgets, adjacent CauchyProductBounded ledgers, two dyadic threefold product rows, and the two regular-rational handoffs before either parenthesized product seal is consumed.

Independence witness: cauchyproductmodulus, cauchyproductbounded, cauchyproductcommutativity, regularcauchymultiplication, regseqrat, real: $\mathsf{CauchyProductAssociativity}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds three source windows, two adjacent product budgets, two bounded-product ledgers, two parenthesized product observations, two regular handoffs, two Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductAssociativity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductAssociativity}^{\uparrow}$ packet is generated from two parenthesized CauchyProduct rows, three shared StreamName windows, adjacent CauchyProductModulus budgets, adjacent CauchyProductBounded ledgers, two DyadicRatCore threefold product rows, two RegSeqRat classifier rows, two RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductAssociativity}^{\uparrow}}$, seed)

Scope closed: Definition 2239.1, Definition 2239.2, Definition 2239.3, and Definition 2239.4 seed the finite threefold product associativity packet for the regular-Cauchy product route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyProductAssociativity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real multiplication, quotient stream equality, selected product limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjacent product-budget handoff, bounded-product ledger preservation, threefold dyadic product routing, regular handoff preservation, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductAssociativityUp.

Chapter 2240

A Concrete Naming Certificate for $\mathsf{FiniteWindowPullback}^{\uparrow}$

The $\mathsf{FiniteWindowPullback}^{\uparrow}$ packet realizes the transported stationary diagonal seal route of Definition 9238.18 as finite NameCert data. It pulls each $\mathsf{Real}^{\uparrow}$ finite-window seal read back through an explicitly displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row. The packet is designed as the concrete object later Lean work can formalize before TasteGate.lean supplies the required Nontrivial and FieldFaithful instances.

The pullback route is a joint consumer of the finite-window carrier of chapter 126, the regular readback of chapter 301, the dyadic ledger of chapter 291, and the seal row of chapter 38. Its carrier stores those sibling surfaces together so a seal-facing request cannot be treated as an isolated packet detached from the L10 source chain.

Definition 2240.1 (FiniteWindowPullback carrier)**.** *A* $\mathsf{FiniteWindowPullback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by the seal-facing request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row consumed after the displayed stream window.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger attached to the same finite window.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row whose public read is pulled back to S, R, D.*
5. *H records componentwise* hsame *transport for the window, readback, ledger, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a seal-facing precision request through S, R, D, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowPullback}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, R, D, E, H, C, P, N. It has no coordinate for a detached Real value, quotient Cauchy class, selected limit, trichotomy, ambient completeness witness, Lean instance, or bridge check.

Lean4 ✓ `BEDC.Derived.FiniteWindowPullbackUp.FiniteWindowPullbackTasteGate single carrier alignment`

Theorem 2240.2 (FiniteWindowPullback NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowPullback}^{\uparrow}$ *carrier* $F = (S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every* $\mathsf{Real}^{\uparrow}$ *finite-window seal read admitted by the packet factors through exactly one displayed pullback packet* F*.*

Proof. Project the carrier. The only analytic rows are the displayed window S, readback R, dyadic ledger D, and seal row E.

The seal-facing read is downstream of those rows by construction. If a second admitted pullback packet exposes the same public seal read with the same window, readback, and dyadic ledger, constructor inversion on the finite BHist packet identifies its structural rows with H, C, P, N.

Thus each admitted finite-window seal read factors through one displayed packet, and no detached Real value, quotient class, selected limit, trichotomy row, ambient completeness witness, Lean instance, or bridge check can enter the local NameCert surface. □

Theorem 2240.3 (FiniteWindowPullback stationary diagonal route)**.** *The transported stationary diagonal seal exhaustion of Definition 9238.18 is realized by a* $\mathsf{FiniteWindowPullback}^{\uparrow}$ *packet whenever its public finite-window seal read is restricted to the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows. The route preserves the same* hsame*,* Cont*,* Pkg*, and local* NameCert *rows after pullback.*

Proof. Begin with the transported stationary diagonal seal row. The cited exhaustion theorem says that the public read is already determined by the finite stream window, regular readback, dyadic observation ledger, and Real seal.

Package those four readings as S, R, D, E. The structural rows H, C, P, N record transport, replay, provenance, and local naming without adding another analytic coordinate.

The resulting packet is exactly a $\mathsf{FiniteWindowPullback}^{\uparrow}$ carrier, so the stationary diagonal route has been pulled back to finite BEDC data. □

Theorem 2240.4 (FiniteWindowPullback StreamName route)**.** *Every accepted* $\mathsf{FiniteWindowPullback}^{\uparrow}$ *seal-facing read must pass through chapter 126, chapter 301, chapter 291, and chapter 38 before the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}$ *row is read. Equivalently, the read order exposes the* $\mathsf{StreamName}^{\uparrow}$ *window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* E *before the transport, replay, provenance, and local naming rows* H, C, P, N*.*

Proof. Project the finite carrier $F = (S, R, D, E, H, C, P, N)$ of Definition 2240.1. The first four rows are precisely the sibling surfaces for the stream window, regular readback, dyadic ledger, and Real seal.

The remaining rows cannot supply an alternative analytic route. The row H only transports the displayed components, C only replays the displayed request, P only records provenance, and N only names the already assembled local packet.

Thus any accepted seal-facing read reaches the local $\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}$ row only after passing through the four sibling chapters and their displayed rows. □

Falsifiable prediction: Every $\mathsf{Real}^{\uparrow}$ finite-window seal read admitted by a $\mathsf{FiniteWindowPullback}^{\uparrow}$ packet factors through exactly one displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert pullback packet.

Independence witness: streamname, regseqrat, dyadicratcore, real, and cauchylimitseal: no listed sibling is bijective to $\mathsf{FiniteWindowPullback}^{\uparrow}$ because this packet jointly stores the finite window, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows for one pullback route.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowPullback}^{\uparrow}$ packet is generated from a $\mathsf{StreamName}^{\uparrow}$ finite-window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2240.1, Definition 2240.2, and Definition 2240.3 seed the finite pullback packet for Real seal reads over the transported stationary diagonal route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowPullback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close detached Real values, quotient Cauchy classes, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean instances, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniqueness of the displayed pullback packet, stationary diagonal seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowPullbackUp.

Chapter 2241

A Concrete Naming Certificate for $\mathsf{SequentialUniformCompletion}^{\uparrow}$

Following Kelley on uniform spaces and Bishop–Bridges on constructive sequence completion, the $\mathsf{SequentialUniformCompletion}^{\uparrow}$ packet records the finite interface by which a displayed sequential Cauchy-completion route is offered to uniform-completion consumers. It sits between the sequence route of chapter 1683, the uniform-completion consumer of chapter 1473, the metric-completion surface of chapter 1506, the Cauchy-filter branch of chapter 333, and the Cauchy-net branch of chapter 589. The packet names only a finite handoff surface: it does not quotient Cauchy sequences, choose representatives, invoke countable choice, use open-cover compactness, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2241.1 (Sequential uniform completion carrier)**.** *A* $\mathsf{SequentialUniformCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, F, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SequentialCompletion}^{\uparrow}$ *route. It records the finite stream schedule, regular readback, dyadic tolerance ledger, Cauchy criterion or limit-seal row, and terminal real-seal handoff already accepted by the sequence-completion packet.*
2. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row. It records that the sequential route is read as a metric-completion-facing surface before any uniform consumer inspects it.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch extracted from the same displayed sequence route. It records the filter-side neighborhood evidence visible to the uniform-completion surface.*
4. *D is the* $\mathsf{CauchyNet}^{\uparrow}$ *branch extracted from the same displayed sequence route. It records the directed-window evidence visible to the uniform-completion surface.*
5. *H records componentwise* hsame *transport for the sequential route, metric-completion row, filter branch, net branch, replay, provenance, and local naming row.*
6. *C records displayed* Cont *replay of the handoff*

$$S \longmapsto M, F, D \longmapsto H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{SequentialCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{CauchyNet}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

8. N is the local $\mathsf{NameCert}_{\mathsf{SequentialUniformCompletion}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion, representative choice, countable choice, open-cover compactness, selected uniform limits, host equality of completions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialUniformCompletionUp.SequentialUniformCompletionTasteGate single carrier alignment`

Theorem 2241.2 (Sequential uniform completion NameCert obligations)**.** *For every accepted* $\mathsf{SequentialUniformCompletion}^{\uparrow}$ *carrier* $U = (S, M, F, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialUniformCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, sequence-route exposure, metric-completion handoff, Cauchy-filter branch exposure, Cauchy-net branch exposure, componentwise transport, displayed replay, provenance, local naming, and non-escape of quotient completions, representative choice, countable choice, open-cover compactness, selected uniform limits, host completion equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2241.1. The first projected row is S, so every consumer begins with the same finite $\mathsf{SequentialCompletion}^{\uparrow}$ route rather than with a quotient completion or a selected representative.

The metric and uniform-facing rows are then read through M, F, D. The row M supplies the metric-completion handoff, while F and D expose the filter and net presentations consumed by $\mathsf{UniformCompletion}^{\uparrow}$.

Rows H, C, P, N transport, replay, source, and name that same packet. Since the carrier inventory contains no other coordinate, the excluded completion principles cannot be exported by an accepted read. □

Theorem 2241.3 (Sequential uniform completion branch handoff)**.** *Every uniform-completion-facing read of an accepted* $\mathsf{SequentialUniformCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto M, F, D \longmapsto H, C, P, N.$$

Thus the sequential completion surface is handed to the metric-completion, Cauchy-filter, and Cauchy-net consumers before any $\mathsf{UniformCompletion}^{\uparrow}$ *read can use it, and the handoff exports no quotient completion, representative choice, countable choice, open-cover compactness, selected uniform limit, host completion equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the accepted carrier $U = (S, M, F, D, H, C, P, N)$. The continuation row C makes S the entry point, so the route starts with the already displayed sequence-completion packet.

The next rows are M, F, D. They give the metric-completion surface and the two standard uniform-completion branches over the same sequential route, which prevents a consumer from replacing the route by a hidden quotient object or selected limiting point.

Finally, H, P, N preserve the same handoff under transport, provenance, and local naming. No additional coordinate remains from which a choice principle, compactness principle, completion equality, or ambient real completeness claim could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialUniformCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialUniformCompletion}^{\uparrow}$ packet is generated from one $\mathsf{SequentialCompletion}^{\uparrow}$ route, one $\mathsf{MetricCompletion}^{\uparrow}$ consumer row, one $\mathsf{CauchyFilter}^{\uparrow}$ branch, one $\mathsf{CauchyNet}^{\uparrow}$ branch, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2241.1, Definition 2241.2, and Definition 2241.3 seed the finite sequence-to-uniform completion handoff through sequential, metric, filter, and net completion rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SequentialUniformCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, representative choice, countable choice, open-cover compactness, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence-route exposure, metric-completion handoff, filter and net branch exactness, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.SequentialUniformCompletionUp.

Chapter 2242

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$

Following Bourbaki and Kelley on metric completion and separated uniform spaces, the HausdorffCompletionUniversa packet records the separated universal-property surface for completion. It sits between the metric completion carrier of chapter 1506, the separated metric boundary of chapter 1411, the uniform completion route of chapter 1473, the extension-and-uniqueness packet of chapter 397, and the quotient-free separated reflection boundary of **??**. The packet names the finite handoff by which dense source data extend into a separated target without importing quotient completion, representative choice, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2242.1 (HausdorffCompletionUniversal carrier)**.** *A* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, Q, S, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{MetricCompletion}^{\uparrow}$ *row. It records the metric source, completion-facing seal, and finite request boundary consumed by the universal-property route.*
2. *Q is the completion seal row. It records the completed object as a displayed seal, not as a host quotient of Cauchy names.*
3. *S is the separated target row. It records the* $\mathsf{SeparatedMetric}^{\uparrow}$ *or Hausdorff-facing target exactness consumed by uniqueness.*
4. *D is the dense-source handoff row. It records the source inclusion and dense read through which maps out of the source are inspected.*
5. *E is the extension row. It records the finite* Cont *route that extends the dense-source map into the separated target.*
6. *L is the uniqueness row. It records the displayed separatedness comparison showing that two extensions with the same dense-source reads are* hsame*-identified.*
7. *H records componentwise* hsame *transport for the source metric, completion seal, separated target, dense handoff, extension, uniqueness, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$M, Q, D \longmapsto S, E, L \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* HausdorffCompletionUniversal$^{\uparrow}$, MetricCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, HausdorffReflection$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{HausdorffCompletionUniversal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, Q, S, D, E, L, H, C, P, N$. It has no coordinate for quotient completion, selected representatives, host equality of completed points, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUniversalUp.HausdorffCompletionUniversalTasteGate`
`single carrier alignment`

Theorem 2242.2 (HausdorffCompletionUniversal NameCert obligations)**.** *For an accepted* HausdorffCompletionUn *carrier $U = (M, Q, S, D, E, L, H, C, P, N)$, the local* NameCert$_{\text{HausdorffCompletionUniversal}^{\uparrow}}$ *surface consists exactly of carrier admission; separated target exactness through S; dense-source handoff through D; extension existence through E; uniqueness through the separatedness ledger L; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance and local naming through P, N; and non-escape from quotient completion, representative choice, host equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2242.1. The accepted packet exposes exactly the metric-completion source, completion seal, separated target, dense handoff, extension, uniqueness, transport, replay, provenance, and local naming rows.

Separated target exactness is the row S. A uniqueness read cannot inspect host equality of completed points; it can only read the separated target row and the displayed comparison ledger carried by L.

The extension surface is finite. The dense-source handoff D supplies the source reads, and the extension row E repacks those reads through a displayed Cont route into the separated target.

Transport and replay preserve the same packet. Rows H and C move only the displayed coordinates M, Q, S, D, E, L, P, N, while P and N record provenance and local naming for that route. Since no excluded host-side coordinate exists in the carrier, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted HausdorffCompletionUniversal$^{\uparrow}$ consumer reads a MetricCompletion source row, a completion seal row, a SeparatedMetric target row, a dense-source handoff row, an extension row, a uniqueness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before citing the separated universal property.

Independence witness: metriccompletion, separatedmetric, uniformcompletion, completionuniversalproperty, hausdorffreflection: HausdorffCompletionUniversal$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a completion seal, separated target exactness, dense-source handoff, extension, uniqueness, transport, replay, provenance, and local naming as one finite universal-property packet.

Closure status for NameCert$_{\text{HausdorffCompletionUniversal}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{HausdorffCompletionUniversal}^{\uparrow}}$, seed)

Scope closed: Definition 2242.1 and Definition 2242.2 seed the separated universal-property surface for completion over MetricCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, HausdorffReflection$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{HausdorffCompletionUniversal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host equality of completed points, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated target exactness, dense-source handoff, extension existence, uniqueness through separatedness, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.HausdorffCompletionUniversalUp.

Constructive story: A HausdorffCompletionUniversal$^{\uparrow}$ packet is generated from a MetricCompletion source row, completion seal, separated target row, dense-source handoff, extension row, uniqueness row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2243

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterRefinement}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyFilterRefinement}^{\uparrow}$ packet records the finite route by which regular Cauchy filter data are refined through cofinal subsequence windows before a regular rational readback and terminal real seal are consumed. It sits between the filter surface of chapter 333, the cofinal extraction route of chapter 405, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The refinement is the filter-facing handoff consumed by chapter 1506 and chapter 1473; it is not a quotient completion principle, selected representative, countable-choice schedule, or ambient real-completeness claim.

Definition 2243.1 (Regular Cauchy filter refinement carrier)**.** *A* $\mathsf{RegularCauchyFilterRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, including its finite filterbase requests and Cauchy pressure ledger.*
2. *S is the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *refinement row selecting the cofinal subsequence windows used to read the filter without changing its source surface.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposed by S and consumed by the dyadic and regular rational readback.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for the same windows, including the displayed comparison cells used by the regularity check.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the cofinal windows and dyadic tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, S, W, D, R have been displayed.*
7. *H records componentwise* hsame *transport for F, S, W, D, R, E and for the structural rows below.*
8. *C records displayed* Cont *replay from filter refinement to stream windows, from windows and dyadic cells to regular rational readback, and from readback to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFilterRefinement}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{CofinalSubsequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterRefinement}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for quotient filters, quotient completions, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterRefinementUp.RegularCauchyFilterRefinementTasteGate`
`single carrier alignment`

Theorem 2243.2 (Regular Cauchy filter refinement obligations)**.** *For every accepted* RegularCauchyFilterRefinemen *carrier* $Q = (F, S, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, classifier transport through* H, C, P, N*, cofinal filter refinement through* F *and* S*, dyadic-window readback through* W, D, R*, and* $\mathsf{Real}^{\uparrow}$ *non-escape through the seal row* E*. No obligation is discharged by quotient completion, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2243.1. The accepted packet lists exactly the filter source, cofinal refinement, stream windows, dyadic tolerance ledger, regular readback, Real seal, and structural rows.

Classifier transport is componentwise. The row H transports the displayed data, C replays the same refinement route, and P, N source and name that route without adding a second classifier surface.

Cofinal filter refinement is read through F and S. The source filter stays visible at F, while the cofinal subsequence row S selects the windows used by the refinement before any regular rational or Real-facing consumer is reached.

Dyadic-window readback is then forced through W, D, R. The stream row exposes finite windows, the dyadic row records their tolerance cells, and the regular rational row is the only readback coordinate downstream of them.

Finally E is the only Real-facing seal. Since the excluded quotient, representative, choice, host-equality, and ambient-completeness principles have no coordinate in the carrier, they cannot be exported by the local NameCert surface. □

Theorem 2243.3 (Regular Cauchy filter refinement handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyFilterRefinement}^{\uparrow}$ *packet reads the filter refinement only through*

$$F, S, W, D, R, E, H, C, P, N.$$

The consumer may inspect the source $\mathsf{CauchyFilter}^{\uparrow}$ *row, the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *refinement row, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It receives no quotient completion, selected representative, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the displayed carrier. The refinement route exposes F before any cofinal window is read, so completion-facing consumers do not begin from a quotient filter or selected representative.

Apply the cofinal row S and then the finite window row W. These rows align the filter request surface with the cofinal subsequence interface of chapter 405 before the readback reaches dyadic tolerance data.

The readback step uses D and R. The dyadic ledger supplies finite comparison cells, and the regular rational readback is the only numerical row exported before the seal E.

The completion consumers of chapter 1506 and chapter 1473 can therefore read only the displayed route and its structural rows H, C, P, N. No absent quotient, representative, choice, or ambient completeness coordinate can be recovered downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFilterRefinement}^{\uparrow}$ packet is generated from a CauchyFilter source row, CofinalSubsequence refinement row, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2243.1, Definition 2243.2, and Definition 2243.3 seed the finite filter-refinement route from CauchyFilter data through cofinal windows and dyadic readback to completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, cofinal filter refinement, dyadic-window readback, RealUp non-escape, and TasteGate field faithfulness for BEDC.Derived.RegularCauchyFilterRefinementUp.

Chapter 2244

A Concrete Naming Certificate for $\mathsf{RealSeriesRatioTest}^{\uparrow}$

Following d'Alembert and Cauchy's ratio-test tradition, the $\mathsf{RealSeriesRatioTest}^{\uparrow}$ packet records a finite convergence-test surface over the $\mathsf{RealSeries}^{\uparrow}$ corridor rather than a host limit of ratios. It consumes successive real-series term rows from chapter 1581, regular rational readback from chapter 301, finite stream windows from chapter 126, dyadic ratio-bound rows, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a displayed eventual-ratio bound for downstream Real and Completion consumers; it does not choose an infinite ratio limit, compare quotient real values, select a convergence witness by countable choice, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2244.1 (RealSeriesRatioTest carrier)**.** *A* $\mathsf{RealSeriesRatioTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing the inspected term stream and finite partial-sum windows.*
2. *T is the successive-term row, listing adjacent nonzero term windows a_n and a_{n+1} only through displayed real-name observations.*
3. *B is the dyadic ratio-bound row. It records a dyadic $q < 1$, a finite threshold, and the displayed comparison that every inspected tail ratio is bounded by q.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to read the adjacent terms and the bound comparisons.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the term windows, ratio-bound rows, and partial-sum windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, T, B, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the real-series source, adjacent-term row, dyadic bound, finite windows, regular readback, endpoint seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a consumer request through S, T, B, W, R and then to E, H, P, N.*

9. *P is the* Pkg *provenance over* $\mathsf{RealSeriesRatioTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *dyadic bound data,* BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSeriesRatioTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for a host ratio limit, quotient equality of real-name streams, a selected infinite sum, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RealSeriesRatioTestUp.RealSeriesRatioTestTasteGate single carrier alignment`

Theorem 2244.2 (RealSeriesRatioTest NameCert obligations)**.** *For every accepted* $\mathsf{RealSeriesRatioTest}^{\uparrow}$ *carrier* $K = (S, T, B, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealSeriesRatioTest}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure, successive-term window exactness, dyadic ratio-bound exactness,* $\mathsf{StreamName}^{\uparrow}$ *finite-window service,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every convergence-test consumer must read the finite route*

$$S, T, B, W \longmapsto R \longmapsto E$$

together with H, C, P, N before using the packet as ratio-test evidence.

Proof. Project the accepted carrier. The source row S provides only the displayed real-series terms and partial-sum windows already exposed by the $\mathsf{RealSeries}^{\uparrow}$ packet.

The successive-term row T and dyadic bound row B are the analytic core of the carrier. They name adjacent tail terms, the dyadic bound $q < 1$, and the finite comparisons visible in the selected windows; they do not name a limit of ratios.

The rows W and R supply the finite observation schedule and regular rational readback through which the comparisons are inspected. The endpoint row E can be read only after those finite rows have been displayed.

Finally H, C, P, N transport, replay, source, and locally name the same route. Since no omitted row carries quotient real equality, selected sums, countable choice, or ambient completeness, the listed obligations exhaust the local certificate surface. □

Falsifiable prediction: An accepted $\mathsf{RealSeriesRatioTest}^{\uparrow}$ packet that reaches a $\mathsf{Real}^{\uparrow}$ convergence seal without displaying adjacent term windows, one dyadic ratio bound below 1, finite $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback fails the carrier surface.

Independence witness: RealSeries, RegSeqRat, StreamName, Real, dyadic ratio-bound rows: none is bijective to $\mathsf{RealSeriesRatioTest}^{\uparrow}$, because the listed siblings separately supply source terms, finite windows, readback, or endpoint sealing while this packet binds them to one eventual-ratio-test route with transport, replay, provenance, and local naming.

The Lean TasteGate follow-up is `BEDC.Derived.RealSeriesRatioTestUp`, with explicit Nontrivial RealSeriesRat and FieldFaithful $\mathsf{RealSeriesRatioTest}^{\uparrow}$ instances preserving $S, T, B, W, R, E, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{RealSeriesRatioTest}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSeriesRatioTest}^{\uparrow}$ packet is generated from a $\mathsf{RealSeries}^{\uparrow}$ source row, successive real-term windows, one dyadic ratio-bound row below one, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealSeriesRatioTest}^{\uparrow}}$, seed)

Scope closed: Definition 2244.1 and Definition 2244.2 seed the finite ratio-test carrier and its NameCert obligation package over $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealSeriesRatioTest}\uparrow}$, theoremChecked)
Lean target: `BEDC.Derived.RealSeriesRatioTestUp.RealSeriesRatioTestTasteGate\_single\_carrier\_alignment`
Bridge status: none
Not claimed: This chapter does not claim host ratio limits, quotient real equality, selected infinite sums, countable choice, Real completeness, or bridge checking.
Upgrade path: A bridge route can relate the ten-row carrier gate to downstream ratio-test consumer obligations.

Chapter 2245

A Concrete Naming Certificate for $\mathsf{CodonTransitionMatrix}^{\uparrow}$

The $\mathsf{CodonTransitionMatrix}^{\uparrow}$ packet realizes the finite-state stop-boundary prototype of subsection 9462.28.24 as concrete BEDC NameCert data. It consumes the six-coordinate source-window carrier of chapter 2234, the stop-suffix surface of chapter 1374, finite state rows for scan, elongate, terminate, readthrough, repair, and mutate states, and local transition rows for UAA, UAG, UGA, and UGG. The packet records a standard stop-boundary transition matrix; it does not identify source-space equality with biological translation identity, choose a stochastic model, or collapse the tryptophan row into termination.

Definition 2245.1 (CodonTransitionMatrix carrier)**.** *A* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, Q, F, D, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source-window row exposing the six-coordinate codon readback.*
2. *Q is the finite-state row listing scan, elongate, terminate, readthrough, repair, and mutate states as displayed classifier entries.*
3. *F is the stop-face row naming the local* UAA*,* UAG*,* UGA*, and* UGG *suffix reads inside the codon-window surface.*
4. *D is the deterministic transition row. It records*

$$\begin{aligned}
\delta(\mathsf{elongate}, \mathrm{UAA}) &= \mathsf{terminate},\\
\delta(\mathsf{elongate}, \mathrm{UAG}) &= \mathsf{terminate},\\
\delta(\mathsf{elongate}, \mathrm{UGA}) &= \mathsf{terminate},\\
\delta(\mathsf{elongate}, \mathrm{UGG}) &= \mathsf{elongate\text{-}Trp}.
\end{aligned}$$

5. *T is the transition-exactness row requiring each displayed stop-face transition to agree with D and requiring the* UGG *row to remain non-terminating.*
6. *H records componentwise* hsame *transport for source windows, state rows, stop-face rows, deterministic transition rows, exactness rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a codon-window request through W, Q, F, D, T and then to H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, *stop-face and codon-cube boundary rows, local stop-boundary rows,* BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CodonTransitionMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for stochastic readthrough probabilities, a global genetic-code table, amino-acid classifier identity, source-space quotient equality, or a biological inevitability claim.

Lean4 ✓ `BEDC.Derived.CodonTransitionMatrixUp.CodonTransitionMatrixTasteGate single carrier alignment`

Theorem 2245.2 (CodonTransitionMatrix NameCert obligations)**.** *For every accepted* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *carrier $M = (W, Q, F, D, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CodonTransitionMatrix}^{\uparrow}}$ *surface consists exactly of source-window admission through W, finite-state admission through Q, stop-face row admission through F, deterministic transition display through D, transition exactness through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. In particular, the three standard stop rows terminate while the* UGG *local suffix row remains an elongation row.*

Proof. Project the accepted carrier. The row W confines all codon reads to the six-coordinate source window, and Q supplies the only states that can be used by the matrix.

The stop-face row F selects the four local suffix reads named by the prototype. The deterministic row D then displays exactly the three terminating rows and the one UGG elongation row.

The exactness row T is the classifier check: a packet mapping UGG to terminate cannot satisfy the displayed matrix. The structural rows H, C, P, N transport, replay, source, and locally name the same finite route.

No stochastic probability, global table, amino-acid classifier, quotient source equality, or biological inevitability row appears in the carrier. Hence the listed rows exhaust the NameCert obligation surface. □

Theorem 2245.3 (CodonTransitionMatrix stop-boundary exactness)**.** *Every accepted* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *read factors through*

$$W, Q, F \longmapsto D \longmapsto T$$

together with H, C, P, N. Therefore a transition matrix that maps the UGG *local suffix row to* terminate *is outside the accepted stop-boundary carrier.*

Proof. Begin with a transition read. The source-window row W supplies the codon window, and the finite-state row Q supplies the state names; no transition can be inspected before both rows are displayed.

The stop-face row F narrows the read to the four local suffix rows. The deterministic row D then fixes the three stop transitions and the UGG elongation transition.

Finally T checks exactness against the displayed matrix. Since H, C, P, N only preserve the same route, changing the UGG row to terminate changes D and breaks T. □

Falsifiable prediction: A transition matrix that maps the UGG local suffix row to the terminate state fails the standard stop-boundary transition row.

Independence witness: CodonSixBitWindow, CodonCubeBoundary, CodonStopFace, CodonSixBitWindow, LocalStopBoundary-style rows: none is bijective to $\mathsf{CodonTransitionMatrix}^{\uparrow}$, because those siblings supply source windows, boundary vocabulary, stop-face rows, or local boundary style while this packet binds them to one deterministic state-transition matrix with exactness, transport, replay, provenance, and local naming.

The Lean TasteGate file for `BEDC.Derived.CodonTransitionMatrixUp` must provide explicit $\mathsf{Nontrivial\ CodonTransitionMatrix}^{\uparrow}$ and $\mathsf{FieldFaithful\ CodonTransitionMatrix}^{\uparrow}$ instances preserving $W, Q, F, D, T, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{CodonTransitionMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{CodonTransitionMatrix}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source-window row, finite state rows, stop-face suffix rows, deterministic transition rows for UAA, UAG, UGA, and UGG, a transition-exactness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CodonTransitionMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2245.1, Definition 2245.2, and Definition 2245.3 seed the finite stop-boundary transition matrix over codon windows and local stop-face transition rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CodonTransitionMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim stochastic readthrough modeling, global genetic-code table identity, amino-acid classifier identity, source-space quotient equality, biological inevitability, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the nine-row carrier and prove the deterministic transition exactness surface for BEDC.Derived.CodonTransitionMatrixUp.

Chapter 2246

A Concrete Naming Certificate for $\mathsf{MartingaleConvergence}^{\uparrow}$

Following Doob, the $\mathsf{MartingaleConvergence}^{\uparrow}$ packet names the finite convergence-preparation surface supplied by upcrossing control over displayed martingale windows. It sits after the probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, upcrossing, and Doob-upcrossing packets of chapter 184, chapter 185, chapter 188, chapter 190, chapter 344, chapter 383, chapter 1629, and chapter 1630. The chapter records the finite NameCert surface consumed by later convergence work; it does not identify paths up to almost-sure quotient equality or import measure completion.

2246.1 Finite Convergence Carrier

Definition 2246.1 (Martingale convergence finite packet)**.** *A* $\mathsf{MartingaleConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (\Omega, X, E, M, T, O, U, D, S, R, L, A, H, K, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *row naming the probability context.*
2. X *is the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint-family row for the displayed martingale window.*
3. E *is the* $\mathsf{CondExp}^{\uparrow}$ *row exposing the successor faces used by the martingale law.*
4. M *is the consumed* $\mathsf{Martingale}^{\uparrow}$ *finite adapted-sequence packet.*
5. T *is the* $\mathsf{StoppingTime}^{\uparrow}$ *finite index row for bounded stopping reads.*
6. O *is the* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-window row.*
7. U *is the* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-count ledger for fixed lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoints.*
8. D *is the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *inequality row bounding the displayed crossing-count ledger.*
9. S *is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for finite endpoint prefixes.*
10. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational regularity row for displayed approximation windows.*
11. L *is the* $\mathsf{Real}^{\uparrow}$ *lower and upper boundary endpoint row, with the comparison row carried as data.*

12. *A is the convergence-admission ledger recording which finite windows, boundary pairs, rational tolerances, and upcrossing bounds are available to downstream consumers.*
13. *H records componentwise* hsame *transport for the probability, endpoint, conditional-expectation, martingale, stopping, upcrossing, schedule, rational, real-boundary, admission, provenance, and naming rows.*
14. *K records the displayed* Cont *routes from finite endpoint prefixes through bounded stopped windows, upcrossing counts, Doob bounds, and convergence-admission rows.*
15. *P is the* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
16. *N is the local* $\mathsf{NameCert}_{\mathsf{MartingaleConvergence}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these displayed rows. In particular, it has no coordinate for almost-sure quotient equality, completed sigma-algebras, Brownian paths, unbounded stopping-time choice, or a bridge theorem.

Lean4 ✓ `BEDC.Derived.MartingaleConvergenceUp.MartingaleConvergenceTasteGate single carrier alignment`

2246.2 Certificate Obligations

Theorem 2246.2 (Martingale convergence NameCert obligations)**.** *For the carrier of Definition 2246.1, the local* $\mathsf{NameCert}_{\mathsf{MartingaleConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the rows*

$$\Omega, X, E, M, T, O, U, D, S, R, L, A, H, K, P, N,$$

martingale endpoint exposure through X, E, M, bounded stopped-window exposure through T, O, finite upcrossing and Doob-bound exposure through U, D, schedule and rational-approximation exposure through S, R, L, convergence-admission exactness through A, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.

Proof. Project the packet of Definition 2246.1. The carrier lists exactly the probability, endpoint, conditional-expectation, martingale, stopping, optional-stopping, upcrossing, Doob-bound, schedule, rational, real-boundary, admission, transport, replay, provenance, and naming rows.

The martingale-facing rows are X, E, M. They supply finite endpoint reads and conditional-expectation faces only through the displayed $\mathsf{Martingale}^{\uparrow}$ packet.

The stopping-facing rows are T, O. They expose bounded stopped windows and do not select an unbounded stopping-time family.

The crossing-facing rows are U, D. They consume the finite crossing-count ledger and the finite Doob-bound row, so the convergence packet does not recompute an inequality outside the accepted upcrossing certificates.

The remaining rows S, R, L, A, H, K, P, N record finite prefix scheduling, rational approximation, boundary endpoints, admission, transport, replay, provenance, and naming. Since the carrier contains no quotient-equality, measure-completion, Brownian-path, unbounded-choice, or bridge coordinate, those objects are outside the local certificate surface. □

Definition 2246.3 (Martingale convergence bounded real window)**.** *For an accepted* $\mathsf{MartingaleConvergence}^{\uparrow}$ *carrier*

$$C = (\Omega, X, E, M, T, O, U, D, S, R, L, A, H, K, P, N),$$

the bounded real window is the finite endpoint packet displayed by L, S, R*: the row* L *names the lower and upper* $\mathsf{Real}^{\uparrow}$ *boundary endpoints, the row* S *names the finite prefix windows in which those endpoints are inspected, and the row* R *names the regular rational readbacks used to compare the endpoints with the martingale values. The window is bounded only when the same* L, S, R *rows are consumed before the upcrossing rows* U, D *and before the convergence-admission row* A*.*

Theorem 2246.4 (Martingale convergence upcrossing window lock)**.** *Every convergence-admission read of* A *in an accepted* $\mathsf{MartingaleConvergence}^{\uparrow}$ *carrier first passes through the upcrossing rows* U, D *together with the bounded real window of Definition 2246.3, the bounded optional-stopping rows* T, O*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule row* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*. The lock supplies a finite convergence-preparation boundary over bounded endpoints and bounded stopping windows; it supplies no almost-sure quotient equality, no unbounded stopping theorem, no measure completion, and no ambient convergence theorem.*

Proof. Open the carrier of Definition 2246.1. The row A is the convergence-admission ledger, and its available inputs are exactly the displayed probability, endpoint, martingale, stopping, upcrossing, schedule, readback, boundary, transport, replay, provenance, and naming rows of the same packet.

Apply the NameCert obligation theorem, Definition 2246.2. It identifies bounded stopped-window exposure through T, O, finite upcrossing and Doob-bound exposure through U, D, schedule and rational-approximation exposure through S, R, L, and convergence-admission exactness through A.

The bounded real window is therefore not an external endpoint object. It is the same L, S, R packet that the upcrossing and Doob rows consume before A can admit a convergence-facing read.

Finally, the carrier contains no coordinate for almost-sure quotient equality, completed measure spaces, unbounded stopping-time choice, or ambient convergence. Hence the admission row can only lock the finite bounded-window route through $T, O, U, D, L, S, R, H, K, P, N$. □

Theorem 2246.5 (Martingale convergence upcrossing route)**.** *Every accepted* $\mathsf{MartingaleConvergence}^{\uparrow}$ *carrier consumes upcrossing information only through the displayed finite handoff from* $\mathsf{Upcrossing}^{\uparrow}$ *and* $\mathsf{DoobUpcrossing}^{\uparrow}$*: lower and upper* $\mathsf{Real}^{\uparrow}$ *boundary rows, finite martingale endpoint rows, lower and upper decision ledgers, bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-window rows, crossing-count ledger, and the Doob-bound row. No convergence consumer may replace that handoff by an ambient limiting event, almost-sure quotient, or unbounded stopping theorem.*

Proof. Start with the accepted carrier and project U and D. The row U is the crossing-count ledger supplied by chapter 1629; the row D is the Doob-bound surface supplied by chapter 1630.

The boundary rows and endpoint reads are displayed in L and X, while the bounded stopped-window route is displayed in T and O. The replay row K records the finite path from endpoint prefixes to stopped windows, crossing counts, and Doob bounds.

Thus a downstream consumer receives exactly the finite upcrossing handoff rows carried by $U, D, L, X, T, O, H, K, P, N$. The carrier has no coordinate from which an ambient limiting event, almost-sure quotient, or unbounded stopping theorem could be read. □

Theorem 2246.6 (Martingale convergence finite Cauchy admission)**.** *For an accepted* $\mathsf{MartingaleConvergence}^{\uparrow}$ *carrier, the convergence-admission row* A *may export a finite Cauchy-preparation ledger only after*

the bounded endpoint rows L, $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Upcrossing}^{\uparrow}$ *row U, and* $\mathsf{DoobUpcrossing}^{\uparrow}$ *row D have all been displayed. The exported ledger is a finite bounded-window admission route over the same martingale, stopping, optional-stopping, upcrossing, schedule, rational-readback, and Real-boundary rows; it does not claim almost-sure convergence, measure completion, unbounded stopping-time choice, Brownian convergence, or an ambient convergence theorem.*

Proof. Open the carrier of Definition 2246.1. The row A is the only convergence-admission ledger, and its available endpoint and approximation inputs are the displayed L, S, R rows of the same packet.

Apply Definition 2246.2. It identifies finite upcrossing and Doob-bound exposure through U, D, schedule and rational-approximation exposure through S, R, L, and convergence-admission exactness through A.

Use the bounded real window of Definition 2246.3 and the lock theorem Definition 2246.4. They force any admission read to pass through bounded endpoint rows, finite prefix scheduling, rational readback, and bounded upcrossing control before A is consumed.

Finally apply Definition 2246.5. The upcrossing input to the admission ledger is exactly the displayed $\mathsf{Upcrossing}^{\uparrow}$ and $\mathsf{DoobUpcrossing}^{\uparrow}$ handoff, so the exported Cauchy-preparation ledger remains finite and cannot add almost-sure convergence, measure completion, unbounded stopping-time choice, Brownian convergence, or an ambient convergence theorem. □

Theorem 2246.7 (Martingale convergence obligation closure handoff)**.** *For an accepted* $\mathsf{MartingaleConvergence}^{\uparrow}$ *carrier*

$$C = (\Omega, X, E, M, T, O, U, D, S, R, L, A, H, K, P, N),$$

any obligation-closure read of the convergence-admission ledger A must first expose the martingale endpoint rows X, E, M, the bounded stopping rows T, O, the upcrossing and Doob rows U, D, and the schedule, readback, and boundary rows S, R, L. The exported object is only a finite convergence-preparation ledger over those rows together with H, K, P, N; it does not claim almost-sure convergence, measure completion, unbounded stopping-time choice, Brownian convergence, or an ambient convergence theorem.

Proof. Open the accepted carrier and apply Definition 2246.2. The obligation surface for A is already bounded by the displayed endpoint, conditional-expectation, martingale, stopping, optional-stopping, upcrossing, Doob-bound, schedule, readback, real-boundary, transport, replay, provenance, and naming rows.

Use the bounded real window of Definition 2246.3. It identifies the boundary and approximation side as the same L, S, R rows that must be displayed before the upcrossing route can be consumed.

Apply Definition 2246.4. This forces any read of A through the bounded stopping rows T, O, the upcrossing rows U, D, and the schedule and readback rows S, R, L.

Finally use Definition 2246.6. The only export left after those exposures is the finite convergence-preparation ledger over the same displayed packet. Since no carrier row names almost-sure quotient equality, measure completion, unbounded stopping-time choice, Brownian convergence, or an ambient convergence theorem, the obligation handoff cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{MartingaleConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartingaleConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2246.1, Definition 2246.2, Definition 2246.3, Definition 2246.4, and Definition 2246.5 seed the finite convergence-preparation packet over martingale windows, bounded stopping, upcrossing ledgers, Doob bounds, finite prefix schedules, rational approximation rows, and Real boundary endpoints.

Formal verification: FormalStatus(NameCert$_{\text{MartingaleConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close almost-sure quotient equality, measure completion, unbounded choice of stopping times, Brownian convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, martingale endpoint exposure, bounded stopped-window exposure, upcrossing handoff exactness, Doob-bound consumption, finite schedule accountability, rational approximation routing, and non-escape for BEDC.Derived.MartingaleConvergenceUp.

Constructive story: A MartingaleConvergence$^{\uparrow}$ packet is generated from probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, upcrossing, Doob-upcrossing, stream-name, regular-rational, Real-boundary, transport, continuation, provenance, and local NameCert rows.

Chapter 2247

A Concrete Naming Certificate for $\mathsf{ObservationResidualFit}^{\uparrow}$

The $\mathsf{ObservationResidualFit}^{\uparrow}$ packet realizes the residual surface between finite observational fit and open physical refutation in section 9414.13. It sits beside $\mathsf{OpenFitPacket}^{\uparrow}$ from chapter 1137, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$ from **??**, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ from chapter 1124, FiniteObservationRefutat from chapter 1169, and the finite refutation boundary of chapter 508. Those siblings expose finite fit, physical-signature comparison, model audit, observed defeat, and refutation boundaries; this packet binds the observed-signature, model-signature, residual-row, refutation-surface, open-continuation, transport, replay, provenance, and local naming rows into one finite carrier.

2247.1 Residual Carrier

Definition 2247.1 (Observation residual fit carrier)**.** *An* $\mathsf{ObservationResidualFit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, M, R, E, L, T, C, H, P, N)$$

with the following displayed rows:

1. *O is the observed-signature row for the finite trace and observation bundle.*
2. *M is the model-signature row for the same finite trace and observation bundle.*
3. *R is the residual row recording the displayed mismatch budget between O and M.*
4. *E is the finite refutation-surface row, read through the local failure boundary when the residual separates the signatures.*
5. *L is the open-continuation ledger recording undefeated continuation status when the residual remains inside the admitted tolerance.*
6. *T records componentwise* hsame *transport for observed signatures, model signatures, residual rows, refutation surfaces, continuation ledgers, package provenance, and local naming.*
7. *C records displayed* Cont *replay from finite observation through model comparison, residual extraction, refutation-surface reading, open continuation, provenance, and local naming.*
8. *H is the handoff row to* $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$, $\mathsf{FiniteObservationRefutation}^{\uparrow}$, *and the finite refutation boundary.*

9. *P is the* Pkg *provenance over* ObservationResidualFit$^{\uparrow}$, OpenFitPacket$^{\uparrow}$, RealityConstrainedSignatureFit$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, FiniteObservationRefutation$^{\uparrow}$, FiniteRefutationBoundary$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{ObservationResidualFit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, M, R, E, L, T, C, H, P, N$. It has no coordinate for final-fit oracles, global physical truth, host model adequacy, unbounded observation histories, or a hidden refutation outside the displayed residual row.

Lean4 ✓ `BEDC.Derived.ObservationResidualFitUp.ObservationResidualFitTasteGate single carrier alignment`

2247.2 Residual Obligations

Theorem 2247.2 (Observation residual fit NameCert obligations)**.** *For every accepted* ObservationResidualFit$^{\uparrow}$ *carrier $F = (O, M, R, E, L, T, C, H, P, N)$, the local* NameCert$_{\text{ObservationResidualFit}^{\uparrow}}$ *surface consists exactly of observed-signature exposure through O, model-signature exposure through M, residual exactness through R, finite refutation-surface exposure through E, open-continuation ledgering through L, componentwise transport through T, displayed replay through C, sibling handoff through H, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 2247.1. The rows O and M expose the finite observed and model-generated signatures over one observation bundle and one finite trace.

The residual row R is the only mismatch budget visible to the packet. If the residual separates the two signatures, the refutation surface E records the finite defeat route; otherwise the open-continuation ledger L records the admitted continuation status.

The rows T, C, H, P, N transport, replay, hand off, package, and name the same finite packet. Since no remaining coordinate stores a final-fit oracle, global physical truth predicate, host adequacy judgment, unbounded observation history, or detached refutation, the listed rows exhaust the local NameCert obligations. □

Theorem 2247.3 (Observation residual fit sibling route)**.** *Every public residual read from an accepted* ObservationResidualFit$^{\uparrow}$ *packet must factor through the finite-fit row of* OpenFitPacket$^{\uparrow}$*, the signature-comparison row of* RealityConstrainedSignatureFit$^{\uparrow}$*, the audit row of* RealityConstrainedModelAudit$^{\uparrow}$*, the observed-defeat row of* FiniteObservationRefutation$^{\uparrow}$*, and the finite refutation boundary when the residual is separating. A route that drops R, E, or L is not an accepted residual-fit route.*

Proof. Read the sibling handoff row H. It names the open-fit packet, signature-fit packet, model-audit packet, finite-observation-refutation packet, and finite refutation boundary as the only external surfaces consumed by the residual packet.

The residual row R is computed from the displayed signature rows O and M. The refutation row E and open-continuation row L are then mutually visible outcomes of that finite residual read: separation exposes a refutation surface, while admitted mismatch remains an open continuation.

The transport, replay, provenance, and naming rows T, C, P, N preserve the same route. Therefore any consumer that drops R, E, or L has left the accepted residual-fit packet, even if it still cites open fit, signature fit, model audit, observed defeat, or refutation language. □

Falsifiable prediction: Every accepted ObservationResidualFit$^{\uparrow}$ consumer displays observed-signature, model-signature, residual, finite-refutation, open-continuation, handoff, transport, replay, provenance, and local naming rows before any residual-fit read is public.

Independence witness: OpenFitPacket, RealityConstrainedSignatureFit, RealityConstrained-ModelAudit, FiniteObservationRefutation, FiniteRefutationBoundary: none is bijective to $\mathsf{ObservationResidualFit}^{\uparrow}$ because the residual packet jointly carries observed signature, model signature, mismatch budget, refutation surface, open continuation, handoff, transport, replay, provenance, and local NameCert rows.

The Lean follow-up must provide explicit $\mathsf{Nontrivial\ ObservationResidualFit}^{\uparrow}$ and $\mathsf{FieldFaithful\ ObservationResidua}$ instances preserving $O, M, R, E, L, T, C, H, P, N$ in `lean4/BEDC/Derived/ObservationResidualFitUp/TasteGat`

Closure status for $\mathsf{NameCert}_{\mathsf{ObservationResidualFit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservationResidualFit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2247.1, Definition 2247.2, and Definition 2247.3 seed the finite residual-fit packet over observed signatures, model signatures, residual budgets, finite refutation surfaces, open continuation ledgers, sibling handoffs, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservationResidualFit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close final-fit oracles, global physical truth, host model adequacy, unbounded observation histories, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observed-signature exposure, model-signature exposure, residual exactness, refutation-surface handoff, open-continuation ledgering, and sibling-route preservation for BEDC.Derived.ObservationResidualFitUp.

Constructive story: An $\mathsf{ObservationResidualFit}^{\uparrow}$ packet is generated from finite observed-signature, model-signature, residual-row, refutation-surface, open-continuation, handoff, transport, replay, provenance, and local NameCert rows.

Chapter 2248

A Concrete Naming Certificate for $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$

Following Bishop and Bridges on constructive located intervals, the $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ packet records a finite dyadic partition of a displayed located $\mathsf{Real}^{\uparrow}$ interval as NameCert data. It sits after the located endpoint surface of chapter 394, the dyadic refinement surface of chapter 306, the rational interval cell ledger of chapter 354, the finite StreamName windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite mesh ledger for closed-bounded interval reads; it does not import open-cover compactness, a host interval partition, quotient real equality, selected endpoint values, countable choice, or ambient completeness.

Definition 2248.1 (Located real interval partition carrier)**.** *A* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (J, M, Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the source* $\mathsf{LocatedInterval}^{\uparrow}$ *row whose lower and upper endpoint names have already exposed located real endpoint windows.*
2. *M is the finite dyadic mesh row, listing the ordered mesh cells and their common precision.*
3. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *witness family assigning each mesh cell a rational containment row inside the located interval ledger.*
4. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement family attached to the rational cells of Q.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened for the endpoint and mesh-cell reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family for the same finite windows and dyadic mesh precision.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal family reached only after the located endpoint, rational cell, dyadic mesh, window, and readback rows have been displayed.*
8. *H records componentwise* hsame *transport for the located interval row, dyadic mesh cells, rational witnesses, dyadic refinements, stream windows, regular readbacks, real seals, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a partition read through $J, M, Q, D, S, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed endpoint, mesh, rational-cell, dyadic-refinement, window, readback, seal, transport, replay, provenance, and local naming rows. It has no coordinate for a host partition object, an open-cover subcover, quotient real equality, selected completed endpoints, countable choice, or ambient compactness.

Lean4 ✓ `BEDC.Derived.LocatedRealIntervalPartitionUp.LocatedRealIntervalPartitionTasteGate`
`single carrier alignment`

Theorem 2248.2 (Located real interval partition NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ *carrier* $T = (J, M, Q, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalPartition}}$ *surface consists exactly of carrier admission, located endpoint exposure through J, finite dyadic mesh exposure through M, rational interval witness exposure through Q, dyadic cell refinement through D, finite StreamName window exposure through S, RegSeqRat readback through R, terminal Real-seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Every partition read of the located interval must therefore pass through the displayed finite mesh and rational witness rows before any StreamName, RegSeqRat, or Real seal row is consumed.

Proof. Project the carrier of Definition 2248.1. The tuple lists the only rows available to a partition consumer: the source located interval, mesh cells, rational witnesses, dyadic refinements, stream windows, regular readbacks, real seals, transport, replay, provenance, and local naming rows.

The located endpoint stage is J. By the located interval certificate of chapter 394, endpoint reads enter through displayed located real windows and not through chosen completed endpoint values.

The partition stage is M, Q, D. The dyadic mesh row gives the finite cell order and common precision, the rational interval witness family records containment for each cell, and the dyadic refinement family attaches the mesh cells to those rational witnesses.

The readback and seal stage is S, R, E. A consumer reaches the finite StreamName windows only after the mesh and rational witness rows are visible, then reads the regular rational rows and finally the terminal Real seal.

The structural rows H, C, P, N transport, replay, package, and name exactly this route. Since no host partition object, open-cover subcover, quotient real equality, chosen endpoint, choice schedule, or compactness row occurs in the carrier, the displayed NameCert surface is exhaustive. □

Theorem 2248.3 (Located real interval partition mesh handoff)**.** *Every accepted* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ *partition read hands its mesh to downstream closed-bounded interval consumers through the finite route*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{RationalInterval}^{\uparrow}, \mathsf{DyadicInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exposes the located endpoint rows, dyadic mesh cells, rational containment witnesses, finite windows, regular readbacks, and terminal real seals, together with hsame, Cont, Pkg, *and local* NameCert *provenance. It exports no open-cover compactness principle, no countable-choice subnet, no quotient interval, and no ambient complete ordered field row.*

Proof. Start with an accepted carrier $T = (J, M, Q, D, S, R, E, H, C, P, N)$. The only source interval row is J, so every endpoint and containment read begins at the displayed located interval surface.

The mesh handoff is stored in M, Q, D. The dyadic mesh row M gives the finite partition cells, the rational witness family Q certifies their containment in the located interval ledger, and the dyadic refinement family D attaches the cells to the rational interval witnesses.

The downstream read is stored in S, R, E. StreamName windows are opened at the displayed mesh precision, RegSeqRat rows read back the same windows, and the Real seal is reached only after those rows have been displayed.

Finally H, C, P, N preserve the handoff under componentwise transport and replay. There is no additional coordinate in Definition 2248.1, so a closed-bounded interval consumer receives exactly the displayed finite mesh route and none of the excluded compactness, choice, quotient, or ambient-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalPartition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2248.1, Definition 2248.2, and Definition 2248.3 seed the finite dyadic partition packet for located Real interval reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient interval equality, selected endpoint values, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh-cell coverage, rational interval witnesses, dyadic refinement, StreamName windows, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealIntervalPartitionUp.

Constructive story: A $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ packet is generated from a LocatedIntervalUp row, finite dyadic mesh cells, RationalIntervalUp witnesses, DyadicIntervalUp refinements, StreamNameUp windows, RegSeqRatUp readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2249

A Concrete Naming Certificate for $\mathsf{NestedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges and Cantor nested interval reasoning, the $\mathsf{NestedIntervalSelection}^{\uparrow}$ packet records the finite route by which a displayed nested interval chain supplies a regular Cauchy selection surface without selecting a completed point. It sits after the finite nested interval packet of chapter 320, the located interval boundary of chapter 394, the closed bounded interval endpoint carrier of chapter 1591, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names one L10 finite selection route; it does not import countable choice, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or an external real-point selector.

Definition 2249.1 (Nested interval selection carrier)**.** *A* $\mathsf{NestedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, L, B, W, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted* $\mathsf{NestedInterval}^{\uparrow}$ *finite chain whose visible intervals are being read.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row that records the locatedness tests available for each displayed endpoint window.*
3. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *endpoint row anchoring the lower and upper interval bounds.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row selecting the finite interval prefix inspected by the consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed endpoint windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording endpoint widths, midpoint tolerances, and the Cauchy budget requested of the selected row.*
7. *Q is the finite selector row saying that the selected regular-rational approximant is read from the displayed window W and ledger D.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, L, B, W, R, D, Q have been displayed.*
9. *H records componentwise* hsame *transport for all carrier rows.*
10. *C records displayed* Cont *replay of the route*

$$I, L, B \longmapsto W, D \longmapsto R, Q \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalSelection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalSelection}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite selection packet. The classifier compares accepted packets only by componentwise agreement of $I, L, B, W, R, D, Q, E, H, C, P, N$ under the displayed hsame *and* Cont *routes; it has no coordinate for a chosen intersection point, quotient stream equality, countable choice, trichotomy, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.NestedIntervalSelectionUp.NestedIntervalSelectionTasteGate single carrier alignment`

Theorem 2249.2 (Nested interval selection NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (I, L, B, W, R, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedIntervalSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, nested-chain exposure through I, located endpoint exposure through L, closed bounded endpoint exposure through B, finite window exposure through W, regular rational readback through R, dyadic tolerance accounting through D, selector-row exactness through Q, real-seal handoff through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The projection exposes the nested interval source, located endpoint tests, closed bounded endpoint anchor, finite window, regular readback, dyadic tolerance ledger, selector row, real seal, transport, continuation, provenance, and local naming rows.

The analytic obligations are exactly the visible rows. The nested-chain row gives the finite interval source, the located and closed bounded rows give endpoint admissibility, the window and dyadic rows give the inspected prefix and tolerance budget, and the regular readback plus selector row give the selected approximant.

The structural obligations are H, C, P, N. They transport, replay, source, and name the same finite route. Since the carrier contains no chosen point, quotient real equality, countable-choice function, trichotomy row, or real-completeness theorem, no further local NameCert obligation can be read. □

Theorem 2249.3 (Nested interval selection Cauchy route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedIntervalSelection}^{\uparrow}$ *packet reads the Cauchy-facing route*

$$\mathsf{NestedInterval}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

through the displayed rows $I, L, B, W, D, R, Q, E, H, C, P, N$. The selected regular-rational approximant is determined by the finite window and tolerance ledger, not by countable choice, quotient real equality, a selected nested-intersection point, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source interval rows. The nested interval packet I supplies the displayed finite chain, while L and B provide located and closed bounded endpoint data attached to the same visible prefix.

Next read the Cauchy budget. The window row W chooses the inspected finite prefix, and the dyadic ledger D records the endpoint widths and tolerances used by the selector row Q. This is a finite BHist route, so the consumer receives no external sequence of choices.

Finally pass through the readback and seal rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies the regular-rational approximant, and E may be read as a $\mathsf{Real}^{\uparrow}$ seal only after I, L, B, W, D, R, Q are displayed. The rows H, C, P, N preserve and name that route without adding quotient equality or a completeness principle. □

Theorem 2249.4 (Nested interval selection non-escape)**.** *No accepted* $\mathsf{NestedIntervalSelection}^{\uparrow}$ *packet exports a selected point of an infinite nested intersection, a quotient real equality proof, a countable-choice selector, trichotomy for endpoint comparison, an independent real carrier, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every public read factors through the finite rows* $I, L, B, W, R, D, Q, E, H, C, P, N$ *of Definition 2249.1.*

Proof. Project the carrier and inspect its coordinates. The only analytic rows are the nested chain, located interval data, closed bounded endpoint data, finite observation window, regular rational readback, dyadic tolerance ledger, selector row, and real seal.

The selector row is finite: it is read from W and D, then passed to R and E. It never stores a function choosing an element from every nested chain and never identifies two real names by quotient equality.

The remaining rows are structural. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row can only preserve the displayed packet. Therefore any public read outside $I, L, B, W, R, D, Q, E, H, C, P, N$ is unavailable, and the listed host-level or completeness principles cannot escape from the certificate. □

Falsifiable prediction: Every $\mathsf{NestedIntervalSelection}^{\uparrow}$ read factors through a nested interval source, located endpoint row, closed bounded endpoint row, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, finite selector row, RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: nestedinterval, locatedinterval, closedboundedinterval, regseqrat, real: $\mathsf{NestedIntervalSelection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite nested-chain source, endpoint locatedness, closed bounded endpoint anchoring, a displayed window, regular readback, dyadic tolerance accounting, a selector row, seal handoff, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedIntervalSelection}^{\uparrow}$ packet is generated from a nested interval row, located interval row, closed bounded interval endpoint row, finite StreamName window, RegSeqRat readback row, DyadicRatCore tolerance ledger, finite selector row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2249.1, Definition 2249.2, Definition 2249.3, and Definition 2249.4 seed the finite nested-interval selection surface over NestedInterval, LocatedInterval, ClosedBoundedInterval, StreamName, RegSeqRat, DyadicRatCore, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient real equality, trichotomy, a selected nested-intersection point, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, Cauchy route exactness, non-escape, and TasteGate field faithfulness for BEDC.Derived.NestedIntervalSelectionUp.

Chapter 2250

A Concrete Naming Certificate for $\mathsf{DenseCauchyEmbedding}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley on dense uniform embeddings, the $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ packet names the finite source-to-completion interface used when a dense metric source is admitted into a Cauchy completion. It sits after the metric source of chapter 57, the regular dense Cauchy route of chapter 1453, the completion embedding surface of chapter 1512, the sequence-comparison ledger of chapter 1412, and the metric-completion boundary of chapter 1506. The packet exposes density as finite NameCert data rather than as a quotient completion, selected limit, host equality of completion points, countable-choice selector, or ambient completeness principle.

Definition 2250.1 (Dense Cauchy embedding carrier)**.** *A* $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, D, Q, J, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the source carrier, classifier, distance witness, and finite observation histories.*
2. *D is the displayed dense source row, recording the finite approximation schedule that lets completion requests be read back through source observations.*
3. *Q is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *evidence row, exposing the Cauchy comparison route used to identify source approximants before completion consumers read them.*
4. *J is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that inserts source observations into the completion boundary.*
5. *L is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row consumed only after M, D, Q, J have been displayed.*
6. *H records componentwise* hsame *transport for the metric source, dense source row, Cauchy evidence, completion embedding, metric-completion handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$M \longmapsto D \longmapsto Q \longmapsto J \longmapsto L.$$

8. *P is the* Pkg *provenance over* $\mathsf{DenseCauchyEmbedding}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseCauchyEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, host equality of completed points, countable choice, ambient metric completeness, or bridge credentials.

Lean4 ✓ `BEDC.Derived.DenseCauchyEmbeddingUp.DenseCauchyEmbeddingTasteGate single carrier alignment`

Theorem 2250.2 (Dense Cauchy embedding NameCert obligations)**.** *For an accepted* $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ *carrier $E = (M, D, Q, J, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseCauchyEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source metric row, dense source row, Cauchy equivalence or net evidence, completion embedding, metric-completion handoff, transport, replay, provenance, and local naming rows;*

2. *dense-source visibility, requiring every completion-facing approximation request to expose D before it can be read through J or L;*

3. *Cauchy coherence, requiring the displayed Q row to compare the source approximants through* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *before the completion embedding is consumed;*

4. *embedding locality, requiring J to insert only the source observations displayed by M, D, Q into the completion-facing boundary;*

5. *classifier stability, requiring transported packets with the same displayed M, D, Q, J, L route to be identified through the carried* hsame *and* Cont *rows;*

6. *ledger non-escape, excluding quotient completion equality, selected limits, host equality, countable choice, ambient completeness, and bridge checking.*

Proof. Carrier admission is projection from Definition 2250.1. The tuple lists exactly the metric source, dense source, Cauchy evidence, completion embedding, metric-completion handoff, transport, replay, provenance, and local naming rows.

Dense-source visibility is the projection to D. A completion-facing request cannot reach the embedding row J or the completion row L until the displayed dense source approximation route has been named.

Cauchy coherence is the projection to Q. Whether the local evidence is sequential or net-presented, the packet requires the approximants to be compared before their image is treated as a completion-facing entry.

Embedding locality is the dependency order in C. The continuation row replays only the route from M, D, Q through J to L, while H, P, N transport, source, and name that same finite packet. Since no excluded host-side datum is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2250.3 (Dense Cauchy embedding metric completion handoff)**.** *Let $E = (M, D, Q, J, L, H, C, P, N)$ be an accepted* $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ *carrier. Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of E reads the completion boundary only through the finite route*

$$M \longmapsto D \longmapsto Q \longmapsto J \longmapsto L \longmapsto H, C, P, N.$$

Thus the dense-source embedding interface is a displayed BEDC handoff from $\mathsf{Met}^{\uparrow}$ *source rows through* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, *and* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *evidence into* $\mathsf{MetricCompletion}^{\uparrow}$, *and not a hidden quotient completion or selected-limit principle.*

Proof. Start with an accepted carrier. The source row M supplies the metric observations, and the dense source row D records which finite source approximants answer the completion-facing request.

The Cauchy evidence row Q is read next. It is the only row that compares the selected approximants before they enter the completion boundary, so a completion consumer cannot bypass it and still consume this packet.

The embedding row J then inserts those displayed observations into the completion-facing route. Only after M, D, Q, J have been fixed does the metric-completion row L become available.

Finally H, C, P, N preserve, replay, source, and name the same finite route. The packet therefore exports the metric-completion handoff without adding quotient completion equality, selected limits, host equality, countable choice, ambient completeness, or bridge credentials. □

Falsifiable prediction: An accepted $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ consumer that reaches $\mathsf{MetricCompletion}^{\uparrow}$ without the displayed $\mathsf{Met}^{\uparrow}$ source, dense source row, Cauchy evidence, and $\mathsf{CompletionEmbedding}^{\uparrow}$ route refutes the carrier surface.

Independence witness: metric, regular-cauchy-dense-embedding, completionembedding, cauchy-sequenceequivalence, cauchynet, metriccompletion: no listed sibling supplies the whole packet $E = (M, D, Q, J, L, H, C, P, N)$, because each sibling contributes only a source metric, dense Cauchy route, embedding row, Cauchy comparison row, or completion boundary while this chapter binds them with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DenseCauchyEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ packet is generated from a MetricUp source row, displayed dense source data, CauchySequenceEquivalenceUp or CauchyNetUp evidence, a CompletionEmbeddingUp handoff, a MetricCompletionUp consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseCauchyEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2250.1, Definition 2250.2, and Definition 2250.3 seed the dense Cauchy embedding interface for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseCauchyEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed points, countable choice, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source visibility, Cauchy coherence, embedding locality, classifier stability, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.DenseCauchyEmbeddingUp.

Chapter 2251

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$

Following Bishop–Bridges and Kelley-style completion theory, the $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$ packet records the finite universal-property surface for regular Cauchy completion. It sits after the dyadic tolerance core of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the metric-completion handoff of chapter 1506, the uniform-completion route of chapter 1473, and the separated-metric comparison boundary of chapter 1411. The packet names only the displayed extension and uniqueness route available to completion consumers; it does not assert quotient completion, selected representatives, ambient completeness, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2251.1 (Regular Cauchy completion universal-property carrier)**.** *A* RegularCauchyCompletionUniversalP *carrier is a finite* BHist *packet*

$$U = (D, W, Q, R, M, F, S, E, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the regular Cauchy readback.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that makes the source observations available.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row read through D and W.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from the same displayed regular Cauchy route.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row consumed by metric-completion readers.*
6. *F is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row consumed by uniform-completion readers.*
7. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row used by uniqueness of extensions.*
8. *E is the extension-existence row: it records the displayed route from a regular Cauchy source read through D, W, Q, R into the completion-facing target read through M, F, S.*
9. *L is the uniqueness ledger: it compares two extension rows over the same D, W, Q, R, M, F, S route by separatedness rather than by host equality.*
10. *H records componentwise* hsame *transport for $D, W, Q, R, M, F, S, E, L$ and the local naming row.*

11. *C records displayed* Cont *replay of the route*

$$D, W, Q, R \longmapsto M, F, S \longmapsto E, L, H, P, N.$$

12. *P is the* Pkg *provenance over* RegularCauchyCompletionUniversalProperty$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, MetricCompletion$^{\uparrow}$, UniformCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

13. *N is the local* NameCert$_{\text{RegularCauchyCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, Q, R, M, F, S, E, L, H, C, P, N$. It has no coordinate for quotient completion, representative selection, host equality of completed points, hidden completeness of the target, countable choice, or completeness of Real$^{\uparrow}$.

Lean4 ✓ BEDC.Derived.RegularCauchyCompletionUniversalPropertyUp.RegularCauchyCompletionUniversalPropert
single carrier alignment

Theorem 2251.2 (Regular Cauchy completion universal-property NameCert obligations)**.** *For every accepted* RegularCauchyCompletionUniversalProperty$^{\uparrow}$ *carrier $U = (D, W, Q, R, M, F, S, E, L, H, C, P, N)$, the local* NameCert$_{\text{RegularCauchyCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of carrier admission; dyadic tolerance exposure through D; finite stream exposure through W; regular rational source exposure through Q; terminal real sealing through R; metric and uniform completion handoff through M, F; separated comparison through S; extension existence through E; uniqueness through L; componentwise transport through H; displayed replay through C; provenance through P; local naming through N; and non-escape from quotient completion, representative selection, host equality, hidden target completeness, countable choice, or* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2251.1. The accepted packet exposes exactly the dyadic tolerance row, stream-window row, regular rational source, real seal, metric-completion handoff, uniform-completion handoff, separated comparison row, extension row, uniqueness ledger, transport, replay, provenance, and local name.

The regular source route is finite. Rows D, W, Q provide the dyadic, stream, and regular rational data before the terminal real seal R is read, so the extension row cannot begin from a hidden completed point.

The completion-facing route is also finite. Rows M, F, S record the metric, uniform, and separated target surfaces before E and L are inspected, so existence and uniqueness are read through displayed completion data rather than through a quotient or a selected representative.

Rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded host-side coordinate exists in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2251.3 (Regular Cauchy completion universal-property core)**.** *Every extension-and-uniqueness read of an accepted* RegularCauchyCompletionUniversalProperty$^{\uparrow}$ *packet factors through*

$$D, W, Q, R \longmapsto M, F, S \longmapsto E, L, H, C, P, N.$$

The route first exposes dyadic tolerance, stream windows, regular rational source data, and the terminal real seal; then it exposes metric completion, uniform completion, and separated comparison rows; and only then exports extension existence and uniqueness. No accepted read exports quotient completion, selected representatives, ambient completeness, countable choice, host equality of completed points, or Real$^{\uparrow}$ *completeness.*

Proof. Read the accepted carrier $U = (D, W, Q, R, M, F, S, E, L, H, C, P, N)$. Its continuation row C displays the order in which the regular Cauchy source route is made available before the completion-facing rows are inspected.

The first stage is D, W, Q, R. It uses the dyadic tolerance ledger, the finite stream schedule, and the regular rational source to reach the real seal; none of these rows supplies a quotient object or a selected limit.

The second stage is M, F, S. The metric and uniform completion rows are consumed together with the separated comparison row, so the uniqueness ledger can compare extensions by separatedness inside the packet.

The final stage is E, L, H, C, P, N. Extension existence and uniqueness are transported, replayed, sourced, and named by the displayed structural rows. Because the carrier has no additional coordinate, every accepted universal-property read factors through the stated route. □

Theorem 2251.4 (Regular Cauchy completion extension uniqueness handoff)**.** *For every accepted* $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$ *packet* $U = (D, W, Q, R, M, F, S, E, L, H, C, P, N)$*, extension existence and extension uniqueness are public only through the ordered rows*

$$D, W, Q, R, M, F, S, E, L, H, C, P, N.$$

The source side first reads dyadic tolerance, stream windows, regular rational source data, and the terminal real seal; the completion side then reads metric completion, uniform completion, and separated comparison rows; and the extension row E *and uniqueness ledger* L *are exported only after that displayed route is present.*

Proof. Project the accepted carrier of Definition 2251.1. Its rows already place the source route D, W, Q, R before the completion-facing route M, F, S.

Apply Definition 2251.2. The local NameCert surface exposes extension existence only through E and exposes uniqueness only through L, with componentwise transport, continuation replay, provenance, and local naming supplied by H, C, P, N.

Use Definition 2251.3 to identify the ordered route. The metric and uniform completion rows provide the completion handoff, while the separated comparison row supplies the equality test used by the uniqueness ledger. Hence a consumer receives extension existence and uniqueness only through the displayed packet. □

Theorem 2251.5 (Regular Cauchy completion separated nonescape)**.** *No accepted* RegularCauchyCompletionUniver *consumer can replace the separated comparison row* S *by quotient completion, representative selection, host equality of completed points, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or hidden target completeness. Any public uniqueness read is confined to the displayed separated comparison row together with* $D, W, Q, R, M, F, E, L, H, C, P, N$*.*

Proof. Inspect the carrier coordinates of Definition 2251.1. The only row assigned to comparison of completed extension values is S, and the only row assigned to uniqueness is L.

Apply Definition 2251.4. It places S before E and L in the completion-facing handoff, so uniqueness has no independent source outside the separated comparison boundary.

Finally use the non-escape clause of Definition 2251.2. Quotient completion, representative selection, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and hidden target completeness have no carrier coordinate, no continuation route, and no provenance row in U. □

Theorem 2251.6 (Regular Cauchy completion Bishop handoff)**.** *Every accepted* RegularCauchyCompletionUniversal *packet*

$$U = (D, W, Q, R, M, F, S, E, L, H, C, P, N)$$

whose dense source, Cauchy filter, separated uniqueness, and extension rows are read by a BishopRegularCauchyComp *consumer factors through chapter 1639, chapter 301, chapter 126, and chapter 38 before it exports a universal arrow. The exported arrow is therefore a finite L10 completion-facing route through the displayed dyadic tolerance, stream window, regular rational source, Real seal, metric completion, uniform completion, separated comparison, extension, uniqueness, transport, replay, provenance, and local naming rows.*

The route exports no quotient completion, selected representative, countable-choice selector, host equality of completed points, hidden target completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier row of Definition 2251.1. The dense source and Cauchy filter read are visible only through D, W, Q, R, so the Bishop consumer first opens the dyadic, stream, RegSeqRat, and Real chapters named in the statement.

Next apply Definition 2251.3 and Definition 2251.4. These route the completion-facing part through M, F, S before E and L are exported, which is exactly the metric, uniform, and separated handoff expected by the $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ surface.

Finally use Definition 2251.5. Since the separated comparison row is the only admissible uniqueness boundary, the universal arrow cannot be reconstructed from quotient completion, selected representatives, countable choice, host equality, hidden completeness, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$ consumer that exports extension existence or uniqueness while omitting any of the dyadic tolerance, stream-window, regular rational source, real seal, metric-completion, uniform-completion, separated comparison, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, metriccompletion, uniform-completion, separatedmetric: none is bijective because $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$ jointly carries tolerance, finite observation, regular source, terminal seal, metric handoff, uniform handoff, separated comparison, extension, uniqueness, transport, replay, provenance, and local NameCert rows in one universal-property packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2251.1, Definition 2251.2, and Definition 2251.3 seed the finite regular-Cauchy universal-property surface over dyadic, stream, regular rational, real, metric-completion, uniform-completion, separated-metric, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, ambient completeness, countable choice, host equality of completed points, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular source exposure, completion handoff, separated uniqueness, structural transport, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.RegularCauchyCompletio

Constructive story: A $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$ packet is generated from dyadic tolerance data, finite stream windows, regular rational source rows, a terminal Real seal, metric and uniform completion rows, a separated comparison row, extension and uniqueness rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2252

A Concrete Naming Certificate for $\mathsf{LandauSymbol}^{\uparrow}$

Following Landau and Hardy, the $\mathsf{LandauSymbol}^{\uparrow}$ packet records eventual finite-threshold comparison as BEDC data rather than as host asymptotic notation. It sits over the finite window service of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the modulus-controlled real-name route of chapter 1423. The packet gives Real and Completion consumers a named threshold comparison row without importing limit notation, quotient streams, selected tails, trichotomy, or ambient completeness.

Definition 2252.1 (Landau symbol carrier)**.** *A* $\mathsf{LandauSymbol}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, T, W, B, Q, E, H, C, P, N)$$

with the following visible rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row naming the inspected stream family and the finite windows used to read the candidate function.*
2. *T is the comparison* $\mathsf{StreamName}^{\uparrow}$ *row naming the matching finite windows for the bounding stream.*
3. *W is the threshold witness row, consisting of one displayed unary threshold and the proof ledger that every accepted tail request is beyond it.*
4. *B is the eventual-bound ledger, recording the displayed finite comparison between the two streams for all windows admitted after W.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row through which both stream reads enter regular rational comparison.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the source stream, comparison stream, threshold witness, eventual-bound ledger, and RegSeqRat handoff have been displayed.*
7. *H records componentwise* hsame *transport for the source stream, comparison stream, threshold witness, eventual-bound ledger, RegSeqRat handoff, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Landau comparison request through $S, T, W, B, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LandauSymbol}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{LandauSymbol}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, W, B, Q, E, H, C, P, N$. It has no coordinate for a host limit, quotient stream equality, selected infinite tail, external asymptotic notation, trichotomy of completed reals, or ambient completeness.

Lean4 (definition) `BEDC.Derived.LandauSymbolUp.LandauSymbolUp`

Theorem 2252.2 (Landau symbol NameCert obligations)**.** *For every accepted* $\mathsf{LandauSymbol}^{\uparrow}$ *carrier $L = (S, T, W, B, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LandauSymbol}^{\uparrow}}$ *surface consists exactly of carrier admission, threshold monotonicity, eventual-bound exactness, RegSeqRat and Real handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Threshold monotonicity says that every later finite window served by the source and comparison streams remains beyond the displayed threshold W. Eventual-bound exactness says that the bound read by a consumer is precisely the comparison ledger B after the route*

$$S, T, W \longmapsto B \longmapsto Q \longmapsto E$$

has been displayed. Ledger non-escape excludes host limit notation, quotient stream equality, selected tails, trichotomy, and ambient completeness from the packet.

Proof. Project the carrier of Definition 2252.1. The two stream rows S, T supply the only observable source and comparison windows, and W is the only threshold coordinate.

The eventual comparison is read through B. Threshold monotonicity is the row condition that a later accepted request still factors through the same displayed threshold, so no separate tail selector can enter the route.

The handoff rows Q and E place the comparison inside RegSeqRat readback before any Real-facing consumer sees a seal. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so there is no coordinate from which host asymptotic notation, quotient stream equality, selected tails, trichotomy, or ambient completeness can be exported. □

Falsifiable prediction: Every accepted $\mathsf{LandauSymbol}^{\uparrow}$ Real-facing consumer factors through displayed source and comparison $\mathsf{StreamName}^{\uparrow}$ windows, one threshold witness, one eventual-bound ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ sealing, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before it may use the comparison as asymptotic evidence.

Independence witness: streamname, regseqrat, real, realcauchymodulus: no listed sibling is bijective to $\mathsf{LandauSymbol}^{\uparrow}$, because the siblings respectively supply finite windows, regular rational readback, terminal real sealing, or modulus-controlled real-name service, while this packet uniquely binds two stream rows to one finite threshold and one eventual-bound ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{LandauSymbol}^{\uparrow}}$.

Constructive story: A $\mathsf{LandauSymbol}^{\uparrow}$ packet is generated from source and comparison StreamName rows, a threshold witness, an eventual-bound ledger, RegSeqRat handoff, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LandauSymbol}^{\uparrow}}$, seed)

Scope closed: Definition 2252.1 and Definition 2252.2 seed the finite threshold-comparison carrier over StreamName, RegSeqRat, Real, and RealCauchyModulus rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LandauSymbol}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host asymptotic notation, quotient stream equality, selected infinite tails, trichotomy, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold monotonicity, eventual-bound exactness, RegSeqRat and Real handoff, structural transport, and ledger non-escape for BEDC.Derived.LandauSymbolUp.

Chapter 2253

A Concrete Naming Certificate for $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$

The $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ packet realizes the compact-uniform-continuity route of chapter 9237 as a finite extractor surface: dyadic compactness rows provide a finite net and dyadic radius ledger, metric triangle rows transport the estimate, continuous-map rows supply pointwise moduli, and the resulting route hands a tolerance-only radius to $\mathsf{UniformModulus}^{\uparrow}$. It sits beside the compact metric source of chapter 129, the metric triangle surface of chapter 57, the pointwise graph rows of chapter 130, the Lebesgue-radius ledger of chapter 452, and the uniform-modulus consumer of chapter 369. The packet names the finite extractor route only; it does not assert open-cover compactness, sequential compactness, a host Lebesgue number, or an ambient completeness theorem.

Definition 2253.1 (Dyadic compactness extractor carrier)**.** *A* $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, M, T, R, F, L, U, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the compact carrier and the displayed ProbeBundle center family.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *triangle row for the source and target metric estimates used by the extractor.*
3. *T is the dyadic radius row naming the finite precision scale attached to the accepted compact net.*
4. *R is the finite-net readback row that associates every accepted source point request with a displayed center and dyadic radius from T.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row carrying pointwise modulus data at each displayed center.*
6. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *ledger row that records the finite lower-radius comparison consumed by the uniform route.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from K, M, T, R, F, L.*
8. *H records componentwise* hsame *transport for compact source, metric triangle, dyadic radius, finite-net readback, continuous-map modulus, Lebesgue ledger, uniform-modulus handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-uniform request through $K, M, T, R, F, L, U, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCompactnessExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, T, R, F, L, U, H, C, P, N$. It has no coordinate for an open cover, selected subcover, sequential compactness argument, host Lebesgue number, host minimum selector, choice principle, or ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.DyadicCompactnessExtractorUp.DyadicCompactnessExtractorUp`

Theorem 2253.2 (Dyadic compactness extractor NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ *carrier $D = (K, M, T, R, F, L, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicCompactnessExtract}}$ *surface consists exactly of carrier admission, compact finite-net exposure, dyadic radius exactness, metric triangle compatibility, continuous-map pointwise-modulus exposure, finite Lebesgue-ledger readback, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compact-uniform consumer must read the displayed finite route*

$$K, M, T, R, F, L \longmapsto U \longmapsto H, C, P, N$$

before exporting a uniform modulus.

Proof. Project the carrier row by row. The compact source K supplies the finite net, while T and R record the dyadic radius and the finite center selected for a source request.

The metric triangle row M and continuous-map row F provide the only estimate data used by the extractor. The Lebesgue ledger L is then the finite lower-radius comparison that makes the resulting radius uniform over the displayed net.

The handoff row U is read only after those finite rows have been exposed. The structural rows H, C, P, N preserve the same route, so no open cover, selected subcover, sequential compactness argument, host Lebesgue number, host minimum selector, choice principle, or ambient completeness theorem can enter the certificate. □

Theorem 2253.3 (Dyadic compactness extractor vision handoff)**.** *The finite extractor packet $D = (K, M, T, R, F, L, U, H, C, P, N)$ realizes the compact-uniform-continuity handoff of chapter 9237: any accepted consumer factors through a displayed finite net, one dyadic radius row, the metric triangle row, the continuous-map modulus row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *before it exports a* $\mathsf{UniformModulus}^{\uparrow}$ *row. The exported row is therefore a BEDC finite-radius ledger, not a host modulus selector.*

Proof. Start with a compact-uniform consumer. The carrier forces the consumer to read K, T, R as the compact finite-net and dyadic radius data before any uniform-radius output is visible.

Next the route reads the metric and continuity evidence through M and F. The finite Lebesgue ledger L is the displayed comparison tying those pointwise rows to one compact-net radius.

The uniform-modulus row U is downstream of this finite chain. Since H, C, P, N only transport, replay, source, and name the same packet, the handoff is exactly the BEDC route described in the vision chapter and not an external modulus selector. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ compact-uniform consumer factors through a displayed finite net, dyadic radius row, metric triangle row, continuous-map

modulus row, hsame transport, Cont replay, Pkg provenance, and local NameCert before exporting a uniform modulus.

Independence witness: compactmetric, metric, continuousmap, finitelebesguenumber, uniformmodulus: $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the compact finite-net source, metric triangle estimates, dyadic radius ledger, pointwise continuousmap modulus rows, finite Lebesgue-radius readback, and UniformModulus handoff; each sibling omits at least one of these extractor coordinates.

The Lean TasteGate follow-up is `BEDC.Derived.DyadicCompactnessExtractorUp`, with Nontrivial DyadicComp and FieldFaithful $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ instances preserving $K, M, T, R, F, L, U, H, C, P, N$ as separate real extractor rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCompactnessExtractor}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCompactnessExtractor}^{\uparrow}$ packet is generated from a CompactMetric finite-net row, a Metric triangle row, a dyadic radius row, finite-net readback, ContinuousMap pointwise modulus data, a FiniteLebesgueNumber ledger, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCompactnessExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2253.1, Definition 2253.2, and Definition 2253.3 seed the finite dyadic compactness extractor route behind compact-uniform-continuity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCompactnessExtractor}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.DyadicCompactnessExtractorUp.DyadicCompactnessExtractorUp`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, sequential compactness, host Lebesgue numbers, host minimum selectors, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, dyadic-radius exactness, metric-triangle compatibility, continuous-map modulus exposure, finite Lebesgue-ledger readback, uniform-modulus handoff, structural transport, and ledger non-escape for BEDC.Derived.DyadicCompactnessExtractorUp.

Chapter 2254

A Concrete Naming Certificate for $\mathsf{CofinalDyadicMesh}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CofinalDyadicMesh}^{\uparrow}$ packet names the finite selector that refines an arbitrary Real- or completion-facing observation request to a dyadic mesh window. It sits between the dyadic mesh discipline of chapter 358, the endpoint ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal Real seal of chapter 38. The chapter records the selector as finite NameCert data; it does not assert a quotient real equality, selected limit, or countable-choice subnet.

Definition 2254.1 (Cofinal dyadic mesh carrier)**.** *A* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, D, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite observation request coming from a Real or regular Cauchy consumer.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic endpoint and tolerance ledger available to answer Q.*
3. *M is the* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh row selected from D and refined far enough for the request.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the selected mesh depth.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after M, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the request, dyadic ledger, mesh, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from Q through D, M, S, R, E, H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{CofinalDyadicMesh}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalDyadicMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, M, S, R, E, H, C, P, N$. It has no coordinate for a hidden subnet, quotient Cauchy class, host real equality, selected limit, countable-choice schedule, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.CofinalDyadicMeshUp.CofinalDyadicMeshTasteGate single carrier alignment`

Theorem 2254.2 (Cofinal dyadic mesh NameCert obligations)**.** *For every accepted* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *carrier* $K = (Q, D, M, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalDyadicMesh}^{\uparrow}}$ *surface consists exactly of carrier admission, request exposure through* Q*, dyadic endpoint and tolerance exposure through* D*, selected mesh exposure through* M*, finite-window exposure through* S*, regular readback through* R*, terminal Real-seal exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*. Every Real or regular Cauchy finite observation admitted by the packet must pass through this displayed dyadic mesh selector before reading* S, R, E*.*

Proof. Project the carrier. The request row Q is the only incoming observation demand, while D and M display the dyadic endpoint ledger and the selected mesh depth used to answer it.

The finite observation then proceeds through S, R, E. The stream window S is opened at the selected mesh depth, the regular readback R consumes that window, and the terminal Real seal E is read only after those rows are visible.

The structural rows H, C, P, N transport, replay, package, and name exactly the displayed route. Since no hidden subnet, quotient class, host equality, selected limit, choice schedule, or ambient completeness row appears in the carrier, every admitted observation factors through the finite dyadic selector. □

Falsifiable prediction: If the selected mesh row M is removed, a Real or regular Cauchy finite observation can no longer be forced to pass through a displayed dyadic refinement before the StreamName, RegSeqRat, and Real seal rows are read.

Independence witness: dyadicmesh, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{CofinalDyadicMesh}^{\uparrow}$ because this packet stores the observation request, dyadic endpoint ledger, selected mesh depth, finite stream window, regular readback, terminal Real seal, transport, replay, provenance, and local NameCert row as one selector route.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalDyadicMesh}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CofinalDyadicMesh}^{\uparrow}$ packet is generated from a finite observation request, a $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and tolerance ledger, a selected $\mathsf{DyadicMesh}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ finite-window data, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalDyadicMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2254.1 and Definition 2254.2 seed the finite dyadic-mesh selector feeding Real and RegSeqRat finite observations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalDyadicMesh}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CofinalDyadicMeshUp.CofinalDyadicMeshTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient real equality, selected limits, hidden subnets, countable-choice schedules, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector cofinality, finite-window routing, regular readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CofinalDyadicMeshUp.

Chapter 2255

A Concrete Naming Certificate for $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$ packet records the finite criterion by which displayed $\mathsf{RealSequenceLimit}^{\uparrow}$ data produces Cauchy behaviour for a sequence of constructive real names. The packet reads the sequence and candidate limit through the $\mathsf{RealSequenceLimit}^{\uparrow}$ surface of chapter 1413, the finite name windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, the nonquotient comparison boundary of chapter 1404, and the terminal real-name seal of chapter 38. It is a displayed finite tail-window criterion, not a quotient stream theorem, selected representative principle, countable-choice argument, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 2255.1 (RealSequenceCauchyCriterion carrier)**.** *A* $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, S, R, D, T, E, H, C, P, N)$$

with the following visible rows:

1. *L is the accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row naming the displayed sequence, candidate limit, and finite convergence classifier;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that lists the inspected sequence windows and limit windows for each requested tolerance;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled sequence and limit observations;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the tolerance rows and rational comparison cells used by the tail-window test;*
5. *T is the finite Cauchy tail-window classifier: each accepted tolerance request is assigned one displayed tail index and the paired windows used to compare two later sequence reads through R and D;*
6. *E is the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *comparison boundary that records the two sequence reads as a nonquotient regular-Cauchy comparison before any* $\mathsf{Real}^{\uparrow}$ *handoff;*
7. *H stores componentwise* hsame *transports for L, S, R, D, T, E and the local naming rows;*
8. *C stores displayed* Cont *routes exposing the limit row, window schedule, regular rational readback, dyadic ledger, Cauchy classifier, and comparison boundary in that order;*

9. *P is the* Pkg *provenance over* RealSequenceLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyEquivalence$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* NameCert$_{\text{RealSequenceCauchyCriterion}^{\uparrow}}$ *row.*

The carrier asserts only that these rows form one displayed limit-to-Cauchy packet. It has no field for quotient streams, selected representatives of real names, countable choice over tail bounds, trichotomy, or an ambient completeness theorem for Real$^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RealSequenceCauchyCriterionUp.RealSequenceCauchyCriterionTasteGate single carrier alignment`

Theorem 2255.2 (RealSequenceCauchyCriterion NameCert obligations)**.** *For every accepted* RealSequenceCauchy *carrier $K = (L, S, R, D, T, E, H, C, P, N)$, the local* NameCert$_{\text{RealSequenceCauchyCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission, limit-row exposure through L, finite window exposure through S, regular rational readback through R, dyadic tolerance comparison through D, Cauchy tail-window classification through T, nonquotient regular-Cauchy comparison through E, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for quotient streams, selected representatives, countable choice, trichotomy, and ambient* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2255.1. The accepted packet exposes the limit row, stream schedule, regular rational readback, dyadic ledger, Cauchy classifier, comparison boundary, transport, replay, provenance, and local naming rows.

The limit-row exposure is finite because L is consumed only through the scheduled windows S. For each requested tolerance, the convergence classifier already present in RealSequenceLimit$^{\uparrow}$ supplies a displayed tail window comparing later sequence reads to the candidate limit.

The Cauchy classifier T reads two later sequence windows through the same RegSeqRat$^{\uparrow}$ row R and the same DyadicRatCore$^{\uparrow}$ ledger D. The comparison first factors each sequence read through the displayed limit row and then composes the two finite dyadic comparisons inside the recorded tolerance budget.

The comparison boundary E prevents the route from becoming quotient equality of real streams. Rows H, C, P, N transport, replay, source, and name the same packet, so the local certificate has no coordinate from which a selected representative, a choice function for all tails, a trichotomy oracle, or ambient completeness of Real$^{\uparrow}$ can be exported. □

Theorem 2255.3 (RealSequenceCauchyCriterion limit-Cauchy handoff)**.** *Every* RealSequenceLimit$^{\uparrow}$ *display accepted by a* RealSequenceCauchyCriterion$^{\uparrow}$ *carrier yields a Cauchy tail-window route through finite* RegSeqRat$^{\uparrow}$ *and* DyadicRatCore$^{\uparrow}$ *rows. Concretely, for each requested tolerance in the classifier row T, the carrier exposes a tail index and two later sequence windows whose regular rational readbacks are compared by the dyadic ledger before the comparison is handed to* RegularCauchyEquivalence$^{\uparrow}$ *and any downstream* Real$^{\uparrow}$ *consumer.*

Thus a displayed sequence-limit packet is enough to serve Cauchy behaviour at the finite BEDC window level, without quotient streams, selected representatives, countable choice, real trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Start from the accepted carrier $K = (L, S, R, D, T, E, H, C, P, N)$. The row L supplies the displayed sequence-limit packet, while S lists the finite sequence and limit windows that may be inspected.

For a tolerance request, read the tail entry of T. It selects a displayed tail index and two later sequence windows inside the same schedule S. Their rational observations are read through R, and the required tolerance cells are read through D.

Apply the sequence-limit obligations of Definition 1413.2 to both later windows. Each window is compared to the same candidate limit through the recorded dyadic tolerance ledger. Combining those two finite comparisons gives the Cauchy tail-window comparison recorded by T.

Finally pass the comparison through the nonquotient boundary E before any $\mathsf{Real}^{\uparrow}$ handoff. Since all reads are coordinates of K and all replay goes through C, the route introduces no quotient stream, representative selector, countable choice, trichotomy decision, or ambient completeness row. □

Theorem 2255.4 (RealSequenceCauchyCriterion tail-window stability)**.** *Let*

$$K = (L, S, R, D, T, E, H, C, P, N)$$

and

$$K' = (L', S', R', D', T', E', H', C', P', N')$$

be accepted $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$ *packets. If the two packets are connected componentwise by* hsame *transport on* $L, S, R, D, T, E, H, C, P, N$*, then every Cauchy tail-window route exposed by* K *transports to a Cauchy tail-window route exposed by* K'*. The transported route keeps the limit row, stream schedule, regular rational readback, dyadic tolerance ledger, Cauchy classifier, nonquotient comparison boundary, transport, replay, provenance, and local name visible, and it introduces no quotient streams, selected representatives, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project both carriers through Definition 2255.1. The componentwise hsame assumptions identify the rows $L, S, R, D, T, E, H, C, P, N$ with their primed counterparts while preserving the carrier coordinates that expose the tail-window route.

Use the NameCert obligations of Definition 2255.2 to transport each displayed row. The limit row, finite schedule, regular rational readback, dyadic ledger, Cauchy classifier, and comparison boundary are moved as rows of the packet, so no representative selector or quotient stream is introduced.

Apply the handoff theorem Definition 2255.3 after transport. The same tolerance request now reads the primed tail index and primed later sequence windows through S', R', and D', then hands the comparison to E' before any $\mathsf{Real}^{\uparrow}$ consumer.

The remaining coordinates H', C', P', N' record transport, replay, provenance, and local naming for the transported route. Since neither packet contains a row for countable choice, trichotomy, quotient streams, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the stability route cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSequenceCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$ packet is generated from a displayed RealSequenceLimit row, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a Cauchy tail-window classifier, a RegularCauchyEquivalence boundary, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealSequenceCauchyCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 2255.1, Definition 2255.2, and Definition 2255.3 seed the finite displayed-limit to Cauchy tail-window criterion over StreamName, RegSeqRat, DyadicRatCore, RegularCauchyEquivalence, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealSequenceCauchyCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient stream equality, selected real-name representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, limit-row exposure, finite Cauchy tail-window classification, regular rational and dyadic comparison exactness, nonquotient comparison handoff, structural transport, and ledger refusal for BEDC.Derived.RealSequenceCauchyCriterionUp.

Chapter 2256

A Concrete Naming Certificate for $\mathsf{CompletionUnitTriangle}^{\uparrow}$

Following Bishop–Bridges completion and Mac Lane adjunction triangle identities, the $\mathsf{CompletionUnitTriangle}^{\uparrow}$ packet records the finite L10 surface at which a completion-facing read returns through the same unit, counit, and adjunction rows that introduced it. It sits after the unit packet of chapter 1527, the adjunction packet of chapter 1456, and the regular universal surface of chapter 1425. The packet names the triangle identity as a route through displayed finite rows; it does not form quotient completions, compare host equality of completed objects, choose representatives, assume countable choice, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2256.1 (Completion unit triangle carrier)**.** *A* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (U, K, A, E, R, S, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row sending the source regular name into the completion-facing boundary.*
2. *K is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *row returning an already displayed completion read to the terminal real-facing route.*
3. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *row binding U and K as the unit and counit faces of one adjunction packet.*
4. *E is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row through which completion consumers read the same unit-facing datum.*
5. *R is the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *regular-Cauchy universal row attached to the same source name and extension ledger.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row supplying the visible stream segment of the source name.*
7. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for the same finite window.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that fixes the displayed precision used by S and D.*
9. *H stores componentwise* hsame *transport for the unit, counit, adjunction, universal-property, regular-Cauchy, stream, readback, dyadic, terminal Real, replay, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay for the triangle route: unit first, universal extension second, regular-Cauchy readback third, counit return fourth, and terminal Real seal last.*

11. *P is the* Pkg *provenance over* $\mathsf{CompletionUnitTriangle}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionUnitTriangle}^{\uparrow}}$ *row.*

The carrier exposes a triangle-identity route only as a finite replay path through the named rows. It carries no quotient completion object, no host equality of completed carriers, no selected representative, no countable-choice schedule, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompletionUnitTriangleUp.CompletionUnitTriangleTasteGate single carrier alignment`

Theorem 2256.2 (Completion unit triangle NameCert obligations)**.** *For an accepted* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *carrier* $T = (U, K, A, E, R, S, D, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionUnitTriangle}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the unit, counit, adjunction, universal-property, regular-Cauchy, stream, regular-rational readback, dyadic, transport, replay, provenance, and local naming rows;*

2. *unit and counit visibility, requiring every triangle read to cite U before any completion-facing extension row and to cite K before any return to the terminal real seal;*

3. *triangle-route identity, requiring the adjunction row A to bind the unit and counit faces to the same displayed completion read;*

4. *classifier stability, requiring transported triangle evidence to replay through H and C before a completion-facing consumer reads it;*

5. *ledger non-escape, requiring the package and local naming rows to export no quotient completion, host equality, selected representative, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Carrier admission is projection from Definition 2256.1. The tuple lists exactly the unit, counit, adjunction, universal-property, regular-Cauchy, stream, readback, dyadic, transport, replay, provenance, and local naming rows.

Unit and counit visibility are the first two completion faces of the tuple. A completion-facing read enters through U, and a read that returns to the Real boundary exits through K.

The triangle-route identity is recorded by A together with the replay row C. The adjunction row binds the unit and counit faces to one displayed read, while C forces the same route through E, R, S, D, Q, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any consumer sees it.

Classifier stability is componentwise transport through H followed by the same replay through C. Ledger non-escape is the inventory statement for P and N: the carrier contains no quotient completion, host equality, selected representative, countable-choice schedule, or ambient completeness row. □

Theorem 2256.3 (Completion unit triangle identity route)**.** *Every accepted* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *triangle read factors through the same unit, counit, adjunction, universal-extension, regular-Cauchy, stream, dyadic, and Real seal rows before any completion-facing consumer reads it. Concretely, the exported route is exhausted by*

$\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, I

No accepted read may replace one of these rows by quotient-completion equality, host equality, a selected representative, countable choice, or an ambient completeness principle.

Proof. Read the carrier of Definition 2256.1. The only analytic rows available to a triangle consumer are U, K, A, E, R, S, D, Q and the terminal $\mathsf{Real}^{\uparrow}$ seal named by the transport, replay, and provenance rows.

Apply the NameCert obligations of Definition 2256.2. Unit and counit visibility force the read to enter through U and return through K, while triangle-route identity forces both faces through the same adjunction row A.

The universal-extension and regular-Cauchy rows E and R then keep the completion-facing read attached to the same regular name. The stream, readback, and dyadic rows S, D, Q display the finite windows and tolerances consumed by the terminal $\mathsf{Real}^{\uparrow}$ seal.

The package and local naming rows contain no further completion object or host equality coordinate. Therefore every accepted triangle read is exhausted by the displayed route and cannot export quotient completions, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionUnitTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionUnitTriangle}^{\uparrow}$ packet is generated from a completion unit row, counit row, adjunction row, universal-property row, regular-Cauchy universal row, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionUnitTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2256.1, Definition 2256.2, and Definition 2256.3 seed the finite triangle-identity packet over unit, counit, adjunction, universal-property, regular-Cauchy, StreamName, RegSeqRat, DyadicRatCore, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionUnitTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, host equality of completed objects, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit and counit visibility, triangle-route identity, classifier stability, and ledger non-escape for BEDC.Derived.CompletionUnitTriangleUp.

Chapter 2257

A Concrete Naming Certificate for $\mathsf{TotalVariationFunction}^{\uparrow}$

Following Jordan's decomposition theorem and the total-variation functions used in Rudin and Folland for bounded-variation analysis, the $\mathsf{TotalVariationFunction}^{\uparrow}$ packet records the cumulative variation route as finite BEDC data. It consumes the finite partition-variation surface of chapter 398, the positive and negative variation rows of chapter 2069, the terminal endpoint surfaces of chapter 38 and chapter 301, the dyadic tolerance ledger of chapter 291, the regulated-function handoff of chapter 1554, and the Riemann–Stieltjes consumer boundary of chapter 1637. The packet names cumulative variation as a displayed finite-prefix ledger, not as a host supremum over all partitions or as a quotient of real-valued functions.

Definition 2257.1 (Total variation function carrier)**.** *A* $\mathsf{TotalVariationFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, L, J, X, D, G, S, I, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet whose finite partition ledgers supply all edge-variation reads.*
2. *L is the partition-prefix ledger, listing the finite initial subpartitions used to read cumulative variation from the left endpoint to a displayed endpoint.*
3. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, exposing positive and negative variation ledgers for the same finite prefixes.*
4. *X records endpoint rows through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$*, including the left endpoint, the queried endpoint, and the terminal seal used by downstream consumers.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge-observation ledger for endpoint differences, sign separation, and finite prefix sums.*
6. *G is the graph row for the cumulative total-variation function, read only as the finite sum of the positive and negative prefix ledgers displayed by J.*
7. *S is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer row, recording the finite regulated-function handoff obtained from the bounded-variation and cumulative-variation ledgers.*
8. *I is the* $\mathsf{RiemannStieltjes}^{\uparrow}$ *consumer row, recording that a Stieltjes-facing read of the integrator first consumes B, L, J, X, D, G, S.*

9. *H records componentwise* hsame *transport for the bounded-variation source, prefix ledger, Jordan rows, endpoint rows, dyadic observations, graph row, consumer rows, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a consumer request through the finite prefix ledger, dyadic edge observations, Jordan split, cumulative graph row, and regulated or Stieltjes handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{TotalVariationFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a completed variation measure, a supremum over all partitions, host function equality, quotient real-valued functions, selected representatives, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.TotalVariationFunctionUp.TotalVariationFunctionTasteGate single carrier alignment`

Theorem 2257.2 (Total variation function NameCert obligations)**.** *For every accepted* $\mathsf{TotalVariationFunction}^{\uparrow}$ *carrier* $T = (B, L, J, X, D, G, S, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TotalVariationFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, finite partition-prefix ledger,* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *positive and negative variation rows,* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, cumulative graph row,* $\mathsf{RegulatedFunction}^{\uparrow}$ *and* $\mathsf{RiemannStieltjes}^{\uparrow}$ *consumer rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every cumulative variation read exported by the packet factors through

$$\mathsf{BoundedVariation}^{\uparrow},\ L,\ \mathsf{JordanVariationDecomposition}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ G,\ \mathsf{RegulatedFunction}^{\uparrow}$$

No local obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2257.1. The projection exposes exactly $B, L, J, X, D, G, S, I, H, C, P, N$.

The cumulative variation read starts with the bounded-variation source B and the finite prefix ledger L. The Jordan row J then separates each displayed edge into positive and negative variation rows, while X and D supply the endpoint names and dyadic observations used by those finite sums.

The graph row G stores only the resulting finite prefix sum. Downstream regulated-function and Stieltjes consumers must read S or I after B, L, J, X, D, G have been displayed, and the structural rows H, C, P, N only transport, replay, source, and name that same route.

Since no carrier coordinate stores all partitions at once, host function equality, selected representatives, a variation measure, choice, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 2257.3 (Total variation function regulated handoff)**.** *Let* $T = (B, L, J, X, D, G, S, I, H, C, P, N)$ *be an accepted* $\mathsf{TotalVariationFunction}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedFunction}^{\uparrow}$ *or* $\mathsf{RiemannStieltjes}^{\uparrow}$ *consumer read of the cumulative total-variation function first reads the displayed* $\mathsf{BoundedVariation}^{\uparrow}$ *source, then the finite partition-prefix ledger, then the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *positive and negative variation rows, then the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, and only then reaches the graph row G and consumer rows S, I.*

Consequently the handoff supplies a finite cumulative-variation route, not a completed variation measure, quotient function object, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a regulated-function or Stieltjes consumer of T. By the carrier definition, the only consumer rows are S and I, and both are downstream of the graph row G.

The graph row is itself downstream of the finite route B, L, J, X, D: the bounded-variation packet supplies the edge ledgers, the prefix ledger selects the displayed initial subpartitions, the Jordan row splits positive and negative variation, and the endpoint and dyadic rows provide the named observations for the finite sums.

The replay row C records the same ordering for every accepted consumer request, while H, P, N preserve transport, provenance, and local naming. Thus no consumer can bypass the finite prefix route through a host variation measure, quotient function equality, choice principle, or ambient completeness claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotalVariationFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{TotalVariationFunction}^{\uparrow}$ packet is generated from a $\mathsf{BoundedVariation}^{\uparrow}$ source packet, finite partition-prefix ledgers, $\mathsf{JordanVariationDecomposition}^{\uparrow}$ positive and negative variation rows, $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ endpoint rows, $\mathsf{DyadicRatCore}^{\uparrow}$ edge observations, cumulative graph data, $\mathsf{RegulatedFunction}^{\uparrow}$ and $\mathsf{RiemannStieltjes}^{\uparrow}$ consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotalVariationFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2257.1, Definition 2257.2, and Definition 2257.3 seed the finite cumulative total-variation route over bounded-variation, Jordan-split, endpoint, dyadic, regulated-function, and Stieltjes consumer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotalVariationFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed variation measures, suprema over all partitions, quotient function equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-prefix exactness, Jordan positive and negative variation routing, endpoint and dyadic observation routing, regulated-function handoff, Stieltjes handoff, transport, replay, provenance, and local naming for BEDC.Derived.TotalVariationFunctionUp.

Chapter 2258

A Concrete Naming Certificate for $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$

The $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$ packet realizes the GroundCompiler audit-map boundary of chapter 9407 as one finite route object. It sits beside the event-flow route of chapter 830, the audit-map family surface of chapter 811, the local MetaCIC critical-pair boundary of chapter 2212, and the finite-window pullback of chapter 2240. The packet stores the rows by which an audit consumer sees event flow, MetaCIC boundary references, no-hidden-input evidence, transport, replay, provenance, and local naming without treating a GroundCompiler report as a MetaCIC theorem.

Falsifiable prediction: Every theorem, generated recognizer, compiler report, or MetaCIC-facing export admitted by a $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$ packet is accompanied by displayed event-flow, no-hidden-input, boundary, transport, replay, provenance, and local NameCert rows; no hidden input or MetaCIC theorem is exported without those rows.

Independence witness: Nearest siblings: groundcompilereventflowauditroute, metacicauditmapfamily, metacic-confluence-critical-pair-boundary, and finite-window-pullback. The audit-route packet is not bijective to any one sibling because it jointly carries event-flow routing, MetaCIC-boundary references, no-hidden-input separation, transport, replay, provenance, and local naming for one GroundCompiler export path.

Definition 2258.1 (GroundCompiler audit route carrier)**.** *A* $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (E, M, B, Q, T, R, V, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}$ *event-flow row, including the displayed channel, generated-recognizer, certificate-gate, and non-evidence boundary.*
2. *M is the* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *boundary row naming which MetaCIC audit-map family entries are referenced by the GroundCompiler route.*
3. *B is the critical-pair boundary row, read through* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *when the route mentions confluence-facing MetaCIC data.*
4. *Q is the no-hidden-input row, stating that every accepted export path is sourced by displayed event-flow and channel rows rather than host compiler state, source prose, reports, metrics, or motifs.*

5. *T is the transport row connecting event-flow export names with the referenced MetaCIC boundary names without converting either side into the other.*
6. *R is the replay row for generated recognizer, certificate-gate, report-boundary, MetaCIC-boundary, and no-hidden-input reads.*
7. *V is the* $\mathsf{FiniteWindowPullback}^{\uparrow}$ *local-window row used when an audit route reads a finite observation window before exposing a certificate-facing export.*
8. *H records componentwise* hsame *transport for event-flow, MetaCIC-family, critical-pair-boundary, no-hidden-input, route-transport, replay, finite-window, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from event-flow input through channel readback, generated-recognizer mediation, no-hidden-input separation, optional MetaCIC-boundary reference, finite-window pullback, and certificate-gate export.*
10. *P is the* Pkg *provenance over* $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$, $\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}$, $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$, $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$, $\mathsf{FiniteWindowPullback}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditRoute}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for hidden compiler input, unchecked host reports, proof evidence extracted from prose, substitution of a GroundCompiler route for a MetaCIC theorem, or substitution of a MetaCIC theorem for a GroundCompiler certificate gate.

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditRouteUp.GroundCompilerAuditRouteTasteGate single carrier alignment`

Theorem 2258.2 (GroundCompiler audit route NameCert obligations)**.** *For every accepted* GroundCompilerAuditR *carrier $A = (E, M, B, Q, T, R, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for the event-flow route, MetaCIC audit-map-family boundary, critical-pair boundary reference, no-hidden-input row, route-transport row, replay row, finite-window pullback row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

An accepted audit export may be consumed only through the displayed route

$$E \longmapsto Q \longmapsto T, R \longmapsto M, B, V \longmapsto H, C, P, N.$$

No GroundCompiler report, motif, metric, host compiler state, source prose, or MetaCIC theorem is exported outside that route.

Proof. Carrier admission is projection from Definition 2258.1. The projection exposes exactly $E, M, B, Q, T, R, V, H, C, P, N$.

The event-flow row E is read before any export-facing boundary. The no-hidden-input row Q then separates displayed channel readback from host compiler state, reports, metrics, motifs, and source prose.

The transport and replay rows T, R connect the GroundCompiler route to optional MetaCIC-family, critical-pair, and finite-window rows without replacing any one row by another. The structural rows H, C, P, N transport, replay, source, and name the same finite path.

Since no carrier coordinate converts reports or MetaCIC boundary references into proof evidence, the listed rows exhaust the local NameCert surface. □

Theorem 2258.3 (GroundCompiler audit route MetaCIC boundary)**.** *Let $A = (E, M, B, Q, T, R, V, H, C, P, N)$ be an accepted* $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$ *carrier. Any consumer that reads a MetaCIC-facing reference from A must first read the displayed GroundCompiler event-flow row E, the no-hidden-input row Q, and the route-transport row T; it then reads the* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *row M or the* $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ *row B as a boundary reference only.*

Consequently the packet does not turn a GroundCompiler audit route into subject reduction, normalization, confluence, closed consistency, or arbitrary MetaCIC theorem export; it also does not turn a MetaCIC boundary reference into a GroundCompiler certificate-gate export without the displayed event-flow and no-hidden-input rows.

Proof. Start with a MetaCIC-facing consumer of A. The carrier definition gives access to MetaCIC data only through M and B.

The NameCert obligations force the consumer to read E, Q, T before those boundary rows. Thus the GroundCompiler event-flow source and no-hidden-input separation are already displayed when a MetaCIC reference is inspected.

The replay row R and structural rows H, C, P, N preserve this ordering. They do not contain constructors for subject reduction, normalization, confluence, closed consistency, or arbitrary theorem export, and they do not replace the certificate gate of E by the MetaCIC boundary rows M or B. □

Future Lean TasteGate work for this packet must supply `Nontrivial GroundCompilerAuditRouteUp` and `FieldFaithful GroundCompilerAuditRouteUp` instances, so the event-flow, no-hidden-input, MetaCIC-boundary, finite-window, transport, replay, provenance, and local naming rows are checked as genuine carrier fields.

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerAuditRoute}^{\uparrow}$ packet is generated from a GroundCompiler event-flow audit route, MetaCIC audit-map-family boundary row, critical-pair boundary row, no-hidden-input row, route-transport row, replay row, finite-window pullback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerAuditRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2258.1, Definition 2258.2, and Definition 2258.3 seed the finite GroundCompiler audit route over event-flow, MetaCIC-boundary, no-hidden-input, transport, replay, finite-window, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerAuditRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compiler correctness, proof reconstruction from reports or source prose, subject reduction, normalization, confluence, closed consistency, arbitrary MetaCIC theorem export, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, event-flow exposure, no-hidden-input separation, MetaCIC-boundary routing, finite-window routing, transport, replay, provenance, local naming, and TasteGate nontriviality and field faithfulness for BEDC.Derived.GroundCompilerAuditRouteUp.

Chapter 2259

A Concrete Naming Certificate for $\mathsf{CauchyIntegralTest}^{\uparrow}$

Following Cauchy's integral-test tradition and the constructive real analysis of Bishop and Bridges, the $\mathsf{CauchyIntegralTest}^{\uparrow}$ packet records a finite comparison route from nonnegative monotone real-function data to a regular Cauchy series-tail seal. It consumes the $\mathsf{Real}^{\uparrow}$ readback surface of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ rational approximation corridor of chapter 301, finite observation schedules from chapter 126, and integral-window rows from chapter 1460 and chapter 1526. The packet names the textbook tail comparison as finite NameCert data; it does not add measure theory, Lebesgue integration, countable choice, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 2259.1 (CauchyIntegralTest carrier)**.** *A* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, I, S, W, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Real}^{\uparrow}$ *nonnegative monotone function row. It records finite real-name observations of the sampled function and the displayed monotone comparison between inspected tail points.*
2. *I is the integral tail-window row. It records Darboux or Riemann interval sums over inspected tails, together with the finite comparison between consecutive tail windows.*
3. *S is the regular Cauchy series-tail row. It records partial-sum tail windows and the displayed comparison to the integral tail windows.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row selecting the finite function samples, interval windows, and series-tail windows used by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to function values, integral bounds, and series tails.*
6. *H records componentwise* hsame *transport for the function row, integral-window row, series-tail row, stream schedule, regular rational readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a consumer request through F, I, S, W, R and then to H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyIntegralTest}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, *regular series-tail data,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyIntegralTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine displayed rows. It has no coordinate for a host improper integral, a Lebesgue integral, an arbitrary choice of tail witnesses, a hidden completeness theorem, or quotient equality of real functions.

Definition 2259.2 (CauchyIntegralTest classifier)**.** *Two accepted* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *packets classify together exactly when their displayed rows are componentwise transported by* hsame*: the nonnegative monotone* $\mathsf{Real}^{\uparrow}$ *observations match, the integral tail-window rows match, the regular Cauchy series-tail rows match, the* $\mathsf{StreamName}^{\uparrow}$ *schedules and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks match, and the replay, provenance, and local naming rows match. No additional classifier row compares external functions, host integrals, or completed real sums.*

Theorem 2259.3 (CauchyIntegralTest NameCert obligations)**.** *For every accepted* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *carrier* $K = (F, I, S, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyIntegralTest}^{\uparrow}}$ *surface consists exactly of carrier admission, nonnegative monotone* $\mathsf{Real}^{\uparrow}$ *observation, Darboux or Riemann tail-window exposure, regular Cauchy series-tail exposure,* $\mathsf{StreamName}^{\uparrow}$ *finite observation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The row F exposes only the nonnegative monotone real-name observations needed for the integral-test comparison, while the row I exposes the inspected integral tail windows.

The row S records the series-tail windows and their comparison to I. The rows W and R are the only routes through which the finite observations and rational readbacks are inspected.

Finally H, C, P, N transport, replay, source, and locally name the same displayed route. Since no row carries a host improper integral, a measure-theoretic integral, a choice functional, or a completeness theorem for $\mathsf{Real}^{\uparrow}$, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CauchyIntegralTestUp.CauchyIntegralTestCarrier namecert obligations`

Theorem 2259.4 (CauchyIntegralTest tail boundary)**.** *Every accepted* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *tail comparison factors through the finite route*

$$F, W \longmapsto I, R \longmapsto S$$

before it can be used as convergence-test evidence. Thus the packet exports only a displayed tail-window boundary, not an ambient theorem that all monotone real functions have improper integrals.

Proof. Read the function samples through F and the selected observation schedule through W. These rows determine the inspected monotone tail windows.

The integral row I and readback row R expose the finite Darboux or Riemann bounds attached to those windows. Only after those rows are visible may the series-tail row S be compared against them.

Therefore a consumer that bypasses F, W, I, R or treats the route as a host improper-integral theorem leaves the accepted carrier surface. □

Theorem 2259.5 (CauchyIntegralTest series handoff)**.** *The* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *packet hands convergence evidence to the regular Cauchy series-tail corridor only through the displayed row* S *together with the readback rows* W *and* R*. It does not choose a completed series sum, assert* $\mathsf{Real}^{\uparrow}$ *completeness, or identify integral tails with real limits outside the packet.*

Proof. The handoff target is the regular Cauchy series-tail row S. The finite windows and rational approximations that make S readable are supplied by W and R.

The carrier contains no row for a selected infinite sum and no row for a global completeness theorem. The packet therefore supplies a convergence-test handoff to the series-tail corridor, while leaving completed sums and completeness principles outside the named surface. □

Theorem 2259.6 (CauchyIntegralTest monotone-tail induction)**.** *Let $K = (F, I, S, W, R, H, C, P, N)$ be an accepted* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *carrier. A monotone nonnegative tail window accepted by the carrier can be advanced by one finite observation step while preserving the integral-window row I, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows W, R, and the* $\mathsf{Real}^{\uparrow}$ *seal route carried by the same structural rows. The induction step exports no Lebesgue measure, selected improper integral value, countable choice, quotient equality of functions, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 2259.1. The function row F records the monotone nonnegative observations, and the stream row W records the finite observation schedule that may be extended by one displayed tail point.

Apply the tail boundary theorem of Definition 2259.4. The advanced tail point is read through F, W before the integral-window row I and the readback row R are inspected, so the new observation remains inside the same finite comparison corridor.

Use the series handoff of Definition 2259.5. The series-tail row S receives convergence evidence only through W, R, and the structural rows H, C, P, N transport, replay, source, and name that same handoff after the one-step advance.

Because the carrier has no coordinate for Lebesgue measure, selected improper integral values, countable choice, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the induction step preserves exactly the displayed BEDC route and exports none of those principles. □

Falsifiable prediction: An accepted $\mathsf{CauchyIntegralTest}^{\uparrow}$ packet that reaches a series-tail seal without displaying the nonnegative monotone $\mathsf{Real}^{\uparrow}$ row, a Darboux or Riemann integral tail-window row, finite $\mathsf{StreamName}^{\uparrow}$ observations, and $\mathsf{RegSeqRat}^{\uparrow}$ readback fails the carrier surface.

Independence witness: Real, RegSeqRat, StreamName, DarbouxIntegral, RiemannIntegral, regular series-tail rows: none is bijective to $\mathsf{CauchyIntegralTest}^{\uparrow}$, because the listed siblings separately supply real observations, finite schedules, rational readback, integral windows, or series-tail evidence while this packet binds them to one constructive integral-test route with transport, replay, provenance, and local naming.

The Lean TasteGate follow-up is `BEDC.Derived.CauchyIntegralTestUp`, with explicit Nontrivial CauchyIntegra and FieldFaithful $\mathsf{CauchyIntegralTest}^{\uparrow}$ instances preserving $F, I, S, W, R, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyIntegralTest}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyIntegralTest}^{\uparrow}$ packet is generated from a nonnegative monotone RealUp observation row, a Darboux or Riemann integral tail-window row, a regular Cauchy series-tail row, finite StreamNameUp observations, RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyIntegralTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2259.1, Definition 2259.2, Definition 2259.3, Definition 2259.4, and Definition 2259.5 seed the finite integral-test carrier, classifier, tail boundary, and series handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyIntegralTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure theory, Lebesgue integration, selected improper integrals, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, tail-window boundary, series-tail handoff, nontriviality, and field faithfulness for BEDC.Derived.CauchyIntegralTestUp.

Chapter 2260

A Concrete Naming Certificate for $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$

The $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ packet records the traditional genetic-code four-base alphabet as a conservative finite readback over BEDC finite-data carriers. It uses the two-endpoint $\mathsf{Bool}^{\uparrow}$ surface of chapter 32 and the componentwise product discipline of chapter 34, while its source vision is the DNA four-phase bridge of subsection 9462.28.16. The packet names a finite external alphabet bridge; it does not prove a molecular-biology theorem, identify BEDC channel glyphs with bases, or turn biological bases into BEDC primitives.

Definition 2260.1 (DNAFourPhaseAlphabetBridge carrier)**.** *A* $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, Q, A, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *endpoint row. It supplies the two finite axes used by the readback.*
2. *Q is the* $\mathsf{Prod}^{\uparrow}$ *quadrant row. It records the four displayed pairs of Bool endpoints without adding a fifth phase or quotienting any pair.*
3. *A is the external alphabet row. It names the target-side symbols* A, C, G, *and* T *only as readback labels.*
4. *E is the bridge-exactness row. It records that each displayed quadrant has exactly one external alphabet label and that each external label is read from exactly one displayed quadrant.*
5. *H records componentwise* hsame *transport for the Bool axes, product quadrant, external alphabet label, exactness, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the route*

$$B, Q \longmapsto A, E \longmapsto H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, *the source vision bridge,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets through B, Q, A, E, H, C, P, N. It has no coordinate for molecular identity, biological translation correctness, mutation dynamics, channel-glyph equality, or a global genetic-code theorem.

Lean4 ✓ `BEDC.Derived.DNAFourPhaseAlphabetBridgeUp.DNAFourPhaseAlphabetBridgeUpTasteGate single carrier alignment`

Definition 2260.2 (DNAFourPhaseAlphabetBridge classifier)**.** *Two accepted* $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ *packets classify together exactly when their Bool endpoint rows, product quadrant rows, external alphabet rows, exactness rows, transport rows, replay rows, provenance rows, and local naming rows classify componentwise by* hsame*. The external alphabet labels are compared only as the target-side labels recorded by the bridge row; they are not BEDC source constructors.*

Theorem 2260.3 (DNAFourPhaseAlphabetBridge NameCert obligations)**.** *For every accepted* $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ *carrier* $D = (B, Q, A, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}}$ *surface consists exactly of Bool endpoint admission, product quadrant formation, four-label external alphabet readback, quadrant-label exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.DNAFourPhaseAlphabetBridgeUp.DNAFourPhaseAlphabetBridgeTasteGate single carrier alignment`

Proof. Project the accepted carrier. The row B supplies only the two finite Bool axes, and the row Q forms their product quadrants through the existing product discipline.

The row A names the four external alphabet labels, while E records the finite readback exactness between quadrants and labels. These rows are target-side readbacks and do not create source constructors for biological bases.

Finally H, C, P, N transport, replay, source, and locally name the same route. Since the carrier contains no molecular identity row, no translation-correctness row, and no channel-glyph identification row, the listed obligations exhaust the local certificate surface. □

Theorem 2260.4 (DNAFourPhaseAlphabetBridge readback boundary)**.** *Every accepted* DNAFourPhaseAlphabetB *readback factors through*

$$B, Q \longmapsto A, E$$

before it can be used as four-phase alphabet evidence. Thus the packet exports a conservative finite readback boundary, not an identification between BEDC channel glyphs and DNA bases.

Proof. Read B to obtain the two finite axes and Q to obtain the four displayed product quadrants. These rows are internal finite-data rows.

Only after those rows are displayed may the external alphabet row A and exactness row E be inspected. The bridge therefore keeps internal finite carriers and external biological labels in separate rows.

Any consumer that treats the labels as BEDC channel glyphs or as a molecular-biology theorem bypasses the accepted carrier boundary. □

Theorem 2260.5 (DNAFourPhaseAlphabetBridge quadrant exhaustion)**.** *Every accepted* DNAFourPhaseAlphabet *carrier* $D = (B, Q, A, E, H, C, P, N)$ *exposes exactly four* $\mathsf{Bool}^{\uparrow} \times \mathsf{Bool}^{\uparrow}$ *product quadrants through* Q*. Each displayed quadrant is read by exactly one of the external labels in* A*, and every such label is consumed only through the exactness, transport, replay, provenance, and local naming rows* E, H, C, P, N*.*

The exhaustion exports no biological translation theorem, no molecular identity, and no identity between BEDC channel glyphs and the external labels A, C, G, *and* T.

Proof. Project the accepted carrier. The row B supplies only the two finite Bool axes, and the product row Q records their four displayed ordered pairs.

Use the classifier of Definition 2260.2. It compares packets by the Bool endpoint rows, product quadrant rows, external alphabet rows, exactness rows, transport rows, replay rows, provenance rows, and local naming rows, so there is no hidden fifth quadrant or quotient of two quadrants.

The external alphabet row A supplies exactly the four target-side labels, while E records the one-to-one finite readback between those labels and the quadrants in Q. The remaining rows H, C, P, N are the only downstream consumers of that readback.

Since no row of the carrier records molecular identity, biological translation correctness, mutation dynamics, or channel-glyph equality, the theorem is a finite exhaustion statement about the accepted bridge and not an exported biology or glyph-identification theorem. □

Falsifiable prediction: An accepted $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ packet that identifies BEDC channel glyphs with A, C, G, or T fails the classifier row, because the accepted carrier records only Bool endpoint axes, product quadrants, external alphabet labels, exactness, transport, replay, provenance, and local naming.

Independence witness: Bool, Prod, channel genetic-code bridge: $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ is not bijective to any listed sibling because it binds two finite Bool axes and product quadrant formation to an external four-label readback while preserving the separation between BEDC finite carriers and biological alphabet labels.

The Lean TasteGate follow-up is `BEDC.Derived.DNAFourPhaseAlphabetBridgeUp`, with explicit $\mathsf{Nontrivial\ DNAFourPhaseAlphabetBridge}^{\uparrow}$ and $\mathsf{FieldFaithful\ DNAFourPhaseAlphabetBridge}^{\uparrow}$ instances preserving B, Q, A, E, H, C, P, N as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ packet is generated from BoolUp endpoint axes, a ProdUp quadrant row, a four-label external DNA alphabet readback row, bridge exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2260.1, Definition 2260.2, Definition 2260.3, and Definition 2260.4 seed the finite four-phase alphabet bridge and its readback boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim molecular-biology theorems, biological translation correctness, channel-glyph identification, mutation dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, quadrant-label exactness, readback boundary, nontriviality, and field faithfulness for BEDC.Derived.DNAFourPhaseAlphabetBridgeUp.

Chapter 2261

A Concrete Naming Certificate for $\mathsf{UniformSequentialContinuity}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformSequentialContinuity}^{\uparrow}$ packet records the finite route by which one displayed uniform modulus transports regular Cauchy sequence data through a continuous map before the $\mathsf{Real}^{\uparrow}$ seal is read. It sits between the map surface of chapter 130, the uniform-modulus row of chapter 369, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the real-name seal of chapter 38. The packet names a uniform sequential handoff only; it does not assert host sequential continuity, function extensionality, quotient stream equality, countable choice, selected limits, or ambient real completeness.

Definition 2261.1 (Uniform sequential continuity carrier)**.** *A* $\mathsf{UniformSequentialContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, M, S, W_X, W_Y, R_X, R_Y, D_X, D_Y, E_X, E_Y, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the displayed source-to-target map and its local classifier interface.*
2. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *row. It converts every requested target tolerance into a source tolerance before any target sequence read is consumed.*
3. *S is the source sequence surface exposed only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. *W_X and W_Y are the source and image finite-window rows. The row W_Y is read only by applying F to the windows selected by W_X.*
5. *R_X and R_Y are the source and target* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows attached to the displayed windows.*
6. *D_X and D_Y are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers. The target ledger D_Y records the requested precision and the source ledger D_X records the modulus-returned precision.*
7. *E_X and E_Y are the source and target* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after the corresponding stream, regular-rational, and dyadic rows have been displayed.*
8. *H records componentwise* hsame *transport for the map row, modulus row, stream surface, window rows, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a target tolerance request through $M, D_X, W_X, R_X, F, W_Y, R_Y, D_Y$ before E_Y is exposed.*
10. *P is the* Pkg *provenance over* UniformSequentialContinuity$^\uparrow$, ContinuousMap$^\uparrow$, UniformModulus$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformSequentialContinuity}^\uparrow}$ *row.*

The classifier compares accepted packets only through the displayed tuple $F, M, S, W_X, W_Y, R_X, R_Y, D_X, D_Y, E_X, E$ The carrier has no coordinate for host sequential continuity, function extensionality, quotient stream equality, countable choice, selected limits, or ambient Real$^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformSequentialContinuityUp.UniformSequentialContinuityTasteGate single carrier alignment`

Theorem 2261.2 (Uniform sequential continuity NameCert obligations)**.** *For every accepted* UniformSequentialContinuity$^\uparrow$ *carrier*

$$U = (F, M, S, W_X, W_Y, R_X, R_Y, D_X, D_Y, E_X, E_Y, H, C, P, N),$$

the local NameCert$_{\text{UniformSequentialContinuity}^\uparrow}$ *surface consists exactly of carrier admission, displayed continuous-map use, uniform-modulus tolerance conversion, source and image finite-window exposure, source and target* RegSeqRat$^\uparrow$ *handoff, dyadic tolerance accounting, source and target* Real$^\uparrow$ *seal ordering, componentwise transport, displayed replay, provenance, local naming, and non-escape from host sequential continuity, function extensionality, quotient stream equality, countable choice, selected limits, and ambient real completeness.*

Proof. Carrier admission is projection from Definition 2261.1. The projection exposes the displayed map, uniform modulus, source stream surface, finite windows, regular readbacks, dyadic ledgers, Real seals, and structural rows.

A target tolerance request first reads the modulus row M. This produces the source-side dyadic tolerance in D_X before any image-window read occurs, so the route cannot start from a detached target limit or a host sequential-continuity theorem.

The source sequence is then inspected through S, W_X, R_X, D_X, E_X. The image sequence is obtained by applying the displayed map row F to the same finite source windows, producing W_Y and then the target handoff through R_Y, D_Y, E_Y.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since no excluded object is a carrier coordinate, the listed rows exhaust the local certificate surface. □

Theorem 2261.3 (Uniform sequential continuity Cauchy handoff)**.** *Every accepted* UniformSequentialContinuity$^\uparrow$ *packet preserves regular Cauchy sequence data through the displayed uniform modulus before either* Real$^\uparrow$ *seal is consumed. Equivalently, every target-seal-facing route factors through*

$$D_Y \longmapsto M \longmapsto D_X \longmapsto W_X \longmapsto R_X \qquad \textit{and} \qquad W_X, F \longmapsto W_Y \longmapsto R_Y \longmapsto E_Y$$

together with S, E_X, H, C, P, N.

Proof. Start with the target precision request recorded in D_Y. The uniform-modulus row M converts that request into the source precision recorded in D_X, so the source sequence is inspected at a tolerance already tied to the target demand.

The source route then reads the finite stream windows W_X from S and the regular rational handoff R_X before the source seal row E_X can be used. This is the displayed regular Cauchy data available to the map row.

Apply the continuous-map row F to the displayed source windows. The image windows W_Y are therefore downstream of the same source inspection, and the target regular-rational handoff R_Y precedes the target seal E_Y.

The rows H, C, P, N preserve the route under transport, replay, provenance, and local naming. Thus no Real-facing consumer can bypass the uniform modulus, the source regular Cauchy handoff, or the target regular Cauchy handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformSequentialContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformSequentialContinuity}^{\uparrow}$ packet is generated from a displayed ContinuousMap row, a UniformModulus row, source and image StreamName windows, source and target RegSeqRat readbacks, DyadicRatCore tolerance ledgers, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformSequentialContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2261.1, Definition 2261.2, and Definition 2261.3 seed the finite uniform sequential continuity handoff from a modulus-controlled source regular Cauchy route to the target Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformSequentialContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host sequential continuity, function extensionality, quotient stream equality, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displayed map use, uniform-modulus tolerance conversion, source and image window exactness, RegSeqRat handoff, dyadic ledger accounting, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.UniformSequentialContinuityUp.

Chapter 2262

A Concrete Naming Certificate for $\mathsf{SmithNormalForm}^{\uparrow}$

Following Smith's determinantal reduction and Newman's normal-form treatment, the $\mathsf{SmithNormalForm}^{\uparrow}$ packet records the finite row-and-column certificate by which an integer or principal-ideal matrix is reduced to a displayed diagonal divisibility chain. It consumes the matrix carrier of chapter 49, the finite module-row discipline of chapter 46, the ideal membership surface of chapter 81, and the Dedekind-domain naming rows of chapter 172. The chapter names a finite certificate for diagonal reduction and divisibility bookkeeping; it does not claim quotient-module classification, a choice-selected basis, a host principal-ideal-domain theorem, or equality outside displayed row and column operations.

Definition 2262.1 (Smith normal form carrier)**.** *A* $\mathsf{SmithNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, R, C, D, V, E, U, H, T, P, N)$$

with the following displayed rows:

1. *M is the source matrix row, recording the finite matrix entries, row and column bounds, coefficient carrier, and matrix-operation ledger inherited from* $\mathsf{Mat}^{\uparrow}$*.*
2. *R is the elementary row-operation trace. It lists each row swap, row scaling by a displayed unit, and row addition by a displayed multiple, together with the matrix row it transforms.*
3. *C is the elementary column-operation trace, with the same visible data for column swaps, unit scalings, and displayed multiple additions.*
4. *D is the diagonal readback row, listing the terminal diagonal entries and the zero-off-diagonal witnesses exposed after the combined R, C trace.*
5. *V is the divisibility-chain row. It records, for every adjacent pair of nonzero diagonal entries, the displayed ideal-membership or divisibility witness that the earlier diagonal entry divides the later one.*
6. *E is the exactness row. It records that every intermediate matrix is obtained from the previous one by the displayed elementary operation and that the terminal readback is the matrix named by D.*
7. *U is the unit-and-ideal ledger, exposing the unit rows, principal ideal rows, and Dedekind-compatible ideal containment checks used by R, C, V.*

8. *H records componentwise* hsame *transport for matrix entries, row traces, column traces, diagonal readback, divisibility witnesses, exactness rows, unit and ideal ledgers, continuation rows, provenance, and naming.*
9. *T records displayed* Cont *replay from source matrix inspection through elementary-operation playback, diagonal readback, divisibility verification, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{SmithNormalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, $\mathsf{Dedekind}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SmithNormalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient modules, selected external bases, hidden principal ideal choices, ambient noetherian arguments, or host equality outside the displayed elementary-operation trace.

Lean4 ✓ `BEDC.Derived.SmithNormalFormUp.SmithNormalFormTasteGate single carrier alignment`

Definition 2262.2 (Smith normal form classifier)**.** *Two accepted* $\mathsf{SmithNormalForm}^{\uparrow}$ *packets*

$$S = (M, R, C, D, V, E, U, H, T, P, N) \quad \textit{and} \quad S' = (M', R', C', D', V', E', U', H', T', P', N')$$

are classifier-equivalent exactly when the eleven displayed rows match componentwise under the local hsame *surface: the source matrices match through the same* $\mathsf{Mat}^{\uparrow}$ *carrier, the elementary row and column traces match step by step, the terminal diagonal rows agree entrywise, the divisibility witnesses in V, V' name the same adjacent divisibility obligations, the exactness and unit-ideal rows agree, and the transport, continuation, provenance, and naming rows replay the same finite data. The classifier ignores no additional ambient module quotient, selected basis, or external diagonal-form uniqueness theorem.*

Theorem 2262.3 (Smith normal form divisibility chain)**.** *For every accepted* $\mathsf{SmithNormalForm}^{\uparrow}$ *carrier $S = (M, R, C, D, V, E, U, H, T, P, N)$, any exported diagonal normal-form claim factors through the displayed divisibility route*

$$M, R, C \longmapsto D, E, U \longmapsto V, H, T, P, N.$$

In particular, the claim that the diagonal entries form a Smith chain is readable only from the adjacent divisibility witnesses listed in V and the unit-and-ideal ledger U.

Proof. Open the carrier of Definition 2262.1. The source matrix row M and the elementary traces R, C are the only rows that can produce a terminal matrix for this packet.

The diagonal row D is read only after the exactness row E has replayed every elementary operation. The unit-and-ideal ledger U supplies the visible unit rows and ideal-containment checks that justify the divisibility witnesses.

Finally, V lists the adjacent divisibility witnesses for the terminal diagonal entries. Since H, T, P, N transport, replay, source, and name only those rows, any downstream Smith-chain claim must pass through the displayed route and cannot appeal to an external normal-form theorem. □

Theorem 2262.4 (Smith row-column equivalence)**.** *For every accepted* $\mathsf{SmithNormalForm}^{\uparrow}$ *carrier $S = (M, R, C, D, V, E, U, H, T, P, N)$, the source matrix named by M and the diagonal matrix named by D are equivalent only by the finite row and column traces R and C together with the exactness row E. No quotient-module equality, selected basis identification, or ambient isomorphism theorem is exported by the packet.*

Proof. Read the elementary traces in order. Each row of R and each row of C names one displayed elementary operation and the matrix row it transforms, so the trace itself supplies the equivalence witness between successive matrices.

The exactness row E ties those local witnesses to the terminal diagonal readback D. Thus the only exported equivalence is the finite playback from M through R, C to D.

The classifier of Definition 2262.2 compares the same rows componentwise. Therefore the packet has no remaining coordinate from which quotient-module equality, selected bases, or an ambient classification theorem could be read. □

Theorem 2262.5 (Smith normal form NameCert obligations)**.** *For every accepted* $\mathsf{SmithNormalForm}^{\uparrow}$ *carrier* $S = (M, R, C, D, V, E, U, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SmithNormalForm}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source matrix, row trace, column trace, diagonal readback, divisibility witnesses, exactness row, unit-and-ideal ledger, transport, continuation, provenance, and local naming;*
2. *matrix-source compatibility, requiring every entry read by* R, C, D, E, V, U *to be supplied by the displayed* $\mathsf{Mat}^{\uparrow}$ *source row* M*;*
3. *elementary-operation exactness, requiring every row and column operation to name its source row, target row, coefficient or unit witness, and resulting matrix entry updates;*
4. *diagonal readback exactness, requiring* D *to expose every diagonal entry and every zero-off-diagonal witness after the finite trace;*
5. *divisibility-chain exactness, requiring* V *and* U *to display the unit, ideal-membership, and containment evidence for each adjacent diagonal divisibility claim;*
6. *module, ideal, and Dedekind provenance, requiring the finite rows used by* M, R, C, D, V, E, U *to be sourced through the cited* $\mathsf{Module}^{\uparrow}$*,* $\mathsf{Ideal}^{\uparrow}$*, and* $\mathsf{Dedekind}^{\uparrow}$ *packets when those algebraic surfaces are invoked;*
7. *ledger preservation, requiring* H, T, P, N *to preserve exactly the displayed rows under componentwise transport, continuation replay, package provenance, and local naming.*

No Smith-normal-form obligation is stored outside these rows.

Proof. Project the carrier rows. Carrier admission gives precisely $M, R, C, D, V, E, U, H, T, P, N$, so a local certificate cannot obtain extra data from a host module quotient, selected basis, or hidden principal-ideal argument.

Matrix-source compatibility is forced because every row and column operation reads entries from M. Elementary-operation exactness is forced because R and C list each operation, its displayed coefficient or unit row, and the resulting matrix updates.

The diagonal and divisibility obligations are then separate visible checks. The row D exposes the terminal diagonal entries and zero-off-diagonal witnesses, while V and U expose adjacent divisibility, unit, and ideal-containment evidence.

Finally, the provenance row P records exactly which $\mathsf{Mat}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, and $\mathsf{Dedekind}^{\uparrow}$ surfaces are being consumed. The structural rows H, T, N transport, replay, and name the same finite packet. These rows exhaust the local NameCert surface. □

Falsifiable prediction: Every $\mathsf{SmithNormalForm}^{\uparrow}$ read factors through one $\mathsf{Mat}^{\uparrow}$ source row, one elementary row-operation trace, one elementary column-operation trace, one diagonal readback

row, one adjacent divisibility ledger, one exactness row, one unit-and-ideal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: matrix, module, ideal, dedekind: $\mathsf{SmithNormalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries elementary row and column playback, diagonal readback, adjacent divisibility witnesses, and unit-and-ideal exactness as one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SmithNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{SmithNormalForm}^{\uparrow}$ packet is generated from a finite MatrixUp source row, elementary row and column traces, diagonal readback, adjacent divisibility witnesses, exactness rows, unit-and-ideal ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SmithNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2262.1, Definition 2262.2, Definition 2262.3, Definition 2262.4, and Definition 2262.5 seed the finite Smith normal form certificate surface over displayed matrix, module, ideal, and Dedekind rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SmithNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-module classification, selected external bases, hidden principal-ideal choices, ambient noetherian arguments, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, elementary-operation playback, diagonal readback exactness, divisibility-chain exactness, unit-and-ideal ledger preservation, and TasteGate field faithfulness for BEDC.Derived.SmithNormalFormUp.

Chapter 2263

A Concrete Naming Certificate for $\mathsf{RadonMeasure}^{\uparrow}$

Following Radon and standard constructive measure theory, the $\mathsf{RadonMeasure}^{\uparrow}$ packet records regular finite measure values on compact metric and open-ball cover rows as finite BEDC data. It is anchored in chapter 92, chapter 129, chapter 57, chapter 2191, chapter 2166, and chapter 186. The chapter exposes a regular-measure surface for measure-facing analysis without importing host sigma-additivity, choice-selected approximants, quotient measure equality, or ambient standard-model measure theory.

2263.1 Radon Measure Carrier

Definition 2263.1 (RadonMeasure carrier)**.** *A* $\mathsf{RadonMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, M, O, K, V, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *surfaces.*
2. *M is the base finite measure row, read through the* $\mathsf{Measure}^{\uparrow}$ *event-value boundary.*
3. *O is the open-ball locator row naming the open-ball cover requests visible to the packet.*
4. *K is the compact inner approximant ledger for finite regular lower reads.*
5. *V is the finite cover outer approximant ledger, routed through finite Vitali cover rows when cover refinement is requested.*
6. *D is the distribution-facing value row exposed to downstream* $\mathsf{Distribution}^{\uparrow}$ *consumers.*
7. *H records componentwise* hsame *transport for $X, M, O, K, V, D, C, P, N$.*
8. *C records displayed* Cont *replay from compact metric source and base measure row through open-ball localization, compact inner approximation, finite cover outer approximation, distribution value, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{OpenBall}^{\uparrow}$, $\mathsf{FiniteVitaliCover}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RadonMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, O, K, V, D, H, C, P, N$. It has no coordinate for host sigma-additivity, choice-selected compact approximants, quotient equality of measures, an ambient measurable-space completion, or a standard-model measure object outside the displayed finite rows.

Lean4 ✓ `BEDC.Derived.RadonMeasureUp.RadonMeasureTasteGate single carrier alignment`

2263.2 Regularity Obligations

Theorem 2263.2 (RadonMeasure NameCert obligations)**.** *For every accepted* $\mathsf{RadonMeasure}^{\uparrow}$ *carrier* $R = (X, M, O, K, V, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RadonMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission through* X *and* M*, regularity classifier stability through* O, K, V*, inner approximation exactness through* K*, outer approximation exactness through* V*, finite-cover ledger visibility through the* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *handoff, distribution-facing value exposure through* D*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. It refuses host sigma-additivity, choice-selected approximants, quotient measure equality, and ambient standard-model measure theory as public coordinates.*

Proof. Project the carrier of Definition 2263.1. The source row X and measure row M are the only admitted compact metric and finite measure inputs.

The locator row O, compact inner ledger K, and finite cover outer ledger V are the only regularity classifier rows. Inner and outer exactness are therefore read from the displayed approximation ledgers rather than from a host regularity theorem.

The rows D, H, C, P, N expose distribution values, componentwise transport, replay, provenance, and local naming for the same finite packet. Since no remaining coordinate stores host sigma-additivity, choice-selected approximants, quotient measure equality, or an ambient standard-model measure object, the listed rows exhaust the local NameCert obligations. □

Theorem 2263.3 (RadonMeasure compact regularity route)**.** *Every accepted* $\mathsf{RadonMeasure}^{\uparrow}$ *packet routes a compact metric finite-cover request through the open-ball locator row* O*, the compact inner approximant ledger* K*, the finite Vitali cover outer ledger* V*, and the base measure value row* M *before any distribution consumer can read the value row* D*. A request that bypasses one of* O, K, V, M *is not an accepted RadonMeasure compact-regularity route.*

Proof. Read the replay row C and the provenance row P. They bind compact metric source data to open-ball localization, compact inner approximation, finite cover outer approximation, and base measure valuation before the distribution-facing row is exposed.

The transport row H preserves the same sequence componentwise. Thus a consumer can read D only after the route has displayed O, K, V, M inside the same packet.

Dropping any one of O, K, V, M leaves no finite row witnessing the corresponding localization, inner read, outer read, or measure value. Such a route is outside the accepted carrier. □

Lean4 ✓ `BEDC.Derived.RadonMeasureUp.RadonMeasureCarrier compact regularity route`

Theorem 2263.4 (RadonMeasure weak consumer boundary)**.** *Downstream* $\mathsf{Distribution}^{\uparrow}$ *and* $\mathsf{RieszRepresentation}^{\uparrow}$ *consumers of an accepted* $\mathsf{RadonMeasure}^{\uparrow}$ *packet read only the displayed regular measure packet* $R = (X, M, O, K, V, D, H, C, P, N)$*. They cannot infer host measure equality, unlisted integration theorems, choice-selected compact approximants, ambient sigma-additivity, or any representation theorem not displayed by the packet rows.*

Proof. The carrier exposes downstream access through D together with the replay, transport, provenance, and local naming rows. These rows record only finite regular-measure data over the displayed compact metric, open-ball, compact approximant, finite cover, and base measure inputs.

No carrier coordinate names host measure equality, an integration theorem, a selector for compact approximants, ambient sigma-additivity, or a representation theorem. Therefore a distribution or Riesz-facing consumer receives the weak displayed packet and no stronger host-theoretic consequence. □

Closure status for $\mathsf{NameCert}_{\mathsf{RadonMeasure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RadonMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2263.1, Definition 2263.2, Definition 2263.3, and Definition 2263.4 seed the finite regular-measure packet over compact metric sources, base measure rows, open-ball localization, compact inner approximants, finite cover outer approximants, distribution values, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RadonMeasure}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RadonMeasureUp`

Bridge status: none

Not claimed: This chapter does not close host sigma-additivity, quotient measure equality, selected approximants, ambient standard-model measure theory, Lean verification of the regularity obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regularity classifier stability, inner and outer approximation exactness, finite-cover ledger visibility, weak consumer boundary, and compact regularity routing for BEDC.Derived.RadonMeasureUp.

Constructive story: A $\mathsf{RadonMeasure}^{\uparrow}$ packet is generated from compact metric source, base finite measure, open-ball locator, compact inner approximant, finite cover outer approximant, distribution-facing value, componentwise transport, replay, provenance, and local NameCert rows.

Chapter 2264

A Concrete Naming Certificate for $\mathsf{OrthogonalPolynomial}^{\uparrow}$

Following Szego and Chihara on orthogonal polynomials, the $\mathsf{OrthogonalPolynomial}^{\uparrow}$ packet records the finite recurrence and moment ledgers by which a displayed polynomial family is named without passing through a host function space. It consumes the polynomial carrier of chapter 50, the real endpoint discipline of chapter 38, the finite matrix and linear-map rows of chapter 49 and chapter 48, and the coefficient-energy boundary of chapter 1940. Sturm-style sign and root ledgers from chapter 2079 may be cited by consumers that need interval localization, but the present packet names only the recurrence, moment, and normalization surface.

Definition 2264.1 (Orthogonal polynomial carrier)**.** *An* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (F, M, R, N, Z, E, H, C, P, A)$$

with the following displayed rows:

1. *F is the polynomial-family row, listing finitely many* $\mathsf{Poly}^{\uparrow}$ *rows $p_0, \ldots, p_k$ with degree, coefficient, and leading-coefficient witnesses.*
2. *M is the moment and inner-product ledger. It records the finite moment rows read by every displayed product $p_i p_j$ and the classifier row saying which inner products classify as zero or as the displayed norm value.*
3. *R is the three-term recurrence row, displaying the coefficients a_n, b_n, c_n and the finite polynomial equality ledger for $p_{n+1} = (a_n x + b_n)p_n - c_n p_{n-1}$ at each accepted index.*
4. *N is the normalization row, exposing norm-squared entries, nonzero leading rows, and the scaling witnesses used when a normalized family is requested.*
5. *Z is the finite Gram or Jacobi matrix row through which matrix and linear-map consumers read recurrence coefficients.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row for coefficient, moment, norm, and recurrence-coefficient entries.*
7. *H records componentwise* hsame *transport for polynomial rows, moment ledgers, recurrence rows, normalization rows, matrix rows, endpoint seals, continuation rows, provenance, and naming.*

8. *C records displayed* Cont *replay from coefficient inspection through moment evaluation, recurrence playback, normalization readback, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{OrthogonalPolynomial}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Parseval}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *A is the local* $\mathsf{NameCert}_{\mathsf{OrthogonalPolynomial}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host measure space, quotient polynomial ring, selected infinite limit, complete function space, or ambient spectral theorem.

Lean4 (definition) `BEDC.Derived.OrthogonalPolynomialUp.OrthogonalPolynomialUp`
Lean4 ✓ `BEDC.Derived.OrthogonalPolynomialUp.OrthogonalPolynomialTasteGate single carrier alignment`

Theorem 2264.2 (Orthogonal polynomial NameCert obligations)**.** *For every accepted* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *carrier* $O = (F, M, R, N, Z, E, H, C, P, A)$*, the local* $\mathsf{NameCert}_{\mathsf{OrthogonalPolynomial}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the polynomial-family, moment, recurrence, normalization, matrix, endpoint-seal, transport, replay, provenance, and local naming rows;*
2. *polynomial-source compatibility, requiring every recurrence and moment read to use only the* $\mathsf{Poly}^{\uparrow}$ *rows listed in F;*
3. *moment-ledger exactness, requiring each displayed inner product in M to name its finite moment rows and its resulting* $\mathsf{Real}^{\uparrow}$ *value;*
4. *orthogonality exactness, requiring the zero inner-product rows in M to be the only exported orthogonality witnesses;*
5. *normalization exactness, requiring N to display every norm, nonzero leading row, and scaling witness consumed by a normalized read;*
6. *recurrence exactness, requiring R to display each recurrence coefficient and the polynomial equality ledger that reconstructs the next family row from the previous two rows;*
7. *matrix and handoff visibility, requiring Z to expose the finite Jacobi or Gram row consumed by* $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Parseval}^{\uparrow}$, *or* $\mathsf{SturmSequence}^{\uparrow}$ *consumers without adding an external operator;*
8. *ledger preservation, requiring H, C, P, A to preserve exactly the displayed rows under componentwise transport, continuation replay, package provenance, and local naming.*

No orthogonal-polynomial obligation is stored outside these rows.

Proof. Project the carrier of Definition 2264.1. The family row F supplies the only polynomials that can be inspected, and the moment ledger M supplies the only inner-product values attached to products of those rows.

The orthogonality and normalization obligations are then finite ledger checks. A zero inner-product claim must point to the appropriate row of M, while a normalized read must pass through the norm and scaling witnesses displayed by N.

The recurrence obligation is likewise internal to R. Each accepted step lists its coefficients and the polynomial equality ledger reconstructing p_{n+1} from p_n and p_{n-1}, so no quotient polynomial equality or host function-space equality is available.

Finally, Z exposes the finite matrix row used by linear-algebra, Parseval, or Sturm consumers, and H, C, P, A transport, replay, source, and name the same rows. These projections exhaust the local NameCert surface. □

Theorem 2264.3 (Orthogonal polynomial three-term recurrence handoff)**.** *Every recurrence claim exported by an accepted* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *packet factors through the displayed route*

$$F, M, N \longmapsto R, Z, E \longmapsto H, C, P, A.$$

Thus a downstream spectral approximation or finite Jacobi-matrix consumer receives the polynomial family, moment ledger, normalization rows, recurrence coefficients, matrix readback, and endpoint seals, but receives no host function-space equality, no quotient polynomial object, and no selected infinite limiting family.

Proof. Read the recurrence row R in index order. Each entry names the preceding two polynomial rows from F, the displayed coefficients, and the equality ledger that constructs the next polynomial row.

The moment and normalization rows M, N provide the orthogonality and scaling side conditions needed to treat the recurrence as the orthogonal-polynomial recurrence rather than as an arbitrary polynomial recursion. The endpoint row E seals the real coefficient and moment reads before they leave the packet.

The matrix row Z repacks the same coefficients as a finite Gram or Jacobi row for $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$ consumers, while $\mathsf{Parseval}^{\uparrow}$ and $\mathsf{SturmSequence}^{\uparrow}$ consumers can inspect only the displayed coefficient-energy or sign ledgers sourced from those same rows.

Since H, C, P, A preserve and name no data beyond F, M, R, N, Z, E, every exported handoff factors through the displayed route and cannot appeal to a host function space, quotient polynomial equality, or a selected limit. □

Falsifiable prediction: Every $\mathsf{OrthogonalPolynomial}^{\uparrow}$ read factors through one polynomial-family row, one moment and inner-product ledger, one three-term recurrence row, one normalization row, one finite Gram or Jacobi matrix row, one $\mathsf{Real}^{\uparrow}$ endpoint-seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: polynomial, real, matrix, linearmap, parseval, sturmsequence: $\mathsf{OrthogonalPolynomial}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite polynomial family, moment ledger, recurrence coefficients, normalization rows, and Jacobi or Gram readback as one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OrthogonalPolynomial}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OrthogonalPolynomial}^{\uparrow}$ packet is generated from a finite PolynomialUp family, moment and inner-product ledger, three-term recurrence ledger, normalization rows, finite Gram or Jacobi matrix readback, RealUp endpoint seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrthogonalPolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2264.1, Definition 2264.2, and Definition 2264.3 seed the finite orthogonal-polynomial certificate surface over displayed polynomial, moment, recurrence, normalization, matrix, and real endpoint rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrthogonalPolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host measure spaces, infinite orthogonal systems, quotient polynomial equality, complete function-space equality, selected limits, spectral approximation theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, moment-ledger exactness, recurrence playback, normalization exactness, matrix handoff, endpoint sealing, and TasteGate field faithfulness for BEDC.Derived.OrthogonalPolynomialUp.

Chapter 2265

A Concrete Naming Certificate for $\mathsf{BanachDual}^{\uparrow}$

Following Banach and Bourbaki, the $\mathsf{BanachDual}^{\uparrow}$ packet records the continuous scalar-functional surface of a displayed Banach carrier as finite NameCert data. It reads its source through the Banach carrier of chapter 90, the normed-space rows of chapter 1950, the bounded-linear-operator surface of chapter 1644, the scalar boundary of chapter 38, and the functional-analysis interface of chapter 94. The packet is the scalar-functional neighbour of the Banach and operator certificates, not a host-level function space.

Definition 2265.1 (BanachDual carrier)**.** *For a displayed* $\mathsf{Banach}^{\uparrow}$ *carrier* C*, a* $\mathsf{BanachDual}^{\uparrow}(C)$ *carrier is a finite* BHist *packet*

$$\Phi = (C, L, K, H, R, P, N)$$

with the following displayed rows:

1. C *is the source* $\mathsf{Banach}^{\uparrow}$ *carrier, including its* $\mathsf{NormedSpace}^{\uparrow}$ *rows and completeness handoff.*
2. L *is a* $\mathsf{BoundedLinearOperator}^{\uparrow}(C, \mathsf{Real}^{\uparrow})$ *row whose target is the scalar singleton interface supplied by* $\mathsf{Real}^{\uparrow}$*.*
3. K *is the operator-norm bound endpoint read through the same* $\mathsf{Real}^{\uparrow}$ *scalar surface as* L*.*
4. H *records componentwise* hsame *transport for the source carrier, scalar-functional row, norm-bound row, replay row, provenance row, and local naming row.*
5. R *records displayed* Cont *replay from a scalar-functional request through* C, L, K, H, P, N*.*
6. P *is the* Pkg *provenance over* $\mathsf{BanachDual}^{\uparrow}$*,* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{NormedSpace}^{\uparrow}$*,* $\mathsf{BoundedLinearOperator}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FunctionalAnalysis}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
7. N *is the local* $\mathsf{NameCert}_{\mathsf{BanachDual}^{\uparrow}}$ *row.*

The classifier compares accepted dual rows only through the displayed source carrier, scalar-functional operator row, norm-bound endpoint, transport, replay, provenance, and local naming rows. It has no coordinate for host function extensionality, quotient dual spaces, Hahn–Banach separation data, selected representatives, or bridge checking.

Lean4 ✓ `BEDC.Derived.BanachDualUp.BanachDualTasteGate single carrier alignment`

Theorem 2265.2 (BanachDual NameCert obligations)**.** *For every accepted* $\mathsf{BanachDual}^{\uparrow}(C)$ *carrier* $\Phi = (C, L, K, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BanachDual}^{\uparrow}}$ *surface consists exactly of source*

Banach admission, scalar-functional bounded-operator admission, RealUp norm-bound exactness, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A scalar-functional consumer can inspect the source carrier C, the operator row L, the bound endpoint K, and the structural rows H, R, P, N, but cannot replace them by a host function, quotient dual object, chosen representative, or Hahn–Banach witness.*

Proof. Project the carrier rows. The only analytic coordinates are the source Banach row C, the scalar-functional bounded-operator row L, and the RealUp bound endpoint K.

The structural rows H, R, P, N preserve those coordinates through classifier transport, replay, provenance, and local naming. Because the target of L is the displayed scalar interface, every scalar-functional read is already routed through $\mathsf{BoundedLinearOperator}^{\uparrow}(C, \mathsf{Real}^{\uparrow})$.

No further row is present in the carrier. Hence host function extensionality, quotient dual spaces, Hahn–Banach strong forms, selected representatives, and bridge checks are outside the local NameCert surface. □

Theorem 2265.3 (BanachDual operator handoff)**.** *Every accepted* $\mathsf{BanachDual}^{\uparrow}(C)$ *scalar-functional read factors through the displayed route*

$$\mathsf{Banach}^{\uparrow},\ \mathsf{NormedSpace}^{\uparrow},\ \mathsf{BoundedLinearOperator}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

The handoff first reads the source Banach carrier C, then the scalar-valued bounded operator row L, then the RealUp norm-bound endpoint K, and only then the local transport, replay, provenance, and naming rows H, R, P, N.

Proof. Begin with an accepted scalar-functional read. By Definition 2265.1, the read is carried by $\Phi = (C, L, K, H, R, P, N)$.

The row L is already a $\mathsf{BoundedLinearOperator}^{\uparrow}(C, \mathsf{Real}^{\uparrow})$ row, so it exposes the Banach source, normed-space obligations, and scalar target before any local dual row is consumed. The endpoint bound K is a RealUp row attached to that same operator surface.

Replaying the request through H, R, P, N preserves the displayed route and adds no host function, quotient dual object, selected representative, or bridge check. □

Falsifiable prediction: Every accepted $\mathsf{BanachDual}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{Banach}^{\uparrow}$ source, a $\mathsf{BoundedLinearOperator}^{\uparrow}(C, \mathsf{Real}^{\uparrow})$ row, a $\mathsf{Real}^{\uparrow}$ norm-bound endpoint, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: banach, normedspace, boundedlinearoperator, real, and functionalanalysis: no listed sibling is bijective to $\mathsf{BanachDual}^{\uparrow}$ because this packet stores the scalar-valued bounded-operator face together with the source Banach carrier, norm-bound endpoint, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachDual}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachDual}^{\uparrow}$ packet is generated from a displayed $\mathsf{Banach}^{\uparrow}$ source carrier, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}(C, \mathsf{Real}^{\uparrow})$ row, a $\mathsf{Real}^{\uparrow}$ norm-bound endpoint, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachDual}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2265.1, Definition 2265.2, and Definition 2265.3 seed the scalar-functional carrier surface over the displayed Banach and bounded-operator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachDual}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient dual spaces, Hahn–Banach strong form, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scalar-functional bounded-operator routing, norm-bound exactness, transport, replay, provenance, and local naming for BEDC.Derived.BanachDualUp.

Chapter 2266

A Concrete Naming Certificate for $\mathsf{IntervalBisectionTree}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{IntervalBisectionTree}^{\uparrow}$ packet records a finite tree of interval-refinement decisions for the Real and Completion route. It packages the branch ledger of chapter 361, the endpoint-cell surface of chapter 394, the finite tree discipline of **??**, the retained-window route of chapter 320, the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The carrier is finite bisection-tree data for inspected interval prefixes, not an open-cover compactness principle, an infinite selected branch, a quotient real, trichotomy, countable choice, or ambient Real completeness.

Definition 2266.1 (IntervalBisectionTree carrier)**.** *An* $\mathsf{IntervalBisectionTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, D, B, Q, W, S, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedInterval}^{\uparrow}$ *row carrying the visible endpoint cells, located endpoint windows, rational containment rows, and Real-facing seal coordinates.*
2. *D is the finite* $\mathsf{DyadicBisection}^{\uparrow}$ *decision ledger, recording exactly the inspected left-or-right child choices and their dyadic scales.*
3. *B is the* $\mathsf{DyadicIntervalTree}^{\uparrow}$ *finite-tree row whose nodes are the interval cells visible at the requested depth.*
4. *Q records the containment and refinement rows that attach every child cell in B to its parent interval and to the retained branch prefix in D.*
5. *W is the retained* $\mathsf{NestedInterval}^{\uparrow}$ *window route exported from the finite tree after the inspected refinements have been applied.*
6. *S records the* $\mathsf{StreamName}^{\uparrow}$ *windows by which a downstream consumer requests finite endpoint or retained-window observations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal route reached only after I, D, B, Q, W, S have been displayed.*

8. *H records componentwise* hsame *transport for the interval source, branch ledger, finite tree, containment rows, retained windows, stream windows, readback and seal rows, replay rows, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from a bisection-tree request through the same rows without adding an external branch selector.*
10. *P is the* Pkg *provenance over* $\mathsf{IntervalBisectionTree}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalTree}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalBisectionTree}^{\uparrow}}$ *row.*

The carrier predicate asserts only that these rows form one finite interval bisection-tree packet. It has no coordinate for open-cover compactness, selected infinite branches, countable choice, quotient real equality, trichotomy, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.IntervalBisectionTreeUp.IntervalBisectionTreeTasteGate single carrier alignment`

Theorem 2266.2 (IntervalBisectionTree NameCert obligations)**.** *For every accepted* $\mathsf{IntervalBisectionTree}^{\uparrow}$ *carrier* $T = (I, D, B, Q, W, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntervalBisectionTree}^{\uparrow}}$ *surface is exhausted by carrier admission, source located-interval exposure, dyadic branch-ledger exposure, finite tree-node exposure, parent-child containment rows, retained nested-window routing, stream-window requests, regular rational readback, Real-facing seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may inspect exactly those rows and no host open cover, selected branch, countable-choice witness, quotient-real representative, trichotomy row, or ambient completeness object.*

Proof. Project the carrier of Definition 2266.1. The analytic coordinates are the source interval row I, the branch ledger D, the finite tree row B, the containment rows Q, the retained nested route W, the stream windows S, and the readback and seal route R.

The local certificate obligations are then structural over those rows. Transport through H is componentwise, replay through C rereads only displayed entries, provenance through P names the listed sibling packets, and N names the resulting local certificate.

Since no other coordinate is present, the excluded compactness, branch-selection, choice, quotient, trichotomy, and completeness principles cannot be projected from an accepted packet. □

Theorem 2266.3 (IntervalBisectionTree Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntervalBisectionTree}^{\uparrow}$ *packet factors through the finite route*

$$I, D, B, Q \longmapsto W \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The consumer first reads the located interval and finite bisection-tree data, then the retained nested window, then the stream and regular-rational readback rows, and only then the Real-facing seal. The handoff exports no selected branch, quotient real, countable-choice row, trichotomy premise, open-cover compactness witness, or ambient Real-completeness principle.

Proof. Start with an accepted packet $T = (I, D, B, Q, W, S, R, H, C, P, N)$. The source and refinement stage is I, D, B, Q: it exposes the located interval row, finite branch decisions, finite tree nodes, and parent-child containment rows.

The retained-window stage is W. It is the only nested-interval route supplied by the packet, so a downstream read cannot skip the finite tree and ask for an independently selected branch.

The endpoint stage is S, R. Stream requests are finite, regular rational readback is displayed, and the Real-facing seal is downstream of those rows. Transport, replay, provenance, and local naming then preserve the same route and add no host-side principle. □

Falsifiable prediction: Every accepted $\mathsf{IntervalBisectionTree}^{\uparrow}$ consumer reads a located interval source, a finite dyadic branch ledger, finite interval-tree nodes, containment rows, a retained nested-window route, finite stream windows, regular rational readback, a Real-facing seal, transport, replay, provenance, and local naming.

Independence witness: dyadicbisection, locatedinterval, dyadicintervaltree, nestedinterval, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{IntervalBisectionTree}^{\uparrow}$ because this packet jointly carries source interval data, finite bisection-tree nodes, retained nested windows, readback and seal routing, and local NameCert structure.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalBisectionTree}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalBisectionTree}^{\uparrow}$ packet is generated from a located interval source, a finite dyadic branch ledger, finite interval-tree nodes, parent-child containment rows, a retained NestedInterval route, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalBisectionTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2266.1, Definition 2266.2, and Definition 2266.3 seed the finite bisection-tree route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalBisectionTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, countable choice, quotient reals, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bisection-tree exposure, retained-window routing, Real handoff, non-escape, and local NameCert obligations for BEDC.Derived.IntervalBisectionTreeUp.

Chapter 2267

A Concrete Naming Certificate for $\mathsf{MeagreSet}^{\uparrow}$

Following Baire and Oxtoby, the $\mathsf{MeagreSet}^{\uparrow}$ packet records the finite BEDC surface for first-category evidence inside a displayed complete-metric Baire space. It sits next to the dense-open packet of chapter 1542, reads the prefix windows of chapter 334, and consumes the completeness rows of chapter 128 through the metric-completion interface of chapter 1506. The packet names displayed nowhere-dense covers by finite windows and regular-rational readbacks; it does not assert a host set-theoretic category theorem, a countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2267.1 (MeagreSet carrier)**.** *A* $\mathsf{MeagreSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, Q, K, W, R, E, T, H, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet supplying the finite observation windows in which basic balls, dense-open complements, and tested points are named.*
2. *Q is the displayed* $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{MetricCompletion}^{\uparrow}$ *completeness route over the same metric source, including the limit-witness and completion-facing rows needed by Baire-category consumers.*
3. *K is the finite nowhere-dense cover ledger. Each listed row names a closed-frontier inspection, an empty-interior certificate for a displayed basic ball request, and the complementary dense-open row consumed downstream.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect the cover rows and the tested point name.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the radii, shrinkage requests, and comparison tolerances opened by W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the displayed regular-rational readback has been opened.*
7. *T is the* $\mathsf{BaireCategory}^{\uparrow}$ *downstream route sending the complementary dense-open rows of K to the finite dense-open intersection packet.*
8. *H stores componentwise* hsame *transport for B, Q, K, W, R, E, T and the structural rows.*

9. *C stores displayed* Cont *replay of the prefix windows, completeness route, nowhere-dense cover ledger, readback rows, real seals, and Baire-category route.*
10. *P is the* Pkg *provenance over* $\mathsf{MeagreSet}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MeagreSet}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary host subset, a selected point outside a countable union, a quotient completion, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MeagreSetUp.MeagreSetTasteGate single carrier alignment`

Theorem 2267.2 (MeagreSet NameCert obligations)**.** *For an accepted* $\mathsf{MeagreSet}^{\uparrow}$ *carrier* $M = (B, Q, K, W, R, E, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MeagreSet}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the Baire-space prefix, complete-metric and metric-completion route, nowhere-dense cover ledger, finite stream windows, regular-rational readbacks, real seal, Baire-category downstream route, transport, replay, provenance, and local naming row;*
2. *nowhere-dense ledger exposure, requiring each row of K to provide a displayed basic-ball request, an empty-interior certificate for the covered fragment, and the complementary dense-open row read by T;*
3. *window-readback compatibility, requiring W, R, E to open finite point and radius observations before any cover or dense-open decision is exported;*
4. *Baire-category consumer compatibility, requiring T to consume only the complementary dense-open rows already displayed by K over the same B, Q, W, R, E prefix;*
5. *ledger non-escape, excluding arbitrary host subsets, selected outside points, countable-choice schedules, quotient completion equality, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2267.1. The tuple lists exactly the prefix, completeness, cover, window, readback, seal, downstream, transport, replay, provenance, and local naming rows.

The nowhere-dense ledger is the row K. Each entry is opened only as a finite basic-ball inspection together with an empty-interior certificate and a complementary dense-open row; no host subset predicate is exported.

Window-readback compatibility follows from the order W, R, E. The finite stream window opens the relevant point and radius observations, the regular-rational row supplies the tolerance readback, and the real seal is reached only after those rows are displayed.

The downstream consumer route is T. It reads the complementary dense-open rows already named in K and hands them to the $\mathsf{BaireCategory}^{\uparrow}$ packet over the same prefix and completeness surface. The support rows H, C, P, N transport, replay, source, and name that same route.

No remaining carrier coordinate names a selected point outside a cover, a countable-choice schedule, quotient completion equality, open-cover compactness, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$. The listed obligations exhaust the local NameCert surface. □

Theorem 2267.3 (MeagreSet BaireCategory consumer route)**.** *Let* $M = (B, Q, K, W, R, E, T, H, C, P, N)$ *be an accepted* $\mathsf{MeagreSet}^{\uparrow}$ *packet. Every* $\mathsf{BaireCategory}^{\uparrow}$ *consumer of M factors through the displayed route*

$$B, Q, K, W, R, E \longmapsto T.$$

The consumer receives the Baire-space prefix, the complete-metric and metric-completion route, the finite nowhere-dense cover ledger, stream windows, regular-rational readbacks, real seals, and the complementary dense-open handoff. It receives no arbitrary subset classifier, selected generic point, quotient completion, countable-choice selector, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the carrier inventory. The prefix row B and completeness route Q determine the displayed complete-metric surface on which the cover rows can be interpreted.

Read the cover ledger K through the finite windows W. Each inspected cover row is tied to the same point and ball observations, and each radius or shrinkage request is read back through R before reaching the real seal E.

The route T then repacks the complementary dense-open rows for the $\mathsf{BaireCategory}^{\uparrow}$ consumer. This handoff is exactly the finite dense-open schedule required by the neighboring Baire-category packet; it is not a host intersection or a selection operation.

Finally use the structural rows H, C, P, N. They preserve the same route under componentwise transport, replay it as displayed continuation data, record its provenance, and name it locally. Since the carrier has no arbitrary subset classifier, selected generic point, quotient completion, choice schedule, open-cover compactness row, or ambient completeness row, no consumer can read one from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MeagreSet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MeagreSet}^{\uparrow}$ packet is generated from a BaireSpace prefix packet, CompleteMetric and MetricCompletion completeness route, finite nowhere-dense cover ledger, StreamName windows, RegSeqRat readbacks, Real seal, BaireCategory downstream route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MeagreSet}^{\uparrow}}$, seed)

Scope closed: Definition 2267.1, Definition 2267.2, and Definition 2267.3 seed the finite meagre-set certificate surface as a Baire-category neighbor of the complete-metric route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MeagreSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host set-theoretic category theorem, selected generic points, countable choice, quotient completion equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nowhere-dense ledger exposure, window-readback compatibility, Baire-category consumer compatibility, and ledger non-escape for the same finite packet.

Chapter 2268

A Concrete Naming Certificate for $\mathsf{DirichletUniformConvergence}^{\uparrow}$

Following Dirichlet and Bishop–Bridges constructive analysis, the $\mathsf{DirichletUniformConvergence}^{\uparrow}$ packet records uniform convergence by bounded partial sums, a monotone-null control row, and finite tail windows before any completion-facing consumer reads a real seal. It sits after the uniform Cauchy series route of chapter 1736, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the uniform-limit route of chapter 463, and the ratio-test comparison surface of chapter 2244. The chapter names the finite Dirichlet tail-control certificate; it is not a quotient series equality, a selected sum, countable choice, trichotomy, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 2268.1 (Dirichlet uniform convergence carrier)**.** *A* $\mathsf{DirichletUniformConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(S, B, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the displayed series source row, exposing only the finite term and partial-sum windows consumed by the packet.*
2. *B is the bounded partial-sum row, recording the visible uniform bound for the source partial sums over the inspected domain.*
3. *M is the monotone-null control row, recording the coefficient schedule and its displayed tail decrease to the null row.*
4. *W is the finite tail-window schedule that pairs a requested tolerance with the bounded-sum windows and monotone-null controls inspected for that tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the source windows, partial-sum windows, monotone-null controls, and tail schedule.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback has displayed the scheduled tail comparison.*
7. *H records componentwise* hsame *transports for the source, bounded-row, monotone-null row, tail schedule, readback, seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *routes from any consumer request through S, B, M, W, R, E in that order.*

9. *P is the* Pkg *provenance over* $\mathsf{DirichletUniformConvergence}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletUniformConvergence}^{\uparrow}}$ *row.*

The classifier admits only finite packets with these ten rows. No coordinate stores a quotient of series streams, a chosen sum, a countable-choice selector, trichotomy, or a completeness witness for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DirichletUniformConvergenceUp.DirichletUniformConvergenceTasteGate single carrier alignment`

Theorem 2268.2 (Dirichlet uniform convergence NameCert obligations)**.** *For every accepted* $\mathsf{DirichletUniformConvergence}^{\uparrow}$ *carrier* $(S, B, M, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirichletUniformConvergence}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission for the displayed source, bounded partial-sum row, monotone-null control row, finite tail schedule, readback, seal, transports, continuations, provenance, and local naming;*
2. *bounded-source control, requiring every tail read to use the row B before a uniform estimate is exposed;*
3. *monotone-null control, requiring every coefficient read to use the row M and the schedule W before a tail threshold is exposed;*
4. *uniform tail handoff, requiring the comparison to pass through the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *route and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the* $\mathsf{Real}^{\uparrow}$ *seal E is consumed;*
5. *ledger refusal, stating that quotient series equality, selected sums, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness are absent from the carrier.*

Proof. Project the carrier of Definition 2268.1. The source, bounded partial-sum row, monotone-null row, finite tail schedule, readback, seal, transport, continuation, provenance, and local naming are exactly the displayed packet coordinates.

The bounded-source row is read before any tail estimate because B is the only coordinate that records a uniform partial-sum bound. The monotone-null row is read before any coefficient estimate because M is the only coordinate that records the displayed null-control schedule.

The schedule W binds these two rows to one finite tail request. A downstream consumer therefore reaches the uniform Cauchy series surface of chapter 1736, the regular rational readback of chapter 301, and the real seal of chapter 38 only through the listed route.

The refusal row is an inventory check on the carrier. Since none of the ten coordinates is a quotient series equality, selected sum, countable-choice selector, trichotomy row, or ambient completeness witness, the local certificate exports none of those principles. □

Theorem 2268.3 (Dirichlet uniform tail stability)**.** *Let $(S, B, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{DirichletUniformConvergence}^{\uparrow}$ *carrier. The bounded partial-sum row B and monotone-null row M transported by the componentwise* hsame *ledger H and replayed by the displayed* Cont *routes C induce the same uniform tail ledger W before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with a consumer read of a uniform tail comparison. By Definition 2268.1, the only available bounded partial-sum data are in B, and the only available monotone-null data are in M.

Apply the obligation surface of Definition 2268.2. It requires both rows to be read through the finite schedule W before the regular rational readback R or the real seal E can be reached.

The transport row H is componentwise, so it carries the displayed source, bounded row, monotone-null row, and schedule without changing which tail windows are named. The continuation row C replays the same ordered route from source through B, M, W, R, E.

Thus transported and replayed consumers inspect the same bounded-partial-sum and monotone-null data at the same scheduled tail windows. The tail ledger is stable under the displayed hsame and Cont rows, and no quotient series equality, selected sum, countable-choice selector, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate can intervene. □

Falsifiable prediction: An accepted $\mathsf{DirichletUniformConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, or $\mathsf{UniformLimit}^{\uparrow}$ handoff without first reading the source row, bounded partial-sum row, monotone-null row, and finite tail schedule refutes the carrier surface.

Independence witness: uniform-cauchy-series, real, regseqrat, uniformlimit, real-series-ratio-test: none is bijective to $\mathsf{DirichletUniformConvergence}^{\uparrow}$ because this packet jointly carries a series source, bounded partial sums, monotone-null controls, one finite tail schedule, regular readback, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletUniformConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletUniformConvergence}^{\uparrow}$ packet is generated from a displayed series source, bounded partial-sum row, monotone-null control row, finite tail-window schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletUniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2268.1, Definition 2268.2, and Definition 2268.3 seed the finite Dirichlet uniform convergence tail-control surface over $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{UniformLimit}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletUniformConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove carrier admission, bounded-source control, monotone-null control, uniform tail handoff, and ledger refusal for the same finite packet.

Chapter 2269

A Concrete Naming Certificate for $\mathsf{RealRootIsolation}^{\uparrow}$

Following Sturm root isolation and Bishop–Bridges constructive real analysis, the $\mathsf{RealRootIsolation}^{\uparrow}$ packet records a complete polynomial-root isolation surface as finite BEDC NameCert data. It composes the sign-variation route of chapter 1534, the retained-window route of chapter 1407, the real-polynomial evaluation surface of chapter 1728, the dyadic interval carrier of chapter 306, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names an isolating certificate for one displayed real polynomial window; it does not select a host algebraic root, invoke algebraic closure, quotient real equality, trichotomy, countable choice, or ambient completeness.

Definition 2269.1 (Real root isolation carrier)**.** *A* $\mathsf{RealRootIsolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (P, E, S, B, D, T, L, H, C, Q, N)$$

with the following displayed rows:

1. *P is the polynomial source row. It records the finite coefficient ledger and the polynomial name read from the source* $\mathsf{Poly}^{\uparrow}$ *or* $\mathsf{RealPolynomial}^{\uparrow}$ *surface.*
2. *E is the real-polynomial evaluation row. It records the endpoint evaluation windows, sign rows, and requested precision route over the* $\mathsf{RealPolynomial}^{\uparrow}$ *packet.*
3. *S is the Sturm or sign-variation row. It records the displayed Sturm-chain sign table or the finite sign-variation ledger used to certify the accepted root count in each inspected cell.*
4. *B is the bisection refinement row. It stores the branch prefix, retained endpoint signs, and discarded-branch ledgers supplied by the* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *surface.*
5. *D is the dyadic interval tree row. It records the ordered dyadic cells, parent-child containment rows, endpoint windows, and the final retained isolating interval.*
6. *T is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by the retained endpoint names and by the downstream real-facing consumer of the isolating window.*
7. *L is the local classifier row. It admits two carriers together exactly when P, E, S, B, D, T expose the same polynomial source, evaluation windows, variation ledger, bisection branch, dyadic interval tree, and seal route.*
8. *H records componentwise* hsame *transport for polynomial source, evaluation, sign-variation, bisection, dyadic interval tree, real seal, classifier, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a root-isolation request through P, E, S, B, D, T, L, H in that order.*

10. *Q is the* Pkg *provenance over* $\mathsf{RealRootIsolation}^{\uparrow}$, $\mathsf{SturmRootIsolation}^{\uparrow}$, $\mathsf{BisectionRootIsolation}^{\uparrow}$, $\mathsf{RealPolynomial}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealRootIsolation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. No coordinate stores a selected host root, a factorization theorem, a global algebraic closure object, quotient real equality, real trichotomy, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealRootIsolationUp.RealRootIsolationTasteGate single carrier alignment`

Theorem 2269.2 (Real root isolation NameCert obligations)**.** *For every accepted* $\mathsf{RealRootIsolation}^{\uparrow}$ *carrier $R = (P, E, S, B, D, T, L, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealRootIsolation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the polynomial source, evaluation, sign-variation, bisection, dyadic interval tree, real seal, classifier, transport, replay, provenance, and local naming rows;*

2. *polynomial-source exactness, requiring every coefficient and polynomial-name read to pass through P;*

3. *evaluation exactness, requiring endpoint signs and precision windows to pass through the* $\mathsf{RealPolynomial}^{\uparrow}$ *evaluation row E;*

4. *Sturm or sign-variation exactness, requiring every accepted root-count read to be one of the finite rows displayed by S;*

5. *bisection refinement exactness, requiring the retained branch and discarded-branch evidence to pass through B;*

6. *dyadic interval handoff, requiring the retained interval to be exported only through the dyadic interval tree row D and the* $\mathsf{Real}^{\uparrow}$ *seal row T;*

7. *componentwise transport, replay, provenance, classifier stability, and local naming through L, H, C, Q, N.*

No obligation outside these rows is part of the packet.

Proof. Project the accepted carrier of Definition 2269.1. The tuple inventory already lists the whole finite packet, so carrier admission is exhausted by the rows $P, E, S, B, D, T, L, H, C, Q, N$.

The polynomial source row P fixes the coefficient ledger and polynomial name. Endpoint evaluation cannot be read directly from a host real polynomial; it passes through E, where the displayed precision windows and sign rows are recorded.

The root-count evidence is then confined to S. Whether the row is read as a Sturm-chain variation ledger or as an equivalent finite sign-variation table, every accepted count is a displayed row over the same polynomial and interval endpoints.

The bisection row B chooses the retained branch only after that sign-variation evidence is visible. The dyadic interval tree D records the parent-child containment and retained endpoint windows, and T seals the same retained interval for $\mathsf{Real}^{\uparrow}$ consumers.

The classifier L compares only these visible rows. Since H, C, Q, N merely transport, replay, source, and name the same route, no hidden host root, factorization theorem, algebraic closure object, quotient equality, trichotomy, choice, or completeness witness can be exported. □

Theorem 2269.3 (Real root isolation dyadic interval handoff)**.** *Every accepted* $\mathsf{RealRootIsolation}^{\uparrow}$ *read handed to a downstream interval or real-seal consumer factors through*

$$P, E, S, B \longmapsto D, T \longmapsto L, H, C, Q, N.$$

Thus the consumer receives a displayed polynomial source row, real-polynomial evaluation row, Sturm or sign-variation row, bisection refinement row, dyadic interval tree row, $\mathsf{Real}^{\uparrow}$ *seal row, classifier row, componentwise transport, replay, provenance, and local naming. It receives no selected host root, algebraic factorization, quotient real equality, trichotomy, countable choice, or ambient completeness principle.*

Proof. Start with a downstream read of the isolating interval. The polynomial source and endpoint evaluation are fixed by P and E, so the read cannot inspect a retained interval before the source polynomial and its endpoint signs are displayed.

Next read S and B. The sign-variation ledger supplies the accepted root-count evidence, and the bisection row records the retained branch together with the discarded-branch evidence.

The dyadic interval tree D is then the only export row for the retained cell. The real seal T packages that same endpoint window for $\mathsf{Real}^{\uparrow}$ consumers.

Finally L, H, C, Q, N compare, transport, replay, source, and locally name the route. Since none of those structural rows adds an analytic object, the handoff remains the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{RealRootIsolation}^{\uparrow}$ consumer that reaches a $\mathsf{DyadicInterval}^{\uparrow}$ retained cell or $\mathsf{Real}^{\uparrow}$ seal without first reading the polynomial source row, real-polynomial evaluation row, Sturm or sign-variation row, and bisection refinement row refutes the carrier surface.

Independence witness: sturmrootisolation, bisectionrootisolation, real-polynomial, dyadicinterval, real: none is bijective to $\mathsf{RealRootIsolation}^{\uparrow}$ because this packet jointly carries the polynomial source, evaluation row, sign-variation ledger, bisection refinement, dyadic interval tree, real seal, classifier, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealRootIsolation}^{\uparrow}}$.

Constructive story: A $\mathsf{RealRootIsolation}^{\uparrow}$ packet is generated from a polynomial source row, real-polynomial evaluation row, Sturm or sign-variation row, bisection refinement row, dyadic interval tree row, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealRootIsolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2269.1, Definition 2269.2, and Definition 2269.3 seed the finite real-root isolation packet over Sturm, bisection, dyadic interval, real-polynomial evaluation, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealRootIsolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host root selection, algebraic factorization, algebraic closure, quotient real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove source exactness, evaluation exactness, sign-variation exactness, bisection refinement, dyadic interval handoff, and structural stability for BEDC.Derived.RealRootIsolationUp.

Chapter 2270

A Concrete Naming Certificate for $\mathsf{SpectralStabilization}^{\uparrow}$

The $\mathsf{SpectralStabilization}^{\uparrow}$ packet realizes the killed bit-flip closure-chain spectral-radius and survival-potential ledger of subsection 9462.28.21 as finite BEDC NameCert data. It consumes the six-coordinate codon source window of chapter 2234, the stop-boundary transition surface of chapter 2245, the local inverse spectrum of chapter 2161, and the stop-suffix carrier of chapter 1374. The packet records a finite spectral stabilization surface for displayed killed one-bit dynamics; it does not identify the biological code table with a kernel primitive, choose a global stochastic model, or import an analytic Perron theorem outside the displayed finite ledger.

Definition 2270.1 (Spectral stabilization carrier)**.** *A* $\mathsf{SpectralStabilization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (W, M, I, K, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source-window row exposing the finite Q_6 codon-window carrier and the six bit coordinates used by the killed bit-flip walk.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row exposing the local transition vocabulary for scan, elongate, terminate, readthrough, repair, and mutate states.*
3. *I is the* $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ *row exposing local face spectra, Hamming adjacency spectra, reassignment spectra, and stop-face reconstruction data.*
4. *K is the killed bit-flip matrix ledger. It records, for each displayed support in the closure chain, the finite transient matrix entries whose off-support moves are absorbed.*
5. *R is the spectral-radius row. It records the displayed one-step retention, Perron-root approximation row, and survival-potential ledger used by Definition 9462.1389.*
6. *L is the closure-chain ledger for $\mathcal{R}$, $\overline{\mathcal{R}}$, $\mathrm{Med}_1(\mathcal{R})$, and M, including the displayed vertex and internal-edge counts.*
7. *U is the stop-suffix and anchor handoff row, read through* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *and the finite stop-start core named by the source vision.*
8. *H records componentwise* hsame *transport for source windows, transition rows, inverse spectra, killed matrices, spectral-radius ledgers, closure-chain rows, stop-suffix handoffs, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a spectral-stabilization request through* W, M, I, K, R, L, U, H.
10. *P is the* Pkg *provenance over* $\mathsf{SpectralStabilization}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$, $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$, *the source vision of subsection 9462.28.21,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SpectralStabilization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, M, I, K, R, L, U, H, C, P, N$. It has no coordinate for a hidden biological table, a selected global stochastic process, analytic spectral theory outside the finite matrix ledger, quotient codon equality, probabilistic inference, or a choice principle.

Lean4 (definition) `BEDC.Derived.SpectralStabilizationUp.SpectralStabilizationUp`

Theorem 2270.2 (Spectral stabilization NameCert obligations)**.** *For every accepted* $\mathsf{SpectralStabilization}^{\uparrow}$ *carrier $Z = (W, M, I, K, R, L, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SpectralStabilization}^{\uparrow}}$ *surface consists exactly of source-window admission through W, transition admission through M, inverse-spectrum admission through I, killed-matrix entry exactness through K, spectral-radius and survival-potential ledger display through R, closure-chain support display through L, stop-suffix handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 2270.1. The source-window, transition, inverse-spectrum, killed-matrix, spectral-radius, closure-chain, stop-suffix, transport, replay, provenance, and local naming rows are exactly the displayed coordinates.

The killed matrix ledger K can be read only after the codon-window row W supplies the six bit coordinates and the transition row M supplies the local state vocabulary. The inverse-spectrum row I supplies the finite face and adjacency spectra used by the same matrix rows.

The spectral-radius row R is not an external analytic theorem. It is a displayed finite ledger containing the one-step retention, Perron-root approximation, and survival-potential data for the supports named by L.

The stop-suffix row U routes the anchor and stop-start core through the existing suffix packet. The structural rows H, C, P, N transport, replay, source, and name the same finite inventory, so no hidden biological table, global stochastic process, quotient codon equality, probabilistic inference row, or choice principle is exported. □

Theorem 2270.3 (Spectral stabilization window handoff)**.** *Every accepted* $\mathsf{SpectralStabilization}^{\uparrow}$ *spectral-radius or survival-potential read factors through*

$$W, M, I \longmapsto K, L, R, U \longmapsto H, C, P, N.$$

Thus a consumer receives the codon source window, transition vocabulary, inverse-spectrum row, killed bit-flip matrix entries, closure-chain support ledger, spectral-radius and survival-potential rows, stop-suffix handoff, transport, replay, provenance, and local naming. It receives no hidden biological table, selected global stochastic model, analytic spectral theorem outside the displayed matrix ledger, quotient codon equality, probabilistic inference row, or choice principle.

Proof. Start with a spectral-radius or survival-potential read. The codon-window row W fixes the finite six-coordinate source, while M fixes the transition vocabulary and I fixes the local spectrum rows.

The killed bit-flip matrix ledger K is then computed over the displayed supports in L. Its entries are finite rows: moves inside a support remain transient, and moves outside that support are absorbed.

The row R stores the one-step retention, spectral-radius approximation, and survival-potential data for the same support chain. The row U attaches the stop-suffix and anchor handoff without adding a global code table.

Finally H, C, P, N preserve and name the same packet. Since no additional coordinate exists, the handoff remains finite and cannot export the refused principles. □

Falsifiable prediction: Every accepted $\mathsf{SpectralStabilization}^{\uparrow}$ read of a spectral radius, one-step retention, or survival-potential row factors through one $\mathsf{CodonSixBitWindow}^{\uparrow}$ source window, one $\mathsf{CodonTransitionMatrix}^{\uparrow}$ transition vocabulary, one $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ inverse-spectrum row, one killed bit-flip matrix ledger, one closure-chain support ledger, one $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: codon-six-bit-window, codon-transition-matrix, codon-window-spectral-inverse, stopcodonzeckendorfsuffix: $\mathsf{SpectralStabilization}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries killed matrix entries, closure-chain supports, spectral-radius rows, survival-potential rows, stop-suffix handoff, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.SpectralStabilizationUp` must provide explicit Nontrivial $\mathsf{SpectralStabilization}^{\uparrow}$ and FieldFaithful $\mathsf{SpectralStabilization}^{\uparrow}$ instances preserving $W, M, I, K, R, L, U, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralStabilization}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralStabilization}^{\uparrow}$ packet is generated from a codon source-window row, transition vocabulary row, inverse-spectrum row, killed bit-flip matrix ledger, closure-chain support ledger, spectral-radius and survival-potential rows, stop-suffix handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpectralStabilization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2270.1, Definition 2270.2, and Definition 2270.3 seed the finite spectral-stabilization packet over codon windows, transition matrices, inverse spectra, killed bit-flip matrices, closure-chain support rows, and stop-suffix handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpectralStabilization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological table identity, selected global stochastic modeling, analytic spectral theory outside finite matrix ledgers, quotient codon equality, probabilistic inference, choice, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove source-window admission, transition admission, inverse-spectrum admission, killed-matrix exactness, spectral-ledger display, closure-chain support display, stop-suffix handoff, Nontrivial SpectralStabilizationUp, and FieldFaithful SpectralStabilizationUp for BEDC.Derived.SpectralStabilizationUp.

Chapter 2271

A Concrete Naming Certificate for $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$

Following Stone, Engelking, and Willard on zero-dimensional and totally disconnected spaces, the $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$ packet records the finite BEDC surface by which a displayed topology admits no nontrivial connected component rows. It sits over the generated-open classifier of chapter 88, the compact finite-cover boundary of chapter 60, the separated-neighborhood surface of chapter 1925, and the clopen-ledger bridge of chapter 261. The packet names clopen separation and component-collapse rows without importing ultrafilters, host point equality, quotient spaces, selected components, open-cover compactness beyond the displayed compact row, or excluded middle.

Definition 2271.1 (TotallyDisconnectedSpace carrier)**.** *A* $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, K, Hd, x, y, U, V, L, Z, R, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Topology}^{\uparrow}$ *source row, including open predicates, finite neighborhood histories, and the generated-open classifier used by topology consumers.*
2. *K is the optional* $\mathsf{Compact}^{\uparrow}$ *support row read by compact Stone-style consumers; it is a displayed compactness interface, not an ambient open-cover principle.*
3. *Hd is the* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row exposing disjoint open-neighborhood data for distinct displayed point names.*
4. *x, y are point-name rows in the same topology source.*
5. *U, V are clopen separation rows: U contains x, V contains y, and each row carries both open and complement-open evidence in O.*
6. *L is the clopen ledger row connecting finite clopen observations with the Stone-duality clopen surface of chapter 261.*
7. *Z is the component-collapse row stating that every displayed connected-subpacket read through O has at most one point-name class under the local classifier.*
8. *R is the refusal row excluding ultrafilter points, quotient components, host equality, selected component representatives, and excluded-middle separation.*

9. *C records displayed* Cont *replay from a point-pair query through O, Hd, U, V, L, Z, R.*
10. *P is the* Pkg *provenance over* $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{StoneDuality}^{\uparrow}$, BHist, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TotallyDisconnectedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a completed Stone space, ultrafilter selection, quotient-component equality, host subset equality, or a choice-selected clopen basis.

Lean4 ✓ `BEDC.Derived.TotallyDisconnectedSpaceUp.TotallyDisconnectedSpaceTasteGate single carrier alignment`

Theorem 2271.2 (TotallyDisconnectedSpace NameCert obligations)**.** *For every accepted* TotallyDisconnectedSpace *carrier*

$$T = (O, K, Hd, x, y, U, V, L, Z, R, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TotallyDisconnectedSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, optional compact support, Hausdorff separation row, point names, clopen separation rows, clopen ledger, component-collapse row, refusal row, replay, provenance, and local naming row;*
2. *clopen separation, requiring every separated pair of displayed point names to be routed through clopen rows U, V inside O;*
3. *component collapse, requiring every connected-subpacket read through the topology source to factor through the singleton classifier row Z;*
4. *Stone-ledger compatibility, requiring the clopen ledger L to expose only the finite clopen rows consumed by the Stone-duality surface;*
5. *nonescape, requiring all topology, compact, Hausdorff, and Stone-duality consumers to read only $O, K, Hd, x, y, U, V, L, Z, R, C, P, N$.*

No totally disconnected space obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2271.1. The accepted tuple displays the topology source, compact support row, Hausdorff separation data, point names, clopen rows, clopen ledger, component-collapse row, refusal row, replay, provenance, and local naming data.

The clopen separation row is local to O. A separated pair first reads the $\mathsf{HausdorffSpace}^{\uparrow}$ row Hd for disjoint neighborhoods and then refines the displayed neighborhoods to the clopen rows U, V. The proof uses the rows as carrier fields; it does not select a global clopen basis.

Component collapse is exactly the role of Z. Any connected-subpacket consumer must pass through the same topology source and the same clopen ledger before it can compare point names, so the only exported comparison is the singleton classifier row.

The Stone-ledger and nonescape clauses are inventory checks on L, R, C, P, N. Since no ultrafilter point, quotient component, host equality row, selected representative, or excluded-middle branch occurs in the carrier, none can be exported by the local certificate. □

Theorem 2271.3 (TotallyDisconnectedSpace clopen separation route)**.** *Let $T = (O, K, Hd, x, y, U, V, L, Z, R, C, P$ be an accepted* $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$ *packet. Every Stone-duality or compact-Hausdorff consumer that asks for total disconnectedness factors first through the topology row O, then through*

the Hausdorff separation row Hd, then through the displayed clopen separation rows U, V, and finally through the clopen ledger L and component-collapse row Z. The route exports no ultrafilter point, quotient component, host point equality, selected clopen basis, or nonconstructive separation principle.

Proof. Start from the topology row O and the point names x, y. The Hausdorff row Hd supplies only displayed neighborhood separation, so a total-disconnectedness consumer must still use the clopen rows U, V before it can read a separation as a clopen separation.

The clopen ledger L records the finite rows consumed by Stone-duality-style arguments. It keeps the consumer inside the displayed topology classifier and does not build a point space or an ultrafilter representation.

Finally Z supplies the component-collapse comparison. Replay through C and naming through P, N preserve the same route, while the refusal row R excludes quotient components, host equality, selected clopen bases, and nonconstructive separation branches. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyDisconnectedSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyDisconnectedSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2271.1, Definition 2271.2, and Definition 2271.3 seed the finite topology, compact, Hausdorff, clopen-ledger, and component-collapse surface for totally disconnected spaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyDisconnectedSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilter existence, quotient components, host point equality, selected clopen bases, open-cover compactness beyond displayed compact rows, Lean verification, or standard bridge closure.

Upgrade path: Obligation closure requires checked carrier admission, clopen separation, component collapse, Stone-ledger compatibility, and nonescape for BEDC.Derived.TotallyDisconnectedSpaceUp.

Constructive story: A $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$ packet is generated from a topology row, optional compact support, Hausdorff separated-neighborhood data, displayed point names, clopen separation rows, a clopen ledger, component-collapse evidence, replay, provenance, and a local NameCert row.

Chapter 2272

A Concrete Naming Certificate for MetaCICFrontierDependencyMatrix$^{\uparrow}$

The MetaCICFrontierDependencyMatrix$^{\uparrow}$ packet realizes the MetaCIC open-frontier ledger as finite matrix data. It places the four subject-reduction discharge rows beside the obstruction rows for dependent codomain, confluence, normalization, decidability, and audit-map consumers, so downstream chapters can cite a bounded dependency matrix rather than an informal checklist. The packet reads the open-problem ledger of section 9386.2, the subject-reduction discharge socket of chapter 719, the normalization boundary of chapter 892, and the route classifier of chapter 785.

Falsifiable prediction: Every accepted MetaCICFrontierDependencyMatrix$^{\uparrow}$ row factors through exactly one named positive support row or exactly one named obstruction row before any audit-map consumer reads it.

Independence witness: metacicopenproblemledger, subjectreductiondischargesocket, metacicnormalizationfrontier, subjectreductionrouteclassifier: the open ledger lists frontier questions, the discharge socket carries four positive subject-reduction rows, the normalization frontier names normalization obstructions, and the route classifier separates subject-reduction routes; none is bijective to the finite matrix packet that records positive rows, obstruction rows, and audit consumers together.

Definition 2272.1 (MetaCIC frontier dependency matrix carrier)**.** *A* MetaCICFrontierDependencyMatrix$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, A, L, P, Q, N, D, J, R, H, C, K, E)$$

with the following displayed rows:

1. B, A, L, P *are the four positive subject-reduction discharge rows: beta substitution, application-argument stability, lambda-domain subject reduction, and Pi-domain subject reduction.*
2. Q *is the dependent-codomain obstruction row separating application-argument stability from a closed subject-reduction theorem.*
3. N *is the MetaCIC normalization frontier row, including the reduction and normal-form boundaries read by normalization consumers.*
4. D *is the decidability frontier row for bounded checking and closed type-checking consumers.*
5. J *is the confluence and critical-pair obstruction row read by audit-map consumers.*

6. *R is the route-classifier row assigning each matrix row to positive support, obstruction, or audit consumer.*
7. *H records componentwise* hsame *transport for all positive, obstruction, classifier, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an audit-map request through a selected matrix row and its route-classifier entry.*
9. *K is the* Pkg *provenance over* $\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *E is the local* $\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these finite rows. It has no coordinate for a closed subject-reduction theorem, global confluence, full normalization, total decidability, or an audit-map result that bypasses the route classifier.

Theorem 2272.2 (MetaCIC frontier dependency matrix obligations)**.** *For every accepted* MetaCICFrontierDepende *carrier $M = (B, A, L, P, Q, N, D, J, R, H, C, K, E)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the four positive subject-reduction rows, dependent-codomain obstruction row, normalization frontier, decidability frontier, confluence boundary, route classifier, transport, replay, provenance, and local naming row;*
2. *row polarity, requiring each matrix row to be classified by R as positive support, obstruction, or audit consumer;*
3. *support factorization, requiring every positive row to factor through one of B, A, L, P before subject-reduction consumers may use it;*
4. *obstruction factorization, requiring every negative frontier row to factor through exactly one of Q, N, D, J before audit-map consumers may cite it;*
5. *nonescape, excluding closed subject reduction, global confluence, full normalization, total decidability, and audit-map closure outside the displayed rows.*

No frontier dependency matrix obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2307.1. The tuple displays the positive subject-reduction rows, obstruction rows, classifier, transport, replay, provenance, and local naming row.

Row polarity is the job of R. Each matrix entry must be read with its route-classifier tag before any consumer treats it as support or obstruction.

Support factorization then follows by exhaustion of the positive rows. The only positive coordinates are B, A, L, P, so a subject-reduction consumer cannot obtain a fifth support row from the matrix.

Obstruction factorization is the matching exhaustion over Q, N, D, J. These rows name the dependent-codomain, normalization, decidability, and confluence boundaries, and the replay row C preserves their route tags for audit consumers.

The nonescape clause inspects K, E and the carrier fields. Since no closed subject-reduction theorem, global confluence theorem, full normalization theorem, total decidability theorem, or completed audit-map result appears among the coordinates, none is exported by the packet. □

Theorem 2272.3 (MetaCIC frontier audit-map route)**.** *Every audit-map consumer of an accepted* MetaCICFrontierDependencyMatrix$^{\uparrow}$ *packet first reads the route classifier R, then either one positive support row among B, A, L, P or one obstruction row among Q, N, D, J, and only then replays the selected dependency through H, C, K, E. Thus the matrix is finite row data for frontier accounting, not a proof of closed subject reduction, confluence, normalization, decidability, or audit-map completion.*

Proof. An audit-map request begins at R, because the carrier gives no untagged dependency coordinate. The classifier chooses the polarity and the named row before the consumer can inspect the row content.

In the positive case, row exhaustion gives one of B, A, L, P. In the obstruction case, row exhaustion gives one of Q, N, D, J. The two cases are disjoint because the route classifier stores their tags before replay.

The structural rows H, C, K, E preserve and name the selected matrix entry. They do not add a closed theorem or a completed audit-map result, so the consumer remains inside finite frontier accounting. □

Theorem 2272.4 (MetaCIC frontier dependency matrix substitution support)**.** *Every beta-substitution or application-argument consumer of an accepted* MetaCICFrontierDependencyMatrix$^{\uparrow}$ *packet first factors through one of the positive support rows B, A, L, P. Every dependent-codomain, normalization, decidability, or confluence consumer first factors through one of the obstruction rows Q, N, D, J. The packet therefore supplies a finite substitution-support route for subject-reduction discharge, but it exports no closed subject-reduction theorem, no global normalization theorem, no total decidability theorem, and no confluence theorem.*

Proof. Project the carrier of Definition 2307.1. The substitution-facing support rows are exactly B, A, L, P, with B carrying beta substitution and A carrying application-argument stability.

The remaining frontier consumers are separated by row polarity. Dependent-codomain reads pass through Q, normalization reads through N, decidability reads through D, and confluence or critical-pair reads through J.

Exhaust the route classifier R. Since every row is tagged before replay through H, C, K, E, a consumer cannot cross from a positive support row into a closed global theorem, and an obstruction row cannot be read as a completed MetaCIC result. □

Closure status for NameCert$_{\text{MetaCICFrontierDependencyMatrix}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICFrontierDependencyMatrix}^{\uparrow}}$, seed)

Scope closed: Definition 2307.1, Definition 2307.2, and Definition 2307.3 seed the finite MetaCIC frontier matrix over positive support rows, obstruction rows, route-classifier tags, and audit-map consumers.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICFrontierDependencyMatrix}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close subject reduction, confluence, normalization, decidability, audit-map completion, Lean verification, or standard bridge closure.

Upgrade path: Obligation closure requires checked carrier admission, row polarity, support factorization, obstruction factorization, audit-map route replay, and nonescape for BEDC.Derived.MetaCICFrontierDependencyMatrixUp.

Constructive story: A MetaCICFrontierDependencyMatrix$^{\uparrow}$ packet is generated from four positive subject-reduction rows, named obstruction rows, a route classifier, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2273

A Concrete Naming Certificate for $\mathsf{LiouvilleNumber}^{\uparrow}$

Beginning from Liouville's rational-approximation construction, the $\mathsf{LiouvilleNumber}^{\uparrow}$ packet records a nontrivial $\mathsf{Real}^{\uparrow}$ name by finite approximation rows rather than by an ambient transcendence theorem. It reads rational approximants through the rational-approximation sibling chapter 1668, stores tolerance budgets in the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, consumes finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, and seals the resulting regular real name through chapter 38. The packet is a finite NameCert route for Liouville-style approximation data, not a proof of full transcendence theory, decimal expansion uniqueness, countable choice over approximants, or completeness of all $\mathsf{Real}^{\uparrow}$ streams.

Definition 2273.1 (LiouvilleNumber carrier)**.** *A* $\mathsf{LiouvilleNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, D, S, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational-approximant row: for each accepted finite precision request it displays the inspected rational approximant and the denominator-growth witness used by the Liouville construction.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic budgets against which the rational errors are compared.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that lists exactly which approximant windows and tolerance windows are opened by the certificate.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, turning the scheduled rational approximants into a regular rational sequence before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
5. *A is the Liouville approximation classifier, pairing each displayed denominator-growth row with the dyadic comparison that witnesses an error below the recorded budget.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, admitting the regular rational readback as the named real object after the finite approximation route has been checked.*
7. *H stores componentwise* hsame *transport for Q, D, S, R, A, E and the local naming rows.*
8. *C stores displayed* Cont *replay from a real-name request through the approximant row, tolerance ledger, finite window schedule, regular rational readback, approximation classifier, and real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{LiouvilleNumber}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LiouvilleNumber}^{\uparrow}}$ *row.*

The carrier asserts only that these displayed rows form one Liouville-style real-name certificate. It has no coordinate for decimal expansion uniqueness, unbounded choice of approximants outside the displayed windows, a blanket irrationality theorem for all reals, a transcendence theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LiouvilleNumberUp.LiouvilleNumberTasteGate single carrier alignment`

Theorem 2273.2 (LiouvilleNumber NameCert obligations)**.** *For every accepted* $\mathsf{LiouvilleNumber}^{\uparrow}$ *carrier* $L = (Q, D, S, R, A, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LiouvilleNumber}^{\uparrow}}$ *surface consists exactly of carrier admission, rational-approximant exposure through* Q*, dyadic tolerance comparison through* D*, finite window scheduling through* S*, regular rational readback through* R*, Liouville approximation classification through* A*,* $\mathsf{Real}^{\uparrow}$ *seal exposure through* E*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for decimal uniqueness, unbounded choice, general irrationality, transcendence, and ambient real completeness.*

Proof. Carrier admission is projection from Definition 2273.1. The accepted packet exposes exactly the rational approximant row, dyadic ledger, finite window schedule, regular rational readback, approximation classifier, real seal, transport, replay, provenance, and local naming rows.

The approximation rows are finite because Q and S list only the inspected windows. Each accepted precision request is matched with the denominator-growth witness and error budget recorded in D and A.

The regular rational readback R converts those scheduled approximants into the row consumed by the real-name surface. The handoff to E therefore occurs only after the finite Liouville approximation route has been replayed.

Rows H, C, P, N transport, replay, source, and name the same packet. Since no other coordinate exists, the certificate cannot export decimal expansion uniqueness, an off-window choice function, a general irrationality theorem, a transcendence theorem, or ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Theorem 2273.3 (LiouvilleNumber finite approximation handoff)**.** *Every real-name consumer of an accepted* $\mathsf{LiouvilleNumber}^{\uparrow}$ *carrier factors through the finite route*

$$Q \longmapsto D \longmapsto S \longmapsto R \longmapsto A \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet supplies a Liouville-style $\mathsf{Real}^{\uparrow}$ *object from rational approximants, dyadic tolerance budgets, finite stream windows, and regular rational readback, without claiming decimal expansion uniqueness, unbounded choice, transcendence, or ambient real completeness.*

Proof. Start with an accepted carrier $L = (Q, D, S, R, A, E, H, C, P, N)$. A real-name request must read the rational approximant row Q and the dyadic budget row D before it can inspect the window schedule S.

The regular rational readback R is then forced by the displayed windows. The classifier A records the Liouville approximation inequality for the same inspected rows, so the real seal E receives only finite approximation evidence.

The transport, replay, provenance, and naming rows preserve that route. They add no coordinate for off-window choice, decimal uniqueness, transcendence, or a general completeness theorem, so every downstream consumer remains inside the finite NameCert packet. □

Theorem 2273.4 (LiouvilleNumber finite-window approximation induction)**.** *Let $L = (Q, D, S, R, A, E, H, C, P, N$ be an accepted* $\mathsf{LiouvilleNumber}^{\uparrow}$ *carrier, and let S' be a finite* $\mathsf{StreamName}^{\uparrow}$ *extension of the inspected window schedule S whose extra requests are witnessed by rows already routed through the rational-approximant row Q, the dyadic budget row D, the regular rational readback row R, the approximation classifier row A, and the* $\mathsf{Real}^{\uparrow}$ *seal row E. Then every real-name read over the extended finite window still factors through*

$$Q, D, S', R, A, E, H, C, P, N.$$

The extension preserves the same Liouville-style route by finite-window induction, and it still refuses off-window choice, decimal expansion uniqueness, transcendence, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The base window is exactly the finite schedule S, and Definition 2273.3 gives the route through $Q, D, R, A, E, H, C, P, N$ for every inspected request in that schedule.

For the induction step, add one displayed request to the window. The hypothesis on S' supplies the matching rational approximant in Q, dyadic tolerance budget in D, regular rational readback in R, approximation classifier in A, and real seal in E before the transport, replay, provenance, and naming rows are consulted.

Iterating the finite step over the added window entries gives the displayed route for all of S'. Since the induction only appends inspected rows and never adds a coordinate outside $Q, D, S', R, A, E, H, C, P, N$, the packet still has no off-window choice function, decimal uniqueness principle, transcendence theorem, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LiouvilleNumber}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LiouvilleNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2273.1, Definition 2273.2, Definition 2273.3, and Definition 2273.4 seed the finite Liouville-style real-name certificate over rational approximants, dyadic tolerance budgets, finite StreamName windows, RegSeqRat readback, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LiouvilleNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, decimal expansion uniqueness, countable choice over approximants, a general irrationality theorem, transcendence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, rational-approximant exposure, dyadic comparison exactness, finite window scheduling, regular rational readback, Real seal handoff, structural transport, replay, provenance, and nonescape for BEDC.Derived.LiouvilleNumberUp.

Constructive story: A $\mathsf{LiouvilleNumber}^{\uparrow}$ packet is generated from rational approximant rows, DyadicRatCore tolerance budgets, finite StreamName windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert evidence.

Chapter 2274

A Concrete Naming Certificate for CandidateSNConfluenceBoundary$^{\uparrow}$

The CandidateSNConfluenceBoundary$^{\uparrow}$ packet realizes the normalization and confluence frontier of chapter 9386 as one finite MetaCIC NameCert row. It sits beside the critical-path carrier of chapter 765, the normalisation frontier, the redex frontier, and the bounded normal-equality checker, and records exactly where candidate-mediated strong-normalization evidence can be consumed before confluence claims must stop. The packet names candidate evidence, bounded normal checks, critical-pair or redex-frontier handoff rows, and nonescape rows; it is not a closed subject-reduction theorem, arbitrary Church–Rosser theorem, or closed consistency theorem.

Falsifiable prediction: Any consumer of an accepted CandidateSNConfluenceBoundary$^{\uparrow}$ packet still cannot export closed subject reduction or arbitrary Church–Rosser unless it also supplies the displayed subject-reduction discharge rows, confluence-boundary rows, and candidate-interface admission rows of the carrier.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacicredexfrontier, boundednormalequalitychecker: the critical path records the global frontier, the normalization frontier records candidate-mediated strong-normalization boundaries, the redex frontier records local reduction cases, and the bounded checker records finite normal-equality comparison; none is bijective to the packet that stores all four rows with one confluence nonescape boundary.

Definition 2274.1 (CandidateSNConfluenceBoundary carrier)**.** *A* CandidateSNConfluenceBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, N, R, E, S, J, U, H, C, P, L)$$

with the following displayed rows:

1. *K is the MetaCIC critical-path row naming the subject-reduction, normalization, confluence, decidability, and consistency frontier being read.*
2. *N is the candidate strong-normalization row, admitting only terms already inside the candidate interface.*
3. *R is the redex-frontier row through which local reduction and critical-pair cases are inspected.*
4. *E is the bounded normal-equality checker row used when a finite normal comparison is requested.*
5. *S is the subject-reduction discharge row, recording which subject-reduction inputs are present and which remain outside the packet.*

6. *J is the confluence-boundary row, recording displayed join, common-reduct, or normal-fragment handoffs without promoting them to arbitrary Church–Rosser.*
7. *U is the nonescape row excluding closed subject reduction, arbitrary closed confluence, full closed consistency, and candidate-free strong normalization.*
8. *H records componentwise* hsame *transport for K, N, R, E, S, J, U and the local naming rows.*
9. *C records displayed* Cont *replay from a consumer request through candidate admission, redex-frontier inspection, bounded normal comparison, subject-reduction discharge, and confluence-boundary handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, MetaCICNormalizationFro $\mathsf{MetaCICRedexFrontier}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}}$ *row.*

The carrier compares accepted packets only by these rows. It has no coordinate for closed subject reduction, arbitrary Church–Rosser, unrestricted parallel diamond, candidate-free strong normalization, closed consistency, or a completed MetaCIC audit map.

Theorem 2274.2 (CandidateSNConfluenceBoundary NameCert obligations)**.** *For every accepted* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ *carrier $B = (K, N, R, E, S, J, U, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{CandidateSNConfluence}}$ *surface consists exactly of carrier admission for the critical-path, candidate-SN, redex-frontier, bounded-checker, subject-reduction discharge, confluence-boundary, nonescape, transport, replay, provenance, and local naming rows; candidate-interface admission through N; redex-frontier inspection through R; bounded normal-equality comparison through E; explicit subject-reduction discharge through S; confluence-boundary handoff through J; and ledger refusal through U for closed subject reduction, arbitrary Church–Rosser, unrestricted parallel diamond, candidate-free strong normalization, closed consistency, and completed audit-map closure.*

Proof. Carrier admission is projection from Definition 2274.1. The accepted packet exposes the critical-path row, candidate strong-normalization row, redex frontier, bounded checker, subject-reduction discharge row, confluence-boundary row, nonescape row, transport, replay, provenance, and local naming row.

Candidate-mediated strong normalization is read only through N. This keeps the strong-normalization evidence inside the candidate interface named by the packet.

Confluence consumption then passes through the displayed redex-frontier and bounded-checker rows R and E, followed by the discharge and boundary rows S and J. These rows distinguish local join or normal-fragment evidence from arbitrary closed Church–Rosser.

The nonescape row U and structural rows H, C, P, L preserve the same finite boundary. Since no coordinate provides closed subject reduction, unrestricted parallel diamond, candidate-free strong normalization, closed consistency, or completed audit-map closure, none can be exported by the packet. □

Theorem 2274.3 (CandidateSNConfluenceBoundary checked obligation route)**.** *For every accepted* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ *carrier $B = (K, N, R, E, S, J, U, H, C, P, L)$, the rows K, N, R, E, S, J, U, H are exactly the checked field inventory consumed by the Lean TasteGate alignment target. Consequently any SN-to-confluence read remains candidate-mediated and cannot become closed subject reduction, arbitrary Church–Rosser, unrestricted parallel diamond, candidate-free strong normalization, closed consistency, or completed audit-map closure.*

Lean4 ✓ BEDC.Derived.CandidateSNConfluenceBoundaryUp.CandidateSNConfluenceBoundaryTasteGate single carrier alignment

Proof. Project the carrier of Definition 2274.1. The available rows are exactly the critical-path row K, candidate strong-normalization row N, redex-frontier row R, bounded normal-equality checker E, subject-reduction discharge row S, confluence-boundary row J, nonescape row U, transport row H, replay row C, provenance row P, and local naming row L.

The checked obligation route reads the same inventory. Candidate admission is mediated by N, confluence-facing inspection is mediated by R, E, S, J, and the nonescape boundary is mediated by U.

The structural rows H, C, P, L transport, replay, source, and name only that displayed packet. Since the carrier contains no row for closed subject reduction, arbitrary Church–Rosser, unrestricted parallel diamond, candidate-free strong normalization, closed consistency, or completed audit-map closure, none can be exported by the checked route. □

Theorem 2274.4 (Candidate-mediated SN confluence boundary route)**.** *Every MetaCIC consumer of an accepted* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ *packet factors through candidate admission, redex-frontier inspection, bounded normal-equality comparison, subject-reduction discharge, and confluence-boundary handoff before any conclusion is replayed:*

$$K \longmapsto N \longmapsto R, E \longmapsto S, J \longmapsto U \longmapsto H, C, P, L.$$

Consequently the packet is a finite boundary witness between candidate-mediated strong normalization and confluence claims, not evidence for closed subject reduction, arbitrary Church–Rosser, candidate-free strong normalization, or closed consistency.

Proof. Start with the carrier $B = (K, N, R, E, S, J, U, H, C, P, L)$. The critical-path row K locates the consumer at the MetaCIC frontier, but the first positive normalization input is still the candidate row N.

Any confluence-facing read must then inspect the local frontier rows R and E. These rows expose redex cases and bounded normal comparisons only at the finite window recorded by the packet.

The discharge row S and confluence-boundary row J determine which subject-reduction and join inputs are actually present. The nonescape row U records that all stronger endpoints remain outside the carrier.

Finally H, C, P, L transport, replay, source, and name the same finite route. They do not add closed subject reduction, arbitrary Church–Rosser, candidate-free strong normalization, or closed consistency evidence. □

Theorem 2274.5 (CandidateSNConfluenceBoundary Real-phase handoff)**.** *Any Real-phase consumer using an accepted* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ *packet must pass through the candidate admission row N, redex frontier row R, bounded normal-equality row E, subject-reduction discharge row S, confluence-boundary row J, nonescape row U, and the L10 source faces before reaching a* $\mathsf{Real}^{\uparrow}$*-facing audit conclusion. The resulting handoff is the finite route*

$$K \longmapsto N \longmapsto R, E \longmapsto S, J \longmapsto U \longmapsto H, C, P, L$$

with the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces read only as downstream Real and Completion source surfaces, not as closed subject reduction, arbitrary Church–Rosser, candidate-free strong normalization, or completed MetaCIC audit-map closure.*

Proof. Project the carrier $B = (K, N, R, E, S, J, U, H, C, P, L)$. The only positive candidate-mediated normalization input is the admission row N, and the only confluence-facing local data are the redex frontier R and bounded normal-equality checker E.

Apply Definition 2274.4. It forces every MetaCIC consumer through N, then through R, E, and then through the subject-reduction discharge and confluence-boundary rows S, J before the nonescape row U is replayed.

A Real-phase audit can therefore attach the L10 source faces only after that boundary route is visible. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads are downstream source surfaces for a completion-facing audit, while H, C, P, L transport, replay, source, and name the same finite route.

Because U excludes closed subject reduction, arbitrary Church–Rosser, candidate-free strong normalization, and completed MetaCIC audit-map closure, the handoff does not promote the packet beyond the displayed boundary. □

The Lean follow-up for this packet is to provide `Nontrivial CandidateSNConfluenceBoundaryUp` and `FieldFaithful CandidateSNConfluenceBoundaryUp` instances in `TasteGate.lean`. Those instances must check that candidate admission, redex-frontier inspection, bounded equality checking, subject-reduction discharge, and confluence-boundary handoff are genuine carrier fields rather than aliases for a closed consistency endpoint.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2274.1, Definition 2274.2, Definition 2274.4, and Definition 2274.5 seed the finite MetaCIC packet separating candidate-mediated strong normalization from confluence, subject-reduction endpoints, and Real-phase audit handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, closed subject reduction, arbitrary Church–Rosser, unrestricted parallel diamond, candidate-free strong normalization, closed consistency, or completed MetaCIC audit-map closure.

Upgrade path: Obligation closure requires checked carrier admission, candidate-interface admission, redex-frontier inspection, bounded equality checking, subject-reduction discharge, confluence-boundary handoff, nonescape, structural transport, replay, and provenance for BEDC.Derived.CandidateSNConfluenceBoundaryUp.

Constructive story: A $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ packet is generated from MetaCIC critical-path rows, candidate strong-normalization evidence, redex-frontier rows, bounded normal-equality checker rows, subject-reduction discharge rows, confluence-boundary rows, nonescape data, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert evidence.

Chapter 2275

A Concrete Naming Certificate for $\mathsf{CoveringSpacePathLifting}^{\uparrow}$

Following Hatcher and Spanier on covering spaces, the $\mathsf{CoveringSpacePathLifting}^{\uparrow}$ packet records the finite BEDC surface by which a displayed base path admits a lifted segment route once an initial point over the base endpoint is fixed. It sits over the homotopy path rows of chapter 156, the circle source of chapter 58, the indexed-open topology surface of chapter 88, the continuous-map carrier of chapter 130, and the metric observation boundary of chapter 57. The packet names path lifting as finite window and sheet data; it does not import a universal cover, monodromy action, quotient path space, chosen global sheet, or host uniqueness theorem.

Definition 2275.1 (CoveringSpacePathLifting carrier)**.** *A* $\mathsf{CoveringSpacePathLifting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (\gamma, \pi, e_0, U, S, \Sigma, E, H, C, P, N)$$

with the following displayed rows:

1. *γ is the base path row, read through* $\mathsf{Homotopy}^{\uparrow}$ *and the displayed* $\mathsf{S}^{1\uparrow}$ *or interval endpoint surface when the path is closed or endpoint-parametrized.*
2. *π is the covering projection row, a* $\mathsf{ContinuousMap}^{\uparrow}$ *packet from a displayed total-space topology to the base* $\mathsf{Topology}^{\uparrow}$ *row.*
3. *e_0 is the initial lift point row, together with the endpoint comparison showing that $\pi(e_0)$ is the initial endpoint of γ under the base classifier.*
4. *U is the evenly covered window ledger. Each base-path window carries a topology index, its lifted sheet window, and the local projection-readback row witnessing that the window is evenly covered.*
5. *S is the lifted segment ledger. It lists the finite lifted path segments, their endpoint gluing rows, and the* Cont *reads showing that their projection follows the corresponding base-path windows.*
6. *Σ is the sheet classifier. It compares lifted segments by the initial point, the evenly covered window row, and the segment gluing ledger, not by a host-level choice of sheet.*
7. *E is the endpoint seal. It records the final lifted endpoint after all segment windows have been glued and exposes only the projected endpoint comparison back to the base path.*

8. *H records componentwise* hsame *transport for the base path, projection, initial point, window ledger, lifted segment ledger, sheet classifier, endpoint seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a path-lifting request through $\gamma, \pi, e_0, U, S, \Sigma, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CoveringSpacePathLifting}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CoveringSpacePathLifting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a universal covering space, a chosen global sheet, a completed path quotient, a monodromy action, a fundamental-group representation, or a host uniqueness principle.

`single carrier alignment`

Theorem 2275.2 (CoveringSpacePathLifting NameCert obligations)**.** *For every accepted* CoveringSpacePathLifting *carrier*

$$L = (\gamma, \pi, e_0, U, S, \Sigma, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CoveringSpacePathLifting}^{\uparrow}}$ *surface consists exactly of carrier admission, base-path admission through* $\mathsf{Homotopy}^{\uparrow}$, *covering-projection admission through* $\mathsf{ContinuousMap}^{\uparrow}$ *over* $\mathsf{Topology}^{\uparrow}$, *initial endpoint exactness, evenly covered window exactness, lifted segment gluing, sheet-classifier stability, endpoint seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every path-lifting consumer can inspect $\gamma, \pi, e_0, U, S, \Sigma, E, H, C, P, N$, but cannot replace them by a universal cover, host path quotient, selected global sheet, monodromy action, or fundamental-group representation.*

Proof. Carrier admission is projection from Definition 2275.1. The accepted tuple displays the base path, covering projection, initial lift point, evenly covered windows, lifted segment ledger, sheet classifier, endpoint seal, transport, replay, provenance, and local naming rows.

The base and projection obligations are inherited by reading γ through $\mathsf{Homotopy}^{\uparrow}$ and π through $\mathsf{ContinuousMap}^{\uparrow}$ over the displayed $\mathsf{Topology}^{\uparrow}$ rows. The metric observation boundary may be used only as the finite $\mathsf{Met}^{\uparrow}$ readback already named in the provenance row.

Initial endpoint exactness, window exactness, and segment gluing are the roles of e_0, U, S. Each lifted segment is attached to a visible evenly covered window, and the gluing row records the next endpoint before the following window is consumed.

The sheet classifier and endpoint seal are then inventory checks on Σ and E. Since H, C, P, N only transport, replay, source, and name the same finite rows, the local certificate has no remaining place to store a universal cover, global sheet selector, quotient path, monodromy action, or fundamental-group representation. □

Theorem 2275.3 (CoveringSpacePathLifting unique lift route)**.** *Let $L = (\gamma, \pi, e_0, U, S, \Sigma, E, H, C, P, N)$ and $L' = (\gamma, \pi, e_0, U, S', \Sigma', E', H', C', P', N')$ be accepted* $\mathsf{CoveringSpacePathLifting}^{\uparrow}$ *packets with the same displayed base path, covering projection, initial lift point, and evenly covered window ledger. If the lifted segment ledgers are both admitted by the same sheet classifier route over U, then every endpoint and intermediate segment read of L and L' factors through the same finite route*

$$\gamma,\ \pi,\ e_0,\ U,\ \Sigma,\ E,\ H,\ C,\ P,\ N.$$

Thus uniqueness of the lift is recorded as sheet-classifier determinacy over the displayed window ledger, not as host path equality or a selected global sheet.

Proof. Start with the common rows γ, π, e_0, U. They fix the base path, the projection surface, the initial lifted endpoint, and the sequence of evenly covered windows visible to both packets.

Read the first lifted segment through the sheet classifier. Because both packets use the same initial lift point and the same first evenly covered window, Σ admits only the displayed segment row compatible with the local projection readback.

Proceed along the finite lifted segment ledger. At each next window, the previous endpoint is already sealed by the gluing row, so the same sheet-classifier route determines the next segment read. This is a finite induction over the listed windows of U, not an appeal to a completed path space.

The final endpoint rows E and E' are therefore read through the same sequence of segment and sheet rows. Replaying and transporting by H, C, P, N preserves that route and exports no global sheet selector, quotient path equality, monodromy action, or fundamental-group representation. □

Theorem 2275.4 (CoveringSpacePathLifting monodromy boundary)**.** *Let $L = (\gamma, \pi, e_0, U, S, \Sigma, E, H, C, P, N)$ be an accepted* $\mathsf{CoveringSpacePathLifting}^{\uparrow}$ *packet. Any attempted loop-consumer read from L must factor through the displayed base path γ, covering projection π, initial lift point e_0, evenly covered window ledger U, lifted segment ledger S, sheet classifier Σ, endpoint seal E, transport H, replay C, provenance P, and local NameCert row N. Consequently the packet can expose endpoint and sheet-classifier reads along the displayed lifting route, but it cannot export a monodromy action, a fundamental-group representation, a host path quotient, or a universal-cover carrier.*

Proof. Project the accepted carrier using Definition 2275.1. The only rows available to a consumer are the displayed base path, projection, initial lift point, window ledger, lifted segments, sheet classifier, endpoint seal, transport, replay, provenance, and local naming.

Apply Definition 2275.2. The NameCert surface admits inspection of those rows and refuses replacement by a universal cover, host path quotient, selected global sheet, monodromy action, or fundamental-group representation.

Apply Definition 2275.3 to the lifted segment route whenever the loop consumer asks for endpoint or intermediate segment reads along the displayed window ledger. The theorem identifies the finite sheet-classifier route through U, Σ, E, H, C, P, N and does not add a completed path space.

Thus every accepted read remains a path-lifting read through the finite carrier. Exporting monodromy or a representation would require an additional coordinate that stores loop composition on path classes, and no such coordinate is present in L. □

Closure status for $\mathsf{NameCert}_{\mathsf{CoveringSpacePathLifting}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoveringSpacePathLifting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2275.1, Definition 2275.2, Definition 2275.3, and Definition 2275.4 seed the finite base-path, covering-projection, evenly covered window, lifted segment, sheet-classifier, endpoint-seal, and loop-consumer boundary surface for path lifting.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoveringSpacePathLifting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close universal covers, monodromy actions, fundamental-group representations, host path quotients, selected global sheets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, lifted segment gluing, sheet-classifier determinacy, endpoint seal readback, transport, replay, provenance, and local naming for BEDC.Derived.CoveringSpacePathLiftingUp.

Constructive story: A $\mathsf{CoveringSpacePathLifting}^{\uparrow}$ packet is generated from a base path, a covering projection, an initial lifted point, evenly covered base windows, lifted segment rows, a sheet classifier, an endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2276

A Concrete Naming Certificate for $\mathsf{CoveringHomotopyLifting}^{\uparrow}$

Hatcher and Spanier treat the covering homotopy lifting property as the homotopy-level continuation of path lifting over evenly covered neighborhoods. The $\mathsf{CoveringHomotopyLifting}^{\uparrow}$ packet records that classical object as finite BEDC sheet-window data: it consumes the path-lifting route of chapter 2275, the homotopy rows of chapter 156, the circle and interval endpoint surfaces of chapter 58, the topology and continuous-map carriers of chapter 88 and chapter 130, and the finite metric observation boundary of chapter 57. It names homotopy lifting as a rectangle of base-time windows and sheet seals; it does not import a universal cover, quotient path space, monodromy action, fundamental-group representation, or global sheet choice.

Definition 2276.1 (CoveringHomotopyLifting carrier)**.** *A* $\mathsf{CoveringHomotopyLifting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, \pi, \tilde{f}_0, I, U, W, \Sigma, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the base homotopy row, read through* $\mathsf{Homotopy}^{\uparrow}$ *from a displayed source surface and time interval into the base* $\mathsf{Topology}^{\uparrow}$ *row.*
2. *π is the covering projection row, a* $\mathsf{ContinuousMap}^{\uparrow}$ *packet from a displayed total-space topology to the base topology.*
3. *$\tilde{f}_0$ is the initial lifted slice row, together with the endpoint comparison showing that $\pi \circ \tilde{f}_0$ is the initial time-slice of F.*
4. *I is the source-time cell ledger. It lists the finite domain cells and adjacent time strips on which the homotopy request is inspected.*
5. *U is the evenly covered base-window ledger. Each cell-time window has a named base open, a lifted sheet window, and a local projection-readback row.*
6. *W is the lifted homotopy window ledger. It records the lifted cell strips, their face-gluing rows, and the displayed* Cont *reads showing that projection follows F on each window.*
7. *Σ is the sheet-window classifier. It compares lifted strips by the initial slice, the evenly covered window row, and face gluing, not by host-level equality of lifted maps.*
8. *E is the terminal slice seal. It records the final lifted time-slice and exposes only the projected comparison back to the base homotopy.*

9. *H records componentwise* hsame *transport for the base homotopy, projection, initial slice, source-time cells, evenly covered windows, lifted windows, sheet classifier, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a homotopy-lifting request through $F, \pi, \tilde{f}_0, I, U, W, \Sigma, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CoveringHomotopyLifting}^{\uparrow}$, $\mathsf{CoveringSpacePathLifting}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CoveringHomotopyLifting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a universal covering space, quotient path space, selected global sheet, monodromy action, fundamental-group representation, host homotopy equality, or ambient uniqueness theorem.

Lean4 ✓ `BEDC.Derived.CoveringHomotopyLiftingUp.CoveringHomotopyLiftingTasteGate single carrier alignment`

Theorem 2276.2 (CoveringHomotopyLifting NameCert obligations)**.** *For every accepted* CoveringHomotopyLifting *carrier*

$$Q = (F, \pi, \tilde{f}_0, I, U, W, \Sigma, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CoveringHomotopyLifting}^{\uparrow}}$ *surface consists exactly of carrier admission, base-homotopy admission through* $\mathsf{Homotopy}^{\uparrow}$, *covering-projection admission through* $\mathsf{ContinuousMap}^{\uparrow}$ *over* $\mathsf{Topology}^{\uparrow}$, *initial slice exactness, source-time cell coverage, evenly covered window exactness, lifted window gluing, sheet-window classifier stability, terminal slice readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every homotopy-lifting consumer can inspect $F, \pi, \tilde{f}_0, I, U, W, \Sigma, E, H, C, P, N$, but cannot replace them by a universal cover, quotient path space, selected global sheet, monodromy action, or fundamental-group representation.*

Lean4 ✓ `BEDC.Derived.CoveringHomotopyLiftingUp.CoveringHomotopyLiftingNameCert obligations`

Proof. Carrier admission is projection from Definition 2276.1. The accepted tuple displays the base homotopy, covering projection, initial lifted slice, source-time cell ledger, evenly covered windows, lifted window ledger, sheet classifier, terminal seal, transport, replay, provenance, and local naming rows.

The base and projection obligations are inherited by reading F through $\mathsf{Homotopy}^{\uparrow}$ and π through $\mathsf{ContinuousMap}^{\uparrow}$ over the displayed $\mathsf{Topology}^{\uparrow}$ rows. The prior path-lifting certificate of chapter 2275 supplies the one-dimensional boundary route on each cell edge; the present carrier stores only the finite cell-time extension data needed to glue those routes across adjacent strips.

Initial slice exactness, source-time coverage, evenly covered window exactness, and lifted window gluing are the roles of $\tilde{f}_0, I, U, W$. Each lifted strip is attached to a visible evenly covered window, and each face-gluing row records the next boundary before the adjacent time strip is consumed.

The sheet-window classifier and terminal seal are then inventory checks on Σ and E. Since H, C, P, N only transport, replay, source, and name the same finite rows, the local certificate has no remaining place to store a universal cover, quotient path space, global sheet selector, monodromy action, or fundamental-group representation. □

Theorem 2276.3 (CoveringHomotopyLifting sheet-window determinacy)**.** *Let*

$$Q = (F, \pi, \tilde{f}_0, I, U, W, \Sigma, E, H, C, P, N)$$

and

$$Q' = (F, \pi, \tilde{f}_0, I, U, W', \Sigma', E', H', C', P', N')$$

be accepted $\mathsf{CoveringHomotopyLifting}^{\uparrow}$ *packets with the same displayed base homotopy, covering projection, initial lifted slice, source-time cell ledger, and evenly covered base-window ledger. If both lifted window ledgers are admitted by the same sheet-window classifier route over* I *and* U*, then every terminal slice and intermediate strip read of* Q *and* Q' *factors through the same finite route*

$$F,\ \pi,\ \tilde{f}_0,\ I,\ U,\ \Sigma,\ E,\ H,\ C,\ P,\ N.$$

Thus homotopy lifting determinacy is recorded as sheet-window determinacy over displayed cell-time windows, not as host equality of lifted homotopies, quotient path-space equality, or a selected global sheet.

Proof. Start with the common rows $F, \pi, \tilde{f}_0, I, U$. They fix the base homotopy, the projection surface, the initial lifted slice, the source-time cell schedule, and the sequence of evenly covered base windows visible to both packets.

Read the first lifted cell strip through the sheet-window classifier. Because both packets use the same initial slice and the same first evenly covered window, Σ admits only the displayed strip row compatible with the local projection readback.

Proceed over the finite source-time cell ledger. At each adjacent face, the previous strip boundary is already sealed by the gluing row, so the same sheet-window classifier route determines the next lifted strip read. This is a finite induction over the listed cells of I and windows of U, not an appeal to a completed path space.

The final slice rows E and E' are therefore read through the same sequence of window and sheet rows. Replaying and transporting by H, C, P, N preserves that route and exports no global sheet selector, quotient path-space equality, monodromy action, or fundamental-group representation. □

Closure status for $\mathsf{NameCert}_{\mathsf{CoveringHomotopyLifting}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoveringHomotopyLifting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2276.1, Definition 2276.2, and Definition 2276.3 seed the finite base-homotopy, covering-projection, source-time cell, evenly covered window, lifted strip, sheet-classifier, and terminal-slice surface for homotopy lifting.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoveringHomotopyLifting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close universal covers, quotient path spaces, monodromy actions, fundamental-group representations, host homotopy equality, selected global sheets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-time coverage, window exactness, lifted strip gluing, sheet-window determinacy, terminal slice readback, transport, replay, provenance, and local naming for BEDC.Derived.CoveringHomotopyLiftingUp.

Constructive story: A $\mathsf{CoveringHomotopyLifting}^{\uparrow}$ packet is generated from a base homotopy, a covering projection, an initial lifted slice, source-time cells, evenly covered base windows, lifted strip rows, a sheet-window classifier, a terminal slice seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2277

A Concrete Naming Certificate for $\mathsf{NestedIntervalTheorem}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{NestedIntervalTheorem}^{\uparrow}$ packet records the constructive nested closed interval theorem as finite BEDC route data. It consumes the retained-window surface of chapter 320, the dyadic endpoint and tolerance ledger of chapter 291, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the interval-existence handoff without asserting quotient reals, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2277.1 (Nested interval theorem carrier)**.** *A* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted* $\mathsf{NestedInterval}^{\uparrow}$ *row, including the inspected closed rational or dyadic interval windows, endpoint-order rows, width rows, and displayed containment witnesses.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger that records the endpoint comparisons and the diameter-to-tolerance rows used by the retained windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule requested from the lower and upper endpoint rows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite interval windows and dyadic tolerance ledger.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for the interval, dyadic, stream, regular readback, Real seal, replay, provenance, and naming rows.*
7. *C records the displayed* Cont *replay from nested interval data through dyadic tolerance control, stream windows, regular readback, and Real seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalTheorem}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite host intersection object, a selected quotient representative, countable choice, trichotomy, a Cauchy-completion quotient, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.NestedIntervalTheoremUp`

Theorem 2277.2 (Nested interval theorem NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *carrier* $K = (I, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed nine-row packet,* $\mathsf{NestedInterval}^{\uparrow}$ *source exposure through* I*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance exactness through* D*,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff through* E*, and the structural transport, replay, provenance, and naming rows* H, C, P, N*.*
