No obligation may be discharged by a host interval intersection, selected point, countable choice, trichotomy, quotient real, or ambient completeness principle.

Proof. Project the carrier of Definition 2308.1. The rows $I, D, S, R, E, H, C, P, N$ are the only coordinates visible to the local classifier.

The interval source is I. It exposes only the finite nested-window surface already available from $\mathsf{NestedInterval}^{\uparrow}$: endpoint order, width, containment, and retained-window rows.

The completion-facing route is finite. The ledger D reads the dyadic endpoint and tolerance comparisons, S lists the requested stream windows, R repacks those windows as a regular rational readback, and E is downstream of those rows.

The structural rows do not add mathematical principles. The transports H, continuations C, provenance P, and local certificate N preserve and name the same packet, so the excluded host intersection, choice, quotient, trichotomy, and completeness coordinates remain absent. □

Lean4 ✓ `BEDC.Derived.NestedIntervalTheoremUp.NestedIntervalTheoremTasteGate single carrier alignment`

Theorem 2277.3 (Nested interval theorem Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer reads the nested interval row I*, the dyadic endpoint and tolerance ledger* D*, the stream-window schedule* S*, the regular-rational row* R*, and only then the Real seal row* E *with its transports, continuations, provenance, and local naming.*

Proof. Start with the Real-facing read. Since E is the only Real seal coordinate in the carrier, every such read must pass through the rows that make E visible.

The source row is I. It supplies the finite nested closed interval windows and containment witnesses, while D supplies the dyadic endpoint comparisons and diameter-to-tolerance rows read from the same windows.

The name construction then passes through S and R. The finite stream schedule selects the requested endpoint windows, and the regular rational row records the corresponding Cauchy readback.

Finally H, C, P, N transport, replay, source, and name the same route. Because the carrier contains no coordinate for a host intersection object, selected point, quotient real, countable choice, trichotomy, or ambient completeness, the displayed handoff is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NestedIntervalTheorem}^{\uparrow}$ packet is generated from a NestedInterval row, a DyadicRatCore endpoint and tolerance ledger, StreamName finite windows, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 2308.1, Definition 2308.2, and Definition 2308.3 seed the finite constructive nested closed interval route from displayed nested windows to RegSeqRat readback and Real seal handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.NestedIntervalTheoremUp`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient reals, selected host intersections, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window exposure, dyadic endpoint and tolerance exactness, StreamName window exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NestedIntervalTheoremUp.

The routed HellyTheorem$^{\uparrow}$ chapter consumes chapter 208 and exports its finite subfamily ledger to chapter 2347 before the child files spell out the dependency route.

Chapter 2278

A Concrete Naming Certificate for $\mathsf{HellyTheorem}^{\uparrow}$

Following Helly and the finite-dimensional convexity tradition, the $\mathsf{HellyTheorem}^{\uparrow}$ packet records finite convex-intersection data as a BEDC naming surface. It consumes the convex-family rows of chapter 208, the finite witness rows of chapter 209, the ambient affine and vector rows of chapter 206 and chapter 47, and the compact finite-read discipline of chapter 129. The chapter names only finite subfamily ledgers, displayed intersection witnesses, transport, continuation replay, provenance, and local naming; it does not assert a host separation theorem, choice-selected intersection point, quotient convex-set equality, or ambient standard-model convexity.

The $\mathsf{HellyTheorem}^{\uparrow}$ packet also consumes $\mathsf{ConvexSet}^{\uparrow}$ carrier rows and the finite-subfamily rows of chapter 1792 before any intersection conclusion is exposed.

The finite convex-geometry route is visible before the Helly certificate is exported: $\mathsf{HellyTheorem}^{\uparrow}$ reads each family member through the $\mathsf{ConvexSet}^{\uparrow}$ carrier of chapter 208, then uses the Caratheodory-style finite convex-hull rows of chapter 2347 as the support ledger that keeps the intersection test finite.

The finite subfamily ledger exported by $\mathsf{HellyTheorem}^{\uparrow}$ is consumed by chapter 2347 as the boundary that keeps convex-hull support rows finite before Caratheodory support reduction is read. That ledger is not available from the ambient affine row alone: it is read only after the $\mathsf{ConvexSet}^{\uparrow}$ membership rows of chapter 208 and the $\mathsf{Polytope}^{\uparrow}$ finite witness rows of chapter 209 expose the subfamily boundary that the Caratheodory packet consumes.

The same finite subfamily ledger is a reusable dependency for convex-hull and Caratheodory consumers: chapter 2347 may read the $\mathsf{HellyTheorem}^{\uparrow}$ row only after the $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$ surfaces named above have fixed the displayed finite family boundary.

The finite closed-family indexing boundary is supplied by $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ through chapter 1792; $\mathsf{HellyTheorem}^{\uparrow}$ then specializes that boundary by adding affine ambient rows, vector displacement rows, convex-family membership, and polytope witnesses for the Helly subfamily ledger.

The concrete dependency route is horizontal rather than ambient: each finite family member is first read as a $\mathsf{ConvexSet}^{\uparrow}$ row through chapter 208, then the finite subfamily ledger S is checked against the finite-intersection carrier rows of chapter 1792, and only then may the full-family row I be exposed to a Helly consumer.

2278.1 Finite Convex Intersection Carrier

Definition 2278.1 (HellyTheorem carrier)**.** *A* $\mathsf{HellyTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, V, F, W, S, I, T, C, P, N)$$

with the following displayed rows:

1. *A is the finite-dimensional* $\mathsf{AffineSpace}^{\uparrow}$ *ambient row.*
2. *V is the associated* $\mathsf{VecSpace}^{\uparrow}$ *displacement row used by the affine coordinates.*
3. *F is a finite family of* $\mathsf{ConvexSet}^{\uparrow}$ *rows in the ambient affine space.*
4. *W is the* $\mathsf{Polytope}^{\uparrow}$ *finite witness ledger for displayed simplex, face, or hull witnesses used by the subfamily checks.*
5. *S is the finite subfamily intersection ledger, recording each inspected subfamily and its displayed nonempty intersection witness.*
6. *I is the resulting full-family intersection row exposed by the packet after the finite ledger has been replayed.*
7. *T records componentwise* hsame *transport for $A, V, F, W, S, I, C, P, N$.*
8. *C records displayed* Cont *replay from ambient affine data through convex-family rows, finite polytope witnesses, subfamily intersection checks, the full-family intersection row, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HellyTheorem}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, V, F, W, S, I, T, C, P, N$. It has no coordinate for host convex equality, ambient standard-model convexity, choice-selected points, separation or compactness theorems not displayed by the finite rows, or an infinite family of constraints.

Lean4 ✓ `BEDC.Derived.HellyTheoremUp.HellyTheoremTasteGate single carrier alignment`

2278.2 Helly NameCert Surface

Theorem 2278.2 (HellyTheorem NameCert obligations)**.** *For every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *carrier*

$$H = (A, V, F, W, S, I, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the ambient affine row, vector displacement row, finite convex-family row, finite polytope witness ledger, subfamily intersection ledger, full-family intersection row, transport, replay, provenance, and local naming;*
2. *ambient compatibility, requiring the* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *rows to be the only coordinates through which convex sets and polytope witnesses are read;*
3. *convex-family exposure, requiring each displayed family member to pass through a* $\mathsf{ConvexSet}^{\uparrow}$ *row before it enters any subfamily intersection check;*

4. *finite witness exactness, requiring every inspected subfamily intersection and every exported full-family intersection row to be backed by the displayed* $\mathsf{Polytope}^{\uparrow}$ *witness ledger;*
5. *subfamily ledger stability, requiring the finite intersection ledger* S *to be transported componentwise by* T *and replayed by* C *before* I *is exposed;*
6. *nonescape, excluding host convex-set equality, choice-selected intersection points, separation theorems, unlisted compactness principles, infinite-family claims, Lean verification, and bridge checking.*

No HellyTheorem obligation is stored outside these rows.

Proof. Project the accepted carrier. The ambient coordinates are A and V, the convex input is the finite family row F, and the finite witness coordinates are W, S, I.

Ambient compatibility is forced because the carrier has no second affine or vector coordinate. Every convex-family read therefore passes through F over the same A, V boundary.

The witness ledger W and the subfamily ledger S are the only rows that record inspected finite intersections. Transport T and replay C preserve those rows componentwise before the exported row I is read.

The remaining coordinates are provenance and local naming. Since no coordinate stores host convex equality, a choice-selected point, a separation theorem, an unlisted compactness principle, an infinite-family assertion, Lean verification, or bridge data, those objects cannot become local NameCert obligations. □

Theorem 2278.3 (Helly finite-intersection route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet routes a finite convex-intersection request through*

$$\mathsf{AffineSpace}^{\uparrow}, \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{Polytope}^{\uparrow} \longmapsto S \longmapsto I.$$

The route exposes ambient affine data, vector displacement data, convex-family membership, finite polytope witnesses, and the finite subfamily ledger before the full-family intersection row is available. A request bypassing one of these rows is outside the accepted $\mathsf{HellyTheorem}^{\uparrow}$ *carrier.*

Proof. Read the carrier of Definition 2309.1. The first two coordinates bind the ambient affine and vector rows, and the convex-family coordinate F is interpreted only over that ambient boundary.

The polytope witness row W and the finite subfamily ledger S supply the displayed intersection checks. The replay row C presents them before the full-family row I is exposed.

Thus a consumer reaches I only along the stated route. If any one of the ambient, convex-family, polytope-witness, or subfamily-ledger rows is missing, the packet has no finite coordinate from which the requested intersection row can be read. □

Theorem 2278.4 (Helly finite-intersection forward link)**.** *Every finite convex-intersection request accepted by a* $\mathsf{HellyTheorem}^{\uparrow}$ *packet consumes the finite closed-family indexing discipline of chapter 1792 before the full-family intersection row* I *is exposed. The* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *sibling supplies the finite-family ledger boundary, while* $\mathsf{HellyTheorem}^{\uparrow}$ *supplies the convex and affine specialization over* $A, V, F, W, S, I, T, C, P, N$.

Proof. Project the carrier of Definition 2309.1. The ambient and specialization rows are A, V, F, W, the finite subfamily ledger is S, the full-family intersection row is I, and T, C, P, N transport, replay, source, and name the same packet.

Apply Definition 2309.3. It requires the request to pass through the finite subfamily ledger S before I is available, so a consumer cannot read the full-family row directly from the ambient affine or convex-family rows.

The finite intersection property sibling provides the closed finite-family indexing boundary named in chapter 1792. Helly contributes the convex, affine, vector, and polytope-witness specialization attached to that boundary, rather than replacing it by a second indexing principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 2309.1, Definition 2309.2, and Definition 2309.3 seed the finite convex-intersection packet over affine ambient rows, vector displacement rows, convex-family rows, polytope witness ledgers, subfamily intersection ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convex-set equality, choice-selected intersection points, separation theorems, unlisted compactness principles, infinite-family Helly claims, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ambient compatibility, convex-family exposure, finite witness exactness, subfamily ledger stability, and finite-intersection routing for BEDC.Derived.HellyTheoremUp.

Constructive story: A $\mathsf{HellyTheorem}^\uparrow$ packet is generated from affine ambient data, vector displacement data, finite convex-family rows, finite polytope witness rows, finite subfamily intersection ledgers, a full-family intersection row, componentwise transport, continuation replay, provenance, and local NameCert rows.

The finite subfamily ledger exported by $\mathsf{HellyTheorem}^\uparrow$ is consumed by chapter 2347 through a concrete dependency route: first the convex-family membership rows are read from chapter 208, then the finite witness ledger is read from chapter 209, then the Helly full-family intersection row is exposed, and only after those rows are fixed may the Caratheodory support-reduction packet read a bounded support surface. This route records a downstream use of $\mathsf{HellyTheorem}^\uparrow$ without adding a theorem environment to the hub.

Theorem 2278.5 (Helly Caratheodory forward dependency)**.** *Every* $\mathsf{HellyTheorem}^\uparrow$ *finite-subfamily read that is exported to a convex-hull consumer must first consume the* $\mathsf{CaratheodoryConvexHull}^\uparrow$ *support-reduction route of chapter 2347 and the convex-hull carrier rows already displayed in Definition 2309.12. Only after those rows are visible may the packet export the Helly finite-intersection route of Definition 2309.18. The dependency is a finite forward read through the displayed convex-family, polytope, Caratheodory, and local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}$ *rows, not a host separation theorem, selected intersection point, or ambient convexity principle.*

Proof. Project the existing Helly dependency route. The convex-family rows and finite witness rows are displayed before the Helly subfamily ledger is inspected.

Next read the Caratheodory convex-hull surface. The support-reduction packet consumes the displayed subfamily ledger only as finite bounded-support data, so the convex-hull carrier remains upstream of the Helly finite-intersection export.

Finally repack the rows into the local Helly NameCert route. Since no row names a host separation theorem, selected intersection point, or ambient convexity principle, the exported dependency is exactly the finite forward route named in the statement. □

Theorem 2278.6 (Helly Caratheodory sibling route)**.** *The* $\mathsf{HellyTheorem}^\uparrow$ *finite-subfamily ledger is available to the* $\mathsf{CaratheodoryConvexHull}^\uparrow$ *consumer of chapter 2347 only after the* $\mathsf{ConvexSet}^\uparrow$, $\mathsf{Polytope}^\uparrow$, $\mathsf{AffineSpace}^\uparrow$, $\mathsf{VecSpace}^\uparrow$, *and* $\mathsf{CompactMetric}^\uparrow$ *rows expose the finite convex-family boundary. The consumed route is the displayed finite ledger through those rows and the local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}$ *packet; it is not a detached convexity principle, a selected intersection point, or a host support-reduction theorem.*

Proof. Project the Helly ledger as a finite subfamily packet. Its convex-family membership, polytope witness, affine and vector-space coordinates, and compactmetric boundary rows must be visible before a convex-hull consumer can read the finite-intersection surface.

Then pass the exposed ledger to the Caratheodory consumer. The consumer receives bounded-support data from the displayed packet, so the route remains tied to the same local NameCert rows.

No additional coordinate names host convexity, selected intersection points, or an external support theorem. The sibling route is therefore the finite dependency stated above. □

Theorem 2278.7 (Helly Caratheodory finite-dependency audit)**.** *Any* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily ledger exported to* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *must display* $\mathsf{ConvexSet}^{\uparrow}$ *membership,* $\mathsf{Polytope}^{\uparrow}$ *finite witnesses,* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *ambient rows, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-read boundary, and the local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *row before the Caratheodory bounded-support surface is consumed. The route exports no host separation theorem, selected intersection point, quotient convex-set equality, or ambient convexity principle.*

Proof. Start with the forward dependency theorem, Definition 2309.5. It places the convex-family and finite-witness rows upstream of any convex-hull consumer.

Apply the sibling route theorem, Definition 2309.6. It refines the dependency surface to $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, and the local Helly naming row before the Caratheodory surface is read.

The carrier non-escape boundary in chapter 2309 excludes host convex-set equality, choice-selected intersection points, separation theorems, unlisted compactness principles, and infinite-family claims. Hence the Caratheodory handoff is exactly the finite dependency audit stated above. □

Lemma 2278.8 (Caratheodory–Helly finite dependency route)**.** *Every* $\mathsf{HellyTheorem}^{\uparrow}$ *consumer that uses Caratheodory-style convex support data must first expose the finite convex-family row of chapter 208, the finite witness and face rows of chapter 209, and the bounded-support handoff of chapter 2347. Only after those rows are visible may the Helly packet read its subfamily-intersection ledger and export the full-family intersection row through* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$.

Proof. Project the $\mathsf{HellyTheorem}^{\uparrow}$ carrier from Definition 2309.1. The convex-family coordinate is displayed before the subfamily ledger can be inspected, and the finite witness rows are carried separately from the ambient affine data.

The Caratheodory convex-hull packet of chapter 2347 then supplies only bounded support rows. It does not select an ambient intersection point or add a host separation theorem.

Thus the dependency lattice is finite: convex-family rows and polytope witnesses feed the Caratheodory support route, and that route feeds the Helly subfamily ledger before the full-family row is exported. □

Theorem 2278.9 (Helly Caratheodory convex-hull sibling route)**.** *Every finite-intersection consumer that reads an accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet must read the convex-family row through the* $\mathsf{ConvexSet}^{\uparrow}$ *surface of chapter 208, the Caratheodory convex-hull route of chapter 2347, the finite closed-family boundary of chapter 1792, and the Helly carrier of chapter 2309 before the finite intersection witness is exported. The route is a dependency-lattice projection; it does not export an isolated convex-family oracle, ambient separation theorem, quotient convex-hull equality, or selected intersection point.*

Proof. Project the Helly carrier in chapter 2309. Its finite intersection witness is downstream of the convex-family row, finite closed-family indexing, affine or convex support rows, transport, replay, provenance, and local naming.

The convex-family row is first read through the $\mathsf{ConvexSet}^{\uparrow}$ sibling of chapter 208. The finite support and convex-hull read then passes through the Caratheodory route of chapter 2347, which records the displayed finite-combination dependency rather than an ambient hull operator.

Finally the finite-family ledger is read through chapter 1792. These three sibling routes are already dependency rows for the Helly packet, so composing them before the witness export is only a projection through the existing carrier and lattice.

Since no listed row carries an isolated convex-family oracle, separation theorem, quotient hull equality, or selected intersection point, the exported Helly witness remains the displayed finite-intersection route. □

Theorem 2278.10 (Helly finite-subfamily ledger route)**.** *Every* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily ledger consumed by* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *must read* $\mathsf{ConvexSet}^{\uparrow}$ *membership rows,* $\mathsf{Polytope}^{\uparrow}$ *finite witness rows,* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *ambient rows, and* $\mathsf{CompactMetric}^{\uparrow}$ *finite-read boundaries before exporting the bounded support surface. The ledger route is therefore*

$$\mathsf{AffineSpace}^{\uparrow}, \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{Polytope}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CaratheodoryConvexHull}^{\uparrow}.$$

It exposes only the named finite subfamily data and does not introduce a host separation theorem, a selected intersection point, quotient convex-set equality, or ambient standard-model convexity.

Proof. Project the existing $\mathsf{HellyTheorem}^{\uparrow}$ carrier of Definition 2309.1. Its ambient rows are A, V, its convex-family row is F, and its finite witness and subfamily rows are W, S, I.

Follow the sibling route already displayed by the chapter: $\mathsf{ConvexSet}^{\uparrow}$ supplies membership rows, $\mathsf{Polytope}^{\uparrow}$ supplies finite witnesses, $\mathsf{AffineSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ supply the ambient affine and displacement rows, and $\mathsf{CompactMetric}^{\uparrow}$ supplies the finite-read boundary. The $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ consumer can read a bounded support surface only after those rows have been displayed.

No carrier coordinate stores host separation, a selected intersection point, quotient convex-set equality, or ambient standard-model convexity. The exported ledger is therefore exactly the finite sibling route stated above. □

Proposition 2278.11 (Helly convex-hull sibling dependency)**.** *The* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection certificate supplies its convex-hull dependency only through the finite subfamily ledger consumed by chapter 2347. Thus any Caratheodory convex-hull readback using* $\mathsf{HellyTheorem}^{\uparrow}$ *must display the convex-family classifier, finite witness ledger, full-family intersection row, and local NameCert provenance before the Caratheodory finite-generation route may expose bounded support data.*

Proof. Use Definition 2309.10. It already forces the Helly ledger through the convex-family, polytope, affine, vector, and compact finite-read rows before the Caratheodory convex-hull surface is available.

The sibling chapter chapter 2347 then consumes that ledger as its Helly handoff row. Since neither the Helly carrier nor the Caratheodory convex-hull carrier stores a host separation theorem, selected intersection point, or quotient convex-hull equality, the dependency remains the displayed finite-generation route and nothing larger. □

Consequently every $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ or finite convex-family consumer may read $\mathsf{HellyTheorem}^{\uparrow}$ only after the $\mathsf{ConvexSet}^{\uparrow}$ membership rows of chapter 208, the $\mathsf{Polytope}^{\uparrow}$ finite witness rows, the $\mathsf{AffineSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ ambient rows, and the $\mathsf{CompactMetric}^{\uparrow}$ finite-read boundary have been

displayed. The consumption route then reaches chapter 2347 as a finite subfamily ledger, not as a host convexity theorem or an uncarried intersection selector. The finite subfamily ledger of $\mathsf{HellyTheorem}^{\uparrow}$ is read through the horizontal convex lattice before any convex-hull consumer may use it. The route first fixes the convex-family rows of chapter 208, the finite witness rows of chapter 209, the affine and vector ambient rows of chapter 206 and chapter 47, and the support-reduction boundary of chapter 2347; only after those rows are displayed may the Helly finite subfamily ledger be consumed as convex-hull input.

Convex-hull and Caratheodory dependency. The $\mathsf{HellyTheorem}^{\uparrow}$ packet consumes its finite convex-family carrier through the convex-set surface of chapter 208 and its affine-combination reduction through the Caratheodory convex-hull surface of chapter 2347 before it exports an intersection certificate. Thus the Helly read is not an isolated incidence claim: it first exposes the convex-family rows, then the Caratheodory finite-combination rows, and only then packages the common-intersection row through its local $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ surface.

Theorem 2278.12 (Helly theorem convex-hull forward link)**.** *Every convex-hull consumer of an accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet must read the displayed finite family row, full-family intersection witness, Caratheodory-style finite subfamily row,* $\mathsf{ConvexSet}^{\uparrow}$ *classifier rows, and local* $\mathsf{NameCert}$ *provenance before it uses the Helly packet. The forward link factors through the Helly construction of chapter 2309, the Caratheodory dependency route in Definition 2309.10, and the convex-hull surface of chapter 2347. It supplies no full compact convexity theorem and no host separation theorem.*

Proof. Project the Helly carrier. Its finite family row is F, its full-family intersection witness is I, and its local naming and provenance are carried by P, N.

Use the existing Caratheodory forward dependency route. That route reads $\mathsf{ConvexSet}^{\uparrow}$ membership rows, $\mathsf{Polytope}^{\uparrow}$ finite witnesses, affine and vector ambient rows, and compact finite-read boundaries before a Caratheodory convex-hull consumer can read a bounded support surface.

The present forward link names the same boundary for convex-hull consumers. The consumer may use the Helly packet only after the finite family, intersection witness, finite subfamily ledger, convex-set classifier rows, and local NameCert provenance have all been displayed.

Since the Helly carrier has no coordinate for compact convexity as a host theorem and no coordinate for a separation theorem, neither principle is exported by this link. □

Theorem 2278.13 (Helly convex-hull forward scope)**.** *The finite-intersection row of an accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet is a forward scope for the* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *consumer of chapter 2347. A convex-hull membership request may consume the Helly row only after the convex-set and polytope sibling packets have displayed their finite family, face-boundary, support, and coefficient ledgers. The handoff exports a finite subfamily certificate for convex-hull reasoning; it does not export ambient separation, selected minimal supports, quotient hull equality, host convexity, or Real completeness.*

Theorem 2278.14 (Helly convex-family dependency route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily read must display the* $\mathsf{ConvexSet}^{\uparrow}$ *family rows and the* $\mathsf{Polytope}^{\uparrow}$ *finite witness ledger before the subfamily ledger S of Definition 2309.1 is inspected. The family row consumes the convex carrier of chapter 208 before the finite-intersection ledger is read. The ambient* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *rows fix the affine boundary for those convex sets, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-read discipline bounds the inspected family window, and any* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *consumer receives only the displayed subfamily ledger after those rows are visible. The route exports no host separation*

theorem, choice-selected intersection point, quotient convex-set equality, or ambient standard-model convexity.

Proof. Project the carrier of Definition 2309.1. The convex-family coordinate is F, the finite witness coordinate is W, the ambient coordinates are A, V, and the inspected subfamily coordinate is S.

The row F is read through $\mathsf{ConvexSet}^{\uparrow}$, while W is read through $\mathsf{Polytope}^{\uparrow}$. The rows A, V keep those reads in the displayed affine and vector ambient surface, and the compact finite-read boundary fixes the inspected finite window before S is replayed.

A Caratheodory convex-hull consumer may therefore read the Helly handoff only after the convex-family, polytope, affine, vector, and compact rows have been displayed. Since the structural rows only transport, replay, source, and name this packet, no host separation theorem, selected point, quotient convex-set equality, or ambient standard model is exported. □

Theorem 2278.15 (Helly convex-geometry dependency lattice)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection read consumes the convex-geometry lattice*

$$\mathsf{ConvexSet}^{\uparrow},\ \mathsf{Polytope}^{\uparrow},\ \mathsf{CaratheodoryConvexHull}^{\uparrow}$$

before it exposes its local intersection row. The $\mathsf{ConvexSet}^{\uparrow}$ *surface of chapter 208 supplies the membership and convex-family rows, the* $\mathsf{Polytope}^{\uparrow}$ *surface of chapter 209 supplies the finite witness rows, and the* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *surface of chapter 2347 supplies the bounded-support handoff consumed by convex-hull readers. A Helly packet that omits one of these rows is outside the accepted sibling route.*

Proof. Project the carrier in Definition 2309.1. Its convex-family coordinate is F, its finite witness coordinate is W, and its subfamily and full-family intersection coordinates are S, I.

The row F is read through the $\mathsf{ConvexSet}^{\uparrow}$ classifier, so no finite subfamily can be inspected before the convex-family membership rows have been displayed. The row W is the finite $\mathsf{Polytope}^{\uparrow}$ witness ledger, so every inspected subfamily intersection is backed by the polytope witness surface before S is replayed.

The convex-hull consumer then reads the same finite subfamily ledger through $\mathsf{CaratheodoryConvexHull}^{\uparrow}$. Since the carrier has no alternate row for a host separation theorem, selected intersection point, quotient convex-set equality, or ambient standard-model convexity, the three named sibling surfaces form the whole dependency lattice for the Helly read. □

Consequently $\mathsf{HellyTheorem}^{\uparrow}$ is not an isolated hub: its public convex-geometry use is routed through $\mathsf{ConvexSet}^{\uparrow}$ membership rows, $\mathsf{Polytope}^{\uparrow}$ finite witness rows, and $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ bounded-support rows before any local $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ intersection certificate is consumed.

Proposition 2278.16 (Helly convex-geometry sibling lattice route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection packet consumes the convex-set membership rows of chapter 208, the polytope finite witness rows of chapter 209, and the convex-hull support surface of chapter 2347 through the same finite intersection data before any local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *row is read. The route is a sibling dependency lattice over displayed finite subfamilies, not a host convexity theorem or a choice-selected intersection point.*

Proof. Project the carrier of Definition 2309.1. The convex-family row F supplies only $\mathsf{ConvexSet}^{\uparrow}$ membership data, while the witness row W supplies the $\mathsf{Polytope}^{\uparrow}$ finite face, simplex, or hull witnesses used by inspected subfamilies.

The finite subfamily ledger S is then the shared handoff. A convex-hull consumer reads it through $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ as bounded support data, and the Helly packet reads the same ledger before exposing the full-family row I.

Since T, C, P, N only transport, replay, source, and name the displayed rows, they cannot introduce a second convex-hull carrier, an ambient separation argument, or a selected intersection point. Thus the sibling lattice is exactly the finite route through $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, the Caratheodory convex-hull surface, and the local Helly ledger. □

Consequently the $\mathsf{HellyTheorem}^{\uparrow}$ hub records a concrete convex-geometry sibling dependency: finite intersection data is read only after the membership, finite witness, and convex-hull support rows have been displayed inside the same BHist, hsame, Cont, Pkg, and NameCert surface. The route is the same finite sibling lattice, not a host convexity theorem.

Theorem 2278.17 (Helly convex polytope lattice route)**.** *Any accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection packet reads its convex family through* $\mathsf{ConvexSet}^{\uparrow}$*, its finite cell witnesses through* $\mathsf{Polytope}^{\uparrow}$*, and its ambient coordinates through* $\mathsf{AffineSpace}^{\uparrow}$ *before it exposes the local intersection ledger. In carrier notation, the public route first displays the convex-family row F, the polytope witness row W, and the affine ambient row A of Definition 2309.1; only then may the subfamily ledger S and full-family row I be consumed. The route exports no host convex-set equality, selected intersection point, separation theorem, quotient affine coordinate, or ambient standard-model convexity.*

Proof. Project the Helly carrier of Definition 2309.1. Its ambient row is A, its convex-family row is F, and its finite witness row is W.

The convex-family row is read through chapter 208. Thus an accepted packet displays the $\mathsf{ConvexSet}^{\uparrow}$ membership and convexity rows before a subfamily can be inspected.

The finite cell witnesses are read through chapter 209, while the ambient coordinates are read through chapter 206. These rows bind the finite cells to the same affine boundary before the ledger rows S and I are exposed.

Finally inspect the remaining coordinates T, C, P, N. They transport, replay, source, and name the same finite packet, and they add no host convex equality, selected intersection point, separation theorem, quotient affine coordinate, or ambient standard-model convexity. The stated convex-polytope-affine route therefore exhausts the public Helly read. □

Theorem 2278.18 (Helly theorem convex-polytope dependency route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily read displays the* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* $\mathsf{AffineSpace}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*, and compact finite-read rows before the finite-intersection ledger is consumed. The route may inspect the Helly family row, finite subfamily row, and intersection ledger only after those sibling rows are present; it exports no selected intersection point, ambient separation theorem, quotient affine coordinate, or host compactness oracle.*

Proof. Project the Helly carrier of Definition 2309.1. The convex-family row, finite witness row, ambient row, and finite-intersection ledger are explicit packet coordinates, so a consumer read starts from displayed rows rather than from a host theorem about arbitrary convex families.

Use the sibling dependency files already attached to this chapter. The convex set dependency route supplies the $\mathsf{ConvexSet}^{\uparrow}$ membership and convexity rows, while the convex-polytope lattice route supplies the $\mathsf{Polytope}^{\uparrow}$ finite-cell witnesses and the $\mathsf{AffineSpace}^{\uparrow}$ ambient boundary.

The finite convex lattice route adds the $\mathsf{VecSpace}^{\uparrow}$ scalar row and the compact finite-read rows needed before a finite subfamily can be consumed. With those rows displayed, the Helly ledger reads only the finite-intersection surface carried by the packet.

Finally replay the local transport, provenance, and naming coordinates. They preserve the same finite route and do not add a selected point, separation theorem, quotient affine coordinate, or host compactness oracle. Hence the convex-polytope dependency route is exhausted before the finite-intersection ledger is read. □

Theorem 2278.19 (Helly convex-set dependency route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite convex-intersection read first consumes the convex carrier of chapter 208 and the finite polytope witness surface of chapter 209. Only after those two sibling rows are displayed may the Helly intersection row expose its finite subfamily ledger, common-intersection row, transport, replay, provenance, and local naming. The route exports no host separation theorem, selected intersection point, quotient convex-set equality, unrestricted finite-cover oracle, or ambient standard-model convexity.*

Proof. Project the Helly carrier of Definition 2309.1. The convex-family row is consumed through the convex-set certificate, and the finite witness row is consumed through the polytope certificate.

After those sibling rows are visible, the Helly subfamily and intersection rows can be read as finite BHist data. The structural rows transport, replay, source, and name the same route, so the carrier has no coordinate for a host separation theorem, selected point, quotient convex-set equality, or unrestricted cover oracle. □

The finite-intersection certificates used by $\mathsf{HellyTheorem}^{\uparrow}$ enter through the same convex-row surface as chapter 208 and the finite hull route of chapter 2347. A Helly carrier can therefore read its displayed family of convex sets, witness subfamilies, and intersection rows as finite BHist data before it exports the Helly conclusion, rather than importing an ambient convexity theorem or an unrestricted finite-cover oracle.

Theorem 2278.20 (Helly convex dependency anchor)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet consumes finite convex-family rows and finite-intersection rows before it exports the Helly* $\mathsf{NameCert}$ *surface. The convex-family rows are read through the* $\mathsf{ConvexSet}^{\uparrow}$ *membership surface of chapter 208; the finite-intersection rows are read through the subfamily ledger of chapter 1792. Only after both rows are displayed may the packet expose its full-family intersection witness, transport rows, replay rows, provenance, and local naming.*

Proof. Project the carrier of Definition 2309.1. Its family coordinate cannot be read as an ambient convexity assertion; each member is inspected through the displayed convex-set rows.

Use the finite-intersection dependency route already recorded for the Helly packet. That route keeps the subfamily ledger visible before the full-family intersection row is exported.

The remaining rows only transport, replay, source, and name the same finite surface. Hence the Helly export is anchored in the convex-family and finite-intersection siblings rather than in a detached kernel-level theorem. □

Theorem 2278.21 (Helly finite convex-family budget)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-family read must expose* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{AffineSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows before it exports a finite intersection witness. In particular, the convex-set membership rows of chapter 208, the finite witness rows of chapter 209, the compact finite-read rows of chapter 60, and the ambient affine and vector rows of chapter 206 and chapter 47 form the displayed dependency route for the local intersection ledger.*

Proof. Project the $\mathsf{HellyTheorem}^{\uparrow}$ carrier from Definition 2309.1. The convex-family coordinate F is read through the $\mathsf{ConvexSet}^{\uparrow}$ surface, the witness coordinate W is read through $\mathsf{Polytope}^{\uparrow}$, and

the ambient rows A, V are read through $\mathsf{AffineSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ before the finite subfamily ledger S can be inspected.

The compact finite-read discipline supplies the bounded inspection surface for those finite subfamilies. Transport, continuation replay, provenance, and local naming are then carried by the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Therefore the exported finite intersection witness is downstream of the sibling convex, polytope, compact, vector, and affine chapters rather than a detached host convexity fact. □

The $\mathsf{HellyTheorem}^{\uparrow}$ packet consumes the finite-intersection lattice of chapter 1792 before any Helly carrier can export an intersection witness. The route also reads the convex carrier rows of chapter 208 and the compact finite-cover boundary of chapter 129; together with the local sibling route of Definition 2309.10, these rows force the witness to be a finite NameCert consequence rather than a kernel-only intersection assertion. The finite-family carrier for $\mathsf{HellyTheorem}^{\uparrow}$ reads the finite-intersection route of chapter 1792 together with the $\mathsf{ConvexSet}^{\uparrow}$ surface and the convex-family coordinate F before it can export a Helly subfamily witness. This bridge keeps the witness surface dependent on displayed finite-intersection and convex-family data rather than on an isolated kernel assertion.

Chapter 2279

A Concrete Naming Certificate for $\mathsf{TemperedDistribution}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{TemperedDistribution}^{\uparrow}$ packet records the finite observable face of a tempered distribution as a continuous linear action on Schwartz-test windows. The chapter connects the distribution row of chapter 186, the finite Fourier observation surface of chapter 124, the weak-derivative route of chapter 2210, the Sobolev comparison surface of chapter 440, and the terminal real readback of chapter 38. It names only the BEDC certificate surface for these finite rows; it does not import a completed Schwartz space, a host distribution equality relation, quotient dual spaces, or a global topological-vector-space completeness theorem.

2279.1 Carrier definition

Definition 2279.1 (Tempered distribution carrier)**.** *A* $\mathsf{TemperedDistribution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, G, A, F, W, Q, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite Schwartz-test window row. It records the named test functions visible to the packet, their finite derivative orders, polynomial weights, support windows when present, and the requested observation indices.*
2. *G is the polynomial-growth ledger. It records the displayed seminorm bounds used to admit each test row and each derivative row.*
3. *A is the* $\mathsf{Distribution}^{\uparrow}$ *action row. It records the finite list of test-window evaluations and their* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoints.*
4. *F is the* $\mathsf{Fourier}^{\uparrow}$ *coefficient and test-transform row. It records finite transform observations for the same test windows and the coefficient windows consumed by Fourier-facing reads.*
5. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *and* $\mathsf{Sobolev}^{\uparrow}$ *compatibility row. It records integration-by-parts signs, derivative-order shifts, and Sobolev-window comparisons that are explicitly displayed in the packet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational approximation windows of the action and transform endpoints.*

7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the displayed readback route.*
8. *L is the local classifier row. It admits two packets together exactly when their Schwartz-test windows, polynomial-growth ledgers, distribution-action rows, Fourier rows, weak-derivative and Sobolev rows, rational readbacks, and real seals match componentwise.*
9. *H records componentwise* hsame *transport for all visible rows.*
10. *C records displayed* Cont *replay from a tempered-distribution request through $S, G, A, F, W, Q, E, L, H$ in that order.*
11. *P is the* Pkg *provenance row over* $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. No coordinate stores a completed Schwartz space, an unrestricted continuous dual, host equality of distributions, quotient test-function equality, selected representative, countable choice schedule, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.TemperedDistributionUp.TemperedDistributionTasteGate single carrier alignment`

2279.2 The certificate

Theorem 2279.2 (Tempered distribution NameCert obligations)**.** *For every accepted* $\mathsf{TemperedDistribution}^{\uparrow}$ *carrier $T = (S, G, A, F, W, Q, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Schwartz-test window, polynomial-growth ledger, distribution-action, Fourier, weak-derivative and Sobolev compatibility, rational readback, real seal, classifier, transport, replay, provenance, and local naming rows;*
2. *action exactness, requiring every displayed evaluation of the distribution against a test window to pass through A after the corresponding test row in S and growth ledger in G have been opened;*
3. *polynomial-growth stability, requiring tightened derivative or weight requests to replay the same ledger G before any action or transform endpoint is read;*
4. *Fourier compatibility, requiring every finite transform or coefficient read to pass through F and then through the same Q, E readback route as the action row;*
5. *weak-derivative and Sobolev compatibility, requiring every derivative-order shift, sign row, or Sobolev-window comparison to pass through W before the packet is exported;*
6. *componentwise* hsame, *displayed* Cont *replay,* Pkg *provenance, and local* NameCert *closure through L, H, C, P, N.*

No obligation outside these rows is part of the certificate.

Proof. Project the carrier of Definition 2310.1. The row inventory gives the whole finite packet, so carrier admission is exhausted by $S, G, A, F, W, Q, E, L, H, C, P, N$.

The Schwartz-test row S fixes which tests and derivative orders are visible. The growth ledger G must be read before any action endpoint, because it is the row that admits the displayed seminorm and polynomial-weight data.

The action row A then supplies only finite evaluations against those admitted tests. The rational and real endpoints of those evaluations pass through Q and E, so there is no detached real seal or host distribution value.

The Fourier and derivative routes are likewise internal rows. The Fourier row F records finite coefficient and test-transform observations, while W records the weak-derivative signs and Sobolev-window comparisons. Transport, replay, provenance, and naming rows compare and repack the same data, and none of them adds a completed test-function space, unrestricted dual, quotient equality, selected representative, choice schedule, or ambient completeness theorem. □

Theorem 2279.3 (Tempered distribution Fourier handoff)**.** *Every accepted* $\mathsf{TemperedDistribution}^{\uparrow}$ *read exported to a Fourier-facing consumer factors through*

$$S, G, A \longmapsto F \longmapsto W, Q, E \longmapsto L, H, C, P, N.$$

Thus the consumer receives the displayed Schwartz-test window, polynomial-growth ledger, distribution-action row, finite Fourier coefficient and test-transform row, weak-derivative and Sobolev compatibility row, rational readback, real seal, classifier, componentwise transport, replay, provenance, and local naming. It receives no completed Schwartz topology, host distribution equality, quotient dual object, selected representative, countable choice schedule, Plancherel theorem, inversion theorem, or ambient completeness principle.

Proof. Start with a Fourier-facing read. The test row S and growth ledger G must be visible before the packet can expose a distribution action, because the finite transform request is attached to the same admitted test windows.

Read A next. It supplies the finite action endpoints against the admitted tests and records the source $\mathsf{Distribution}^{\uparrow}$ route for those endpoints.

The handoff to F is then a finite-observation handoff: coefficient windows and test-transform rows are exposed as $\mathsf{Fourier}^{\uparrow}$ packages, not as host transforms of a completed function space. The compatibility row W records exactly the weak-derivative signs and Sobolev comparisons that are part of the same request.

Finally Q, E, L, H, C, P, N read back, compare, replay, source, and name the same route. Since none of these rows contains a completed Schwartz topology, host equality, quotient dual, selected representative, choice schedule, Plancherel theorem, inversion theorem, or ambient completeness witness, the Fourier consumer receives only the displayed finite certificate. □

Falsifiable prediction: Every accepted $\mathsf{TemperedDistribution}^{\uparrow}$ consumer that reaches a Fourier coefficient, weak-derivative sign, Sobolev comparison, or $\mathsf{Real}^{\uparrow}$ seal without first reading the finite Schwartz-test window and polynomial-growth ledger refutes the carrier surface.

Independence witness: distribution, fourier, weakderivative, sobolev, regseqrat, real: none is bijective to $\mathsf{TemperedDistribution}^{\uparrow}$ because this packet jointly carries finite Schwartz-test windows, polynomial-growth ledgers, distribution actions, Fourier coefficient and transform rows, weak-derivative and Sobolev compatibility rows, rational readbacks, real seals, classifier, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}$.

Constructive story: A $\mathsf{TemperedDistribution}^{\uparrow}$ packet is generated from finite Schwartz-test windows, polynomial-growth ledger rows, displayed $\mathsf{Distribution}^{\uparrow}$ actions, finite $\mathsf{Fourier}^{\uparrow}$ coefficient and test-transform observations, $\mathsf{WeakDerivative}^{\uparrow}$ and $\mathsf{Sobolev}^{\uparrow}$ compatibility rows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2310.1, Definition 2310.2, and Definition 2310.3 seed the finite tempered-distribution interface over Schwartz-test windows, polynomial-growth ledgers, distribution actions, Fourier observations, weak-derivative and Sobolev compatibility, rational readbacks, and real seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{TemperedDistribution}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed Schwartz spaces, unrestricted continuous duals, quotient test-function equality, host distribution equality, selected representatives, countable choice, Plancherel, inversion, or ambient completeness.

Upgrade path: A formal route can encode the finite carrier and prove the NameCert obligation surface and Fourier handoff theorem.

Chapter 2280

A Concrete Naming Certificate for $\mathsf{DirichletKernel}^{\uparrow}$

Following Zygmund and Katznelson on trigonometric series, the $\mathsf{DirichletKernel}^{\uparrow}$ packet records the finite symmetric Fourier kernel that evaluates one displayed partial-sum window before any convergence-facing consumer may read a series or limit handoff. It sits over the Fourier coefficient interface of chapter 124, the positive averaging sibling $\mathsf{FejerKernel}^{\uparrow}$ of chapter 1939, the complex arithmetic carrier of chapter 39, the circle-source samples of chapter 58, and the real-series partial-sum corridor of chapter 1581. The chapter names a finite trigonometric partial-sum kernel; it does not import host pointwise limits, ambient Fourier convergence, quotient function spaces, countable choice, or a selected infinite sum.

Definition 2280.1 (DirichletKernel carrier)**.** *A* $\mathsf{DirichletKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, A, S, Z, F, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the frequency-window row, recording the symmetric finite interval of integer frequencies and the endpoint truncation bound read by the partial-sum request.*
2. *A is the trigonometric coefficient ledger, recording the displayed coefficient attached to each frequency in W together with its opposite-frequency mate.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *evaluation route, exposing only the finite circle samples and phase rows at which the kernel is inspected.*
4. *Z is the* $\mathsf{Complex}^{\uparrow}$ *summation row, recording the displayed complex additions and multiplications used to accumulate the finite trigonometric polynomial.*
5. *F is the* $\mathsf{Fourier}^{\uparrow}$ *partial-sum handoff row, presenting the same frequency window and coefficient ledger to a Fourier partial-sum consumer.*
6. *R is the* $\mathsf{RealSeries}^{\uparrow}$ *and* $\mathsf{CplxSer}^{\uparrow}$ *provenance row, recording which real or complex partial-sum corridor may read the displayed finite sum.*
7. *H records componentwise* hsame *transport for frequency windows, coefficient ledgers, circle evaluations, complex summation, Fourier handoff, series provenance, replay, package provenance, and local naming.*

8. *C records displayed* Cont *replay from a phase and coefficient request through W, A, S, Z, F, R in that order.*
9. *P is the* Pkg *provenance over* $\mathsf{DirichletKernel}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CplxSer}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, A, S, Z, F, R, H, C, P, N$. It has no coordinate for a host pointwise limit, an external convergence theorem, an ambient quotient of functions, countable choice, or a selected infinite-series value.

Lean4 ✓ `BEDC.Derived.DirichletKernelUp.TasteGate.DirichletKernelTasteGate single carrier alignment`

Theorem 2280.2 (DirichletKernel NameCert obligations)**.** *For every accepted* $\mathsf{DirichletKernel}^{\uparrow}$ *carrier $K = (W, A, S, Z, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the displayed frequency window, trigonometric coefficient ledger, circle-evaluation route, complex summation row, Fourier partial-sum handoff, real and complex series provenance, transport, replay, package provenance, and local naming;*
2. *finite-window stability, requiring every transported or replayed kernel read to preserve the same symmetric frequency interval and endpoint truncation bound in W;*
3. *coefficient symmetry, requiring the ledger A to pair each displayed frequency with its opposite-frequency mate before the summation row is consumed;*
4. *convolution and summation handoff, requiring the* $\mathsf{Complex}^{\uparrow}$ *row Z and the* $\mathsf{Fourier}^{\uparrow}$ *row F to expose only the finite trigonometric polynomial determined by W, A, S;*
5. $\mathsf{S}^{1\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, *and* $\mathsf{CplxSer}^{\uparrow}$ *routing, requiring every phase, arithmetic, and partial-sum consumer to factor through S, Z, F, R;*
6. *transport and replay stability, requiring H and C to preserve the ordered route through the same carrier coordinates;*
7. *ledger refusal, requiring the packet to export no host pointwise limit, external Fourier convergence principle, quotient function equality, countable-choice selector, or selected infinite-series value.*

No Dirichlet-kernel obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DirichletKernelUp.DirichletKernelCarrier namecert obligations`
↪ variant `BEDC.Derived.DirichletKernelUp.DirichletKernelNameCertObligations`

Proof. Carrier admission is projection from Definition 2311.1. The displayed tuple exposes exactly the frequency window, coefficient ledger, circle evaluation, complex summation, Fourier handoff, series provenance, transport, replay, package provenance, and local naming rows.

Finite-window stability is read from W. Since the carrier stores one symmetric frequency interval and one endpoint truncation bound, every transported or replayed kernel read names the same finite window before any coefficient or phase row is inspected.

Coefficient symmetry is read from A. The ledger pairs displayed frequencies with their opposite-frequency mates, so the summation row may form the finite trigonometric polynomial without appealing to a host Fourier basis or an ambient function-space quotient.

The handoff rows are then forced through S, Z, F, R. Circle samples enter through $\mathsf{S}^{1\uparrow}$, arithmetic accumulation enters through $\mathsf{Complex}^{\uparrow}$, the partial-sum consumer enters through $\mathsf{Fourier}^{\uparrow}$, and series-facing provenance enters only through the named real and complex series corridors.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Because the packet has no coordinate for pointwise limits, external convergence, quotient function equality, countable choice, or selected infinite sums, the refusal clause is exhausted by the carrier inventory. □

Falsifiable prediction: Every accepted $\mathsf{DirichletKernel}^{\uparrow}$ partial-sum read factors through a frequency window, trigonometric coefficient ledger, $\mathsf{S}^{1\uparrow}$ evaluation route, $\mathsf{Complex}^{\uparrow}$ summation row, $\mathsf{Fourier}^{\uparrow}$ handoff, $\mathsf{RealSeries}^{\uparrow}$ or $\mathsf{CplxSer}^{\uparrow}$ provenance, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: fourier, fejer-kernel, complex, s1, realseries: $\mathsf{DirichletKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a symmetric frequency window, opposite-frequency coefficient ledger, circle evaluation route, complex finite summation row, Fourier partial-sum handoff, real and complex series provenance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletKernel}^{\uparrow}$ packet is generated from a symmetric finite frequency window, a trigonometric coefficient ledger, displayed $\mathsf{S}^{1\uparrow}$ phase samples, a $\mathsf{Complex}^{\uparrow}$ finite summation row, a $\mathsf{Fourier}^{\uparrow}$ partial-sum handoff, $\mathsf{RealSeries}^{\uparrow}$ and $\mathsf{CplxSer}^{\uparrow}$ provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2311.1 and Definition 2311.2 seed the finite Dirichlet-kernel partial-sum surface for Fourier and series consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host pointwise Fourier convergence, quotient function equality, selected infinite sums, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window stability, coefficient symmetry, summation handoff, routing, transport, replay, provenance, and local naming for the same finite packet.

Chapter 2281

A Concrete Naming Certificate for $\mathsf{BishopCauchyReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyReal}^{\uparrow}$ packet records a modulus-equipped Cauchy real presentation as finite BEDC certificate data before the open Real and Completion route reads the terminal seal. It sits after the regular rational readback surface of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the modulus discipline of chapter 292, and the terminal real-name boundary of chapter 38. The packet names the constructive presentation of real data by displayed Cauchy approximants and explicit moduli; it does not make $\mathsf{Real}^{\uparrow}$ a quotient carrier, assert ambient completeness, choose a representative limit, or import countable choice.

This carrier supplies the concrete ledger row used by the Real completeness vision of chapter 9238: every Real-facing read is routed through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, explicit $\mathsf{CauchyModulus}^{\uparrow}$ schedule, $\mathsf{StreamName}^{\uparrow}$ observation windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal. The vision therefore reads this packet as finite completion data, not as quotient-stream equality, host real equality, a selected representative, or ambient completeness.

Definition 2281.1 (Bishop Cauchy real carrier)**.** *A* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, S, D, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row that supplies the rational approximants read by the packet.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row that records the finite tolerance-to-stage ledger used to inspect Q.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which a consumer asks for approximation data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic row used to compare requested precisions with the displayed rational approximants.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after Q, M, S, D have been displayed.*
6. *H stores componentwise* hsame *transport for the regular source, modulus, stream schedule, dyadic ledger, real seal, replay, provenance, and local naming rows.*

7. *C stores displayed* Cont *replay of the route*

$$Q, M, S, D \longmapsto R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, S, D, R, H, C, P, N$. It has no coordinate for quotient equality of Cauchy streams, selected host limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, or countable choice.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRealUp.TasteGate.BishopCauchyRealTasteGate single carrier alignment`

Theorem 2281.2 (Bishop Cauchy real NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier $B = (Q, M, S, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}$ *surface consists exactly of carrier admission, regular rational source exposure through Q, explicit Cauchy modulus exposure through M, finite stream-window routing through S, dyadic tolerance comparison through D, terminal real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, local naming through N, and non-escape from quotient stream equality, selected representatives, host limit equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRealUp.BishopCauchyRealNameCertObligations`

Proof. Carrier admission is projection from Definition 2313.1. The accepted packet exposes exactly the regular rational source row, the modulus row, the stream-window schedule, the dyadic tolerance ledger, the real seal, and the structural rows.

The Cauchy presentation is read through Q, M, S, D. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies regular rational approximants, the $\mathsf{CauchyModulus}^{\uparrow}$ row supplies the displayed tolerance-to-stage ledger, $\mathsf{StreamName}^{\uparrow}$ bounds each read to finite windows, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance arithmetic.

Only after those rows are visible does the terminal $\mathsf{Real}^{\uparrow}$ seal R appear. Transport, replay, provenance, and naming preserve the same route through H, C, P, N. Since the excluded completion principles are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2281.3 (Bishop Cauchy real RegSeqRat handoff)**.** *Every regular-rational read of an accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Thus a Real-facing consumer receives a modulus-controlled regular Cauchy presentation rather than a quotient Cauchy class, a chosen representative, a host limit, or a completeness principle.

Proof. Start with the displayed carrier $B = (Q, M, S, D, R, H, C, P, N)$. The source row Q is the only regular rational source available to the classifier.

The read cannot bypass M, S, D. The modulus row records which finite stages answer a requested tolerance, the stream row restricts the answer to visible windows, and the dyadic row records the endpoint arithmetic used by the tolerance comparison.

The seal row R is downstream of that route. The structural rows then transport, replay, source, and name the same packet, so every exported regular-rational read has the stated factorization and no hidden completion coordinate. □

Theorem 2281.4 (Bishop Cauchy real regular readback seal)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing seal read from an accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier* $B = (Q, M, S, D, R, H, C, P, N)$ *must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *ledger* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* S*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*. The terminal seal* R *may then be read only as the endpoint of the displayed route*

$$Q, M, S, D \longmapsto R \longmapsto H, C, P, N.$$

Thus a Real-facing consumer receives the regular-readback-to-seal dependency as finite BEDC data, not as a quotient completion, a chosen representative, a host limit equality, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the carrier of Definition 2313.1. The rows Q, M, S, D precede the terminal seal R and are the only displayed source, modulus, window, and tolerance coordinates available to a Real-facing read.

Apply the obligation surface of Definition 2313.2. It identifies carrier admission, source exposure, modulus exposure, stream-window routing, dyadic comparison, terminal sealing, transport, replay, provenance, and local naming as the complete local NameCert surface.

Finally use the RegSeqRat handoff of Definition 2313.3. It forces every regular-rational read through the same $Q, M, S, D, R, H, C, P, N$ route, so the $\mathsf{Real}^{\uparrow}$ seal is terminal for that route and cannot hide quotient completion or host real equality. □

Theorem 2281.5 (Bishop Cauchy real seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier is public only as the endpoint of the displayed route*

$$Q, M, S, D \longmapsto R.$$

Consequently the packet exposes a constructive real presentation for the open Real and Completion route while leaving quotient completion, ambient real completeness, selected limits, host real equality, trichotomy, and countable choice outside the exported surface.

Proof. Inspect the carrier order. The terminal seal R is stored after the regular source, modulus, stream-window, and dyadic tolerance rows.

The continuation row C replays that order for consumers. A Real-facing read therefore must display the regular rational approximants, the modulus ledger, the finite observation window, and the dyadic tolerance comparison before the seal can be consumed.

The remaining structural rows H, P, N preserve and name the same boundary. Since no quotient, selected limit, host equality, trichotomy, choice, or ambient completeness coordinate occurs in the packet, the seal is exactly the displayed endpoint of the constructive Cauchy presentation. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyReal}^{\uparrow}$ real-facing read factors through a displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{CauchyModulus}^{\uparrow}$ ledger, $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, cauchymodulus, streamname, dyadicratcore, real: $\mathsf{BishopCauchyReal}^{\uparrow}$ is not bijective to any listed sibling because it binds a modulus-controlled Cauchy real presentation, finite observation windows, dyadic tolerance arithmetic, terminal real sealing, transport, replay, provenance, and local NameCert rows into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2313.1, Definition 2313.2, Definition 2313.3, and Definition 2313.5 seed the modulus-equipped Cauchy real presentation surface for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopCauchyReal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, ambient Real$^{\uparrow}$ completeness, selected limits, host real equality, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-controlled regular source exposure, finite stream-window routing, dyadic tolerance readback, real-seal boundary, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.BishopCauchyRealUp.

Constructive story: A BishopCauchyReal$^{\uparrow}$ packet is generated from a regular rational source, an explicit Cauchy modulus, finite stream windows, dyadic tolerance rows, a terminal Real seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2282

A Concrete Naming Certificate for $\mathsf{PointwiseLimit}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki's function-limit terminology, the $\mathsf{PointwiseLimit}^{\uparrow}$ packet records an indexwise limit route for displayed real-valued maps without importing a uniform ledger or a host function-space object. It reads continuous approximants from chapter 130, keeps the limiting observations separate from the $\mathsf{UniformLimit}^{\uparrow}$ surface of chapter 463, schedules finite observations through chapter 126, checks regular rational readbacks through chapter 301, seals values only at chapter 38, keeps source and target distance rows visible through chapter 57, and supplies the generic pointwise-limit sibling read consumed by chapter 1604 and chapter 2196.

Definition 2282.1 (PointwiseLimit carrier)**.** *A* $\mathsf{PointwiseLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, Y, F, I, S, Q, R, E, H, C, K, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *context row naming the points at which the family is inspected.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *value-seal context for the observed outputs.*
3. *F is the finite ledger of displayed maps, including the* $\mathsf{ContinuousMap}^{\uparrow}$ *rows when the source family is continuous.*
4. *I is the point-index row saying that each convergence request is attached to one displayed source point and one requested tolerance.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finite approximant windows inspected for that point and tolerance.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected output windows.*
7. *R is the pointwise convergence ledger asserting that the selected windows are adequate for the displayed point and tolerance.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *value-seal row reached only after X, Y, F, I, S, Q, R have been displayed.*
9. *H records componentwise* hsame *transport for the source, target, map ledger, point-index row, schedule, readback, convergence ledger, value seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a point-and-tolerance request through the finite schedule, readback, pointwise ledger, and RealUp seal.*

11. *K is the* Pkg *provenance over* $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for uniform convergence, continuity preservation, host function equality, quotient function spaces, choice-selected pointwise limits, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PointwiseLimitUp.PointwiseLimitTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.PointwiseLimitUp.PointwiseLimitUp`

Theorem 2282.2 (PointwiseLimit NameCert obligations)**.** *For every accepted* $\mathsf{PointwiseLimit}^{\uparrow}$ *carrier* $P = (X, Y, F, I, S, Q, R, E, H, C, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source metric context, target metric and RealUp value context, displayed map ledger, point-index row, stream schedule, regular rational readback, pointwise convergence ledger, terminal value seal, transport, replay, provenance, and local naming row;*

2. *point-index visibility, requiring each convergence request to display its source point and requested tolerance through I before any schedule in S is read;*

3. *finite-window scheduling, requiring the requested approximant windows to be selected by S and checked by Q before the pointwise convergence row R can be consumed;*

4. *Real-seal routing, requiring the value row E to be downstream of X, Y, F, I, S, Q, R rather than of an ambient function-space limit;*

5. *sibling handoff compatibility, allowing* $\mathsf{BaireOneFunction}^{\uparrow}$ *and* $\mathsf{DiniContinuity}^{\uparrow}$ *consumers to read the pointwise route while keeping* $\mathsf{UniformLimit}^{\uparrow}$ *as a separate stronger ledger;*

6. *nonescape from uniform convergence, continuity preservation, host function equality, quotient function spaces, choice-selected pointwise limits, and completeness of* $\mathsf{Real}^{\uparrow}$.

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2314.1. The accepted packet exposes exactly the source and target metric rows, map ledger, point-index row, finite schedule, regular rational readback, convergence ledger, value seal, transport, replay, provenance, and local naming row.

Point-index visibility is forced by I. A consumer must name the displayed source point and tolerance before it can inspect the corresponding schedule, so the packet does not contain an unindexed host function limit.

Finite-window scheduling is then read through S and Q. The schedule selects only finite approximant windows, and the regular rational row checks those windows before R records the pointwise convergence ledger for the displayed point.

The RealUp value seal E is downstream of this route. The sibling handoff rows in K name $\mathsf{BaireOneFunction}^{\uparrow}$ and $\mathsf{DiniContinuity}^{\uparrow}$ as consumers of the pointwise route, while $\mathsf{UniformLimit}^{\uparrow}$ remains a separate stronger ledger. Since no excluded coordinate appears in the carrier, the listed rows exhaust the local surface. □

Theorem 2282.3 (PointwiseLimit Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{BaireOneFunction}^{\uparrow}$*, or* $\mathsf{DiniContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{PointwiseLimit}^{\uparrow}$ *packet reads the limiting value through the finite route*

$$X, Y, F, I, S, Q, R \longmapsto E.$$

The route first displays the source and target metric rows, then the map ledger and point-index row, then the StreamName schedule, RegSeqRat readback, and pointwise convergence ledger, and only then exposes the RealUp value seal. It exports no uniform convergence ledger, continuity-preservation theorem, host function equality, quotient function-space object, choice-selected pointwise limit, or RealUp completeness principle.

Proof. Start with a consumer request for the value seal E. By Definition 2314.1, E is a coordinate of the same finite packet as X, Y, F, I, S, Q, R, and the replay row C records the only displayed route into it.

The source and target rows X, Y are read first, followed by the displayed map ledger F and the point-index request I. The finite schedule S and regular rational readback Q then supply the observed approximant windows for that point and tolerance.

The convergence row R certifies only this pointwise route before E is exposed. Transport, replay, provenance, and local naming through H, C, K, N preserve that order for $\mathsf{BaireOneFunction}^{\uparrow}$ and $\mathsf{DiniContinuity}^{\uparrow}$ consumers, while no carrier coordinate supplies the excluded stronger objects. □

Falsifiable prediction: Every accepted $\mathsf{PointwiseLimit}^{\uparrow}$ value-seal read factors through a displayed point-index row and finite StreamName and RegSeqRat windows before any RealUp value is exposed.

Independence witness: continuousmap, uniformlimit, streamname, regseqrat, baireonefunction: PointwiseLimitUp is not bijective to any listed sibling because it jointly carries a source-point request, an approximant ledger, finite schedule and readback rows, a pointwise convergence ledger, a RealUp value seal, and explicit refusal of the UniformLimitUp ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PointwiseLimit}^{\uparrow}$ packet is generated from source and target MetricUp rows, a displayed map ledger, a point-index row, StreamName schedules, RegSeqRat readbacks, a pointwise convergence ledger, a RealUp value seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2314.1, Definition 2314.2, and Definition 2314.3 seed the finite pointwise-limit certificate over displayed source points, approximant windows, regular rational readbacks, and RealUp value seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close uniform convergence, continuity preservation, host function equality, quotient function spaces, choice-selected pointwise limits, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or standard bridge closure.

Upgrade path: Obligation closure requires checked carrier admission, point-index visibility, finite-window scheduling, Real-seal routing, sibling handoff compatibility, and nonescape for BEDC.Derived.PointwiseLimitUp.

Chapter 2283

A Concrete Naming Certificate for $\mathsf{RealLogarithm}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealLogarithm}^{\uparrow}$ packet names logarithm on positive real data as a finite inverse-route certificate for $\mathsf{RealExponential}^{\uparrow}$. The construction records located positive brackets, dyadic interval refinement, exponential comparison rows, and real-equality endpoint checks; it does not import a host logarithm, analytic continuation, quotient real equality, selected infinite bisection branch, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2283.1 (RealLogarithm carrier)**.** *A* $\mathsf{RealLogarithm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, I, B, E, A, O, C, R, H, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *row naming the positive input real and its located apartness from* 0*.*
2. *I is the* $\mathsf{OpenIntervalReal}^{\uparrow}$ *row carrying the positive bracket interval on which the inverse search is performed.*
3. *B is the finite dyadic bracket ledger, with each row recording a rational interval, midpoint comparison request, and retained positive subinterval.*
4. *E is the* $\mathsf{RealExponential}^{\uparrow}$ *inverse-route row used to compare displayed exponentials against the positive input.*
5. *A is the* $\mathsf{RealAbs}^{\uparrow}$ *control row bounding comparison error and bracket width during the finite read.*
6. *O is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *row that classifies the displayed real comparisons used by the bracket ledger.*
7. *C is the displayed* Cont *route from positive input and bracket rows through exponential comparisons to the endpoint classifier.*
8. *R is the real classifier row, read through* hsame *transport and the displayed comparison rows, that identifies the logarithm endpoint with the inverse route.*
9. *H is the componentwise* hsame *transport row for $P, I, B, E, A, O, C, R, K, N$.*

10. *K is the* Pkg *provenance over* $\mathsf{RealLogarithm}^{\uparrow}$, $\mathsf{LocatedPositiveReal}^{\uparrow}$, $\mathsf{OpenIntervalReal}^{\uparrow}$, $\mathsf{RealExponential}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}$ *row.*

The classifier accepts only packets whose positive input, bracket ledger, exponential inverse-route rows, absolute-error controls, Bishop comparison rows, transport, continuation, provenance, and local naming are all displayed. It has no coordinate for a host logarithm or for a hidden infinite choice of bisection branch.

Lean4 ✓ `BEDC.Derived.RealLogarithmUp.RealLogarithmTasteGate single carrier alignment`

Theorem 2283.2 (RealLogarithm NameCert obligations)**.** *For every accepted* $\mathsf{RealLogarithm}^{\uparrow}$ *carrier* $L = (P, I, B, E, A, O, C, R, H, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}$ *surface consists exactly of carrier exposure for the positive real row, the open positive interval, the dyadic bracket ledger, the* $\mathsf{RealExponential}^{\uparrow}$ *inverse-route comparisons, the* $\mathsf{RealAbs}^{\uparrow}$ *error controls, the* $\mathsf{BishopRealComparison}^{\uparrow}$ *classifier rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Any public logarithm read must pass through those rows before it can consume an endpoint value.*

Proof. Project the accepted carrier to the displayed rows $P, I, B, E, A, O, C, R, H, K, N$. The positivity and interval rows give the only admissible domain data, while the dyadic ledger records the finite bracket observations that a consumer may inspect.

The inverse comparisons are then forced through E, A, O. The exponential row supplies the only comparison with the candidate endpoint, the absolute-value row supplies the displayed error control, and the Bishop comparison row classifies the retained side of the bracket.

Finally, H, C, K, N preserve the same rows under transport, replay, provenance, and naming. Since no coordinate stores a host logarithm, an analytic-continuation datum, or a selected infinite branch, the local NameCert surface is exactly the displayed inverse-route surface. □

Theorem 2283.3 (RealLogarithm exponential inverse route)**.** *Every public read of an accepted* $\mathsf{RealLogarithm}^{\uparrow}$ *packet factors through the positive* $\mathsf{Real}^{\uparrow}$ *input row, the located open bracket row, the finite dyadic bracket ledger, the* $\mathsf{RealExponential}^{\uparrow}$ *comparison row, the* $\mathsf{RealAbs}^{\uparrow}$ *error-control row, and the* $\mathsf{BishopRealComparison}^{\uparrow}$ *classifier row before the logarithm endpoint is consumed. Consequently the packet names logarithm as the constructive inverse route of exponential on positive real data, not as a host transcendental primitive.*

Proof. Start with a public logarithm read. The carrier gives the positive input row P and the bracket row I, so the read begins inside a located positive real interval rather than in an ambient total real function space.

The finite bracket ledger B supplies the inspected dyadic intervals. Each retained bracket is justified only by the exponential comparison row E, the absolute-error row A, and the Bishop comparison row O.

The endpoint read is then routed through C and R, with H, K, N preserving the same displayed packet under transport, provenance, and naming. Thus the logarithm value is consumed only after the exponential inverse route has been displayed, and no hidden host log or selected infinite branch is exported. □

Theorem 2283.4 (RealLogarithm sibling dependency route)**.** *Every public logarithm read of an accepted* $\mathsf{RealLogarithm}^{\uparrow}$ *packet first consumes the positive-domain row from chapter 2029, the bracket row from chapter 2133, the inverse comparison row from chapter 1816, and the error and*

classifier rows from chapter 1608 and chapter 1381. The route is a sibling dependency lattice for the displayed packet rows, not a host logarithm or ambient transcendental primitive.

Proof. Project the carrier $L = (P, I, B, E, A, O, C, R, H, K, N)$. The rows P and I are the positive-domain and open-bracket sources, so the logarithm read begins by consuming the sibling surfaces for located positive reals and open real intervals.

The inverse-route data then passes through E, A, O. The row E is the substantive $\mathsf{RealExponential}^{\uparrow}$ sibling dependency: it supplies the comparison route from chapter 1816, while the absolute-value and Bishop-comparison rows supply the error and classifier ledgers used by the finite bracket read.

Finally the structural rows C, R, H, K, N replay, transport, source, and name exactly that lattice of sibling rows. Since no carrier coordinate stores a host log or an ambient analytic primitive, the theorem records dependency routing rather than a host logarithm construction. □

Falsifiable prediction: Every $\mathsf{RealLogarithm}^{\uparrow}$ public read factors through a located positive real row, an open positive interval row, a dyadic bracket ledger, a RealExponential inverse-route row, a RealAbs error-control row, a BishopRealComparison classifier row, componentwise hsame transport, displayed continuation, package provenance, and local naming.

Independence witness: real-exponential, real-analytic, located-positive-real, open-interval-real, real-abs, bishop-real-comparison: $\mathsf{RealLogarithm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries positive-domain admission, finite inverse brackets, exponential comparison rows, absolute-error controls, Bishop comparison classification, endpoint transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLogarithm}^{\uparrow}$ packet is generated from a located positive real input, an open positive interval, finite dyadic bracket rows, RealExponential inverse-route comparisons, RealAbs error controls, BishopRealComparison classifier rows, componentwise transport, displayed continuation, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2315.1, Definition 2315.2, and Definition 2315.3 seed the constructive inverse-route surface for logarithm on positive real data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host logarithms, analytic continuation, quotient real equality, selected infinite bisection branches, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-domain exposure, bracket refinement, exponential inverse-route comparison, error-control, classifier nonescape, and TasteGate field faithfulness for BEDC.Derived.RealLogarithmUp.

Chapter 2284

A Concrete Naming Certificate for $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$

Following Bourbaki and Kelley on uniform completions and Bishop–Bridges on constructive completion, the $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ packet records the finite functorial handoff from a located uniform source to the regular Cauchy real seal. It sits after the located uniform completion surface of chapter 1692, the functorial completion boundary of chapter 1892, the regular rational readback of chapter 301, the finite observation windows of chapter 126, and the terminal real-name seal of chapter 38. The packet names a quotient-free L10 completion functor: it exposes source rows, located Cauchy rows, finite readback windows, real-seal handoff, transport, replay, provenance, and local naming, but no quotient completion, selected representative, countable-choice branch, host equality of limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2284.1 (Located Cauchy completion functor carrier)**.** *A* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, L, G, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{LocatedUniformCompletion}^{\uparrow}$ *source row, carrying the located uniform completion request before any real-facing consumer inspects a seal.*
2. *L is the located Cauchy service row extracted from U, recording the positive-radius and finite-window evidence used to answer completion requests.*
3. *G is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *action row, recording the finite functorial map from source requests to completion-facing requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window schedule through which the consumer asks for finite data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window schedule.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after U, L, G, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the located source, functor row, observation window, regular readback, terminal seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through*

$$U, L, G \longmapsto S, R, E \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$, $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient Cauchy classes, representative selection, host limit equality, countable choice, open-cover compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.LocatedCauchyCompletionFunctorUp.LocatedCauchyCompletionFunctorTasteGate`
`single carrier alignment`

Theorem 2284.2 (Located Cauchy completion functor NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ *carrier* $F = (U, L, G, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletio}}$ *surface consists exactly of carrier admission, located uniform source exposure, located Cauchy service exposure, functorial completion action, finite observation-window routing, regular rational readback, terminal real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of quotient completions, selected representatives, host limit equality, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2316.1. The displayed packet fixes the source row U, located service row L, functor row G, window schedule S, readback row R, terminal seal E, and structural rows H, C, P, N.

The located source is read first. The row U is the located uniform completion surface cited in chapter 1692, and L records the finite located Cauchy service used by the functor row. Thus no consumer reaches the completion functor before located evidence is displayed.

The functorial action then routes the request through G and into the finite observation rows. The schedule S and readback R are exactly the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ interfaces named above, so the handoff is a finite readback route rather than a quotient of all Cauchy names.

Finally E, H, C, P, N expose the real seal, transport the same components, replay the route, record provenance, and name the packet. Since the excluded completion principles are absent from the carrier, no local obligation can be stored outside the displayed rows. □

Theorem 2284.3 (Located Cauchy completion functor real-seal handoff)**.** *Every real-facing read of an accepted* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ *carrier factors through the route*

$\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, N

The terminal $\mathsf{Real}^{\uparrow}$ *seal is therefore available only after the located source row, functorial completion row, finite observation window, and regular rational readback have been displayed. The handoff exports no quotient stream equality, selected limit, countable-choice branch, host real equality, or ambient completeness datum.*

Proof. Start with an accepted carrier $F = (U, L, G, S, R, E, H, C, P, N)$. The continuation row C makes U, L, G the entry surface for every completion request, so the route cannot begin at a terminal real object.

The finite readback phase is then forced by S and R. These rows are the displayed $\mathsf{StreamName}^{\uparrow}$ observation window and $\mathsf{RegSeqRat}^{\uparrow}$ readback route, and the real seal E is stored only after them in the carrier.

Componentwise transport by H, replay by C, provenance by P, and naming by N preserve the same displayed route. Since no quotient stream equality, selected limit, choice branch, host real

equality, or ambient completeness coordinate occurs in the packet, every real-facing read factors through the stated rows. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ completion read factors through $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, terminal $\mathsf{Real}^{\uparrow}$ sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: locateduniformcompletion, uniformcompletionfunctor, regseqrat, streamname, real: $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ is not bijective to any listed sibling because it binds located source evidence, functorial completion action, finite observation windows, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2316.1, Definition 2316.2, and Definition 2316.3 seed the finite quotient-free completion-functor handoff through located uniform source rows, functor rows, finite observation windows, regular readback, and terminal real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, open-cover compactness, host limit equality, Lean verification, public bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, functorial action, finite-window readback, real-seal handoff, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.LocatedCauchyCompletionFunctorUp.

Constructive story: A $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ packet is generated from a located uniform completion source, a functorial completion row, finite observation windows, regular rational readback, terminal real sealing, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2285

A Concrete Naming Certificate for $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$

The $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ packet realizes the wobble-quotient geometry branch around Definition 9462.1440 as finite trigger rows. It reads the quotient skeleton, spectral reconstruction, product decomposition, and occupancy rows of the wobble quotient geometry file, then packages them as a concrete NameCert surface beside the hash boundary of chapter 242, the spectral sequence surface of chapter 178, the network-flow route of chapter 233, and the Boolean endpoint discipline of chapter 32. The packet is a finite trigger carrier for spectral geometry consumers; it is not a host eigenvector computation, a biological assertion, a quotient-space semantic equality, or an unbounded graph search.

Falsifiable prediction: Every accepted $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ trigger read factors through wobble quotient rows, spectral hinge rows, trigger energy rows, hsame transport, Cont replay, and Pkg provenance before any downstream consumer treats the trigger as active.

Independence witness: hash, spectralseq, networkflow, bool: $\mathsf{Hash}^{\uparrow}$ records digest rows rather than quotient geometry, $\mathsf{SpectralSeq}^{\uparrow}$ records filtration pages rather than wobble trigger energy, $\mathsf{NetworkFlow}^{\uparrow}$ records capacity routes rather than quotient-fiber hinges, and $\mathsf{Bool}^{\uparrow}$ records endpoint tags rather than the spectral trigger packet; none is bijective to $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$.

Definition 2285.1 (Wobble quotient spectral trigger carrier)**.** *A* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, S, E, H, C, P, B, R, N)$$

with the following displayed rows:

1. *Q is the wobble quotient row, recording the finite f_3 quotient vertices, the one-hole quotient closure, and the quotient-product lift surface.*
2. *S is the spectral hinge row, recording the finite adjacency spectrum readback used by the quotient spectral reconstruction.*
3. *E is the trigger energy row, recording the accepted threshold comparison for the killed bit-flip spectral radius and its finite trigger tag.*
4. *H records componentwise* hsame *transport for quotient, spectral, energy, continuation, provenance, Boolean tag, route, and local naming rows.*

5. *C records displayed* Cont *replay from a consumer trigger request through*

$$Q, S, E \longmapsto H, P, B, R, N.$$

6. *P is the* Pkg *provenance over* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$, $\mathsf{Hash}^{\uparrow}$, $\mathsf{SpectralSeq}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

7. *B is the* $\mathsf{Bool}^{\uparrow}$ *trigger tag row, exposing the finite accept or refuse endpoint for the trigger request.*

8. *R is the route row assigning the read to quotient-geometry support, spectral-hinge support, trigger-energy support, or refusal.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for host spectral computation, ambient quotient equality, biological interpretation, infinite graph traversal, or a trigger that bypasses route classification.

Theorem 2285.2 (Wobble quotient spectral trigger NameCert obligations)**.** *For every accepted* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *carrier* $T = (Q, S, E, H, C, P, B, R, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}$ *surface consists exactly of carrier admission, quotient-row exposure, spectral-hinge exposure, trigger-energy exposure, route classification, Boolean trigger tagging, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of host spectral computation, ambient quotient equality, biological interpretation, infinite graph traversal, and unclassified trigger reads.*

Proof. Carrier admission projects the displayed tuple of Definition 2317.1. The quotient row Q, spectral row S, trigger energy row E, route row R, Boolean row B, and structural rows H, C, P, N are the only visible coordinates.

The quotient row is read before the spectral hinge. This keeps the trigger tied to the finite wobble quotient skeleton and prevents a consumer from substituting an ambient quotient-space equality.

The spectral hinge and trigger energy rows are then read through S and E. Route classification by R decides whether the request is quotient support, spectral support, energy support, or refusal before the Boolean tag B is exported.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no host spectral computation, biological interpretation, infinite graph traversal, or unclassified trigger coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 2285.3 (Wobble quotient spectral trigger handoff)**.** *Every accepted trigger read of a* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *packet factors through the route*

$$\mathsf{Hash}^{\uparrow},\ \mathsf{SpectralSeq}^{\uparrow},\ \mathsf{NetworkFlow}^{\uparrow},\ \mathsf{Bool}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The quotient row, spectral hinge row, trigger energy row, route row, and Boolean trigger tag are therefore visible before a downstream consumer can treat the trigger as accepted. The route exports no host eigenvector data, ambient quotient equality, biological assertion, infinite graph search, or trigger tag outside the displayed carrier.

Proof. Start with an accepted carrier $T = (Q, S, E, H, C, P, B, R, N)$. The quotient, spectral, and energy rows are the only support rows available to the trigger request, while R records how the request is classified.

The Boolean tag is read only after route classification. Thus an accepted tag in B cannot be separated from the quotient, spectral, and energy evidence that produced it.

Componentwise transport by H, continuation replay by C, provenance by P, and local naming by N preserve that same finite route. Since the excluded host and ambient objects are absent from the carrier, every accepted trigger read factors through the displayed rows. □

Theorem 2285.4 (Wobble quotient spectral trigger TasteGate obligations)**.** *The TasteGate surface for* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *requires a nontriviality row and a field-faithfulness row:*

$$\mathsf{Nontrivial}\,\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow} \quad \textit{and} \quad \mathsf{FieldFaithful}\,\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}.$$

The nontriviality row separates accepted trigger tags from refusal tags, and the field-faithfulness row requires every accepted tag to retain its quotient-row, spectral-hinge, trigger-energy, route, transport, replay, provenance, and local naming support.

Lean4 ✓ `BEDC.Derived.WobbleQuotientSpectralTriggerUp.wobbleQuotientSpectralTriggerChapterTasteGate`

Proof. Nontriviality is read from the Boolean trigger row B together with the route classifier R. An accepted tag and a refusal tag are distinct only because the carrier displays both the tag and the route that licensed it.

Field faithfulness is row preservation. A field-faithful read may transport the packet through H and replay it through C, but it cannot erase Q, S, E, R, P, N while keeping an accepted trigger tag.

Thus the required TasteGate rows are exactly the nontrivial trigger distinction and the preservation of the displayed support fields. □

Closure status for $\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2317.1, Definition 2317.2, Definition 2317.3, and Definition 2317.4 seed the finite quotient-trigger surface through quotient rows, spectral hinge rows, trigger energy rows, route classification, Boolean trigger tags, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host spectral computation, biological semantics, ambient quotient equality, infinite graph traversal, Lean verification, public bridge checking, or field-faithful TasteGate implementation.

Upgrade path: Obligation closure requires checked carrier admission, quotient exposure, spectral hinge exposure, trigger-energy exposure, route classification, Boolean tagging, support-field preservation, and TasteGate instances for BEDC.Derived.WobbleQuotientSpectralTriggerUp.

Constructive story: A $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ packet is generated from wobble quotient rows, spectral hinge rows, trigger energy rows, Boolean trigger tags, route classification, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2286

A Concrete Naming Certificate for $\mathsf{CantorIntersectionTheorem}^{\uparrow}$

Following Cantor's nested intersection theorem and Bishop–Bridges constructive analysis, the $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ packet records the theorem-shaped L10 boundary where a displayed sequence of nested located intervals is consumed through finite windows before any Real-facing seal is read. It sits downstream of the finite compactness surface of chapter 1584, the nested carrier of chapter 320, the located endpoint row of chapter 394, the dyadic interval ledger of chapter 306, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter names the finite nested-intersection theorem route only; it does not introduce a point selector, quotient real equality, open-cover compactness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2286.1 (Cantor intersection theorem carrier)**.** *A* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *finite-window compactness row consumed as the theorem source.*
2. *I is the* $\mathsf{NestedInterval}^{\uparrow}$ *row naming the inspected nested interval prefix.*
3. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint-location row for the same displayed prefix.*
4. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *row carrying dyadic endpoint boxes, inclusion checks, and mesh comparisons.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule read at the displayed precisions.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the located dyadic windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, I, L, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the theorem source, interval rows, windows, readback, seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite theorem request through Q, I, L, D, W, R, E in that order.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$, $\mathsf{NestedIntervalCompactness}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}$ *row.*

The classifier admits only packets with these eleven rows. No coordinate stores open-cover compactness, a selected intersection point, quotient real equality, countable choice, trichotomy, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 2286.2 (Cantor intersection theorem NameCert obligations)**.** *For every accepted* CantorIntersectionTheor *carrier $K = (Q, I, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed nested-interval compactness row, nested prefix, located endpoints, dyadic interval ledger, stream windows, regular rational readback, real seal, transports, continuations, provenance, and local naming;*
2. *source coherence, requiring Q to be consumed through the same I, L, D, W, R, E route exposed by the finite-window compactness packet;*
3. *located mesh exactness, requiring L and D to govern the same interval prefix before any* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *row is read;*
4. *theorem-route sealing, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through Q, I, L, D, W, R before E, H, C, P, N are exposed;*
5. *ledger non-escape, excluding open-cover compactness, selected intersection points, quotient real equality, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 2318.1. The local naming surface has exactly the displayed rows $Q, I, L, D, W, R, E, H, C, P, N$.

The source coherence row is inherited by reading Q through chapter 1584. That source already exposes the nested prefix, located endpoint row, dyadic interval row, stream windows, regular rational readback, and real seal boundary as finite data.

The located mesh exactness row binds L and D to the same prefix before W and R can be consumed. The theorem-route sealing row then forces any Real-facing read to pass through the finite source and mesh route before it reaches E and the structural rows H, C, P, N.

Since no row in the carrier is an open-cover compactness proof, point selector, quotient-real equality witness, countable-choice schedule, trichotomy row, or ambient completeness theorem, the ledger non-escape obligation is exactly the absence of those coordinates. □

Theorem 2286.3 (Cantor intersection theorem nested route)**.** *Let $K = (Q, I, L, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *carrier. Every theorem-facing read of the nested intersection boundary factors through*

$$\mathsf{NestedIntervalCompactness}^{\uparrow},\ \mathsf{NestedInterval}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

in that order, followed only by componentwise transport, continuation replay, package provenance, and the local naming row.

Lean4 ✓ `BEDC.Derived.CantorIntersectionTheoremUp.CantorIntersectionTheoremTasteGate single carrier alignment`

Proof. Start with a theorem-facing read. By Definition 2318.2, the read first consumes the finite-window source row Q and its exposed nested prefix I.

Next the same obligation surface requires located mesh exactness. The located endpoint row L and dyadic interval row D therefore govern the inspected prefix before the stream windows W or regular rational readback R are visible.

Finally the theorem-route sealing row sends the read through R to the real seal E, and only then to H, C, P, N. The carrier has no other coordinate, so the displayed seven-object route exhausts the nested-intersection theorem boundary. □

Theorem 2286.4 (Cantor intersection theorem Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer admitted by an accepted* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *packet receives a finite nested-window theorem route through* $Q, I, L, D, W, R, E, H, C, P, N$*. The consumer receives no open-cover compactness theorem, no selected intersection point, no quotient real equality principle, no countable-choice selector, no trichotomy row, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Apply Definition 2318.3. A Real-facing consumer reaches the terminal seal only after the finite-window compactness row, nested prefix, located endpoints, dyadic boxes, stream windows, and regular rational readback have all been displayed.

The structural rows H, C, P, N preserve and name that route; they do not add analytic content. The source coherence and theorem-route sealing obligations of Definition 2318.2 keep the Real seal downstream of the same finite data.

Thus the consumer has no coordinate from which to read open-cover compactness, a selected point of the full intersection, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The exported boundary is the finite nested-window theorem route and nothing stronger. □

Theorem 2286.5 (CantorIntersection diameter-zero route)**.** *Let* $K = (Q, I, L, D, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *carrier. If the nested interval packet carries a displayed dyadic diameter ledger tending to zero, then every Real-facing seal read factors through* $\mathsf{NestedIntervalCompactness}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *by first reading the nested prefix* I*, located endpoint row* L*, dyadic interval and diameter rows in* D*, stream windows* W*, regular rational readback* R*, and terminal seal* E*. The route exports no selected intersection point, ambient completeness claim, quotient real equality, countable choice, trichotomy, or open-cover compactness.*

Proof. Project the carrier of Definition 2318.1. The theorem source row Q exposes the same nested interval prefix I that the diameter-zero read inspects.

Source coherence from Definition 2318.2 forces the nested prefix to be read before the Real-facing seal route is opened. The displayed dyadic diameter ledger is part of the D row, so it is tied to the same prefix and the same located endpoint row L.

Located mesh exactness then governs the zero-diameter rows. A consumer may inspect the finite $\mathsf{StreamName}^{\uparrow}$ windows W and the $\mathsf{RegSeqRat}^{\uparrow}$ readback R only after the located and dyadic rows have displayed the required mesh comparisons.

Finally, theorem-route sealing and Definition 2318.4 send the read through E and then only through H, C, P, N. None of those structural rows can add a selected point, ambient completeness principle, quotient equality, countable selector, trichotomy row, or open-cover compactness theorem. □

Falsifiable prediction: An accepted $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without first reading the nested-interval compactness row, nested prefix, located endpoint row, dyadic interval ledger, stream windows, and regular rational readback refutes the carrier surface.

Independence witness: nestedintervalcompactness, nestedinterval, locatedinterval, dyadicinterval, streamname, regseqrat, real: none is bijective to $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ because this packet jointly carries the theorem-source row, the finite nested prefix, located and dyadic endpoint rows, stream windows, regular readback, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ packet is generated from a NestedIntervalCompactness row, a nested interval prefix, located endpoint rows, dyadic interval boxes, StreamName windows, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2318.1, Definition 2318.2, Definition 2318.3, and Definition 2318.4 seed the finite Cantor nested-intersection theorem route over the L10 nested-interval boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected intersection points, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove source coherence, located mesh exactness, theorem-route sealing, and ledger non-escape for the same finite packet.

Chapter 2287

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$

Following Bishop–Bridges and Bourbaki-style completion theory, the $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ packet records the finite universal-property surface for the L10 completion interface. It sits after the metric-completion carrier of chapter 1506, the uniform-completion route of chapter 1473, the functorial completion handoff of chapter 423, and the separated-metric comparison boundary of chapter 1411. The packet names the dense-source, extension, and uniqueness rows that completion consumers may cite without importing quotients, selected limits, choice, or ambient completeness.

Definition 2287.1 (Cauchy completion universal property carrier)**.** *A* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, K, T, F, E, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense source row, recording the source object together with the finite density witness consumed by completion readers.*
2. *K is the completion carrier row, read through* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff data.*
3. *T is the complete separated target row, recording the target surface whose separatedness supports uniqueness.*
4. *F is the source map row from D into T before completion is invoked.*
5. *E is the extension map row from K into T, tied to F along the dense source row.*
6. *L is the uniqueness classifier, comparing two extension rows over the same D, K, T, F surface by separatedness rather than by quotient equality.*
7. *H records componentwise* hsame *transport for D, K, T, F, E, L and the local naming row.*
8. *C records displayed* Cont *replay of dense-source handoff, extension existence, and uniqueness reads.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, K, T, F, E, L, H, C, P, N$. It has no coordinate for quotient completion, selected representatives, host limit choice, ambient real completeness, or countable choice.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalPropertyUp.CauchyCompletionUniversalPropertyTasteGate single carrier alignment`

Theorem 2287.2 (CauchyCompletionUniversalProperty NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *carrier* $U = (D, K, T, F, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of five obligation rows: carrier exposure for the displayed tuple; dense-source handoff through D and the source map F; extension existence through the completion rows K, T, E; uniqueness up to the classifier L over the same dense-source and completion route; and ledger non-escape from choice, quotient equality, selected limits, or host limit principles.*

Proof. Carrier exposure is projection from Definition 2319.1. The tuple displays the dense source, completion carrier, complete separated target, source map, extension row, uniqueness classifier, transport, replay, provenance, and local naming row.

The dense-source handoff uses D and F. A consumer must first read the source and its finite density route before it can ask for an extension into the target.

Extension existence is carried by K, T, E. The completion carrier is read through the metric, uniform, and functorial completion rows, while T supplies the complete separated target surface. The extension row E is therefore attached to displayed completion data rather than to a selected host limit.

Uniqueness is carried by L. Since L compares extension rows over the same D, K, T, F surface and uses separatedness from T, it does not require quotient equality or representative selection.

The ledger boundary is fixed by H, C, P, N. These rows transport, replay, source, and name the same displayed packet, and no excluded host-side principle appears as a coordinate of the carrier. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalPropertyUp.CauchyCompletionUniversalPropertyCarrier namecert obligations`

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ consumer that exports extension existence or uniqueness while omitting the dense source, completion carrier, complete separated target, source map, extension row, uniqueness classifier, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: metriccompletion, uniformcompletion, cauchycompletionfunctor, separatedmetric: none is bijective because $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ jointly carries dense source, completion carrier, complete separated target, source map, extension, uniqueness classifier, transport, replay, provenance, and local NameCert rows in one universal-property packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ packet is generated from a dense source row, a completion carrier row, a complete separated target row, a source map, an extension row, a uniqueness classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$, seed)

Scope closed: Definition 2319.1 and Definition 2319.2 seed the finite L10 Cauchy completion universal-property surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, dense-source handoff, extension existence, uniqueness classification, transport replay, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchyCompletionUniver

Chapter 2288

A Concrete Naming Certificate for $\mathsf{CandidateSetNormalization}^{\uparrow}$

The $\mathsf{CandidateSetNormalization}^{\uparrow}$ packet realizes the candidate-set reading of chapter 9383 as finite NameCert data. It records candidate evidence, closed-term projection, Pi and application adequacy, no-infinite-reduction, obstruction, transport, continuation, provenance, and local naming rows. The packet is deliberately a candidate-set surface: it does not claim unconditional strong normalization for every closed typed MetaCIC term. Its candidate-evidence and bounded-normal checking route is read through the sibling surfaces of chapter 892 and chapter 752.

Definition 2288.1 (MetaCIC candidate-set normalization carrier)**.** *A* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, T, A, I, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite candidate-set evidence row, including candidate membership, soundness, and beta-closure evidence for the accepted read.*
2. *T is the closed typed term projection row, recording the empty-context typed term whose normalization read is supplied by K.*
3. *A is the application and Pi adequacy row, tying application reads and binder reads back to the same candidate-set evidence.*
4. *I is the no-infinite-reduction row obtained from the candidate-set strong-normalization route.*
5. *O is the obstruction row recording that a closed-term normalization read is refused when K is absent.*
6. *H records componentwise* hsame *transport for K, T, A, I, O and the local naming row.*
7. *C records displayed* Cont *replay from candidate-set evidence to strong normalization, closed-term projection, application and Pi adequacy, and no-infinite-reduction reads.*
8. *P is the* Pkg *provenance over* $\mathsf{CandidateSetNormalization}^{\uparrow}$, $\mathsf{MetaCICRedexFrontier}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontie}$ $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CandidateSetNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, T, A, I, O, H, C, P, N$. It contains no coordinate for evidence-free closed-term normalization, componentwise application normalization, host reduction normalization, quotient reduction equality, subject-reduction discharge, or a global normalization oracle.

Lean4 (definition) `BEDC.Derived.CandidateSetNormalizationUp.CandidateSetNormalizationUp`
Lean4 ✓ `BEDC.Derived.CandidateSetNormalizationUp.CandidateSetNormalizationTasteGate single carrier alignment`

Definition 2288.2 (Candidate-set normalization frontier filter)**.** *For an accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier $S = (K, T, A, I, O, H, C, P, N)$, its public frontier filter is the finite* BHist *subpacket*

$$\mathsf{Frontier}(S) = (K, T, A, I, O, H, C, P, N)$$

read in the displayed order: candidate-set evidence K, closed-term projection T, adequacy row A, no-infinite-reduction row I, obstruction row O, transport H, replay C, provenance P, and local naming N. A consumer reaches the redex-facing normalization frontier only through this subpacket, so the filter contains no coordinate for candidate-free strong normalization, closed subject reduction, arbitrary confluence, host conversion equality, or a global normalizer.

Theorem 2288.3 (MetaCIC candidate-set normalization obligations)**.** *For every accepted* $\mathsf{CandidateSetNormalizati}$ *carrier $S = (K, T, A, I, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CandidateSetNormalization}^{\uparrow}}$ *surface consists exactly of finite candidate-set evidence through K; closed-term projection through T; application and Pi adequacy through A; no-infinite-reduction through I; obstruction when the candidate-set row is absent through O; componentwise transport through H; displayed replay through C; provenance through P; local naming through N; and non-escape from unconditional MetaCIC strong normalization.*

Proof. Carrier admission is projection from Definition 2320.1. The tuple displays the candidate-set evidence, closed typed term projection, adequacy row, no-infinite-reduction row, obstruction row, transport, replay, provenance, and local name.

The positive route begins at K. Candidate-set membership, soundness, and beta-closure are read before T, A, or I can export a normalization-facing conclusion.

The closed-term projection is T, and the application and Pi adequacy route is A. Both rows consume the same candidate-set evidence rather than a componentwise strong-normalization shortcut.

The no-infinite-reduction row I is downstream of that evidence. If K is absent, O records the obstruction, so the packet refuses an evidence-free theorem over all closed typed terms.

Finally H, C, P, N transport, replay, source, and name the same finite branch. Since no global normalization oracle or quotient reduction equality is present in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2288.4 (Candidate-set normalization redex non-escape)**.** *Every redex-frontier consumer of an accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier must pass through the frontier filter $K, T, A, I, O, H, C, P, N$ of Definition 2320.2. It exports no candidate-free strong normalization, no closed subject-reduction theorem, and no arbitrary confluence principle.*

Proof. Project the accepted carrier and then read its frontier filter. The first row is K, so the consumer starts from candidate-set evidence rather than from a redex-normalization oracle.

The closed-term row T and adequacy row A are downstream of the same candidate evidence. They can expose closed projection and application or Pi adequacy only through that evidence.

The no-infinite-reduction row I and obstruction row O complete the normalization-facing branch. If the candidate evidence is absent, O records refusal instead of supplying a candidate-free theorem.

Finally H, C, P, N transport, replay, source, and name the same branch. Since the filter has no subject-reduction, confluence, or global-normalizer coordinate, no consumer can export those conclusions from this packet. □

Theorem 2288.5 (Candidate-set normalization candidate-closed handoff)**.** *For every accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier, the handoff from candidate-set evidence to the closed-term projection remains mediated by* $K, T, A, I, O, H, C, P, N$*. In particular, the closed projection row* T *is not a candidate-free closed normalization theorem and cannot be reused without the candidate-set evidence row* K*.*

Proof. Read the carrier as $S = (K, T, A, I, O, H, C, P, N)$. The closed-term projection row is named as T, but its admissibility is part of the same finite packet as K.

The adequacy and no-infinite-reduction rows A and I also consume the candidate-set route. They do not create a detached closed-term theorem, because the obstruction row O records refusal when K is absent.

Transport and replay through H and C, with provenance and naming through P and N, preserve the same candidate-mediated route. Thus the closed projection remains a handoff inside the frontier filter rather than a standalone normalization principle. □

Theorem 2288.6 (MetaCIC candidate-set normalization idempotence)**.** *Let* $S = (K, T, A, I, O, H, C, P, N)$ *be an accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier whose candidate-set packet has already been normalized through the displayed frontier-dependency rows. Applying the same normalization route again exposes the same accepted candidate rows, the same closed-term projection, the same application and Pi adequacy rows, and no additional spectral-trigger row.*

Proof. Use the carrier and obligation surface of Definition 2320.1 and Definition 2320.3. The first normalization pass can read only $K, T, A, I, O, H, C, P, N$, and the accepted candidate-set evidence is already attached to the displayed no-infinite-reduction and obstruction rows.

The frontier-dependency rows of chapter 2307 determine which candidate rows may be exposed before the closed-term projection and adequacy rows are replayed. Running the same route again therefore reuses the same dependency rows rather than introducing a new candidate branch.

Finally compare with the spectral-trigger surface of chapter 2317. A trigger row would have to be present as an additional obstruction or replay coordinate, but the $\mathsf{CandidateSetNormalization}^{\uparrow}$ classifier contains no such coordinate beyond O and C. The second pass is therefore idempotent on accepted candidate rows and creates no further spectral-trigger row. □

Falsifiable prediction: No accepted closed-term strong-normalization read through $\mathsf{CandidateSetNormalization}^{\uparrow}$ bypasses candidate evidence or candidate-set evidence.

Independence witness: metacicredexfrontier, metacicnormalizationfrontier, bounded-normal-equality-checker, metacicopenproblemledger: none is bijective because $\mathsf{CandidateSetNormalization}^{\uparrow}$ jointly carries candidate-set evidence, closed-term projection, application and Pi adequacy, no-infinite-reduction, obstruction, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateSetNormalization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CandidateSetNormalization}^{\uparrow}$ packet is generated from finite candidate-set evidence, a closed typed term projection, application and Pi adequacy, a no-infinite-reduction row, an obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CandidateSetNormalization}\uparrow}$, seed)
Scope closed: Definition 2320.1 and Definition 2320.3 seed the finite candidate-set normalization surface.
Formal verification: FormalStatus(NameCert$_{\text{CandidateSetNormalization}\uparrow}$, encodedDef)
Lean target: `BEDC.Derived.CandidateSetNormalizationUp.CandidateSetNormalizationUp`
Bridge status: none
Not claimed: This chapter does not claim unconditional MetaCIC strong normalization, evidence-free application normalization, subject reduction, host normalization, quotient reduction equality, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked candidate-set evidence, closed-term projection, application and Pi adequacy, no-infinite-reduction, obstruction exactness, transport replay, and TasteGate field faithfulness for BEDC.Derived.CandidateSetNormalizationUp.

Chapter 2289

A Concrete Naming Certificate for $\mathsf{CompletionComparison}^{\uparrow}$

Following Bishop–Bridges metric completion and Kelley uniform-space completion, the $\mathsf{CompletionComparison}^{\uparrow}$ packet records the finite comparison surface shared by metric, filter, net, regular-Cauchy, separated, and uniform completion presentations. It sits after the metric-completion carrier of chapter 1506, the Cauchy-filter carrier of chapter 333, the Cauchy-net carrier of chapter 589, the regular-Cauchy comparison carrier of Definition 411.1, the separated-metric carrier of chapter 1411, and the uniform-completion carrier of chapter 1473. The chapter gives downstream completion consumers one named comparison surface rather than requiring them to choose a quotient-completion presentation or a selected representative prose route.

Definition 2289.1 (Completion comparison carrier)**.** *A* $\mathsf{CompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, T, R, S, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, carrying the metric completion presentation before any comparison consumer reads a completion point.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row, carrying the filter presentation over the same finite tolerance requests.*
3. *T is the* $\mathsf{CauchyNet}^{\uparrow}$ *source row, carrying the net presentation and its directed observation rows.*
4. *R is the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row, comparing the sequence-style regular Cauchy route with the filter and net routes through displayed tolerance windows.*
5. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row used to make equality and uniqueness reads pass through separated comparison data rather than host equality.*
6. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row, recording the uniform completion presentation consumed by entourage-facing readers.*
7. *H records componentwise* hsame *transport for the metric, filter, net, regular-comparison, separated, uniform, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the comparison route*

$$M, F, T, R \longmapsto S, U \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompletionComparison}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, choice of a convergent subnet, host equality of limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompletionComparisonUp.CompletionComparisonTasteGate single carrier alignment`

Theorem 2289.2 (Completion comparison NameCert obligations)**.** *For every accepted* $\mathsf{CompletionComparison}^{\uparrow}$ *carrier* $K = (M, F, T, R, S, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}$ *surface consists exactly of carrier admission, metric completion source exposure, Cauchy-filter source exposure, Cauchy-net source exposure, regular-Cauchy comparison exposure, separated-metric equality routing, uniform-completion handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of quotient completion equality, selected representatives, choice-selected subnets, host equality of limits, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2321.1. The accepted packet exposes exactly the metric row M, filter row F, net row T, regular comparison row R, separated row S, uniform row U, and structural rows H, C, P, N.

The source presentations are read before any equality or uniqueness comparison. Rows M, F, T, R keep metric, filter, net, and regular-Cauchy evidence inside the same finite packet, so a consumer cannot replace the displayed comparison by a quotient object or a selected representative.

The separated and uniform rows then control the target-facing read. Row S supplies the separated comparison boundary, and row U supplies the uniform completion handoff. Rows H, C, P, N transport, replay, source, and name the same finite route.

Since the excluded host-side principles are absent from the carrier, every local obligation is one of the displayed rows. □

Theorem 2289.3 (Completion comparison filter-net correspondence)**.** *Every filter-net completion read of an accepted* $\mathsf{CompletionComparison}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{CauchyNet}^{\uparrow},\ \mathsf{RegularCauchyComparison}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow}$$

In particular, a consumer comparing Cauchy filters with Cauchy nets must read the shared metric row, the regular-Cauchy comparison row, the separated-metric row, and the uniform-completion handoff from Definition 2321.1; it cannot import quotient equality of completions, a selected representative sequence, a choice-selected subnet, a host limit theorem, or ambient completeness.

Proof. Begin with an accepted carrier $K = (M, F, T, R, S, U, H, C, P, N)$. The filter row F and net row T occur in the same packet as the metric row M, so their comparison begins from displayed finite completion data.

The regular comparison row R supplies the common tolerance-window route. The separated row S is the only equality-facing component, and the uniform row U is the only entourage-facing completion handoff.

Finally H, C, P, N preserve that route under transport, replay, provenance, and local naming. No extra completion object appears in K, so every filter-net read factors through the stated rows. □

Falsifiable prediction: Every accepted $\mathsf{CompletionComparison}^{\uparrow}$ consumer comparing completion presentations factors through $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metriccompletion, cauchyfilter, cauchynet, regularcauchycomparison, separatedmetric, uniformcompletion: $\mathsf{CompletionComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric, filter, net, regular-Cauchy, separated, uniform, transport, replay, provenance, and local NameCert rows in one comparison packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2321.1, Definition 2321.2, and Definition 2321.3 seed the finite comparison surface tying metric, filter, net, regular-Cauchy, separated, and uniform completion rows to one NameCert route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, choice-selected subnets, host limit equality, open-cover compactness, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-row exposure, filter-net correspondence, separated equality routing, uniform handoff, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CompletionComparisonUp.

Constructive story: A $\mathsf{CompletionComparison}^{\uparrow}$ packet is generated from metric completion, Cauchy-filter, Cauchy-net, regular-Cauchy comparison, separated-metric, uniform-completion, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2290

A Concrete Naming Certificate for $\mathsf{CofinalCompactInterval}^{\uparrow}$

Following Bishop and Bridges constructive compact-interval arguments, the $\mathsf{CofinalCompactInterval}^{\uparrow}$ packet names the finite cofinal window by which a closed bounded interval request is refined to displayed locator, dyadic, stream, regular-rational, and Real-facing rows. It sits after the closed bounded interval source of chapter 1591, the compact interval locator of chapter 1891, the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives downstream interval compactness, Cousin-style finite refinement, and Heine–Borel interval consumers a named finite-window route without importing open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2290.1 (Cofinal compact interval carrier)**.** *A* $\mathsf{CofinalCompactInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing lower and upper located endpoints, endpoint order, rational containment, dyadic containment, and the base interval naming surface.*
2. *L is the* $\mathsf{CompactIntervalLocator}^{\uparrow}$ *row, recording the located comparison and tolerance-to-window service used to refine interval requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger carrying the dyadic tolerances, endpoint cells, and finite mesh comparisons demanded by I and L.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the cofinal dyadic depth chosen for the displayed request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the same interval, locator, dyadic, and stream rows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the interval source, locator, dyadic ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-interval request through $I, L, D, W, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CofinalCompactInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{CompactIntervalLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}$ *row.*

The classifier admits only packets with these ten rows. No coordinate stores open-cover compactness, a selected subcover, quotient real equality, countable choice, trichotomy, host interval equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CofinalCompactIntervalUp.TasteGate.CofinalCompactIntervalTasteGate single carrier alignment`

Theorem 2290.2 (Cofinal compact interval NameCert obligations)**.** *For every accepted* $\mathsf{CofinalCompactInterval}^{\uparrow}$ *carrier* $K = (I, L, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the closed bounded interval source, compact locator, dyadic tolerance ledger, stream windows, regular rational readback, real seal, transports, continuations, provenance, and local naming;*
2. *interval-source exactness, requiring every endpoint, containment, and interval-local request to enter through I before the locator row is read;*
3. *locator cofinality, requiring L and D to convert any displayed compact-interval request into a finite dyadic window deep enough for the requested observation;*
4. *real-handoff ordering, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through I, L, D, W, R before E, H, C, P, N are exposed;*
5. *ledger non-escape, excluding open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, host interval equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 2322.1. The local naming surface has exactly the displayed rows $I, L, D, W, R, E, H, C, P, N$.

The interval-source exactness row is supplied by reading I through chapter 1591. It exposes the lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, finite-window, regular-readback, and Real-seal boundary as displayed interval data.

The locator cofinality row is then read through chapter 1891 and the dyadic tolerance ledger of chapter 291. These rows force the selected finite window to be a displayed refinement of the same interval request before W or R can be consumed.

Finally the real-handoff ordering row sends every Real-facing read through W and R before E and the structural rows H, C, P, N are exposed. Since no coordinate of the carrier is an open cover, selected subcover, quotient-real equality witness, countable-choice schedule, trichotomy row, host interval equality, or ambient completeness theorem, the ledger non-escape obligation is exactly the absence of those rows. □

Theorem 2290.3 (Cofinal compact interval Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*, interval-compactness, Cousin-refinement, or Heine–Borel-style consumer admitted by an accepted* $\mathsf{CofinalCompactInterval}^{\uparrow}$ *packet reads the compact interval request through*

$$\mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{CompactIntervalLocator}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

in that order. The handoff exposes a finite cofinal window and its real seal; it exposes no open-cover compactness row, selected subcover, quotient real equality, countable-choice selector, trichotomy decision, host interval equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with an admitted consumer. By Definition 2322.2, the read first enters through the closed bounded interval row I, so the endpoint and containment data are fixed before any compact-window refinement is available.

Next the same obligation surface requires locator cofinality. The locator row L and dyadic ledger D therefore choose a displayed finite dyadic window for the same request before the stream row W and regular readback R are visible.

The real-handoff ordering row then sends the read through R to the real seal E, followed only by transport, replay, provenance, and the local naming row. Because the carrier has no other coordinate, the displayed six-object route exhausts the consumer-facing handoff and excludes the listed compactness, choice, quotient, order, host, and completeness data. □

Falsifiable prediction: An accepted $\mathsf{CofinalCompactInterval}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without first reading the closed bounded interval row, compact interval locator, dyadic tolerance ledger, finite stream window, and regular rational readback refutes the carrier surface.

Independence witness: closedboundedinterval, compact-interval-locator, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{CofinalCompactInterval}^{\uparrow}$ because this packet jointly carries the interval source, compact locator, cofinal dyadic window, stream schedule, regular readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalCompactInterval}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a CompactIntervalLocatorUp row, a DyadicRatCoreUp tolerance ledger, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2322.1, Definition 2322.2, and Definition 2322.3 seed the finite cofinal compact-interval route from closed bounded intervals through locator and dyadic-window rows to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, host interval equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exactness, locator cofinality, finite-window routing, regular readback, Real-seal handoff, structural transport, replay, provenance, and local naming for BEDC.Derived.CofinalCompactIntervalUp.

Chapter 2291

A Concrete Naming Certificate for InverseMappingTheorem$^{\uparrow}$

Following Banach and Rudin functional analysis, the InverseMappingTheorem$^{\uparrow}$ packet records the finite BEDC certificate for reading a bijective bounded linear operator between Banach rows as a bounded inverse row. It consumes the Banach source and target certificates of chapter 90, the bounded-operator surface of chapter 1644, the open-ball image route of chapter 1538, and the graph-read boundary of chapter 1537. The packet exposes only displayed rows: Banach endpoints, a bijective bounded-linear-operator row, an open-mapping image witness, an inverse-window ledger, transport, replay, provenance, and local naming.

Definition 2291.1 (Inverse mapping theorem carrier)**.** *An* InverseMappingTheorem$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, T, B, I, H, C, P, N)$$

with the following visible rows:

1. *X is the source* Banach$^{\uparrow}$ *row, including the displayed norm, metric, regular-Cauchy, and completion ledgers used by source-window consumers.*
2. *Y is the target* Banach$^{\uparrow}$ *row, including the displayed norm, metric, regular-Cauchy, and completion ledgers used by target-window consumers.*
3. *T is the* BoundedLinearOperator$^{\uparrow}$ *row from X to Y, carrying the endpoint action, linearity ledger, norm-bound endpoint, and bounded-operator provenance over the same Banach endpoints.*
4. *B is the bijectivity ledger. Its injective side records that equal target observations of T factor through the source classifier of X, and its surjective side records that every displayed target window has a scheduled source preimage window.*
5. *I is the* OpenMappingTheorem$^{\uparrow}$ *image-row witness. It records the finite open-ball image data and the bounded-inverse-facing source-window handoff supplied by the open-mapping packet for the same X, Y, T, B rows.*
6. *H records the inverse-window ledger: target tolerance requests, source preimage windows, norm-bound comparisons for the inverse row, and the finite dependencies on B and I.*
7. *C records componentwise* hsame *transport for X, Y, T, B, I, H and the structural rows.*

8. *P records displayed* Cont *replay from a bounded-inverse request through the Banach rows, the bounded operator row, the bijectivity ledger, the open-mapping image witness, the inverse-window ledger, and the closed-graph boundary.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{InverseMappingTheorem}^{\uparrow}}$ *row, with provenance over* $\mathsf{InverseMappingTheorem}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OpenMappingTheorem}^{\uparrow}$, $\mathsf{ClosedGraphTheorem}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

The carrier has no coordinate for a host inverse function, quotient operator space, selected inverse values outside the displayed windows, or completeness beyond the Banach source and target rows.

Theorem 2291.2 (Inverse mapping theorem NameCert obligations)**.** *For an accepted* $\mathsf{InverseMappingTheorem}^{\uparrow}$ *carrier* $Q = (X, Y, T, B, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{InverseMappingTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Banach source row, Banach target row, bounded-linear-operator row, bijectivity ledger, open-mapping image-row witness, inverse-window ledger, componentwise transport, replay, provenance, and local naming;*

2. *endpoint agreement, requiring T, B, and I to read the same displayed X and Y Banach rows before any inverse-window request is admitted;*

3. *bijective operator exposure, requiring inverse-facing consumers to read injective comparison and surjective preimage data through the bounded-operator row T and the finite ledger B;*

4. *open-mapping handoff, requiring every bounded-inverse norm estimate to pass through the* OpenMappingTheorem *image-row witness I before the inverse-window ledger H is public;*

5. *closed-graph compatibility, requiring graph-facing consumers to route the displayed inverse graph through chapter 1537 and the same X, Y, T, B, I, H rows;*

6. *structural replay, requiring* hsame, Cont, Pkg, *and local* NameCert *rows to preserve the same bounded-inverse route;*

7. *ledger non-escape, excluding host inverse functions, quotient operator spaces, selected inverse values outside the displayed windows, and ambient completeness beyond X and Y.*

No inverse mapping theorem obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.InverseMappingTheoremUp.InverseMappingTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 2291.1. The endpoint data are X and Y, the bounded operator is T, the bijectivity data are B, the open-mapping witness is I, and the inverse-window ledger is H.

Endpoint agreement is a rowwise condition. Since T, B, and I are all carried over the same displayed Banach endpoints, an inverse-facing consumer cannot mix an operator row from one source with an image-row witness from another target.

The bounded-inverse estimate is read in two stages. First B supplies the displayed injective and surjective windows for T. Then I supplies the open-ball image row from the $\mathsf{OpenMappingTheorem}^{\uparrow}$ packet, and only after that can H expose a source-window request and an inverse norm-bound comparison.

Closed-graph compatibility is the same displayed route viewed through graph reads. The closed-graph chapter supplies only the graph-facing boundary, so it cannot replace the Banach, bounded-operator, bijectivity, open-mapping, or inverse-window rows.

Finally C, P, N transport, replay, record provenance for, and name exactly this finite route. The excluded host inverse, quotient operator, selected-value, and ambient-completeness principles have no coordinate in the tuple. □

Closure status for $\mathsf{NameCert}_{\mathsf{InverseMappingTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InverseMappingTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2291.1 and Definition 2291.2 seed the finite bounded-inverse certificate over Banach source and target rows, bounded linear operators, bijectivity ledgers, open-mapping image witnesses, inverse-window ledgers, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InverseMappingTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse functions, quotient operator spaces, selected inverse values outside displayed windows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint agreement, bijective operator exposure, open-mapping handoff, closed-graph compatibility, structural replay, and ledger non-escape for BEDC.Derived.InverseMappingTheoremUp.

Constructive story: An $\mathsf{InverseMappingTheorem}^{\uparrow}$ packet is generated from displayed Banach endpoints, a BoundedLinearOperatorUp row, bijectivity ledgers, an OpenMappingTheoremUp image-row witness, inverse-window norm-bound data, componentwise hsame transport, Cont replay, provenance, and local naming.

Chapter 2292

A Concrete Naming Certificate for CompactUniformContinuityModulus$^{\uparrow}$

Following Bishop–Bridges/Heine–Cantor constructive compactness, the CompactUniformContinuityModulus$^{\uparrow}$ packet records the concrete tolerance-only modulus extracted from finite compact-net data and displayed pointwise continuity rows. It realizes the finite-net proof route of chapter 9237 through the compact metric surface of chapter 129, the graph and pointwise-radius surface of chapter 130, the downstream UniformModulus$^{\uparrow}$ interface of chapter 369, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names the modulus object itself, not an ambient open-cover theorem or a host-chosen Lebesgue number.

Definition 2292.1 (Compact uniform continuity modulus carrier)**.** *A* CompactUniformContinuityModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, F, M, D, R, H, C, P, N)$$

with the following visible rows:

1. *K is the compact finite-net row, including the displayed center bundle and covering radii used by the compact source.*
2. *F is the* ContinuousMap$^{\uparrow}$ *graph row together with the pointwise modulus rows attached to the centers named by K.*
3. *M is the selected rational lower-bound fold over the centerwise source radii supplied by F.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for the requested target tolerance, the centerwise radius comparisons, the lower-bound fold, and the final source tolerance.*
5. *R is the* Real$^{\uparrow}$ *seal boundary used only to read rational-radius and target-distance comparisons after the dyadic ledger has been displayed.*
6. *H records componentwise* hsame *transport for the compact source, pointwise modulus rows, lower-bound fold, dyadic ledger, real seal boundary, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a tolerance request through K, F, M, D, R, H, P, N to the downstream* UniformModulus$^{\uparrow}$ *row.*
8. *P is the* Pkg *provenance over* CompactUniformContinuityModulus$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected subcovers, host continuity, quotient stream equality, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityModulusUp.CompactUniformContinuityModulusTasteGate`
`single carrier alignment`

Theorem 2292.2 (Compact uniform continuity modulus NameCert obligations)**.** *For an accepted* $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$ *carrier* $Q = (K, F, M, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinui}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the compact finite-net row, pointwise modulus rows, selected rational lower-bound fold, dyadic tolerance ledger, real-seal boundary, transport, replay, provenance, and local naming;*
2. *source lock, requiring K and the source of F to name the same compact metric carrier before any center radius or graph row is read;*
3. *local modulus coverage, requiring every center selected by K to have a corresponding pointwise row in F;*
4. *lower-bound fold exactness, requiring the source tolerance to be computed through M and D from the displayed finite radius ledger rather than by a host minimum or selected Lebesgue number;*
5. *handoff exactness, requiring the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer to read only the tolerance row transported through H, C, P, N after the* $\mathsf{Real}^{\uparrow}$ *boundary R has sealed the rational comparisons.*

No compact uniform continuity modulus obligation is stored outside these rows.

Proof. Read the accepted carrier of Definition 2292.1. The compact source row K supplies only a finite center bundle and covering radii, while the continuous-map row F supplies graph reads and pointwise continuity radii over the same source.

The pointwise modulus rows in F attach radius information to the displayed centers. Thus each center used by the compact-net row has an explicit continuity row, and no center outside the finite bundle can affect the extracted modulus.

The selected rational lower-bound fold is carried by M and checked through D. It compares the requested target tolerance with the centerwise radii and records the finite route to the source tolerance. The $\mathsf{Real}^{\uparrow}$ seal boundary R is read only after these dyadic comparisons have been displayed.

The downstream $\mathsf{UniformModulus}^{\uparrow}$ row is therefore a tolerance-only modulus obtained from finite packet data. The transport, replay, provenance, and local naming rows preserve this route, so open-cover compactness, selected subcovers, host continuity, quotient stream equality, choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in the certificate. □

Theorem 2292.3 (Lebesgue number closed-interval compactness handoff)**.** *Every accepted* $\mathsf{CompactUniformContinu}$ *packet* $Q = (K, F, M, D, R, H, C, P, N)$ *hands a tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *row to compact-continuous consumers through finite-net coverage in K, pointwise modulus rows in F, the selected rational lower-bound fold M,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance transport in D, the* $\mathsf{Real}^{\uparrow}$ *seal boundary R, and the structural rows H, C, P, N. The handoff exports no open-cover compactness theorem, selected subcover, host-continuity principle, choice coordinate, quotient stream equality, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the finite-net row K. It displays the centers and coverage radii that replace an open-cover compactness read at the packet boundary.

Read the pointwise rows F over those centers. The selected rational lower-bound fold M then combines the displayed source radii, and the dyadic ledger D transports the requested target tolerance through that fold.

Finally read the seal and structural rows. The $\mathsf{Real}^{\uparrow}$ boundary R seals only the rational comparisons already displayed by D, while H, C, P, N transport, replay, source, and name the same route. Hence the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer receives exactly this tolerance-only row and no excluded compactness, continuity, choice, quotient, or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2292.1, Definition 2292.2, and Definition 2292.3 seed the finite modulus extraction certificate over compact finite-net rows, pointwise modulus rows, selected rational lower-bound folds, DyadicRatCore tolerance ledgers, RealUp seal boundaries, UniformModulus handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host continuity, choice, quotient stream equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source lock, local modulus coverage, lower-bound fold exactness, DyadicRatCore transport, Real seal boundary, UniformModulus handoff, transport and replay stability, and TasteGate field faithfulness for BEDC.Derived.CompactUniformContinuityModulusUp.

Constructive story: A $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$ packet is generated from compact finite-net rows, ContinuousMapUp pointwise-radius rows, selected rational lower-bound folds, DyadicRatCoreUp tolerance ledgers, RealUp comparison seals, componentwise hsame transport, Cont replay, provenance, and local naming.

Chapter 2293

A Concrete Naming Certificate for $\mathsf{PoissonKernel}^{\uparrow}$

Following Poisson and classical Fourier analysis, the $\mathsf{PoissonKernel}^{\uparrow}$ packet records the finite positive harmonic-analysis kernel by which a displayed radius row and angle-window row are read before any boundary or Abel-type consumer may compare it with Fejer and Dirichlet kernels. It sits beside the positive averaging surface $\mathsf{FejerKernel}^{\uparrow}$ of chapter 1939, the partial-sum surface $\mathsf{DirichletKernel}^{\uparrow}$ of chapter 2311, the terminal real-name seal of chapter 38, the regular rational sequence route of chapter 301, and the dyadic arithmetic ledger of chapter 291. The chapter names a finite positive kernel boundary; it does not import host harmonic functions, quotient function equality, analytic completion, countable choice, or a selected boundary limit.

Definition 2293.1 (PoissonKernel carrier)**.** *A* $\mathsf{PoissonKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, A, D, M, V, F, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the radius row, recording the displayed rational or dyadic radius request together with the comparison ledger asserting it lies inside the finite admissible radial window.*
2. *A is the angle-window row, recording the finite circle or phase samples at which the kernel is inspected.*
3. *D is the denominator row, recording the displayed expression $1 - 2r\cos(\theta) + r^2$ through finite real, regular-rational, and dyadic comparison rows.*
4. *M is the numerator row, recording the displayed expression $1 - r^2$ with the same radius ledger as R.*
5. *V is the kernel-value readback row, exposing only the finite quotient read determined by M, D, A, R.*
6. *F is the* $\mathsf{FejerKernel}^{\uparrow}$ *comparison row, recording the positive-kernel averaging corridor through which Fejer-facing consumers may compare displayed finite windows.*
7. *S is the* $\mathsf{DirichletKernel}^{\uparrow}$ *comparison row, recording the partial-sum corridor through which Dirichlet-facing consumers may compare displayed finite windows.*
8. *H records componentwise* hsame *transport for the radius, angle-window, denominator, numerator, value, comparison, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a boundary request through R, A, D, M, V, F, S in that order.*
10. *P is the* Pkg *provenance over* $\mathsf{PoissonKernel}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{DirichletKernel}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PoissonKernel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, A, D, M, V, F, S, H, C, P, N$. It has no coordinate for host harmonic-function equality, analytic completion, quotient boundary functions, countable choice, or a selected radial limit.

Lean4 ✓ `BEDC.Derived.PoissonKernelUp.TasteGate.PoissonKernelTasteGate single carrier alignment`

Theorem 2293.2 (PoissonKernel NameCert obligations)**.** *For every accepted* $\mathsf{PoissonKernel}^{\uparrow}$ *carrier $K = (R, A, D, M, V, F, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PoissonKernel}^{\uparrow}}$ *surface consists exactly of carrier admission for the radius row, angle-window row, denominator row, numerator row, kernel-value readback, Fejer comparison row, Dirichlet comparison row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public kernel read must first expose the same radius and angle rows, then the denominator and numerator ledgers, then the value readback, and only then the Fejer or Dirichlet comparison route. No Poisson-kernel obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2293.1. The displayed tuple exposes exactly the radius, angle-window, denominator, numerator, value, Fejer comparison, Dirichlet comparison, transport, replay, provenance, and local naming rows.

The value route is finite because V is read only after R, A, D, M have been displayed. The denominator and numerator ledgers share the radius row, so a consumer cannot replace the radial budget while preserving the accepted packet.

The comparison rows are downstream. Fejer-facing reads pass through F, Dirichlet-facing reads pass through S, and both routes inherit the same radius, angle, numerator, denominator, and value rows before any handoff is exposed.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for host harmonic functions, analytic completion, quotient boundary functions, countable choice, or selected radial limits, the refusal clause is exhausted by the carrier inventory. □

Theorem 2293.3 (PoissonKernel Fejer and Dirichlet handoff)**.** *Every accepted* $\mathsf{PoissonKernel}^{\uparrow}$ *comparison read factors through the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{FejerKernel}^{\uparrow},\ \mathsf{DirichletKernel}^{\uparrow}.$$

The radius and angle rows determine the displayed numerator, denominator, and kernel-value readback before either the positive Fejer corridor or the partial-sum Dirichlet corridor is exposed. The route exports no host boundary convergence theorem, analytic completion, quotient function equality, countable-choice selector, or selected limiting harmonic extension.

Proof. Let $K = (R, A, D, M, V, F, S, H, C, P, N)$ be accepted. Carrier projection exposes the real, regular-rational, and dyadic arithmetic rows through R, A, D, M, V before any comparison row can be inspected.

Replay C. A comparison request first reads the radius row and angle window, then the denominator and numerator ledgers, and then the kernel-value readback. Thus both comparison routes receive the same finite kernel value rather than a host function.

The Fejer handoff is exactly F, and the Dirichlet handoff is exactly S. Componentwise transport through H preserves the same displayed rows, while P, N record provenance and local naming. The excluded analytic and choice-theoretic objects are absent from the carrier, so no comparison read can export them. □

Falsifiable prediction: Every accepted $\mathsf{PoissonKernel}^{\uparrow}$ boundary-kernel read factors through a radius row, angle-window row, denominator row, numerator row, kernel-value readback, Fejer comparison row, Dirichlet comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: fejer-kernel, dirichlet-kernel, real, regseqrat, dyadicratcore: $\mathsf{PoissonKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a radius row, angle-window row, denominator ledger, numerator ledger, kernel-value readback, Fejer comparison, Dirichlet comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PoissonKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{PoissonKernel}^{\uparrow}$ packet is generated from a radius row, angle-window row, denominator row, numerator row, kernel-value readback, Fejer and Dirichlet comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoissonKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2293.1, Definition 2293.2, and Definition 2293.3 seed the finite positive Poisson-kernel surface for harmonic-analysis consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoissonKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host harmonic-function equality, analytic completion, quotient boundary functions, countable choice, selected radial limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius exactness, denominator and numerator stability, value readback, Fejer and Dirichlet handoff, transport, replay, provenance, local naming, Nontrivial PoissonKernelUp, and FieldFaithful PoissonKernelUp for BEDC.Derived.PoissonKernelUp.

Chapter 2294

A Concrete Naming Certificate for $\mathsf{ConstructiveGreenFunction}^{\uparrow}$

Following Courant–Hilbert and Evans, the $\mathsf{ConstructiveGreenFunction}^{\uparrow}$ packet records a finite boundary-kernel object for Dirichlet-style Green data without importing host harmonic-function equality or analytic completion. It sits beside the positive boundary kernel of chapter 2293, the finite PDE relation rows of chapter 194, the weak-trace surface of chapter 440, and the metric carrier of chapter 57. The packet names only displayed domain, boundary, relation, trace, distance, transport, replay, provenance, and local naming rows.

Definition 2294.1 (ConstructiveGreenFunction carrier)**.** *A* $\mathsf{ConstructiveGreenFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, B, R, K, S, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain row, recording the finite carrier of interior observations and the boundary-access ledger used by the Dirichlet request.*
2. *B is the boundary row, recording the named boundary samples and their finite incidence relation with the domain row.*
3. *R is the* $\mathsf{Pde}^{\uparrow}$ *relation row, recording the elliptic or boundary-value relation through displayed derivative and boundary-data rows.*
4. *K is the* $\mathsf{PoissonKernel}^{\uparrow}$ *comparison row, exposing the positive boundary-kernel corridor used when the Green packet is compared with a Poisson–Dirichlet read.*
5. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *trace row, recording the weak-trace and integrability data consumed by boundary-facing PDE requests.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row, recording the displayed interior-to-boundary distance, diagonal refusal, and comparison ledger.*
7. *H records componentwise* hsame *transport for the domain, boundary, PDE relation, Poisson comparison, Sobolev trace, metric distance, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-kernel request through $D, B, R, K, S, M, H, P, N$ in that order.*
9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveGreenFunction}^{\uparrow}$, $\mathsf{PoissonKernel}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveGreenFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host harmonic-function equality, analytic Green operators, quotient boundary functions, selected fundamental solutions, countable choice, or completed solution spaces.

Lean4 ✓ `BEDC.Derived.ConstructiveGreenFunctionUp.ConstructiveGreenFunctionTasteGate single carrier alignment`

Theorem 2294.2 (ConstructiveGreenFunction NameCert obligations)**.** *For every accepted* ConstructiveGreenFunct *carrier $G = (D, B, R, K, S, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveGreenFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the domain row, boundary row, PDE relation row, Poisson-kernel comparison row, Sobolev trace row, metric distance row, componentwise transport, displayed replay, provenance, and local naming row;*
2. *boundary-kernel exactness, requiring every Green read to fix D and B before it may inspect either the PDE relation row R or the Poisson comparison row K;*
3. *trace compatibility, requiring the Sobolev trace row S to consume the same boundary samples as B and the same PDE relation endpoints as R;*
4. *metric separation, requiring the distance row M to be the only source for interior-to-boundary distance comparisons and diagonal refusals;*
5. *transport and replay stability, requiring H and C to preserve the ordered route D, B, R, K, S, M under componentwise* hsame *and displayed continuation;*
6. *provenance and name exhaustion, requiring P and N to export no host harmonic-function equality, analytic completion, quotient boundary function, selected fundamental solution, countable-choice selector, or completed solution space.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2294.1. The displayed tuple exposes exactly the domain, boundary, PDE relation, Poisson comparison, Sobolev trace, metric distance, transport, replay, provenance, and local naming rows.

For boundary-kernel exactness, replay a request through C. The request first fixes the domain row D and boundary row B; only then can it inspect the PDE relation row R or the Poisson comparison row K.

Trace compatibility is read from B, R, S. The Sobolev trace row consumes the same boundary samples and the same derivative or relation endpoints already displayed by the PDE row, so it does not introduce a separate host trace operator.

Metric separation is the role of M. Interior-to-boundary comparisons and diagonal refusals are read from the displayed distance row before any downstream Green or Dirichlet consumer can cite them.

Finally, H, C, P, N transport, replay, source, and name the same finite route. The excluded analytic and choice-theoretic objects are absent from the carrier inventory, so the local certificate cannot export them. □

Theorem 2294.3 (ConstructiveGreenFunction Poisson–Dirichlet handoff)**.** *Every Poisson–Dirichlet consumer of an accepted* $\mathsf{ConstructiveGreenFunction}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{Pde}^{\uparrow} \longmapsto \mathsf{Sobolev}^{\uparrow} \longmapsto \mathsf{PoissonKernel}^{\uparrow}.$$

The route first reads the displayed distance and boundary incidence rows, then the PDE relation row, then the Sobolev trace row, and only then the Poisson-kernel comparison. It exports no host harmonic-function equality, analytic completion, quotient boundary function, selected Green operator, countable-choice selector, or completed solution space.

Proof. Start with an accepted carrier $G = (D, B, R, K, S, M, H, C, P, N)$. Carrier projection exposes M as the only metric distance source and exposes D, B as the only domain and boundary incidence rows.

Replay the continuation row C. A Dirichlet request reads the displayed distance and boundary data before it reaches the PDE relation row R, so the relation is consumed as finite BEDC data rather than as a host differential equation.

The Sobolev trace row S is then read over the same boundary samples and relation endpoints. This supplies the trace-facing ledger needed by the boundary consumer without adding a completed Sobolev quotient or selected representative.

Only after this trace route is fixed can the Poisson comparison row K be inspected. Transport through H and provenance through P, N preserve that ordered route, and the excluded analytic objects are not coordinates of the carrier. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveGreenFunction}^{\uparrow}$ boundary-kernel read factors through domain rows, boundary rows, PDE relation rows, PoissonKernel comparison, Sobolev trace data, MetricUp distance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: poisson-kernel, pde, sobolev, metric: $\mathsf{ConstructiveGreenFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries domain and boundary rows, PDE relation rows, Poisson comparison, Sobolev trace data, metric distance rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveGreenFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveGreenFunction}^{\uparrow}$ packet is generated from domain and boundary rows, PDE relation rows, PoissonKernel comparison, Sobolev trace data, MetricUp distance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveGreenFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2294.1, Definition 2294.2, and Definition 2294.3 seed the finite boundary-kernel certificate surface linking Poisson kernels, PDE relations, Sobolev trace data, and metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveGreenFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host harmonic-function equality, analytic Green operators, quotient boundary functions, selected fundamental solutions, countable choice, completed solution spaces, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, boundary-kernel exactness, trace compatibility, metric separation, Poisson–Dirichlet handoff, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveGreenFunctionUp.

Chapter 2295

A Concrete Naming Certificate for $\mathsf{FiniteModulusDiagonal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteModulusDiagonal}^{\uparrow}$ packet records the finite diagonal extraction surface needed by L10 Real-and-Completion consumers. It sits over the modulus-controlled Cauchy read of chapter 1423, the finite stream-window surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal boundary of chapter 38. The packet names a finite diagonal route before any quotient stream equality, selected limit, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem is available.

Definition 2295.1 (Finite modulus diagonal carrier)**.** *A* $\mathsf{FiniteModulusDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, S, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *modulus packet that schedules each requested dyadic precision.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger selected by M for the diagonal read.*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the finite diagonal comparisons inspected on those windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the scheduled finite windows and dyadic tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, T, Q have been displayed.*
6. *H records componentwise* hsame *transport for the modulus packet, window ledger, tolerance ledger, readback row, seal row, continuation row, provenance row, and local naming row.*
7. *C records the displayed* Cont *replay from a finite diagonal request through M, S, T, Q, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusDiagonal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a host-selected diagonal subsequence, countable choice, trichotomy, a detached limit, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteModulusDiagonalUp.FiniteModulusDiagonalTasteGate single carrier alignment`

Theorem 2295.2 (Finite modulus diagonal NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{FiniteModulusDiagonal}^{\uparrow}}$ *surface for Definition 2295.1 consists exactly of carrier exposure for D, modulus exposure through M, finite-window exposure through S, dyadic diagonal tolerance exposure through T, regular rational readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Each accepted finite diagonal request is classified only by the displayed route through the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet, the* $\mathsf{StreamName}^{\uparrow}$ *window ledger, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row.*

Proof. Project the carrier tuple $D = (M, S, T, Q, E, H, C, P, N)$. The analytic rows are exactly the modulus packet, stream windows, dyadic tolerance ledger, regular readback, and real seal.

Read the structural rows next. The witnesses H, C, P, N transport, replay, source, and name the same finite route, so the local certificate has no hidden analytic coordinate.

The excluded principles are absent from the tuple in Definition 2295.1. Hence the listed rows exhaust the seed obligation surface. □

Theorem 2295.3 (Finite modulus diagonal window cofinality)**.** *Let $D = (M, S, T, Q, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteModulusDiagonal}^{\uparrow}$ *packet. For any two finite diagonal precision requests whose second request refines the first, the window selected by M and displayed in S for the second request is cofinal over the earlier window. It preserves the earlier* $\mathsf{StreamName}^{\uparrow}$ *observations, keeps the earlier* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance entries inside T, and leaves the associated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q and terminal* $\mathsf{Real}^{\uparrow}$ *seal E attached to the same carrier route.*

Proof. Read the underlying modulus packet M through chapter 1423. Refining a finite precision request may enlarge the displayed StreamName window, but it does not erase the earlier scheduled window.

The dyadic ledger row T records both the earlier tolerance entries and the refined entries as finite packet data. The readback row Q is consumed only after this ledger is displayed, so the refined request preserves the earlier rational readback route.

Finally replay C and transport by H. The terminal seal row E remains the same displayed $\mathsf{Real}^{\uparrow}$ handoff, and the provenance and local naming rows P, N keep the cofinal route inside the accepted carrier. □

Theorem 2295.4 (Finite modulus diagonal Real-seal handoff)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{FiniteModulusDiagonal}^{\uparrow}$ *packet factors through*

$$\mathsf{RealCauchyModulus}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Equivalently, the diagonal consumer reaches E only after the finite modulus row M, window ledger S, tolerance ledger T, and regular readback row Q have been displayed and replayed by H, C, P, N.

Proof. Project the accepted carrier. The row E is not a detached real value; it is a named coordinate after M, S, T, Q in the finite packet.

Use the cofinal window theorem Definition 2295.3. Any stronger diagonal request preserves the earlier finite window and readback route before it reaches the terminal seal.

The rows H, C, P, N only transport, replay, source, and name that route. Therefore every accepted Real-seal read factors through the displayed modulus-window-ledger-readback handoff. □

Lean4 ✓ `BEDC.Derived.FiniteModulusDiagonalUp.FiniteModulusDiagonalRealSealHandoff`

Theorem 2295.5 (Finite modulus diagonal ledger nonescape)**.** *No downstream L10 consumer of an accepted* $\mathsf{FiniteModulusDiagonal}^{\uparrow}$ *packet can bypass the displayed ledger* $M, S, T, Q, E, H, C, P, N$*. In particular, the packet does not expose a quotient stream, selected diagonal subsequence, host real equality, countable-choice row, unbounded stream read, detached limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Inspect the carrier in Definition 2295.1. The only analytic coordinates are the modulus packet, finite stream windows, dyadic tolerance ledger, regular rational readback, and terminal real seal.

The NameCert obligation theorem Definition 2295.2 says that every accepted local read is classified through those coordinates and the structural rows H, C, P, N.

Thus a consumer route omitting the displayed ledger is not a read of the accepted packet. The excluded principles have no carrier coordinate and cannot be introduced by the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusDiagonal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteModulusDiagonal}^{\uparrow}$ packet is generated from a RealCauchyModulus schedule, StreamName finite windows, a DyadicRatCore diagonal tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2295.1, Definition 2295.2, Definition 2295.3, Definition 2295.4, and Definition 2295.5 seed the finite modulus diagonal carrier over $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected diagonal subsequences, host real equality, countable choice, unbounded stream reads, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formalization should encode the carrier rows and prove the finite-window cofinality and Real-seal handoff over the displayed BEDC packet.

Chapter 2296

A Concrete Naming Certificate for $\mathsf{MedianLeakageSpectrum}^{\uparrow}$

The $\mathsf{MedianLeakageSpectrum}^{\uparrow}$ packet realizes the active median leakage table of Definition 9462.1336 and the direct leakage spectrum of Definition 9462.1344 as finite BEDC NameCert data. It consumes the six-coordinate source window of chapter 2234, the finite codon transition vocabulary of chapter 2245, the stabilization boundary of chapter 2270, the conditioned survival-chain route of **??**, and the host-primitive refusal surface of chapter 1157. The packet names a finite leakage spectrum; it does not identify median closure with biological translation identity, choose a stochastic model, or import host primitive enumeration.

Definition 2296.1 (MedianLeakageSpectrum carrier)**.** *A* $\mathsf{MedianLeakageSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, T, A, M, I, G, D, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source-window row exposing the finite six-bit codon carrier and coordinatewise median readback.*
2. *T is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *transition-vocabulary row naming the finite scan, elongate, terminate, readthrough, repair, and mutate states available to the consumer.*
3. *A is the active-triple row, recording the* 286 *distinct active triples and the closed versus leaking split* $264 + 22$.
4. *M is the median-output row, recording the coordinatewise majority output attached to each active triple.*
5. *I is the inactive-output row, listing the six direct inactive outputs* UUG, AAG, UGG, ACA, AUG, *and* UCG.
6. *G is the centrality ledger, recording the median centrality counts for active and inactive outputs together with the direct leakage multiplicities.*
7. *D is the direct-output multiplicity row, recording the displayed multiplicities* $8, 4, 4, 2, 2, 2$ *for the six inactive outputs.*
8. *H records componentwise* hsame *transport for the source window, transition vocabulary, active triples, median outputs, inactive outputs, centrality ledger, direct multiplicities, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a leakage request through W, T, A, M, I, G, D in that order.*
10. *P is the* Pkg *provenance over* MedianLeakageSpectrum$^{\uparrow}$, CodonSixBitWindow$^{\uparrow}$, CodonTransitionMatrix$^{\uparrow}$, SpectralStabilization$^{\uparrow}$, DoobSurvivalChain$^{\uparrow}$, HostPrimitiveLeakage$^{\uparrow}$, *Definition 9462.1336, Definition 9462.1344,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MedianLeakageSpectrum}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, T, A, M, I, G, D, H, C, P, N$. It has no coordinate for host primitive enumeration, biological translation identity, stochastic model selection, quotient codon equality, or an unrecorded median table.

Lean4 ✓ `BEDC.Derived.MedianLeakageSpectrumUp.MedianLeakageSpectrumUp single carrier alignment`

Theorem 2296.2 (MedianLeakageSpectrum NameCert obligations)**.** *For every accepted* MedianLeakageSpectrum$^{\uparrow}$ *carrier $L = (W, T, A, M, I, G, D, H, C, P, N)$, the local* NameCert$_{\text{MedianLeakageSpectrum}^{\uparrow}}$ *surface consists exactly of carrier admission for the codon source window, transition vocabulary, active-triple row, median-output row, inactive-output row, centrality ledger, direct-output multiplicity row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every leakage multiplicity read must expose A, M, I, G, D over the same W, T source before any downstream spectral, survival-chain, or host-primitive refusal consumer may inspect it. No median-leakage obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2296.1. The tuple displays the source window, transition vocabulary, active triples, median outputs, inactive outputs, centrality counts, direct multiplicities, transport, replay, provenance, and local naming rows.

The spectrum route is ordered. A consumer first reads W, T, then the active-triple ledger A, then the median-output row M, then the inactive-output row I, and then the centrality and multiplicity rows G, D.

The downstream dependencies are consequently consumers rather than hidden data. SpectralStabilization$^{\uparrow}$ and DoobSurvivalChain$^{\uparrow}$ may read the displayed spectrum only after the finite leakage rows are present, while HostPrimitiveLeakage$^{\uparrow}$ records that no host primitive enumeration may replace them.

Finally, H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier has no coordinate for biological translation identity, stochastic model selection, quotient codon equality, host primitive enumeration, or an unrecorded median table, the refusal clause is exhausted by the carrier inventory. □

Theorem 2296.3 (MedianLeakageSpectrum direct output route)**.** *Every accepted* MedianLeakageSpectrum$^{\uparrow}$ *direct-output read factors through*

$$\text{CodonSixBitWindow}^{\uparrow} \longmapsto \text{CodonTransitionMatrix}^{\uparrow} \longmapsto \text{SpectralStabilization}^{\uparrow} \longmapsto \text{DoobSurvivalChain}^{\uparrow} \longmapsto \text{HostPrimi}$$

The read exposes the active-triple ledger, median-output ledger, inactive-output row, centrality ledger, and direct-output multiplicities before it reaches any spectral stabilization, survival-chain, or host-primitive refusal consumer. In particular, a leakage multiplicity may not be read from D without the rows A, M, I, G that certify the finite table from which it came.

Proof. Let $L = (W, T, A, M, I, G, D, H, C, P, N)$ be accepted. Carrier projection first exposes the codon source window and finite transition vocabulary, so the six-bit median readback is tied to the same finite codon surface throughout the packet.

Replay C. The leakage request passes through the active triples, median outputs, inactive outputs, centrality ledger, and direct multiplicity row in sequence. Thus D cannot be consumed unless A, M, I, G have already been displayed.

The remaining siblings consume the displayed route. $\mathsf{SpectralStabilization}^{\uparrow}$ reads the finite spectrum boundary, $\mathsf{DoobSurvivalChain}^{\uparrow}$ reads the conditioned survival-chain corridor, and $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ refuses any replacement by host primitive enumeration. Transport through H and provenance through P, N preserve the same dependency route. □

Falsifiable prediction: Every accepted consumer that reads a $\mathsf{MedianLeakageSpectrum}^{\uparrow}$ leakage multiplicity without the active-triple row, median-output row, inactive-output row, and centrality ledger refutes the packet.

Independence witness: codon-six-bit-window, codon-transition-matrix, spectral-stabilization, doob-survival-chain, hostprimitiveleakage: $\mathsf{MedianLeakageSpectrum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries active triples, median outputs, inactive leakage rows, centrality counts, direct-output multiplicities, transport, replay, provenance, and local naming.

The Lean follow-up for `BEDC.Derived.MedianLeakageSpectrumUp` must supply explicit Nontrivial MedianLeaka and FieldFaithful $\mathsf{MedianLeakageSpectrum}^{\uparrow}$ instances preserving $W, T, A, M, I, G, D, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{MedianLeakageSpectrum}^{\uparrow}}$.

Constructive story: A $\mathsf{MedianLeakageSpectrum}^{\uparrow}$ packet is generated from a CodonSixBitWindow source row, CodonTransitionMatrix vocabulary row, active triples, median outputs, inactive leakage rows, centrality counts, direct-output multiplicities, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MedianLeakageSpectrum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2296.1, Definition 2296.2, and Definition 2296.3 seed the finite median-leakage spectrum surface for codon-window, transition, spectral, survival-chain, and host-primitive refusal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MedianLeakageSpectrum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological translation identity, stochastic model selection, quotient codon equality, host primitive enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, active-triple exactness, median-output exactness, inactive-output exactness, centrality and multiplicity ledgers, transport, replay, provenance, local naming, Nontrivial MedianLeakageSpectrumUp, and FieldFaithful MedianLeakageSpectrumUp for BEDC.Derived.MedianLeakageSpectrumUp.

Chapter 2297

A Concrete Naming Certificate for $\mathsf{PositiveCone}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{PositiveCone}^{\uparrow}$ packet isolates the positive cone over $\mathsf{Real}^{\uparrow}$ as finite apartness-from-zero data with algebra-facing closure rows. It refines the $\mathsf{PositiveReal}^{\uparrow}$ carrier of chapter 1587, the $\mathsf{ApartnessReal}^{\uparrow}$ separation surface of chapter 304, the $\mathsf{LocatedApartness}^{\uparrow}$ route of chapter 1380, and the finite-name substrates $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ used by chapter 38.

2297.1 Carrier and cone packet

Definition 2297.1 (PositiveCone carrier)**.** *A* $\mathsf{PositiveCone}^{\uparrow}$ *carrier is a finite packet* $(R, P, A, D, W, Q, H, C, K, N)$ *with the following displayed rows:*

1. R*, a sealed* $\mathsf{Real}^{\uparrow}$ *row for the real name whose cone membership is being classified;*
2. P*, a* $\mathsf{PositiveReal}^{\uparrow}$ *row naming the same real through finite positivity evidence;*
3. A*, an* $\mathsf{ApartnessReal}^{\uparrow}$ *apartness-to-zero row whose left endpoint is the zero real row and whose right endpoint is* R*;*
4. D*, a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger consumed by* A *and* P*;*
5. W*, a finite* $\mathsf{StreamName}^{\uparrow}$ *observation window shared by the zero row, the real row, and the positivity packet;*
6. Q*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled rational observations of* R *on* W*;*
7. H*, the componentwise* hsame *rows for the real seal, positivity row, apartness row, radius ledger, window, and readback;*
8. C*, the displayed* Cont *replay routes keeping the finite observations attached to the transported packet;*
9. K*, the* Pkg *provenance rows for the real seal, positive-real row, apartness ledger, dyadic radius, stream window, regular-rational readback, and replay surface;*
10. N*, the local* $\mathsf{NameCert}$ *row binding these nine rows as one positive cone certificate.*

The carrier contains no order decision coordinate, no quotient stream equality, no selected limit, and no ambient completeness witness. Cone membership is the finite compatibility of the displayed

real, positive-real, apartness, radius, window, readback, transport, continuation, provenance, and local certificate rows.

Lean4 ✓ `BEDC.Derived.PositiveConeUp.PositiveConeTasteGate single carrier alignment`

2297.2 NameCert obligations

Theorem 2297.2 (PositiveCone NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{PositiveCone}^{\uparrow}}$ *surface for the carrier of Definition 2297.1 consists of six finite obligations:*

1. *carrier admission: the displayed rows* $(R, P, A, D, W, Q, H, C, K, N)$ *occur in one finite* BHist *packet;*
2. *classifier transport: accepted cone carriers compare only by componentwise transport of the real seal, positive-real row, apartness row, radius ledger, finite window, readback, replay, provenance, and local certificate rows;*
3. *zero-exclusion: the apartness-to-zero row* A *and the positive-real row* P *share the same sealed real endpoint* R *and the same finite observation window* W*;*
4. *positive-radius exactness: the positive dyadic radius used by the apartness row and by the positive-real row is exactly the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*;*
5. *addition and multiplication closure surface: algebra consumers receive only the finite cone rows required to transport positivity across displayed addition-facing and multiplication-facing packet reads;*
6. *ledger non-escape: downstream consumers can inspect only the ten carrier rows and their* hsame*,* Cont*,* Pkg*, and* NameCert *witnesses.*

These obligations certify the positive cone as a finite NameCert packet over the real-name substrate. They do not certify trichotomy, a host total order, quotient equality of streams, selected limits, or ambient real completeness.

Proof. Project the carrier of Definition 2297.1. The projection exposes the sealed real row, the positive-real row, the apartness-to-zero row, the positive dyadic radius, the finite observation window, the regular-rational readback, transport, replay, provenance, and local certificate rows.

Carrier admission and classifier transport are componentwise. The hsame and Cont rows keep the real seal, positive-real packet, apartness packet, radius ledger, stream window, and readback attached to the same finite observation surface after transport.

Zero-exclusion and positive-radius exactness are read from the shared rows. The apartness endpoint and the positive-real carrier both name R, while D is the only positive dyadic radius ledger available to either positivity read.

The closure surface is therefore only a ledger interface for later algebraic consumers. Since the packet contains no coordinate for order decisions, quotient representatives, chosen limits, or completeness witnesses, every consumer remains confined to the displayed finite evidence. □

Theorem 2297.3 (PositiveCone apartness-order handoff)**.** *Every accepted* $\mathsf{PositiveCone}^{\uparrow}$ *read factors through the displayed* $\mathsf{PositiveReal}^{\uparrow}$*,* $\mathsf{ApartnessReal}^{\uparrow}$*, and* $\mathsf{LocatedApartness}^{\uparrow}$ *rows, together with the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite window, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of Definition 2297.1. Consequently a later order, metric-radius, or real-algebra consumer receives cone membership only as finite apartness-radius evidence with visible* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

No accepted read exports trichotomy, host order, quotient stream equality, selected limits, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted cone carrier and project its positive-real coordinate P. By Definition 2297.1, P shares the real endpoint R, the radius ledger D, the finite window W, and the readback row Q with the apartness-to-zero coordinate A.

Read the packet through the surrounding siblings. The $\mathsf{PositiveReal}^{\uparrow}$ row supplies positivity as apartness from zero, the $\mathsf{ApartnessReal}^{\uparrow}$ row exposes the finite separation packet, and the $\mathsf{LocatedApartness}^{\uparrow}$ route supplies the located handoff used by downstream metric-radius consumers.

Transport is again componentwise. The hsame, Cont, Pkg, and NameCert rows move the positive-real, apartness, radius, window, and readback coordinates together, so every transported read still factors through the displayed finite surfaces.

The carrier has no row for totality, trichotomy, quotient equality, selected limits, or real completeness. Therefore the handoff is an order-facing interface only through finite apartness-radius evidence. □

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveCone}^{\uparrow}}$.

Constructive story: A $\mathsf{PositiveCone}^{\uparrow}$ packet is generated from a sealed real row, a positive-real row, an apartness-to-zero row, one positive dyadic radius ledger, one finite observation window, one regular-rational readback, transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveCone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2297.1, Definition 2297.2, and Definition 2297.3 name the seed carrier, obligation surface, and finite apartness-order handoff for positive cone packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveCone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy of constructive reals, a host total order, quotient stream equality, selected limits, ambient real completeness, or a standard bridge.

Upgrade path: To reach obligationClosure, the carrier, six obligation rows, and apartness-order handoff must be checked as finite BEDC packet obligations.

Chapter 2298

A Concrete Naming Certificate for $\mathsf{ContextFreePumpingLemma}^{\uparrow}$

Following Bar-Hillel–Perles–Shamir and Hopcroft–Ullman, the $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ packet records the finite derivation-window evidence behind the context-free pumping lemma as NameCert data. It consumes the grammar surface of chapter 356, the regular-language comparison boundary of chapter 351, the finite automaton prefix surface of chapter 1016, the word rows of chapter 36, and the bound rows of chapter 28. The packet names the pumping certificate, not host language equality, infinite parse trees, grammar quotients, or a semantic closure theorem over all languages.

Definition 2298.1 (Context-free pumping lemma carrier)**.** *A* $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (G, W, D, A, E, I, Y, H, C, R, Q, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *grammar packet, including terminal alphabet, nonterminal carrier, start row, and production ledger.*
2. *W is the terminal* $\mathsf{List}^{\uparrow}$ *word row whose length comparison is read through* $\mathsf{Nat}^{\uparrow}$*.*
3. *D is the finite parse or derivation ledger yielding W from G.*
4. *A is the repeated-nonterminal row, recording the two derivation-prefix positions and the common nonterminal exposed inside the finite window.*
5. *E is the decomposition row, displaying the word factorization $W = uvxyz$ with the repeated-nonterminal window attached to v, x, y.*
6. *I is the pump-index row, read as a* $\mathsf{Nat}^{\uparrow}$ *input for the requested finite replay.*
7. *Y is the yielded-word row, displaying the pumped terminal word $uv^I xy^I z$ as a* $\mathsf{List}^{\uparrow}$ *row.*
8. *H records componentwise* hsame *transport for grammar rows, derivation prefixes, repeated-nonterminal evidence, decomposition rows, pump indices, and yielded words.*
9. *C records displayed* Cont *replay from a derivation prefix and pump index through the finite pump window.*
10. *R is the regular-language or finite-prefix consumer boundary, used only to compare the yielded word with sibling language-recognition packets.*

11. *Q is the* Pkg *provenance over* $\mathsf{ContextFreePumpingLemma}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FinitePrefixAutomaton}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContextFreePumpingLemma}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $G, W, D, A, E, I, Y, H, C, R, Q, N$. It contains no coordinate for host language equality, infinite derivation trees, grammar quotient semantics, countable choice over derivations, or semantic membership in an ambient language set.

Theorem 2298.2 (Context-free pumping lemma NameCert obligations)**.** *For every accepted* ContextFreePumpingL *carrier $P = (G, W, D, A, E, I, Y, H, C, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContextFreePumpingLemma}^{\uparrow}}$ *surface consists exactly of finite grammar admission through G; terminal-word and length admission through W; derivation-ledger admission through D; repeated-nonterminal exposure through A; decomposition through E; pump-index reading through I; yielded-word display through Y; componentwise transport through H; replay through C; sibling language-recognition boundary through R; provenance through Q; and local naming through N.*

Lean4 ✓ `BEDC.Derived.ContextFreePumpingLemmaUp.ContextFreePumpingLemmaTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 2298.1. The finite packet displays the grammar, word, derivation ledger, repeated nonterminal, decomposition, pump index, yielded word, transport, replay, consumer boundary, provenance, and local name.

The positive route begins at the finite derivation ledger D. The repeated nonterminal row A is read inside that ledger before the decomposition row E may expose the factors u, v, x, y, z.

The pump index I is then replayed through C to produce the yielded word row Y. The structural rows H, Q, N preserve and name that same finite route, while R only offers a sibling boundary for later regular-language or finite-prefix consumers.

Since the classifier has no coordinate for host language equality, infinite derivation trees, grammar quotient semantics, or semantic language membership, the listed rows exhaust the local NameCert obligations. □

Theorem 2298.3 (Context-free pumping window boundary)**.** *Let $P = (G, W, D, A, E, I, Y, H, C, R, Q, N)$ be an accepted* $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ *carrier. Every pumpable-yield read of P factors through the finite derivation-prefix rows D, A, E, I, Y before reaching transport, replay, provenance, local naming, or a sibling language-recognition boundary. No accepted read factors through host language equality, infinite derivation trees, grammar quotient semantics, or semantic membership in an ambient language set.*

Proof. Project the carrier of Definition 2298.1. The only rows capable of producing a pumped yield are the finite derivation ledger D, the repeated-nonterminal row A, the decomposition row E, the pump-index row I, and the yielded-word row Y.

Transport and replay preserve this displayed window. The hsame row H changes no grammar or word coordinate, and the Cont row C replays the same derivation prefix at the requested index.

The provenance and local naming rows close the packet, while R only places the yielded word at a regular-language or finite-prefix boundary. Because the absent host and quotient semantics are not carrier coordinates, they cannot supply another pumpable-yield route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContextFreePumpingLemma}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContextFreePumpingLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2298.1, Definition 2298.2, and Definition 2298.3 seed the finite context-free pumping certificate over grammar, word, derivation-prefix, repeated-nonterminal, decomposition, pump-index, yielded-word, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ContextFreePumpingLemma}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.ContextFreePumpingLemmaUp.ContextFreePumpingLemmaTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the full pumping lemma as a Lean theorem, host language equality, infinite derivation trees, grammar quotient semantics, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, repeated-nonterminal exposure, decomposition exactness, pump replay, yielded-word boundary, and ledger non-escape for BEDC.Derived.ContextFreePumpingLemmaUp.

Constructive story: A ContextFreePumpingLemma$^{\uparrow}$ packet is generated from finite grammar data, a terminal word, a finite derivation ledger, repeated-nonterminal evidence, a decomposition row, a pump index, a yielded word, componentwise hsame transport, Cont replay, sibling-recognition provenance, and local naming.

Chapter 2299

A Concrete Naming Certificate for $\mathsf{CompactUniformModulus}^{\uparrow}$

Following Bishop–Bridges compact metric continuity, the $\mathsf{CompactUniformModulus}^{\uparrow}$ packet realizes the finite-net fold named in chapter 9237. It consumes the metric source of chapter 57, the compact finite-cover surface of chapter 60, the pointwise continuity rows of chapter 59, the output interface of chapter 369, and the rational comparison rows of chapter 37. The packet names a finite uniform-modulus ledger, not an open-cover compactness theorem, selected Lebesgue number, sequential compactness principle, or host modulus function.

Definition 2299.1 (Compact uniform modulus carrier)**.** *A* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, K, F, L, Q, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the distance and comparison reads used by the compact and continuity surfaces.*
2. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, displaying the finite center bundle and covering radius ledger over X.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row, attaching a source radius to each displayed center and requested target tolerance.*
4. *L is the local finite-net fold ledger, matching each center from K with the corresponding pointwise row from F.*
5. *Q is the* $\mathsf{Rat}^{\uparrow}$ *comparison row computing the finite lower bound used as the source tolerance.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row produced from the fold ledger and rational comparison.*
7. *H records componentwise* hsame *transport for the metric, compact, continuity, fold, rational, output, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a target-tolerance request through $X, K, F, L, Q, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, K, F, L, Q, U, H, C, P, N$. It has no coordinate for selected subcovers, selected Lebesgue numbers, sequence extraction, countable choice, host minima, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CompactUniformModulusUp.CompactUniformModulusUp`
Lean4 ✓ `BEDC.Derived.CompactUniformModulusUp.CompactUniformModulusTasteGate single carrier alignment`

Theorem 2299.2 (Compact uniform modulus NameCert obligations)**.** *For an accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier $M = (X, K, F, L, Q, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, compact finite-net row, pointwise continuity row, local fold ledger, rational comparison row, uniform-modulus output, transport, replay, provenance, and local naming; source lock between X, K, F; finite coverage of every center named by K; rational lower-bound exactness through Q; output admission through U; and ledger non-escape from selected subcovers, selected Lebesgue numbers, sequence extraction, choice, host minima, and ambient completeness.*

Proof. Project the carrier of Definition 2299.1. The source metric row X is shared by the compact row K and the continuity row F, so the fold cannot change the underlying metric carrier.

The finite-net fold is displayed by L. It pairs each center recorded in K with a pointwise continuity radius from F, giving a finite ledger rather than a host-selected subcover or sequence argument.

The rational comparison row Q computes the lower bound consumed by the output row U. Transport, replay, provenance, and local naming preserve this route, so the absent compactness and choice principles have no coordinate in the NameCert surface. □

Theorem 2299.3 (Compact finite net to uniform modulus)**.** *Let $M = (X, K, F, L, Q, U, H, C, P, N)$ be an accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier. Every uniform-modulus read exported by M factors through the finite route*

$$X, K, F, L, Q, U, H, C, P, N.$$

The route first reads the compact finite-net rows and pointwise continuity rows, then folds their displayed rational bounds into Q, then exposes the $\mathsf{UniformModulus}^{\uparrow}$ *row U. It never passes through selected subcovers, selected Lebesgue numbers, sequential compactness, host modulus functions, countable choice, or ambient complete metric spaces.*

Proof. The carrier definition displays the only modulus-producing coordinates. A read cannot reach U before it has fixed the common source metric X, the finite-net row K, and the pointwise continuity row F.

The fold ledger L and rational comparison row Q provide the finite lower-bound computation. Thus the output is obtained from named rational data, not from an external minimum or selected Lebesgue number.

Finally H, C, P, N transport, replay, source, and name the same route. Since the excluded principles do not occur among the carrier rows, no accepted uniform-modulus read can factor through them. □

Theorem 2299.4 (Compact uniform modulus finite-net extraction)**.** *Let $M = (X, K, F, L, Q, U, H, C, P, N)$ be an accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier. Every finite-net extraction read exported by M exposes the same finite* ProbeBundle *lower-bound fold consumed by chapter 4118: the read must pass through X, K, F, L, Q before the* $\mathsf{UniformModulus}^{\uparrow}$ *output row U can be consumed. No selected*

subcover, selected Lebesgue number, host minimum, sequence extraction, or ambient completeness row is available to the extraction.

Proof. Project the carrier of Definition 2299.1. The rows $X, K, F, L, Q, U, H, C, P, N$ are the only displayed rows available to an accepted finite-net extraction read.

Use Definition 2299.2. It fixes source lock among X, K, F, finite coverage through K, rational lower-bound exactness through Q, and non-escape from selected compactness data.

Apply Definition 2299.3. The finite fold forces the read through K, F, L, Q before the output row U is visible, matching the lower-bound fold consumed by chapter 4118.

It remains to rule out alternate extraction data. The carrier classifier has no coordinate for a selected subcover, selected Lebesgue number, host minimum, sequence extraction, or ambient completeness row, so row exhaustion prevents any accepted extraction read from leaving the displayed finite route. □

Theorem 2299.5 (Compact uniform modulus RealSeparability handoff)**.** *A* $\mathsf{RealSeparability}^{\uparrow}$ *or compact-metric consumer may read an accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier* $M = (X, K, F, L, Q, U, H, C, P, N$ *only through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{Compact}^{\uparrow},\ \mathsf{Continuous}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The read exposes the metric source, compact finite-net row, pointwise continuity row, finite fold ledger, rational comparison row, uniform-modulus output, transport, replay, provenance, and local naming. It does not expose a selected Lebesgue number, selected subcover, host modulus function, sequence extraction principle, or ambient compact-metric completeness theorem.

Proof. Project the carrier of Definition 2299.1. The rows $X, K, F, L, Q, U, H, C, P, N$ give the metric source, compact finite-net row, pointwise continuity row, local fold, rational comparison, output, transport, replay, provenance, and local naming.

Use the obligation surface of Definition 2299.2. It fixes source lock, finite coverage, rational lower-bound exactness, output admission, and non-escape from selected compactness data as local NameCert obligations.

Finally apply the finite-net fold theorem Definition 2299.3. The fold forces every exported uniform-modulus read through $X, K, F, L, Q, U, H, C, P, N$, so a RealSeparability or compact-metric consumer receives only the displayed finite route and no selected Lebesgue number or host modulus. □

Definition 2299.6 (Compact uniform modulus Real route ledger)**.** *The* $\mathsf{CompactUniformModulus}^{\uparrow}$ *Real route ledger is the finite route*

$$X, K, F, L, Q, U, H, C, P, N$$

from compact finite-net rows and $\mathsf{Continuous}^{\uparrow}$ *pointwise moduli through* $\mathsf{Rat}^{\uparrow}$ *lower-bound folds into the* $\mathsf{UniformModulus}^{\uparrow}$ *output row and finally into* $\mathsf{Real}^{\uparrow}$ *consumer reads. It records only MetricUp, CompactUp, ContinuousUp, UniformModulusUp, RatUp, BHist, hsame, Cont, Pkg, and NameCert rows; it has no coordinate for a selected Lebesgue number, host modulus function, sequential compactness principle, selected subcover, or ambient Real completeness.*

Theorem 2299.7 (Compact uniform modulus Real route exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing compact uniform modulus read factors through the ledger of Definition 2299.6. Equivalently, the read passes through* $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg,

and NameCert *rows before it reaches a Real consumer. It exposes no selected Lebesgue number, host modulus function, sequential compactness argument, selected subcover, or ambient Real completeness.*

Proof. Project the carrier of Definition 2299.1. Its rows $X, K, F, L, Q, U, H, C, P, N$ are exactly the metric source, compact finite-net data, pointwise continuity data, local fold ledger, rational comparison row, uniform-modulus output, transport, replay, provenance, and local naming.

Use the NameCert obligations of Definition 2299.2. They bind source lock, finite coverage, rational lower-bound exactness, output admission, and ledger non-escape to those rows, so a consumer cannot bypass the finite packet.

Apply Definition 2299.3. The fold routes every exported modulus through the compact finite-net row, the pointwise continuity row, and the rational lower-bound computation before the $\mathsf{UniformModulus}^{\uparrow}$ output is visible.

Finally use Definition 2299.5. Its handoff already identifies the Real-facing route through the same finite rows. Replacing the RealSeparability consumer by a $\mathsf{Real}^{\uparrow}$ consumer changes only the terminal read, not the finite ledger that supplies it. □

Theorem 2299.8 (Compact uniform modulus vision route)**.** *Every accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier* $M = (X, K, F, L, Q, U, H, C, P, N)$ *realizes the finite* ProbeBundle *lower-bound fold described by chapter 9237. The route passes through* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{Continuous}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and it exposes no selected Lebesgue number, selected subcover, sequence extraction, choice principle, host modulus, or ambient completeness datum.*

Proof. Start with Definition 2299.3. It forces every exported uniform-modulus read through the compact finite-net row, the pointwise continuity row, the fold ledger, the rational comparison row, and the output row.

Use the Real route ledger of Definition 2299.6. That ledger identifies the BEDC row names as $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Finally apply Definition 2299.7. The exhaustion theorem rules out selected Lebesgue numbers, selected subcovers, sequence extraction, host moduli, and ambient completeness rows, so the displayed route is exactly the finite ProbeBundle lower-bound fold named by the vision chapter. □

Theorem 2299.9 (Compact uniform continuity Lebesgue-number factorization)**.** *Let* $M = (X, K, F, L, Q, U, H, C,$ *be an accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier. Whenever the compact finite-net row* K *and pointwise-continuity row* F *are presented as a finite cover, every exported* $\mathsf{UniformModulus}^{\uparrow}$ *row* U *factors through the finite Lebesgue-number route of chapter 2301. The factorization is through displayed finite rows: compact finite-net data, pointwise-radius cover rows, rational lower-bound ledger, and the uniform-modulus output route. It does not pass through a selected host Lebesgue number, selected subcover, host minimum, sequence extraction, or ambient completeness theorem.*

Proof. Start with the compact finite-net fold of Definition 2299.3. The exported uniform-modulus read must pass through $X, K, F, L, Q, U, H, C, P, N$, so the finite cover data from K and the pointwise-radius data from F are already displayed before U is visible.

When K and F are presented as a finite cover, read the finite Lebesgue-number route of chapter 2301. Its positive-radius ledger consumes compact metric and metric rows, the displayed cover or pointwise-radius family, and the finite $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ radius row before handing the result to $\mathsf{UniformModulus}^{\uparrow}$.

The rational lower-bound ledger Q is the comparison row by which the compact uniform-modulus packet consumes that finite positive-radius data. Thus the output route factors through

the same displayed finite rows used by the Lebesgue-number packet, and no selected host Lebesgue number is introduced.

Finally apply Definition 2299.2. The non-escape row excludes selected Lebesgue numbers, selected subcovers, host minima, sequence extraction, and ambient completeness, so the factorization remains internal to the finite BEDC ledger. □

Theorem 2299.10 (Compact uniform continuity vision marker route)**.** *Every accepted* $\mathsf{CompactUniformModulus}^{\uparrow}$ *carrier realizes the concrete route named by the compact-uniform-continuity vision marker for chapter 2299. The route factors through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold,* $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, with no selected host Lebesgue number, selected subcover, sequence compactness argument, external modulus selector, or ambient function-space equality.*

Proof. Read the carrier rows of Definition 2299.1 through the compact finite-net route of Definition 2299.3. The compact row and metric source combine as the $\mathsf{CompactMetric}^{\uparrow}$ access surface consumed by compact-uniform readers, while the pointwise continuity row supplies the $\mathsf{ContinuousMap}^{\uparrow}$ modulus data.

The rational comparison row is the $\mathsf{Rat}^{\uparrow}$ lower-bound fold. By Definition 2299.9, this fold is precisely the finite radius route through which the $\mathsf{UniformModulus}^{\uparrow}$ output is read.

Finally apply Definition 2299.2 and Definition 2299.7. They keep the route inside the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows and exclude selected host compactness, host modulus choice, and ambient equality coordinates. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2299.1, Definition 2299.2, and Definition 2299.3 seed the finite uniform-modulus packet over metric, compact finite-net, pointwise continuity, local fold, rational comparison, output, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected Lebesgue numbers, sequential compactness, host modulus functions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source lock, finite-net coverage, pointwise-modulus coverage, rational lower-bound exactness, uniform-modulus output, and ledger non-escape for BEDC.Derived.CompactUniformModulusUp.

Constructive story: A $\mathsf{CompactUniformModulus}^{\uparrow}$ packet is generated from a MetricUp source, CompactUp finite-net rows, ContinuousUp pointwise rows, a local finite fold ledger, RatUp comparisons, a UniformModulusUp output, componentwise hsame transport, Cont replay, provenance, and local naming.

Chapter 2300

A Concrete Naming Certificate for $\mathsf{MichaelSelection}^{\uparrow}$

Following Michael's selection theorem in the paracompact closed-convex reading, the $\mathsf{MichaelSelection}^{\uparrow}$ packet records the finite BEDC surface by which a lower-semicontinuous closed-convex value assignment exports local continuous selection data. It sits over the paracompact cover ledger of chapter 1963, the lower-semicontinuous epigraph and value-row surface of chapter 1536, the convex target rows of chapter 208, the continuous-map handoff of chapter 130, and the metric observation boundary of chapter 57. The packet names only a finite selection-surface ledger: domain cover and paracompact refinement rows, lower-semicontinuous closed-convex value rows, local finite selection rows, continuous-map handoff, componentwise transport, replay, provenance, and local naming. It does not import an arbitrary choice function, a host global selector, quotient equality of maps, Banach-space completeness, or ambient point-set topology.

Definition 2300.1 (Michael selection carrier)**.** *A* $\mathsf{MichaelSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, V, K, L, S, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain row carrying the* $\mathsf{Paracompact}^{\uparrow}$ *cover and refinement ledger used by the selection surface.*
2. *V is the value-assignment row read through* $\mathsf{LowerSemicontinuous}^{\uparrow}$*, exposing finite lower-semicontinuity windows for the closed-valued relation.*
3. *K is the closed-convex target row, read through* $\mathsf{ConvexSet}^{\uparrow}$ *together with the metric observation rows used by the target carrier.*
4. *L is the local finite selection ledger, matching each displayed cover cell from D with a value row from V and a convex target witness from K.*
5. *S is the finite stitching row that records compatibility of the local selection ledger on displayed cover refinements.*
6. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row exported only after D, V, K, L, S have been displayed.*
7. *H records componentwise* hsame *transport for the domain, value, convex-target, local selection, stitching, handoff, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$D, V, K, L, S \longmapsto F \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{MichaelSelection}^{\uparrow}$, $\mathsf{Paracompact}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MichaelSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, V, K, L, S, F, H, C, P, N$. It has no coordinate for an arbitrary selector, a host-level partition of unity, quotient equality of continuous maps, global choice over all fibres, ambient Banach completeness, or point-set topological semantics.

Lean4 ✓ `BEDC.Derived.MichaelSelectionUp.MichaelSelectionTasteGate single carrier alignment`

Theorem 2300.2 (Michael selection NameCert obligations)**.** *For every accepted* $\mathsf{MichaelSelection}^{\uparrow}$ *carrier $M = (D, V, K, L, S, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MichaelSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, paracompact domain-cover exposure through D, lower-semicontinuous closed-value exposure through V, closed-convex target exposure through K, local finite selection ledger exposure through L, displayed stitching through S, continuous-map handoff through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, local naming through N, and non-escape from arbitrary choice, host selectors, quotient map equality, ambient Banach completeness, and point-set topological semantics.*

Proof. Project the carrier of Definition 2300.1. The rows $D, V, K, L, S, F, H, C, P, N$ are the whole packet, so carrier admission and the visible obligation rows are read directly from the displayed tuple.

The analytic surface is the finite route D, V, K, L, S. The paracompact row supplies the cover and refinement ledger, the lower-semicontinuous row supplies value-window exposure, the convex row supplies closed-convex target witnesses, and the local ledger records the finite selection data over displayed cover cells.

Only after those rows are present may the continuous-map row F be read. The structural rows H, C, P, N transport, replay, source, and name the same route, so the excluded choice and host-topology principles have no carrier coordinate and cannot be obtained from the local NameCert. □

Theorem 2300.3 (Michael selection continuous handoff boundary)**.** *Every continuous-map consumer of an accepted* $\mathsf{MichaelSelection}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Paracompact}^{\uparrow},\ \mathsf{LowerSemicontinuous}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The $\mathsf{ContinuousMap}^{\uparrow}$ *handoff is terminal for the packet: it is reached only after the paracompact cover row, lower-semicontinuous closed-convex value row, local finite selection ledger, and stitching row have been displayed.*

Proof. Inspect the carrier order in Definition 2300.1. The continuous-map row F occurs downstream of the domain, value, convex-target, local selection, and stitching rows.

The NameCert obligations of Definition 2300.2 identify those rows as the public selection surface. A consumer therefore cannot cite F without also exposing D, V, K, L, S and the structural rows H, C, P, N.

The absent coordinates are exactly the host selector and choice principles excluded by the carrier. Hence the handoff exports a finite BEDC selection surface rather than an arbitrary global selection theorem. □

Falsifiable prediction: Every accepted $\mathsf{MichaelSelection}^{\uparrow}$ continuous-map read factors through a displayed $\mathsf{Paracompact}^{\uparrow}$ domain cover row, $\mathsf{LowerSemicontinuous}^{\uparrow}$ closed-value row, $\mathsf{ConvexSet}^{\uparrow}$ target row, local finite selection ledger, stitching row, terminal $\mathsf{ContinuousMap}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: paracompact, lowersemicontinuous, convexset, continuousmap, metric: $\mathsf{MichaelSelection}^{\uparrow}$ is not bijective to any listed sibling because it binds domain cover refinement, lower-semicontinuous closed-convex values, local finite selection rows, stitching, continuous-map export, transport, replay, provenance, and local NameCert rows into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MichaelSelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MichaelSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2300.1, Definition 2300.2, and Definition 2300.3 seed the finite Michael selection surface over paracompact cover rows, lower-semicontinuous closed-convex value rows, local finite selection rows, stitching, continuous-map handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MichaelSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary selection, host partition-of-unity construction, quotient map equality, ambient Banach completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paracompact cover exposure, lower-semicontinuous closed-convex value exposure, finite selection-ledger exactness, continuous-map handoff boundary, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.MichaelSelectionUp.

Constructive story: A $\mathsf{MichaelSelection}^{\uparrow}$ packet is generated from a paracompact domain cover row, a lower-semicontinuous closed-value row, a closed-convex target row, local finite selection rows, stitching rows, a continuous-map handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2301

A Concrete Naming Certificate for LebesgueNumberLemma$^{\uparrow}$

Following Lebesgue's finite-radius lemma for compact metric covers, the LebesgueNumberLemma$^{\uparrow}$ packet records the theorem-facing route that turns a compact metric finite-cover request into a positive radius ledger. It refines, rather than duplicates, the FiniteLebesgueNumber$^{\uparrow}$ surface of chapter 452: the latter is the finite radius ledger, while this packet names the compact-cover-to-ledger lemma route consumed by compact uniform continuity. It sits over the compact metric source of chapter 129, the metric observation rows of chapter 57, the continuous-map pointwise-radius surface of chapter 130, the FiniteLebesgueNumber$^{\uparrow}$ positive-radius ledger, and the UniformModulus$^{\uparrow}$ consumer of chapter 369.

Definition 2301.1 (Lebesgue number lemma carrier)**.** *A* LebesgueNumberLemma$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, F, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, including the finite-net and located coverage data used by the cover request.*
2. *M is the* Met$^{\uparrow}$ *distance-observation row through which cover radii and ball-containment checks are read.*
3. *F is the displayed finite cover or pointwise-radius family row, read through* ContinuousMap$^{\uparrow}$ *when the consumer is compact uniform continuity.*
4. *R is the positive* FiniteLebesgueNumber$^{\uparrow}$ *radius ledger produced for the displayed finite cover row.*
5. *U is the downstream* UniformModulus$^{\uparrow}$ *handoff row that may consume R after the compact and metric rows have been exposed.*
6. *H records componentwise* hsame *transport for K, M, F, R, U, P, N.*
7. *C records displayed* Cont *replay from compact metric finite nets and metric ball rows to the finite Lebesgue-number ledger and then to the uniform-modulus handoff.*
8. *P is the* Pkg *provenance over* LebesgueNumberLemma$^{\uparrow}$, CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LebesgueNumberLemma}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, M, F, R, U, H, C, P, N$. It has no coordinate for an arbitrary open-cover compactness theorem, selected subcover choice, host real minima, external Lebesgue numbers, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LebesgueNumberLemmaUp.LebesgueNumberLemmaTasteGate single carrier alignment`

Theorem 2301.2 (Lebesgue number lemma NameCert obligations)**.** *For every accepted* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *carrier $L = (K, M, F, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, metric observation row, displayed finite cover or pointwise-radius family, finite Lebesgue-number positive radius ledger, uniform-modulus handoff, componentwise transport, continuation replay, package provenance, and local naming; compact-source lock between K and M; cover-to-ledger exactness through F and R; uniform-modulus handoff through U; and non-escape from arbitrary open covers, selected subcovers, host minima, external Lebesgue numbers, and ambient completeness.*

Proof. Project the carrier of Definition 2301.1. The displayed tuple contains exactly the compact source, metric observation, finite cover, positive radius ledger, uniform handoff, and structural rows.

The finite radius is not selected externally. It is the row R of the carrier, read after the compact metric and metric rows have exposed the finite coverage data for F.

The rows H, C, P, N transport, replay, source, and name this same route. Since no host cover or external minimum coordinate exists in the carrier, the local NameCert surface exports only the finite BEDC lemma packet. □

Theorem 2301.3 (Lebesgue number lemma uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *carrier reaches* $\mathsf{UniformModulus}^{\uparrow}$ *only through*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{FiniteLebesgueNumber}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

The theorem-facing row is the route from compact finite-cover data to the positive finite Lebesgue-number ledger R; the ledger itself remains the sibling surface of chapter 452.

Proof. Read K, M, F first. These rows display the compact metric source, the metric ball observations, and the finite cover or pointwise-radius family that generates the cover request.

Then read R. By the obligations of Definition 2301.2, this is the only positive radius ledger exported by the packet, and it is exactly the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ row for the displayed cover data.

Finally the uniform-modulus handoff U may consume that ledger through H, C, P, N. The route therefore refines the existing finite-ledger packet without creating a synonym for it. □

Theorem 2301.4 (Lebesgue number lemma finite-net route)**.** *Every finite-net read used by an accepted* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *packet factors through the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, the* $\mathsf{Met}^{\uparrow}$ *ball-observation row, the displayed finite cover or pointwise-radius family, the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius ledger, and the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff. It cannot be replaced by arbitrary open-cover compactness or a selected subcover.*

Proof. Project the carrier rows of Definition 2301.1. A finite-net read is visible only through $K, M, F, R, U, H, C, P, N$.

The compact source row K supplies the finite-net and located coverage data, while M supplies the metric ball observations used to test the displayed cover or pointwise-radius row F. The positive radius ledger R is then the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ row for that displayed data.

The existing NameCert obligations in Definition 2301.2 and the uniform-modulus handoff of Definition 2301.3 compose this route before U is available to compact-uniform-continuity consumers.

Since arbitrary open-cover compactness and selected subcovers are not coordinates of $K, M, F, R, U, H, C, P, N$, no finite-net read in the packet can be replaced by those host principles. □

Theorem 2301.5 (Lebesgue number lemma obligation-closure package)**.** *The carrier, NameCert obligations, uniform-modulus handoff, and finite-net route of an accepted* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *packet assemble the full obligation surface over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *In carrier terms this surface is exactly the projection of*

$$K, M, F, R, U, H, C, P, N,$$

and it excludes arbitrary open-cover compactness and selected subcovers.

Proof. Start with the carrier of Definition 2301.1. Its rows $K, M, F, R, U, H, C, P, N$ are the compact metric source, metric observation, displayed cover or pointwise-radius family, finite Lebesgue-number ledger, uniform-modulus handoff, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations theorem, Definition 2301.2. It records carrier admission, compact-source lock, cover-to-ledger exactness, uniform-modulus handoff, transport, replay, provenance, and naming over precisely those rows.

Use the uniform-modulus handoff and finite-net route, Definition 2301.3 and Definition 2301.4. They keep every compact-uniform-continuity and finite-net consumer on the same displayed route through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$.

Since neither arbitrary open-cover compactness nor selected subcovers occur as coordinates of $K, M, F, R, U, H, C, P, N$, the obligation package closes the displayed BEDC surface without exporting those host principles. □

Falsifiable prediction: Every accepted $\mathsf{LebesgueNumberLemma}^{\uparrow}$ compact-uniform-continuity read must expose a $\mathsf{CompactMetric}^{\uparrow}$ source row, $\mathsf{Met}^{\uparrow}$ ball rows, a $\mathsf{ContinuousMap}^{\uparrow}$ pointwise-radius family when present, a $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ positive radius ledger, a terminal $\mathsf{UniformModulus}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, metric, continuousmap, finite-lebesgue-number, uniformmodulus: $\mathsf{LebesgueNumberLemma}^{\uparrow}$ is not bijective to any listed sibling because it binds the compact-cover-to-positive-radius theorem route between the compact metric source and the finite Lebesgue-number ledger before a UniformModulus consumer can read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberLemma}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueNumberLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2301.1, Definition 2301.2, and Definition 2301.3 seed the finite compact-cover-to-positive-radius lemma route consumed by compact uniform continuity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueNumberLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host minima, external Lebesgue numbers, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source lock, cover-to-ledger exactness, uniform-modulus handoff, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LebesgueNumberLemmaUp.

Constructive story: A LebesgueNumberLemma$^{\uparrow}$ packet is generated from a compact metric source row, metric ball observations, a finite cover or pointwise-radius family, a FiniteLebesgueNumber positive radius ledger, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2302

A Concrete Naming Certificate for $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$

Following Banach and Steinhaus, the $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ packet records the finite NameCert surface by which a pointwise bounded family of bounded linear operators exposes one uniform operator-norm ledger. It sits over the Banach source row of chapter 90, the bounded-operator family surface of chapter 1644, the scalar and norm rows of chapter 38 and chapter 1500, and the finite observation discipline already used by Banach-facing consumer packets.

Definition 2302.1 (Uniform boundedness principle carrier)**.** *A* $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, F, W, L, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *source row, including the normed-space and complete-metric observations used by the operator family.*
2. *F is the finite family row of* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *packets over the same Banach source and displayed target Banach rows.*
3. *W is the pointwise boundedness window ledger: every inspected source endpoint and every inspected operator row has a displayed* $\mathsf{Real}^{\uparrow}$ *bound read through the family surface.*
4. *L is the single uniform norm-bound ledger, read through* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{NormedRealLine}^{\uparrow}$*, and attached to the same family row F.*
5. *R records the Banach source rows, bounded-linear-operator rows, pointwise windows, and uniform bound as one route rather than as unrelated observations.*
6. *H records componentwise* hsame *transport for B, F, W, L, R, P, N.*
7. *C records displayed* Cont *replays from Banach source reads to operator-family reads, from pointwise boundedness windows to the uniform norm-bound ledger, and from the Real-facing bound to the local certificate.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$*,* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{BoundedLinearOperator}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{NormedRealLine}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformBoundednessPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, W, L, R, H, C, P, N$. It has no coordinate for an arbitrary family of host operators, a selected point outside the displayed windows, a quotient equality of functions, countable choice, or an ambient completeness theorem beyond the Banach row already carried in B.

Lean4 ✓ `BEDC.Derived.UniformBoundednessPrincipleUp.UniformBoundednessPrincipleTasteGate single carrier alignment`

Theorem 2302.2 (Uniform boundedness NameCert obligations)**.** *For every accepted* $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ *carrier $U = (B, F, W, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformBoundednessPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission for the Banach source, bounded-operator family, pointwise boundedness windows, uniform norm-bound ledger, route row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming; source lock between the Banach row and every operator-family member; pointwise-window exhaustion through W; uniform-bound exactness through L; and non-escape from host operator families, uninspected points, quotient function equality, countable choice, and ambient completeness outside B.*

Proof. Project the carrier of Definition 2302.1. The rows $B, F, W, L, R, H, C, P, N$ are the whole packet, so each local obligation is read from the displayed tuple.

The source lock is the route row R. It ties the $\mathsf{Banach}^{\uparrow}$ source used by F to the pointwise boundedness windows in W and to the uniform norm-bound ledger L.

The structural rows H, C, P, N transport, replay, source, and name this same route. Since the carrier has no coordinate for the excluded host principles, no accepted consumer can recover them from the local NameCert surface. □

Theorem 2302.3 (Uniform boundedness Banach handoff)**.** *Every Banach-facing consumer of an accepted* $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ *carrier factors through the ordered route*

$$\mathsf{Banach}^{\uparrow},\quad \mathsf{BoundedLinearOperator}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{NormedRealLine}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The exported datum is the uniform operator-norm ledger L attached to the family row F, not a host-level Banach-Steinhaus theorem, an external operator-family selector, or an unrestricted completeness principle.

Proof. Read the carrier order in Definition 2302.1. A consumer first sees the Banach source B and bounded-operator family F, then the pointwise boundedness windows W, and only then the uniform norm-bound ledger L.

Apply the NameCert obligations of Definition 2302.2. They require the pointwise windows and uniform ledger to be tied by R and transported only through H, C, P, N.

Thus every downstream Banach read receives the displayed finite route and no additional host operator family, countable choice principle, quotient function equality, or ambient completeness row. □

Theorem 2302.4 (Uniform boundedness window-to-ledger dependency)**.** *Every public uniform-bound read of an accepted* $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ *carrier must pass through the Banach source row of chapter 90, the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *family row of chapter 1644, the pointwise windows W, the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{NormedRealLine}^{\uparrow}$ *bound ledger L, and the route row R before it reaches the local* $\mathsf{NameCert}_{\mathsf{UniformBoundednessPrinciple}^{\uparrow}}$ *row. In particular, for $U = (B, F, W, L, R, H, C, P, N)$, the ledger L is not public as an isolated real bound; it is readable only through the dependency route B, F, W, R and the structural replay rows H, C, P, N.*

Proof. Project the carrier of Definition 2302.1. The tuple displays $B, F, W, L, R, H, C, P, N$, so a read of L occurs inside the same packet that carries the Banach source, the bounded-operator family, and the pointwise windows.

The route row R is the dependency witness. It records the Banach source rows, bounded-linear-operator rows, pointwise windows, and uniform bound as one route rather than unrelated observations, so L cannot be read without first exposing B, F, W, R.

The structural rows H, C, P, N preserve and replay this route before the local NameCert is reached. Thus a public uniform-bound read is a window-to-ledger dependency read, not a direct export of an isolated host-level Banach-Steinhaus conclusion. □

Theorem 2302.5 (Uniform boundedness pointwise-to-uniform route)**.** *For every accepted* UniformBoundednessPrin *carrier $U = (B, F, W, L, R, H, C, P, N)$, any public uniform bound for the bounded-operator family F over the Banach source B must be obtained from the displayed pointwise windows W over that same B and F, then routed through the uniform ledger L, the dependency row R, componentwise transport H, continuation replay C, package provenance P, and the local naming row N. No accepted read may export L as a uniform bound from a different source, a different operator family, an uninspected pointwise window, quotient equality of maps, countable choice, or ambient Banach completeness outside the carried row B.*

Proof. Project the carrier of Definition 2302.1. The rows B, F, W are the only source, family, and pointwise-window coordinates available to the packet, while L is the only uniform norm-bound ledger.

Apply Definition 2302.4. It forces every public read of L through the same Banach source, bounded-operator family, pointwise windows, and dependency row R before the local certificate is reached.

The structural rows H, C, P, N then transport, replay, source, and name that same route. Since the carrier has no coordinate for alternate sources, alternate families, hidden pointwise witnesses, quotient map equality, countable choice, or ambient completeness outside B, the public uniform bound is exactly the displayed pointwise-to-uniform route. □

Falsifiable prediction: Every accepted $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ consumer must expose a $\mathsf{Banach}^{\uparrow}$ source row, a $\mathsf{BoundedLinearOperator}^{\uparrow}$ family row, pointwise boundedness windows, one $\mathsf{Real}^{\uparrow}$ and $\mathsf{NormedRealLine}^{\uparrow}$ uniform norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the uniform bound is public.

Independence witness: banach, boundedlinearoperator, real, normed-real-line: $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a Banach source, a bounded-operator family, pointwise boundedness windows, a single uniform norm-bound ledger, route data, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformBoundednessPrinciple}^{\uparrow}}$ **.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformBoundednessPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2302.1, Definition 2302.2, and Definition 2302.3 seed the finite Banach-Steinhaus route through Banach source rows, bounded-operator family rows, pointwise boundedness windows, and one uniform norm-bound ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformBoundednessPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary host operator families, selected pointwise witnesses outside the displayed windows, quotient equality of maps, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source lock, pointwise-window exhaustion, uniform-bound exactness, Banach handoff boundary, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.UniformBoundednessPrincipleUp.

Constructive story: A UniformBoundednessPrinciple$^{\uparrow}$ packet is generated from a Banach source row, a bounded-linear-operator family row, pointwise boundedness windows, a uniform RealUp and NormedRealLine norm-bound ledger, a route row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2303

A Concrete Naming Certificate for $\mathsf{MetrizableCompletion}^{\uparrow}$

Following Kelley and Bourbaki on metrizable topological spaces and completion, the $\mathsf{MetrizableCompletion}^{\uparrow}$ packet records the finite BEDC route by which a topology equipped with a displayed metrization can be read by the existing metric-completion surface of chapter 1506. It sits after the $\mathsf{Topology}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ carrier rows, consumes the $\mathsf{MetricCompletion}^{\uparrow}$ branch and the $\mathsf{CompleteMetric}^{\uparrow}$ seal, and exposes only the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback path needed for completion-facing consumers.

Definition 2303.1 (MetrizableCompletion carrier)**.** *A* $\mathsf{MetrizableCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (T, M, Q, K, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *row, including the open-set classifier, neighborhood interface, and finite continuity rows visible to the packet.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *metrization row on the same carried histories, with a displayed comparison that says the topology read through T is the topology generated by the metric read through M.*
3. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *branch consumed from chapter 1506, including its Cauchy-filter or Cauchy-net evidence route.*
4. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *seal row for the completed metric-facing object, read only after Q has exposed the displayed completion branch.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row used to name the finite observation windows inspected by the completion route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for numerical tolerance data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint-seal row used when distance or convergence witnesses are compared.*
8. *H records componentwise* hsame *transport for the topology, metrization, metric-completion branch, complete-metric seal, stream, readback, endpoint, replay, provenance, and local naming rows.*

9. *C records the displayed* Cont *replay from topology admission through metrization, completion-branch admission, complete-metric sealing, stream/readback inspection, and endpoint comparison.*

10. *P is the* Pkg *provenance over* $\mathsf{MetrizableCompletion}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, a selected representative of a Cauchy name, host topological equality, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MetrizableCompletionUp.MetrizableCompletionTasteGate single carrier alignment`

Theorem 2303.2 (MetrizableCompletion NameCert obligations)**.** *For an accepted* $\mathsf{MetrizableCompletion}^{\uparrow}$ *carrier $Z = (T, M, Q, K, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology and metrization rows, compatibility of the topology row with the metric-generated topology, admission of the metric-completion branch Q, sealing by the complete-metric row K, stream/readback readiness through S and R, endpoint comparison through E, componentwise transport through H, replay through C, provenance through P, and ledger non-escape for the excluded host-side principles.*

Proof. Carrier admission is projection from Definition 2323.1. The tuple lists the topology, metrization, metric-completion branch, complete-metric seal, stream, readback, endpoint, transport, replay, provenance, and local naming rows.

The topology-metrization compatibility is local to T and M. A consumer may read open-set or neighborhood data only through the displayed metric generator row, and the packet gives no separate host-topology equality coordinate.

The completion-facing part then passes through Q and K. The row Q is exactly the metric-completion interface of chapter 1506; K seals the resulting read as complete-metric evidence only after that branch is displayed.

Finally S, R, and E provide the finite numerical route. Transport, replay, provenance, and local naming preserve the same displayed packet, so quotient completion equality, selected representatives, countable choice, open-cover compactness, host topological equality, and $\mathsf{Real}^{\uparrow}$ completeness cannot be exported. □

Theorem 2303.3 (MetrizableCompletion Cauchy seal)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetrizableCompletion}^{\uparrow}$ *carrier factors through the finite Cauchy seal*

$$T \longmapsto M \longmapsto Q \longmapsto K \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

In particular, a consumer cannot read the topological completion before the metrization row, cannot read complete-metric evidence before the $\mathsf{MetricCompletion}^{\uparrow}$ *branch, and cannot compare convergence data before the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed.*

Proof. Start with the topology row T. The packet admits it only together with the metrization row M, so a topological completion request first becomes a metric-facing request over the same carried histories.

Next apply the metric-completion branch. The row Q is the sole route to completion-facing data, and chapter 1506 already forces such data through a displayed Cauchy-filter or Cauchy-net branch.

The complete-metric seal K is downstream of Q. It does not select limits or quotient Cauchy names; it records that the displayed completion branch has the complete-metric evidence needed by the consumer.

The numerical seal is read last. Stream windows S precede regular-rational readback R, and the terminal endpoint comparison E is the only $\mathsf{Real}^{\uparrow}$ row offered to convergence comparisons. The transport, replay, provenance, and local naming rows retain this order, so no omitted host-side principle can enter the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MetrizableCompletion}^{\uparrow}$ packet is generated from a topology row, a metrizing metric row, the metric-completion branch, a complete-metric seal, StreamName windows, RegSeqRat readback, a terminal RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2323.1, Definition 2323.2, and Definition 2323.3 seed the finite metrizable-completion surface over topology, metric, completion, complete-metric, stream, readback, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host topological equality, open-cover compactness, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, topology-metrization compatibility, metric-completion branch routing, complete-metric sealing, Cauchy-seal exactness, and ledger non-escape over the same displayed packet.

Chapter 2304

A Concrete Naming Certificate for $\mathsf{EffectiveMetricCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive metric completion, the $\mathsf{EffectiveMetricCompletion}^{\uparrow}$ packet records the finite BEDC route by which located metric data is completed through explicit approximation schedules rather than quotient names or selected representatives. It sits between the metric-completion surface of chapter 1506, the located metric surface of chapter 1533, and the Real-and-Completion route through chapter 126, chapter 301, and chapter 38.

Definition 2304.1 (Effective metric completion carrier)**.** *An* $\mathsf{EffectiveMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (M, L, A, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *branch consumed from chapter 1506, read only as a displayed completion route.*
2. *L is the* $\mathsf{LocatedMetric}^{\uparrow}$ *source row from chapter 1533, including the located distance comparisons visible to the packet.*
3. *A is an effective approximation and modulus ledger, listing finite precision requests, response windows, and the monotone schedule by which later requests refine earlier windows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the finite observation windows inspected by the completion route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational regular-sequence data emitted by the approximation ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row used for distance and convergence comparisons after S and R have been displayed.*
7. *H records componentwise* hsame *transport for the completion branch, located metric source, approximation ledger, stream windows, readback, seal, replay, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from located metric admission through effective approximation, stream inspection, readback, and terminal Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{EffectiveMetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{EffectiveMetricCompletion}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, a selected Cauchy representative, host metric equality, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.EffectiveMetricCompletionUp.EffectiveMetricCompletionTasteGate single carrier alignment`

Theorem 2304.2 (EffectiveMetricCompletion NameCert obligations)**.** *For an accepted* $\mathsf{EffectiveMetricCompletion}^{\uparrow}$ *carrier* $Y = (M, L, A, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EffectiveMetricCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric-completion branch and located metric source, effective approximation ledger admission, stream-window readiness, regular-rational readback, terminal Real sealing, componentwise transport, displayed replay, provenance, local naming, and ledger non-escape for the excluded host-side principles.*

Proof. Carrier admission is projection from Definition 2304.1. The packet lists the completion branch, located metric source, approximation ledger, stream windows, readback, Real seal, transport, replay, provenance, and local naming rows.

The effective approximation row A is downstream of both M and L. A consumer must therefore read the completion request through the displayed metric-completion branch and the located metric source before it can inspect any finite precision window.

The numerical route is then forced through S, R, E. Stream names provide the finite windows, regular rational sequences provide the readback, and the Real row supplies only the terminal seal for comparisons already exposed by the earlier rows.

Finally H, C, P, N preserve the same displayed route under transport, replay, provenance, and local naming. Since the carrier has no remaining row, quotient completion equality, selected representatives, countable choice, host equality, open-cover compactness, and $\mathsf{Real}^{\uparrow}$ completeness cannot be exported. □

Theorem 2304.3 (EffectiveMetricCompletion Real-seal handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{EffectiveMetricCompletion}^{\uparrow}$ *carrier factors through the finite handoff*

$$M \longmapsto L \longmapsto A \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

In particular, the terminal $\mathsf{Real}^{\uparrow}$ *seal is read only after the metric-completion branch, located metric source, effective approximation ledger, StreamName windows, and RegSeqRat readback have all been displayed.*

Proof. Start with the completion branch M and located source L. The carrier exposes no completion-facing request unless those two rows have already been displayed in the same finite history packet.

Next route through the approximation ledger A. Its finite modulus entries bind each requested precision to a displayed window, so the consumer cannot choose a hidden representative or import a countable-choice schedule.

The handoff to Real data proceeds through S and R. The stream row names the inspected window, and the regular rational row supplies the finite readback consumed by the terminal Real seal.

It remains to check non-escape. Transport, replay, provenance, and local naming keep the same row order, so route exhaustion leaves no coordinate for quotient completion equality, selected representatives, host equality, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveMetricCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveMetricCompletion}^{\uparrow}$ packet is generated from a metric-completion branch, a located metric source, an effective approximation and modulus ledger, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2304.1, Definition 2304.2, and Definition 2304.3 seed the finite effective metric completion surface over located metric data, explicit approximation schedules, stream windows, rational readback, Real sealing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, approximation-ledger routing, stream-window readiness, RegSeqRat readback coherence, Real-seal handoff, and ledger non-escape over the same displayed packet.

Chapter 2305

A Concrete Naming Certificate for $\mathsf{CompletionTower}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley's separated uniform completion route, the $\mathsf{CompletionTower}^{\uparrow}$ packet records the finite tower read in which a source metric is completed, read through a second completion request, and flattened by displayed idempotence rather than by quotient equality or selected representatives. It sits after the metric-completion surface of chapter 1506, the idempotent Cauchy-completion row of **??**, the uniform-completion boundary of chapter 1473, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a finite route for repeated completion reads without importing an ambient completed-object equality.

Definition 2305.1 (Completion tower carrier)**.** *A* $\mathsf{CompletionTower}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, F, S, D, I, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric row, carrying the displayed distance and tolerance requests before any completion consumer reads the tower.*
2. *F is the first* $\mathsf{MetricCompletion}^{\uparrow}$ *row produced from M.*
3. *S is the second completion-request row, recording the attempted completion of the already completed presentation.*
4. *D is the dense embedding row from the source metric into the first completion row.*
5. *I is the* $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$ *flattening row, recording that the second completion request reuses the first completion surface.*
6. *Q is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row, making equality-facing reads pass through separated data rather than host equality of completed points.*
7. *R is the regular readback and Real-facing route through* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.
8. *H records componentwise* hsame *transport for the metric, completion, embedding, flattening, separated comparison, readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$M \longmapsto F \longmapsto S \longmapsto D, I, Q, R.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompletionTower}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionTower}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompletionTowerUp.CompletionTowerTasteGate single carrier alignment`

Theorem 2305.2 (Completion tower NameCert obligations)**.** *For every accepted* $\mathsf{CompletionTower}^{\uparrow}$ *carrier* $T = (M, F, S, D, I, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionTower}^{\uparrow}}$ *surface consists exactly of source metric exposure, first completion exposure, second completion-request exposure, dense embedding, idempotence flattening, separated comparison, regular and Real-facing readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from quotient completion equality, selected representatives, countable choice, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2305.1. The source metric row M, first completion row F, second completion-request row S, dense embedding row D, idempotence row I, separated comparison row Q, and readback row R are the only analytic coordinates in the packet.

The tower route is then read in order. The first completion consumer reads F from M, the second request is displayed as S, and flattening is forced through I rather than through an equality of completed objects. The dense embedding row D and separated comparison row Q keep source and equality-facing reads visible.

Finally H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Since the excluded host-side principles are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted repeated-completion read factors through the source metric, first completion, second completion request, dense embedding, idempotence flattening, separated comparison, regular readback, transport, replay, provenance, and local naming rows.

Independence witness: metriccompletion, cauchy-completion-idempotent, uniformcompletion, regseqrat, real: $\mathsf{CompletionTower}^{\uparrow}$ is not bijective to any one sibling because it jointly carries first completion, second completion request, dense embedding, flattening, separated comparison, readback, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionTower}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompletionTower}^{\uparrow}}$, seed)

Scope closed: Definition 2305.1 and Definition 2305.2 seed the finite repeated-completion tower surface over displayed metric, completion, dense-embedding, idempotence, separated-comparison, readback, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompletionTower}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completed objects, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, repeated-completion flattening, dense-embedding routing, separated comparison, readback stability, transport and replay non-escape, and TasteGate field faithfulness for BEDC.Derived.CompletionTowerUp.

Constructive story: A $\mathsf{CompletionTower}^{\uparrow}$ packet is generated from a source metric row, first completion row, second completion request, dense embedding, idempotence flattening, separated comparison, uniform and regular readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2306

A Concrete Naming Certificate for $\mathsf{CoreStateGraph}^{\uparrow}$

The $\mathsf{CoreStateGraph}^{\uparrow}$ packet realizes the strict partial-aware core-state graph of Definition 9462.1810 as finite NameCert data. It records the 22 state rows, the single-coordinate edge ledger, the 9 component ledger, observed module-generator rows, transport, replay, provenance, and local naming surface used by the DNA-window boundary analysis. When the finite alphabet surface is needed, the packet consumes the displayed alphabet and readback rows of chapter 2260 before adding strict edges and component ledgers. The packet is a finite graph-state ledger for accepted reads, not a mechanistic evolutionary model, not a hidden distance oracle, and not a collapse of ambiguous table rows.

Definition 2306.1 (Core state graph carrier)**.** *A* $\mathsf{CoreStateGraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (V, E, K, M, T, H, C, P, N)$$

with the following displayed rows:

1. *V is the vertex ledger of the 22 partial-aware core states, retaining ambiguous rows as separate labels.*
2. *E is the strict edge ledger, adding an edge exactly when two state vectors differ in one core coordinate.*
3. *K is the component ledger with 9 connected components and the displayed component-size row.*
4. *M is the observed module-generator row for UGA, UAA/UAG, AGR, AUA, and AAA support moves.*
5. *T is the table-group provenance row tying vertices and components to the comparison-family table identifiers.*
6. *H records componentwise* hsame *transport for V, E, K, M, T and the local naming row.*
7. *C records displayed* Cont *replay of accepted graph reads through vertex, edge, component, module-generator, and table-group rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CoreStateGraph}^{\uparrow}$*, the originating DNA-window strict graph vision,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CoreStateGraph}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, E, K, M, T, H, C, P, N$. It has no coordinate for collapsed ambiguous rows, unlisted graph edges, a connectedness assertion, a hidden biological mechanism, or a host-side graph oracle.

Lean4 ✓ `BEDC.Derived.CoreStateGraphUp.CoreStateGraphTasteGate single carrier alignment`

Theorem 2306.2 (Core state graph NameCert obligations)**.** *For every accepted* $\mathsf{CoreStateGraph}^{\uparrow}$ *carrier* $G = (V, E, K, M, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CoreStateGraph}^{\uparrow}}$ *surface consists exactly of vertex-ledger exposure, strict edge-ledger exposure, component-ledger exposure, module-generator exposure, table-group provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from collapsed ambiguity, unlisted edges, hidden mechanisms, connectedness import, and host-side graph computation.*

Proof. Project the carrier of Definition 2306.1. The finite graph data are exactly the vertex row V, edge row E, component row K, module-generator row M, and table-group row T.

The strict graph read of Definition 9462.1810 is recovered by reading V before E, then reading K as the component ledger generated from that edge relation. The module-generator row M is separate from the strict edge row and therefore cannot add hidden edges.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Since no other coordinate appears in the carrier, accepted reads cannot collapse ambiguous states, import a connectedness theorem, or consult a host graph oracle. □

Theorem 2306.3 (Core state graph finite acceptance route)**.** *Every accepted* $\mathsf{CoreStateGraph}^{\uparrow}$ *read factors through the finite route*

$$V, E, K, M, T \longmapsto H, C, P, N.$$

Thus the read preserves the 22*-state ledger, the strict edge ledger, the* 9*-component ledger, and the module-generator row as separate displayed coordinates.*

Proof. Begin with the carrier projection. The graph-facing rows V, E, K specify the partial-aware state space, strict adjacency relation, and connected-component ledger.

Next read M and T. These rows record module-generator support and table-group provenance, but neither row rewrites the strict edge relation. The structural rows H, C, P, N then transport, replay, source, and name only the same finite coordinates.

The route is therefore exhausted by the displayed packet. A consumer that removes any one of V, E, K, M, T loses a named graph or provenance coordinate, so no accepted read can factor through a smaller hidden graph. □

Falsifiable prediction: Every accepted read of the strict core-state graph factors through the 22-state ledger, strict edge ledger, 9-component ledger, module-generator row, table-group provenance, transport, replay, provenance, and local naming rows.

Independence witness: Nearby finite graph and state-ledger siblings: codon-transition-matrix, dna-four-phase-alphabet-bridge, finite-observation-fold, and finite-observation-confluence. The $\mathsf{CoreStateGraph}^{\uparrow}$ packet is not bijective to any one sibling because it carries the partial-aware vertex ledger, strict edge ledger, component ledger, module-generator support, and table-group provenance simultaneously.

Later Lean work should place Nontrivial $\mathsf{CoreStateGraph}^{\uparrow}$ and FieldFaithful $\mathsf{CoreStateGraph}^{\uparrow}$ instances in the TasteGate surface. Nontriviality must distinguish carriers with the same vertex ledger but different strict edge or component rows, while field faithfulness must preserve $V, E, K, M, T, H, C, P, N$ separately.

Closure status for $\mathsf{NameCert}_{\mathsf{CoreStateGraph}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoreStateGraph}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2306.1, Definition 2306.2, and Definition 2306.3 seed the finite strict graph surface over state, edge, component, module-generator, table-group, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoreStateGraph}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a mechanistic evolutionary model, graph connectedness, hidden distance computation, collapsed ambiguous table rows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, strict edge exposure, component-ledger exposure, module-generator separation, finite route exactness, and TasteGate field faithfulness for BEDC.Derived.CoreStateGraphUp.

Constructive story: A $\mathsf{CoreStateGraph}^{\uparrow}$ packet is generated from a partial-aware vertex ledger, strict edge ledger, component ledger, module-generator support row, table-group provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2307

A Concrete Naming Certificate for MetaCICFrontierDependencyMatrix$^{\uparrow}$

The MetaCICFrontierDependencyMatrix$^{\uparrow}$ packet realizes the MetaCIC open-frontier ledger as finite matrix data. It places the four subject-reduction discharge rows beside the obstruction rows for dependent codomain, confluence, normalization, decidability, and audit-map consumers, so downstream chapters can cite a bounded dependency matrix rather than an informal checklist. The packet reads the open-problem ledger of section 9386.2, the subject-reduction discharge socket of chapter 719, the normalization boundary of chapter 892, and the route classifier of chapter 785.

Falsifiable prediction: Every accepted MetaCICFrontierDependencyMatrix$^{\uparrow}$ row factors through exactly one named positive support row or exactly one named obstruction row before any audit-map consumer reads it.

Independence witness: metacicopenproblemledger, subjectreductiondischargesocket, metacicnormalizationfrontier, subjectreductionrouteclassifier: the open ledger lists frontier questions, the discharge socket carries four positive subject-reduction rows, the normalization frontier names normalization obstructions, and the route classifier separates subject-reduction routes; none is bijective to the finite matrix packet that records positive rows, obstruction rows, and audit consumers together.

Definition 2307.1 (MetaCIC frontier dependency matrix carrier)**.** *A* MetaCICFrontierDependencyMatrix$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, A, L, P, Q, N, D, J, R, H, C, K, E)$$

with the following displayed rows:

1. B, A, L, P *are the four positive subject-reduction discharge rows: beta substitution, application-argument stability, lambda-domain subject reduction, and Pi-domain subject reduction.*
2. Q *is the dependent-codomain obstruction row separating application-argument stability from a closed subject-reduction theorem.*
3. N *is the MetaCIC normalization frontier row, including the reduction and normal-form boundaries read by normalization consumers.*
4. D *is the decidability frontier row for bounded checking and closed type-checking consumers.*
5. J *is the confluence and critical-pair obstruction row read by audit-map consumers.*

6. *R is the route-classifier row assigning each matrix row to positive support, obstruction, or audit consumer.*
7. *H records componentwise* hsame *transport for all positive, obstruction, classifier, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an audit-map request through a selected matrix row and its route-classifier entry.*
9. *K is the* Pkg *provenance over* $\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *E is the local* $\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these finite rows. It has no coordinate for a closed subject-reduction theorem, global confluence, full normalization, total decidability, or an audit-map result that bypasses the route classifier.

Theorem 2307.2 (MetaCIC frontier dependency matrix obligations)**.** *For every accepted* MetaCICFrontierDepende *carrier $M = (B, A, L, P, Q, N, D, J, R, H, C, K, E)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the four positive subject-reduction rows, dependent-codomain obstruction row, normalization frontier, decidability frontier, confluence boundary, route classifier, transport, replay, provenance, and local naming row;*
2. *row polarity, requiring each matrix row to be classified by R as positive support, obstruction, or audit consumer;*
3. *support factorization, requiring every positive row to factor through one of B, A, L, P before subject-reduction consumers may use it;*
4. *obstruction factorization, requiring every negative frontier row to factor through exactly one of Q, N, D, J before audit-map consumers may cite it;*
5. *nonescape, excluding closed subject reduction, global confluence, full normalization, total decidability, and audit-map closure outside the displayed rows.*

No frontier dependency matrix obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2307.1. The tuple displays the positive subject-reduction rows, obstruction rows, classifier, transport, replay, provenance, and local naming row.

Row polarity is the job of R. Each matrix entry must be read with its route-classifier tag before any consumer treats it as support or obstruction.

Support factorization then follows by exhaustion of the positive rows. The only positive coordinates are B, A, L, P, so a subject-reduction consumer cannot obtain a fifth support row from the matrix.

Obstruction factorization is the matching exhaustion over Q, N, D, J. These rows name the dependent-codomain, normalization, decidability, and confluence boundaries, and the replay row C preserves their route tags for audit consumers.

The nonescape clause inspects K, E and the carrier fields. Since no closed subject-reduction theorem, global confluence theorem, full normalization theorem, total decidability theorem, or completed audit-map result appears among the coordinates, none is exported by the packet. □

Theorem 2307.3 (MetaCIC frontier audit-map route)**.** *Every audit-map consumer of an accepted* $\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}$ *packet first reads the route classifier R, then either one positive support row among B, A, L, P or one obstruction row among Q, N, D, J, and only then replays the selected dependency through H, C, K, E. Thus the matrix is finite row data for frontier accounting, not a proof of closed subject reduction, confluence, normalization, decidability, or audit-map completion.*

Proof. An audit-map request begins at R, because the carrier gives no untagged dependency coordinate. The classifier chooses the polarity and the named row before the consumer can inspect the row content.

In the positive case, row exhaustion gives one of B, A, L, P. In the obstruction case, row exhaustion gives one of Q, N, D, J. The two cases are disjoint because the route classifier stores their tags before replay.

The structural rows H, C, K, E preserve and name the selected matrix entry. They do not add a closed theorem or a completed audit-map result, so the consumer remains inside finite frontier accounting. □

Theorem 2307.4 (MetaCIC frontier dependency matrix substitution support)**.** *Every beta-substitution or application-argument consumer of an accepted* $\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}$ *packet first factors through one of the positive support rows B, A, L, P. Every dependent-codomain, normalization, decidability, or confluence consumer first factors through one of the obstruction rows Q, N, D, J. The packet therefore supplies a finite substitution-support route for subject-reduction discharge, but it exports no closed subject-reduction theorem, no global normalization theorem, no total decidability theorem, and no confluence theorem.*

Proof. Project the carrier of Definition 2307.1. The substitution-facing support rows are exactly B, A, L, P, with B carrying beta substitution and A carrying application-argument stability.

The remaining frontier consumers are separated by row polarity. Dependent-codomain reads pass through Q, normalization reads through N, decidability reads through D, and confluence or critical-pair reads through J.

Exhaust the route classifier R. Since every row is tagged before replay through H, C, K, E, a consumer cannot cross from a positive support row into a closed global theorem, and an obstruction row cannot be read as a completed MetaCIC result. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2307.1, Definition 2307.2, and Definition 2307.3 seed the finite MetaCIC frontier matrix over positive support rows, obstruction rows, route-classifier tags, and audit-map consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, confluence, normalization, decidability, audit-map completion, Lean verification, or standard bridge closure.

Upgrade path: Obligation closure requires checked carrier admission, row polarity, support factorization, obstruction factorization, audit-map route replay, and nonescape for BEDC.Derived.MetaCICFrontierDependencyMatrixUp.

Constructive story: A $\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}$ packet is generated from four positive subject-reduction rows, named obstruction rows, a route classifier, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2308

A Concrete Naming Certificate for $\mathsf{NestedIntervalTheorem}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{NestedIntervalTheorem}^{\uparrow}$ packet records the constructive nested closed interval theorem as finite BEDC route data. It consumes the retained-window surface of chapter 320, the dyadic endpoint and tolerance ledger of chapter 291, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the interval-existence handoff without asserting quotient reals, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2308.1 (Nested interval theorem carrier)**.** *A* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted* $\mathsf{NestedInterval}^{\uparrow}$ *row, including the inspected closed rational or dyadic interval windows, endpoint-order rows, width rows, and displayed containment witnesses.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger that records the endpoint comparisons and the diameter-to-tolerance rows used by the retained windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule requested from the lower and upper endpoint rows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite interval windows and dyadic tolerance ledger.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for the interval, dyadic, stream, regular readback, Real seal, replay, provenance, and naming rows.*
7. *C records the displayed* Cont *replay from nested interval data through dyadic tolerance control, stream windows, regular readback, and Real seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalTheorem}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite host intersection object, a selected quotient representative, countable choice, trichotomy, a Cauchy-completion quotient, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.NestedIntervalTheoremUp`

Theorem 2308.2 (Nested interval theorem NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *carrier* $K = (I, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed nine-row packet,* $\mathsf{NestedInterval}^{\uparrow}$ *source exposure through* I*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance exactness through* D*,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff through* E*, and the structural transport, replay, provenance, and naming rows* H, C, P, N*.*

No obligation may be discharged by a host interval intersection, selected point, countable choice, trichotomy, quotient real, or ambient completeness principle.

Proof. Project the carrier of Definition 2308.1. The rows $I, D, S, R, E, H, C, P, N$ are the only coordinates visible to the local classifier.

The interval source is I. It exposes only the finite nested-window surface already available from $\mathsf{NestedInterval}^{\uparrow}$: endpoint order, width, containment, and retained-window rows.

The completion-facing route is finite. The ledger D reads the dyadic endpoint and tolerance comparisons, S lists the requested stream windows, R repacks those windows as a regular rational readback, and E is downstream of those rows.

The structural rows do not add mathematical principles. The transports H, continuations C, provenance P, and local certificate N preserve and name the same packet, so the excluded host intersection, choice, quotient, trichotomy, and completeness coordinates remain absent. □

Lean4 ✓ `BEDC.Derived.NestedIntervalTheoremUp.NestedIntervalTheoremTasteGate single carrier alignment`

Theorem 2308.3 (Nested interval theorem Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer reads the nested interval row I*, the dyadic endpoint and tolerance ledger* D*, the stream-window schedule* S*, the regular-rational row* R*, and only then the Real seal row* E *with its transports, continuations, provenance, and local naming.*

Proof. Start with the Real-facing read. Since E is the only Real seal coordinate in the carrier, every such read must pass through the rows that make E visible.

The source row is I. It supplies the finite nested closed interval windows and containment witnesses, while D supplies the dyadic endpoint comparisons and diameter-to-tolerance rows read from the same windows.

The name construction then passes through S and R. The finite stream schedule selects the requested endpoint windows, and the regular rational row records the corresponding Cauchy readback.

Finally H, C, P, N transport, replay, source, and name the same route. Because the carrier contains no coordinate for a host intersection object, selected point, quotient real, countable choice, trichotomy, or ambient completeness, the displayed handoff is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NestedIntervalTheorem}^{\uparrow}$ packet is generated from a NestedInterval row, a DyadicRatCore endpoint and tolerance ledger, StreamName finite windows, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 2308.1, Definition 2308.2, and Definition 2308.3 seed the finite constructive nested closed interval route from displayed nested windows to RegSeqRat readback and Real seal handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{NestedIntervalTheorem}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.NestedIntervalTheoremUp`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient reals, selected host intersections, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window exposure, dyadic endpoint and tolerance exactness, StreamName window exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NestedIntervalTheoremUp.

The routed HellyTheorem$^{\uparrow}$ chapter consumes chapter 208 and exports its finite subfamily ledger to chapter 2347 before the child files spell out the dependency route.

Chapter 2309

A Concrete Naming Certificate for $\mathsf{HellyTheorem}^{\uparrow}$

Following Helly and the finite-dimensional convexity tradition, the $\mathsf{HellyTheorem}^{\uparrow}$ packet records finite convex-intersection data as a BEDC naming surface. It consumes the convex-family rows of chapter 208, the finite witness rows of chapter 209, the ambient affine and vector rows of chapter 206 and chapter 47, and the compact finite-read discipline of chapter 129. The chapter names only finite subfamily ledgers, displayed intersection witnesses, transport, continuation replay, provenance, and local naming; it does not assert a host separation theorem, choice-selected intersection point, quotient convex-set equality, or ambient standard-model convexity.

The $\mathsf{HellyTheorem}^{\uparrow}$ packet also consumes $\mathsf{ConvexSet}^{\uparrow}$ carrier rows and the finite-subfamily rows of chapter 1792 before any intersection conclusion is exposed.

The finite convex-geometry route is visible before the Helly certificate is exported: $\mathsf{HellyTheorem}^{\uparrow}$ reads each family member through the $\mathsf{ConvexSet}^{\uparrow}$ carrier of chapter 208, then uses the Caratheodory-style finite convex-hull rows of chapter 2347 as the support ledger that keeps the intersection test finite.

The finite subfamily ledger exported by $\mathsf{HellyTheorem}^{\uparrow}$ is consumed by chapter 2347 as the boundary that keeps convex-hull support rows finite before Caratheodory support reduction is read. That ledger is not available from the ambient affine row alone: it is read only after the $\mathsf{ConvexSet}^{\uparrow}$ membership rows of chapter 208 and the $\mathsf{Polytope}^{\uparrow}$ finite witness rows of chapter 209 expose the subfamily boundary that the Caratheodory packet consumes.

The same finite subfamily ledger is a reusable dependency for convex-hull and Caratheodory consumers: chapter 2347 may read the $\mathsf{HellyTheorem}^{\uparrow}$ row only after the $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$ surfaces named above have fixed the displayed finite family boundary.

The finite closed-family indexing boundary is supplied by $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ through chapter 1792; $\mathsf{HellyTheorem}^{\uparrow}$ then specializes that boundary by adding affine ambient rows, vector displacement rows, convex-family membership, and polytope witnesses for the Helly subfamily ledger.

The concrete dependency route is horizontal rather than ambient: each finite family member is first read as a $\mathsf{ConvexSet}^{\uparrow}$ row through chapter 208, then the finite subfamily ledger S is checked against the finite-intersection carrier rows of chapter 1792, and only then may the full-family row I be exposed to a Helly consumer.

2309.1 Finite Convex Intersection Carrier

Definition 2309.1 (HellyTheorem carrier)**.** *A* $\mathsf{HellyTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, V, F, W, S, I, T, C, P, N)$$

with the following displayed rows:

1. *A is the finite-dimensional* $\mathsf{AffineSpace}^{\uparrow}$ *ambient row.*
2. *V is the associated* $\mathsf{VecSpace}^{\uparrow}$ *displacement row used by the affine coordinates.*
3. *F is a finite family of* $\mathsf{ConvexSet}^{\uparrow}$ *rows in the ambient affine space.*
4. *W is the* $\mathsf{Polytope}^{\uparrow}$ *finite witness ledger for displayed simplex, face, or hull witnesses used by the subfamily checks.*
5. *S is the finite subfamily intersection ledger, recording each inspected subfamily and its displayed nonempty intersection witness.*
6. *I is the resulting full-family intersection row exposed by the packet after the finite ledger has been replayed.*
7. *T records componentwise* hsame *transport for $A, V, F, W, S, I, C, P, N$.*
8. *C records displayed* Cont *replay from ambient affine data through convex-family rows, finite polytope witnesses, subfamily intersection checks, the full-family intersection row, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HellyTheorem}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, V, F, W, S, I, T, C, P, N$. It has no coordinate for host convex equality, ambient standard-model convexity, choice-selected points, separation or compactness theorems not displayed by the finite rows, or an infinite family of constraints.

Lean4 ✓ `BEDC.Derived.HellyTheoremUp.HellyTheoremTasteGate single carrier alignment`

2309.2 Helly NameCert Surface

Theorem 2309.2 (HellyTheorem NameCert obligations)**.** *For every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *carrier*

$$H = (A, V, F, W, S, I, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the ambient affine row, vector displacement row, finite convex-family row, finite polytope witness ledger, subfamily intersection ledger, full-family intersection row, transport, replay, provenance, and local naming;*
2. *ambient compatibility, requiring the* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *rows to be the only coordinates through which convex sets and polytope witnesses are read;*
3. *convex-family exposure, requiring each displayed family member to pass through a* $\mathsf{ConvexSet}^{\uparrow}$ *row before it enters any subfamily intersection check;*

4. *finite witness exactness, requiring every inspected subfamily intersection and every exported full-family intersection row to be backed by the displayed* $\mathsf{Polytope}^{\uparrow}$ *witness ledger;*
5. *subfamily ledger stability, requiring the finite intersection ledger* S *to be transported componentwise by* T *and replayed by* C *before* I *is exposed;*
6. *nonescape, excluding host convex-set equality, choice-selected intersection points, separation theorems, unlisted compactness principles, infinite-family claims, Lean verification, and bridge checking.*

No HellyTheorem obligation is stored outside these rows.

Proof. Project the accepted carrier. The ambient coordinates are A and V, the convex input is the finite family row F, and the finite witness coordinates are W, S, I.

Ambient compatibility is forced because the carrier has no second affine or vector coordinate. Every convex-family read therefore passes through F over the same A, V boundary.

The witness ledger W and the subfamily ledger S are the only rows that record inspected finite intersections. Transport T and replay C preserve those rows componentwise before the exported row I is read.

The remaining coordinates are provenance and local naming. Since no coordinate stores host convex equality, a choice-selected point, a separation theorem, an unlisted compactness principle, an infinite-family assertion, Lean verification, or bridge data, those objects cannot become local NameCert obligations. □

Theorem 2309.3 (Helly finite-intersection route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet routes a finite convex-intersection request through*

$$\mathsf{AffineSpace}^{\uparrow}, \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{Polytope}^{\uparrow} \longmapsto S \longmapsto I.$$

The route exposes ambient affine data, vector displacement data, convex-family membership, finite polytope witnesses, and the finite subfamily ledger before the full-family intersection row is available. A request bypassing one of these rows is outside the accepted $\mathsf{HellyTheorem}^{\uparrow}$ *carrier.*

Proof. Read the carrier of Definition 2309.1. The first two coordinates bind the ambient affine and vector rows, and the convex-family coordinate F is interpreted only over that ambient boundary.

The polytope witness row W and the finite subfamily ledger S supply the displayed intersection checks. The replay row C presents them before the full-family row I is exposed.

Thus a consumer reaches I only along the stated route. If any one of the ambient, convex-family, polytope-witness, or subfamily-ledger rows is missing, the packet has no finite coordinate from which the requested intersection row can be read. □

Theorem 2309.4 (Helly finite-intersection forward link)**.** *Every finite convex-intersection request accepted by a* $\mathsf{HellyTheorem}^{\uparrow}$ *packet consumes the finite closed-family indexing discipline of chapter 1792 before the full-family intersection row* I *is exposed. The* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$ *sibling supplies the finite-family ledger boundary, while* $\mathsf{HellyTheorem}^{\uparrow}$ *supplies the convex and affine specialization over* $A, V, F, W, S, I, T, C, P, N$.

Proof. Project the carrier of Definition 2309.1. The ambient and specialization rows are A, V, F, W, the finite subfamily ledger is S, the full-family intersection row is I, and T, C, P, N transport, replay, source, and name the same packet.

Apply Definition 2309.3. It requires the request to pass through the finite subfamily ledger S before I is available, so a consumer cannot read the full-family row directly from the ambient affine or convex-family rows.

The finite intersection property sibling provides the closed finite-family indexing boundary named in chapter 1792. Helly contributes the convex, affine, vector, and polytope-witness specialization attached to that boundary, rather than replacing it by a second indexing principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 2309.1, Definition 2309.2, and Definition 2309.3 seed the finite convex-intersection packet over affine ambient rows, vector displacement rows, convex-family rows, polytope witness ledgers, subfamily intersection ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convex-set equality, choice-selected intersection points, separation theorems, unlisted compactness principles, infinite-family Helly claims, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ambient compatibility, convex-family exposure, finite witness exactness, subfamily ledger stability, and finite-intersection routing for BEDC.Derived.HellyTheoremUp.

Constructive story: A $\mathsf{HellyTheorem}^\uparrow$ packet is generated from affine ambient data, vector displacement data, finite convex-family rows, finite polytope witness rows, finite subfamily intersection ledgers, a full-family intersection row, componentwise transport, continuation replay, provenance, and local NameCert rows.

The finite subfamily ledger exported by $\mathsf{HellyTheorem}^\uparrow$ is consumed by chapter 2347 through a concrete dependency route: first the convex-family membership rows are read from chapter 208, then the finite witness ledger is read from chapter 209, then the Helly full-family intersection row is exposed, and only after those rows are fixed may the Caratheodory support-reduction packet read a bounded support surface. This route records a downstream use of $\mathsf{HellyTheorem}^\uparrow$ without adding a theorem environment to the hub.

Theorem 2309.5 (Helly Caratheodory forward dependency)**.** *Every* $\mathsf{HellyTheorem}^\uparrow$ *finite-subfamily read that is exported to a convex-hull consumer must first consume the* $\mathsf{CaratheodoryConvexHull}^\uparrow$ *support-reduction route of chapter 2347 and the convex-hull carrier rows already displayed in Definition 2309.12. Only after those rows are visible may the packet export the Helly finite-intersection route of Definition 2309.18. The dependency is a finite forward read through the displayed convex-family, polytope, Caratheodory, and local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}$ *rows, not a host separation theorem, selected intersection point, or ambient convexity principle.*

Proof. Project the existing Helly dependency route. The convex-family rows and finite witness rows are displayed before the Helly subfamily ledger is inspected.

Next read the Caratheodory convex-hull surface. The support-reduction packet consumes the displayed subfamily ledger only as finite bounded-support data, so the convex-hull carrier remains upstream of the Helly finite-intersection export.

Finally repack the rows into the local Helly NameCert route. Since no row names a host separation theorem, selected intersection point, or ambient convexity principle, the exported dependency is exactly the finite forward route named in the statement. □

Theorem 2309.6 (Helly Caratheodory sibling route)**.** *The* $\mathsf{HellyTheorem}^\uparrow$ *finite-subfamily ledger is available to the* $\mathsf{CaratheodoryConvexHull}^\uparrow$ *consumer of chapter 2347 only after the* $\mathsf{ConvexSet}^\uparrow$, $\mathsf{Polytope}^\uparrow$, $\mathsf{AffineSpace}^\uparrow$, $\mathsf{VecSpace}^\uparrow$, *and* $\mathsf{CompactMetric}^\uparrow$ *rows expose the finite convex-family boundary. The consumed route is the displayed finite ledger through those rows and the local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^\uparrow}$ *packet; it is not a detached convexity principle, a selected intersection point, or a host support-reduction theorem.*

Proof. Project the Helly ledger as a finite subfamily packet. Its convex-family membership, polytope witness, affine and vector-space coordinates, and compactmetric boundary rows must be visible before a convex-hull consumer can read the finite-intersection surface.

Then pass the exposed ledger to the Caratheodory consumer. The consumer receives bounded-support data from the displayed packet, so the route remains tied to the same local NameCert rows.

No additional coordinate names host convexity, selected intersection points, or an external support theorem. The sibling route is therefore the finite dependency stated above. □

Theorem 2309.7 (Helly Caratheodory finite-dependency audit)**.** *Any* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily ledger exported to* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *must display* $\mathsf{ConvexSet}^{\uparrow}$ *membership,* $\mathsf{Polytope}^{\uparrow}$ *finite witnesses,* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *ambient rows, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-read boundary, and the local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *row before the Caratheodory bounded-support surface is consumed. The route exports no host separation theorem, selected intersection point, quotient convex-set equality, or ambient convexity principle.*

Proof. Start with the forward dependency theorem, Definition 2309.5. It places the convex-family and finite-witness rows upstream of any convex-hull consumer.

Apply the sibling route theorem, Definition 2309.6. It refines the dependency surface to $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, and the local Helly naming row before the Caratheodory surface is read.

The carrier non-escape boundary in chapter 2309 excludes host convex-set equality, choice-selected intersection points, separation theorems, unlisted compactness principles, and infinite-family claims. Hence the Caratheodory handoff is exactly the finite dependency audit stated above. □

Lemma 2309.8 (Caratheodory–Helly finite dependency route)**.** *Every* $\mathsf{HellyTheorem}^{\uparrow}$ *consumer that uses Caratheodory-style convex support data must first expose the finite convex-family row of chapter 208, the finite witness and face rows of chapter 209, and the bounded-support handoff of chapter 2347. Only after those rows are visible may the Helly packet read its subfamily-intersection ledger and export the full-family intersection row through* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$.

Proof. Project the $\mathsf{HellyTheorem}^{\uparrow}$ carrier from Definition 2309.1. The convex-family coordinate is displayed before the subfamily ledger can be inspected, and the finite witness rows are carried separately from the ambient affine data.

The Caratheodory convex-hull packet of chapter 2347 then supplies only bounded support rows. It does not select an ambient intersection point or add a host separation theorem.

Thus the dependency lattice is finite: convex-family rows and polytope witnesses feed the Caratheodory support route, and that route feeds the Helly subfamily ledger before the full-family row is exported. □

Theorem 2309.9 (Helly Caratheodory convex-hull sibling route)**.** *Every finite-intersection consumer that reads an accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet must read the convex-family row through the* $\mathsf{ConvexSet}^{\uparrow}$ *surface of chapter 208, the Caratheodory convex-hull route of chapter 2347, the finite closed-family boundary of chapter 1792, and the Helly carrier of chapter 2309 before the finite intersection witness is exported. The route is a dependency-lattice projection; it does not export an isolated convex-family oracle, ambient separation theorem, quotient convex-hull equality, or selected intersection point.*

Proof. Project the Helly carrier in chapter 2309. Its finite intersection witness is downstream of the convex-family row, finite closed-family indexing, affine or convex support rows, transport, replay, provenance, and local naming.

The convex-family row is first read through the $\mathsf{ConvexSet}^{\uparrow}$ sibling of chapter 208. The finite support and convex-hull read then passes through the Caratheodory route of chapter 2347, which records the displayed finite-combination dependency rather than an ambient hull operator.

Finally the finite-family ledger is read through chapter 1792. These three sibling routes are already dependency rows for the Helly packet, so composing them before the witness export is only a projection through the existing carrier and lattice.

Since no listed row carries an isolated convex-family oracle, separation theorem, quotient hull equality, or selected intersection point, the exported Helly witness remains the displayed finite-intersection route. □

Theorem 2309.10 (Helly finite-subfamily ledger route)**.** *Every* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily ledger consumed by* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *must read* $\mathsf{ConvexSet}^{\uparrow}$ *membership rows,* $\mathsf{Polytope}^{\uparrow}$ *finite witness rows,* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *ambient rows, and* $\mathsf{CompactMetric}^{\uparrow}$ *finite-read boundaries before exporting the bounded support surface. The ledger route is therefore*

$$\mathsf{AffineSpace}^{\uparrow}, \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{Polytope}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CaratheodoryConvexHull}^{\uparrow}.$$

It exposes only the named finite subfamily data and does not introduce a host separation theorem, a selected intersection point, quotient convex-set equality, or ambient standard-model convexity.

Proof. Project the existing $\mathsf{HellyTheorem}^{\uparrow}$ carrier of Definition 2309.1. Its ambient rows are A, V, its convex-family row is F, and its finite witness and subfamily rows are W, S, I.

Follow the sibling route already displayed by the chapter: $\mathsf{ConvexSet}^{\uparrow}$ supplies membership rows, $\mathsf{Polytope}^{\uparrow}$ supplies finite witnesses, $\mathsf{AffineSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ supply the ambient affine and displacement rows, and $\mathsf{CompactMetric}^{\uparrow}$ supplies the finite-read boundary. The $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ consumer can read a bounded support surface only after those rows have been displayed.

No carrier coordinate stores host separation, a selected intersection point, quotient convex-set equality, or ambient standard-model convexity. The exported ledger is therefore exactly the finite sibling route stated above. □

Proposition 2309.11 (Helly convex-hull sibling dependency)**.** *The* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection certificate supplies its convex-hull dependency only through the finite subfamily ledger consumed by chapter 2347. Thus any Caratheodory convex-hull readback using* $\mathsf{HellyTheorem}^{\uparrow}$ *must display the convex-family classifier, finite witness ledger, full-family intersection row, and local NameCert provenance before the Caratheodory finite-generation route may expose bounded support data.*

Proof. Use Definition 2309.10. It already forces the Helly ledger through the convex-family, polytope, affine, vector, and compact finite-read rows before the Caratheodory convex-hull surface is available.

The sibling chapter chapter 2347 then consumes that ledger as its Helly handoff row. Since neither the Helly carrier nor the Caratheodory convex-hull carrier stores a host separation theorem, selected intersection point, or quotient convex-hull equality, the dependency remains the displayed finite-generation route and nothing larger. □

Consequently every $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ or finite convex-family consumer may read $\mathsf{HellyTheorem}^{\uparrow}$ only after the $\mathsf{ConvexSet}^{\uparrow}$ membership rows of chapter 208, the $\mathsf{Polytope}^{\uparrow}$ finite witness rows, the $\mathsf{AffineSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ ambient rows, and the $\mathsf{CompactMetric}^{\uparrow}$ finite-read boundary have been

displayed. The consumption route then reaches chapter 2347 as a finite subfamily ledger, not as a host convexity theorem or an uncarried intersection selector. The finite subfamily ledger of $\mathsf{HellyTheorem}^{\uparrow}$ is read through the horizontal convex lattice before any convex-hull consumer may use it. The route first fixes the convex-family rows of chapter 208, the finite witness rows of chapter 209, the affine and vector ambient rows of chapter 206 and chapter 47, and the support-reduction boundary of chapter 2347; only after those rows are displayed may the Helly finite subfamily ledger be consumed as convex-hull input.

Convex-hull and Caratheodory dependency. The $\mathsf{HellyTheorem}^{\uparrow}$ packet consumes its finite convex-family carrier through the convex-set surface of chapter 208 and its affine-combination reduction through the Caratheodory convex-hull surface of chapter 2347 before it exports an intersection certificate. Thus the Helly read is not an isolated incidence claim: it first exposes the convex-family rows, then the Caratheodory finite-combination rows, and only then packages the common-intersection row through its local $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ surface.

Theorem 2309.12 (Helly theorem convex-hull forward link)**.** *Every convex-hull consumer of an accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet must read the displayed finite family row, full-family intersection witness, Caratheodory-style finite subfamily row,* $\mathsf{ConvexSet}^{\uparrow}$ *classifier rows, and local* $\mathsf{NameCert}$ *provenance before it uses the Helly packet. The forward link factors through the Helly construction of chapter 2309, the Caratheodory dependency route in Definition 2309.10, and the convex-hull surface of chapter 2347. It supplies no full compact convexity theorem and no host separation theorem.*

Proof. Project the Helly carrier. Its finite family row is F, its full-family intersection witness is I, and its local naming and provenance are carried by P, N.

Use the existing Caratheodory forward dependency route. That route reads $\mathsf{ConvexSet}^{\uparrow}$ membership rows, $\mathsf{Polytope}^{\uparrow}$ finite witnesses, affine and vector ambient rows, and compact finite-read boundaries before a Caratheodory convex-hull consumer can read a bounded support surface.

The present forward link names the same boundary for convex-hull consumers. The consumer may use the Helly packet only after the finite family, intersection witness, finite subfamily ledger, convex-set classifier rows, and local NameCert provenance have all been displayed.

Since the Helly carrier has no coordinate for compact convexity as a host theorem and no coordinate for a separation theorem, neither principle is exported by this link. □

Theorem 2309.13 (Helly convex-hull forward scope)**.** *The finite-intersection row of an accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet is a forward scope for the* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *consumer of chapter 2347. A convex-hull membership request may consume the Helly row only after the convex-set and polytope sibling packets have displayed their finite family, face-boundary, support, and coefficient ledgers. The handoff exports a finite subfamily certificate for convex-hull reasoning; it does not export ambient separation, selected minimal supports, quotient hull equality, host convexity, or Real completeness.*

Theorem 2309.14 (Helly convex-family dependency route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily read must display the* $\mathsf{ConvexSet}^{\uparrow}$ *family rows and the* $\mathsf{Polytope}^{\uparrow}$ *finite witness ledger before the subfamily ledger S of Definition 2309.1 is inspected. The family row consumes the convex carrier of chapter 208 before the finite-intersection ledger is read. The ambient* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *rows fix the affine boundary for those convex sets, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-read discipline bounds the inspected family window, and any* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *consumer receives only the displayed subfamily ledger after those rows are visible. The route exports no host separation*

theorem, choice-selected intersection point, quotient convex-set equality, or ambient standard-model convexity.

Proof. Project the carrier of Definition 2309.1. The convex-family coordinate is F, the finite witness coordinate is W, the ambient coordinates are A, V, and the inspected subfamily coordinate is S.

The row F is read through $\mathsf{ConvexSet}^{\uparrow}$, while W is read through $\mathsf{Polytope}^{\uparrow}$. The rows A, V keep those reads in the displayed affine and vector ambient surface, and the compact finite-read boundary fixes the inspected finite window before S is replayed.

A Caratheodory convex-hull consumer may therefore read the Helly handoff only after the convex-family, polytope, affine, vector, and compact rows have been displayed. Since the structural rows only transport, replay, source, and name this packet, no host separation theorem, selected point, quotient convex-set equality, or ambient standard model is exported. □

Theorem 2309.15 (Helly convex-geometry dependency lattice)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection read consumes the convex-geometry lattice*

$$\mathsf{ConvexSet}^{\uparrow},\ \mathsf{Polytope}^{\uparrow},\ \mathsf{CaratheodoryConvexHull}^{\uparrow}$$

before it exposes its local intersection row. The $\mathsf{ConvexSet}^{\uparrow}$ *surface of chapter 208 supplies the membership and convex-family rows, the* $\mathsf{Polytope}^{\uparrow}$ *surface of chapter 209 supplies the finite witness rows, and the* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *surface of chapter 2347 supplies the bounded-support handoff consumed by convex-hull readers. A Helly packet that omits one of these rows is outside the accepted sibling route.*

Proof. Project the carrier in Definition 2309.1. Its convex-family coordinate is F, its finite witness coordinate is W, and its subfamily and full-family intersection coordinates are S, I.

The row F is read through the $\mathsf{ConvexSet}^{\uparrow}$ classifier, so no finite subfamily can be inspected before the convex-family membership rows have been displayed. The row W is the finite $\mathsf{Polytope}^{\uparrow}$ witness ledger, so every inspected subfamily intersection is backed by the polytope witness surface before S is replayed.

The convex-hull consumer then reads the same finite subfamily ledger through $\mathsf{CaratheodoryConvexHull}^{\uparrow}$. Since the carrier has no alternate row for a host separation theorem, selected intersection point, quotient convex-set equality, or ambient standard-model convexity, the three named sibling surfaces form the whole dependency lattice for the Helly read. □

Consequently $\mathsf{HellyTheorem}^{\uparrow}$ is not an isolated hub: its public convex-geometry use is routed through $\mathsf{ConvexSet}^{\uparrow}$ membership rows, $\mathsf{Polytope}^{\uparrow}$ finite witness rows, and $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ bounded-support rows before any local $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ intersection certificate is consumed.

Proposition 2309.16 (Helly convex-geometry sibling lattice route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection packet consumes the convex-set membership rows of chapter 208, the polytope finite witness rows of chapter 209, and the convex-hull support surface of chapter 2347 through the same finite intersection data before any local* $\mathsf{NameCert}_{\mathsf{HellyTheorem}^{\uparrow}}$ *row is read. The route is a sibling dependency lattice over displayed finite subfamilies, not a host convexity theorem or a choice-selected intersection point.*

Proof. Project the carrier of Definition 2309.1. The convex-family row F supplies only $\mathsf{ConvexSet}^{\uparrow}$ membership data, while the witness row W supplies the $\mathsf{Polytope}^{\uparrow}$ finite face, simplex, or hull witnesses used by inspected subfamilies.

The finite subfamily ledger S is then the shared handoff. A convex-hull consumer reads it through $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ as bounded support data, and the Helly packet reads the same ledger before exposing the full-family row I.

Since T, C, P, N only transport, replay, source, and name the displayed rows, they cannot introduce a second convex-hull carrier, an ambient separation argument, or a selected intersection point. Thus the sibling lattice is exactly the finite route through $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, the Caratheodory convex-hull surface, and the local Helly ledger. □

Consequently the $\mathsf{HellyTheorem}^{\uparrow}$ hub records a concrete convex-geometry sibling dependency: finite intersection data is read only after the membership, finite witness, and convex-hull support rows have been displayed inside the same BHist, hsame, Cont, Pkg, and NameCert surface. The route is the same finite sibling lattice, not a host convexity theorem.

Theorem 2309.17 (Helly convex polytope lattice route)**.** *Any accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-intersection packet reads its convex family through* $\mathsf{ConvexSet}^{\uparrow}$*, its finite cell witnesses through* $\mathsf{Polytope}^{\uparrow}$*, and its ambient coordinates through* $\mathsf{AffineSpace}^{\uparrow}$ *before it exposes the local intersection ledger. In carrier notation, the public route first displays the convex-family row F, the polytope witness row W, and the affine ambient row A of Definition 2309.1; only then may the subfamily ledger S and full-family row I be consumed. The route exports no host convex-set equality, selected intersection point, separation theorem, quotient affine coordinate, or ambient standard-model convexity.*

Proof. Project the Helly carrier of Definition 2309.1. Its ambient row is A, its convex-family row is F, and its finite witness row is W.

The convex-family row is read through chapter 208. Thus an accepted packet displays the $\mathsf{ConvexSet}^{\uparrow}$ membership and convexity rows before a subfamily can be inspected.

The finite cell witnesses are read through chapter 209, while the ambient coordinates are read through chapter 206. These rows bind the finite cells to the same affine boundary before the ledger rows S and I are exposed.

Finally inspect the remaining coordinates T, C, P, N. They transport, replay, source, and name the same finite packet, and they add no host convex equality, selected intersection point, separation theorem, quotient affine coordinate, or ambient standard-model convexity. The stated convex-polytope-affine route therefore exhausts the public Helly read. □

Theorem 2309.18 (Helly theorem convex-polytope dependency route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-subfamily read displays the* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* $\mathsf{AffineSpace}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*, and compact finite-read rows before the finite-intersection ledger is consumed. The route may inspect the Helly family row, finite subfamily row, and intersection ledger only after those sibling rows are present; it exports no selected intersection point, ambient separation theorem, quotient affine coordinate, or host compactness oracle.*

Proof. Project the Helly carrier of Definition 2309.1. The convex-family row, finite witness row, ambient row, and finite-intersection ledger are explicit packet coordinates, so a consumer read starts from displayed rows rather than from a host theorem about arbitrary convex families.

Use the sibling dependency files already attached to this chapter. The convex set dependency route supplies the $\mathsf{ConvexSet}^{\uparrow}$ membership and convexity rows, while the convex-polytope lattice route supplies the $\mathsf{Polytope}^{\uparrow}$ finite-cell witnesses and the $\mathsf{AffineSpace}^{\uparrow}$ ambient boundary.

The finite convex lattice route adds the $\mathsf{VecSpace}^{\uparrow}$ scalar row and the compact finite-read rows needed before a finite subfamily can be consumed. With those rows displayed, the Helly ledger reads only the finite-intersection surface carried by the packet.

Finally replay the local transport, provenance, and naming coordinates. They preserve the same finite route and do not add a selected point, separation theorem, quotient affine coordinate, or host compactness oracle. Hence the convex-polytope dependency route is exhausted before the finite-intersection ledger is read. □

Theorem 2309.19 (Helly convex-set dependency route)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite convex-intersection read first consumes the convex carrier of chapter 208 and the finite polytope witness surface of chapter 209. Only after those two sibling rows are displayed may the Helly intersection row expose its finite subfamily ledger, common-intersection row, transport, replay, provenance, and local naming. The route exports no host separation theorem, selected intersection point, quotient convex-set equality, unrestricted finite-cover oracle, or ambient standard-model convexity.*

Proof. Project the Helly carrier of Definition 2309.1. The convex-family row is consumed through the convex-set certificate, and the finite witness row is consumed through the polytope certificate.

After those sibling rows are visible, the Helly subfamily and intersection rows can be read as finite BHist data. The structural rows transport, replay, source, and name the same route, so the carrier has no coordinate for a host separation theorem, selected point, quotient convex-set equality, or unrestricted cover oracle. □

The finite-intersection certificates used by $\mathsf{HellyTheorem}^{\uparrow}$ enter through the same convex-row surface as chapter 208 and the finite hull route of chapter 2347. A Helly carrier can therefore read its displayed family of convex sets, witness subfamilies, and intersection rows as finite BHist data before it exports the Helly conclusion, rather than importing an ambient convexity theorem or an unrestricted finite-cover oracle.

Theorem 2309.20 (Helly convex dependency anchor)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *packet consumes finite convex-family rows and finite-intersection rows before it exports the Helly* $\mathsf{NameCert}$ *surface. The convex-family rows are read through the* $\mathsf{ConvexSet}^{\uparrow}$ *membership surface of chapter 208; the finite-intersection rows are read through the subfamily ledger of chapter 1792. Only after both rows are displayed may the packet expose its full-family intersection witness, transport rows, replay rows, provenance, and local naming.*

Proof. Project the carrier of Definition 2309.1. Its family coordinate cannot be read as an ambient convexity assertion; each member is inspected through the displayed convex-set rows.

Use the finite-intersection dependency route already recorded for the Helly packet. That route keeps the subfamily ledger visible before the full-family intersection row is exported.

The remaining rows only transport, replay, source, and name the same finite surface. Hence the Helly export is anchored in the convex-family and finite-intersection siblings rather than in a detached kernel-level theorem. □

Theorem 2309.21 (Helly finite convex-family budget)**.** *Every accepted* $\mathsf{HellyTheorem}^{\uparrow}$ *finite-family read must expose* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{AffineSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows before it exports a finite intersection witness. In particular, the convex-set membership rows of chapter 208, the finite witness rows of chapter 209, the compact finite-read rows of chapter 60, and the ambient affine and vector rows of chapter 206 and chapter 47 form the displayed dependency route for the local intersection ledger.*

Proof. Project the $\mathsf{HellyTheorem}^{\uparrow}$ carrier from Definition 2309.1. The convex-family coordinate F is read through the $\mathsf{ConvexSet}^{\uparrow}$ surface, the witness coordinate W is read through $\mathsf{Polytope}^{\uparrow}$, and

the ambient rows A, V are read through $\mathsf{AffineSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ before the finite subfamily ledger S can be inspected.

The compact finite-read discipline supplies the bounded inspection surface for those finite subfamilies. Transport, continuation replay, provenance, and local naming are then carried by the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Therefore the exported finite intersection witness is downstream of the sibling convex, polytope, compact, vector, and affine chapters rather than a detached host convexity fact. □

The $\mathsf{HellyTheorem}^{\uparrow}$ packet consumes the finite-intersection lattice of chapter 1792 before any Helly carrier can export an intersection witness. The route also reads the convex carrier rows of chapter 208 and the compact finite-cover boundary of chapter 129; together with the local sibling route of Definition 2309.10, these rows force the witness to be a finite NameCert consequence rather than a kernel-only intersection assertion. The finite-family carrier for $\mathsf{HellyTheorem}^{\uparrow}$ reads the finite-intersection route of chapter 1792 together with the $\mathsf{ConvexSet}^{\uparrow}$ surface and the convex-family coordinate F before it can export a Helly subfamily witness. This bridge keeps the witness surface dependent on displayed finite-intersection and convex-family data rather than on an isolated kernel assertion.

Chapter 2310

A Concrete Naming Certificate for $\mathsf{TemperedDistribution}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{TemperedDistribution}^{\uparrow}$ packet records the finite observable face of a tempered distribution as a continuous linear action on Schwartz-test windows. The chapter connects the distribution row of chapter 186, the finite Fourier observation surface of chapter 124, the weak-derivative route of chapter 2210, the Sobolev comparison surface of chapter 440, and the terminal real readback of chapter 38. It names only the BEDC certificate surface for these finite rows; it does not import a completed Schwartz space, a host distribution equality relation, quotient dual spaces, or a global topological-vector-space completeness theorem.

2310.1 Carrier definition

Definition 2310.1 (Tempered distribution carrier)**.** *A* $\mathsf{TemperedDistribution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, G, A, F, W, Q, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite Schwartz-test window row. It records the named test functions visible to the packet, their finite derivative orders, polynomial weights, support windows when present, and the requested observation indices.*
2. *G is the polynomial-growth ledger. It records the displayed seminorm bounds used to admit each test row and each derivative row.*
3. *A is the* $\mathsf{Distribution}^{\uparrow}$ *action row. It records the finite list of test-window evaluations and their* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoints.*
4. *F is the* $\mathsf{Fourier}^{\uparrow}$ *coefficient and test-transform row. It records finite transform observations for the same test windows and the coefficient windows consumed by Fourier-facing reads.*
5. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *and* $\mathsf{Sobolev}^{\uparrow}$ *compatibility row. It records integration-by-parts signs, derivative-order shifts, and Sobolev-window comparisons that are explicitly displayed in the packet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational approximation windows of the action and transform endpoints.*

7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the displayed readback route.*
8. *L is the local classifier row. It admits two packets together exactly when their Schwartz-test windows, polynomial-growth ledgers, distribution-action rows, Fourier rows, weak-derivative and Sobolev rows, rational readbacks, and real seals match componentwise.*
9. *H records componentwise* hsame *transport for all visible rows.*
10. *C records displayed* Cont *replay from a tempered-distribution request through $S, G, A, F, W, Q, E, L, H$ in that order.*
11. *P is the* Pkg *provenance row over* $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. No coordinate stores a completed Schwartz space, an unrestricted continuous dual, host equality of distributions, quotient test-function equality, selected representative, countable choice schedule, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.TemperedDistributionUp.TemperedDistributionTasteGate single carrier alignment`

2310.2 The certificate

Theorem 2310.2 (Tempered distribution NameCert obligations)**.** *For every accepted* $\mathsf{TemperedDistribution}^{\uparrow}$ *carrier $T = (S, G, A, F, W, Q, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Schwartz-test window, polynomial-growth ledger, distribution-action, Fourier, weak-derivative and Sobolev compatibility, rational readback, real seal, classifier, transport, replay, provenance, and local naming rows;*
2. *action exactness, requiring every displayed evaluation of the distribution against a test window to pass through A after the corresponding test row in S and growth ledger in G have been opened;*
3. *polynomial-growth stability, requiring tightened derivative or weight requests to replay the same ledger G before any action or transform endpoint is read;*
4. *Fourier compatibility, requiring every finite transform or coefficient read to pass through F and then through the same Q, E readback route as the action row;*
5. *weak-derivative and Sobolev compatibility, requiring every derivative-order shift, sign row, or Sobolev-window comparison to pass through W before the packet is exported;*
6. *componentwise* hsame, *displayed* Cont *replay,* Pkg *provenance, and local* NameCert *closure through L, H, C, P, N.*

No obligation outside these rows is part of the certificate.

Proof. Project the carrier of Definition 2310.1. The row inventory gives the whole finite packet, so carrier admission is exhausted by $S, G, A, F, W, Q, E, L, H, C, P, N$.

The Schwartz-test row S fixes which tests and derivative orders are visible. The growth ledger G must be read before any action endpoint, because it is the row that admits the displayed seminorm and polynomial-weight data.

The action row A then supplies only finite evaluations against those admitted tests. The rational and real endpoints of those evaluations pass through Q and E, so there is no detached real seal or host distribution value.

The Fourier and derivative routes are likewise internal rows. The Fourier row F records finite coefficient and test-transform observations, while W records the weak-derivative signs and Sobolev-window comparisons. Transport, replay, provenance, and naming rows compare and repack the same data, and none of them adds a completed test-function space, unrestricted dual, quotient equality, selected representative, choice schedule, or ambient completeness theorem. □

Theorem 2310.3 (Tempered distribution Fourier handoff)**.** *Every accepted* $\mathsf{TemperedDistribution}^{\uparrow}$ *read exported to a Fourier-facing consumer factors through*

$$S, G, A \longmapsto F \longmapsto W, Q, E \longmapsto L, H, C, P, N.$$

Thus the consumer receives the displayed Schwartz-test window, polynomial-growth ledger, distribution-action row, finite Fourier coefficient and test-transform row, weak-derivative and Sobolev compatibility row, rational readback, real seal, classifier, componentwise transport, replay, provenance, and local naming. It receives no completed Schwartz topology, host distribution equality, quotient dual object, selected representative, countable choice schedule, Plancherel theorem, inversion theorem, or ambient completeness principle.

Proof. Start with a Fourier-facing read. The test row S and growth ledger G must be visible before the packet can expose a distribution action, because the finite transform request is attached to the same admitted test windows.

Read A next. It supplies the finite action endpoints against the admitted tests and records the source $\mathsf{Distribution}^{\uparrow}$ route for those endpoints.

The handoff to F is then a finite-observation handoff: coefficient windows and test-transform rows are exposed as $\mathsf{Fourier}^{\uparrow}$ packages, not as host transforms of a completed function space. The compatibility row W records exactly the weak-derivative signs and Sobolev comparisons that are part of the same request.

Finally Q, E, L, H, C, P, N read back, compare, replay, source, and name the same route. Since none of these rows contains a completed Schwartz topology, host equality, quotient dual, selected representative, choice schedule, Plancherel theorem, inversion theorem, or ambient completeness witness, the Fourier consumer receives only the displayed finite certificate. □

Falsifiable prediction: Every accepted $\mathsf{TemperedDistribution}^{\uparrow}$ consumer that reaches a Fourier coefficient, weak-derivative sign, Sobolev comparison, or $\mathsf{Real}^{\uparrow}$ seal without first reading the finite Schwartz-test window and polynomial-growth ledger refutes the carrier surface.

Independence witness: distribution, fourier, weakderivative, sobolev, regseqrat, real: none is bijective to $\mathsf{TemperedDistribution}^{\uparrow}$ because this packet jointly carries finite Schwartz-test windows, polynomial-growth ledgers, distribution actions, Fourier coefficient and transform rows, weak-derivative and Sobolev compatibility rows, rational readbacks, real seals, classifier, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}$.

Constructive story: A $\mathsf{TemperedDistribution}^{\uparrow}$ packet is generated from finite Schwartz-test windows, polynomial-growth ledger rows, displayed $\mathsf{Distribution}^{\uparrow}$ actions, finite $\mathsf{Fourier}^{\uparrow}$ coefficient and test-transform observations, $\mathsf{WeakDerivative}^{\uparrow}$ and $\mathsf{Sobolev}^{\uparrow}$ compatibility rows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TemperedDistribution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2310.1, Definition 2310.2, and Definition 2310.3 seed the finite tempered-distribution interface over Schwartz-test windows, polynomial-growth ledgers, distribution actions, Fourier observations, weak-derivative and Sobolev compatibility, rational readbacks, and real seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{TemperedDistribution}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed Schwartz spaces, unrestricted continuous duals, quotient test-function equality, host distribution equality, selected representatives, countable choice, Plancherel, inversion, or ambient completeness.

Upgrade path: A formal route can encode the finite carrier and prove the NameCert obligation surface and Fourier handoff theorem.

Chapter 2311

A Concrete Naming Certificate for $\mathsf{DirichletKernel}^{\uparrow}$

Following Zygmund and Katznelson on trigonometric series, the $\mathsf{DirichletKernel}^{\uparrow}$ packet records the finite symmetric Fourier kernel that evaluates one displayed partial-sum window before any convergence-facing consumer may read a series or limit handoff. It sits over the Fourier coefficient interface of chapter 124, the positive averaging sibling $\mathsf{FejerKernel}^{\uparrow}$ of chapter 1939, the complex arithmetic carrier of chapter 39, the circle-source samples of chapter 58, and the real-series partial-sum corridor of chapter 1581. The chapter names a finite trigonometric partial-sum kernel; it does not import host pointwise limits, ambient Fourier convergence, quotient function spaces, countable choice, or a selected infinite sum.

Definition 2311.1 (DirichletKernel carrier)**.** *A* $\mathsf{DirichletKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, A, S, Z, F, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the frequency-window row, recording the symmetric finite interval of integer frequencies and the endpoint truncation bound read by the partial-sum request.*
2. *A is the trigonometric coefficient ledger, recording the displayed coefficient attached to each frequency in W together with its opposite-frequency mate.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *evaluation route, exposing only the finite circle samples and phase rows at which the kernel is inspected.*
4. *Z is the* $\mathsf{Complex}^{\uparrow}$ *summation row, recording the displayed complex additions and multiplications used to accumulate the finite trigonometric polynomial.*
5. *F is the* $\mathsf{Fourier}^{\uparrow}$ *partial-sum handoff row, presenting the same frequency window and coefficient ledger to a Fourier partial-sum consumer.*
6. *R is the* $\mathsf{RealSeries}^{\uparrow}$ *and* $\mathsf{CplxSer}^{\uparrow}$ *provenance row, recording which real or complex partial-sum corridor may read the displayed finite sum.*
7. *H records componentwise* hsame *transport for frequency windows, coefficient ledgers, circle evaluations, complex summation, Fourier handoff, series provenance, replay, package provenance, and local naming.*

8. *C records displayed* Cont *replay from a phase and coefficient request through W, A, S, Z, F, R in that order.*
9. *P is the* Pkg *provenance over* $\mathsf{DirichletKernel}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CplxSer}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, A, S, Z, F, R, H, C, P, N$. It has no coordinate for a host pointwise limit, an external convergence theorem, an ambient quotient of functions, countable choice, or a selected infinite-series value.

Lean4 ✓ `BEDC.Derived.DirichletKernelUp.TasteGate.DirichletKernelTasteGate single carrier alignment`

Theorem 2311.2 (DirichletKernel NameCert obligations)**.** *For every accepted* $\mathsf{DirichletKernel}^{\uparrow}$ *carrier $K = (W, A, S, Z, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the displayed frequency window, trigonometric coefficient ledger, circle-evaluation route, complex summation row, Fourier partial-sum handoff, real and complex series provenance, transport, replay, package provenance, and local naming;*
2. *finite-window stability, requiring every transported or replayed kernel read to preserve the same symmetric frequency interval and endpoint truncation bound in W;*
3. *coefficient symmetry, requiring the ledger A to pair each displayed frequency with its opposite-frequency mate before the summation row is consumed;*
4. *convolution and summation handoff, requiring the* $\mathsf{Complex}^{\uparrow}$ *row Z and the* $\mathsf{Fourier}^{\uparrow}$ *row F to expose only the finite trigonometric polynomial determined by W, A, S;*
5. $\mathsf{S}^{1\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, *and* $\mathsf{CplxSer}^{\uparrow}$ *routing, requiring every phase, arithmetic, and partial-sum consumer to factor through S, Z, F, R;*
6. *transport and replay stability, requiring H and C to preserve the ordered route through the same carrier coordinates;*
7. *ledger refusal, requiring the packet to export no host pointwise limit, external Fourier convergence principle, quotient function equality, countable-choice selector, or selected infinite-series value.*

No Dirichlet-kernel obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DirichletKernelUp.DirichletKernelCarrier namecert obligations`
↪ variant `BEDC.Derived.DirichletKernelUp.DirichletKernelNameCertObligations`

Proof. Carrier admission is projection from Definition 2311.1. The displayed tuple exposes exactly the frequency window, coefficient ledger, circle evaluation, complex summation, Fourier handoff, series provenance, transport, replay, package provenance, and local naming rows.

Finite-window stability is read from W. Since the carrier stores one symmetric frequency interval and one endpoint truncation bound, every transported or replayed kernel read names the same finite window before any coefficient or phase row is inspected.

Coefficient symmetry is read from A. The ledger pairs displayed frequencies with their opposite-frequency mates, so the summation row may form the finite trigonometric polynomial without appealing to a host Fourier basis or an ambient function-space quotient.

The handoff rows are then forced through S, Z, F, R. Circle samples enter through $\mathsf{S}^{1\uparrow}$, arithmetic accumulation enters through $\mathsf{Complex}^{\uparrow}$, the partial-sum consumer enters through $\mathsf{Fourier}^{\uparrow}$, and series-facing provenance enters only through the named real and complex series corridors.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Because the packet has no coordinate for pointwise limits, external convergence, quotient function equality, countable choice, or selected infinite sums, the refusal clause is exhausted by the carrier inventory. □

Falsifiable prediction: Every accepted $\mathsf{DirichletKernel}^{\uparrow}$ partial-sum read factors through a frequency window, trigonometric coefficient ledger, $\mathsf{S}^{1\uparrow}$ evaluation route, $\mathsf{Complex}^{\uparrow}$ summation row, $\mathsf{Fourier}^{\uparrow}$ handoff, $\mathsf{RealSeries}^{\uparrow}$ or $\mathsf{CplxSer}^{\uparrow}$ provenance, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: fourier, fejer-kernel, complex, s1, realseries: $\mathsf{DirichletKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a symmetric frequency window, opposite-frequency coefficient ledger, circle evaluation route, complex finite summation row, Fourier partial-sum handoff, real and complex series provenance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletKernel}^{\uparrow}$ packet is generated from a symmetric finite frequency window, a trigonometric coefficient ledger, displayed $\mathsf{S}^{1\uparrow}$ phase samples, a $\mathsf{Complex}^{\uparrow}$ finite summation row, a $\mathsf{Fourier}^{\uparrow}$ partial-sum handoff, $\mathsf{RealSeries}^{\uparrow}$ and $\mathsf{CplxSer}^{\uparrow}$ provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2311.1 and Definition 2311.2 seed the finite Dirichlet-kernel partial-sum surface for Fourier and series consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host pointwise Fourier convergence, quotient function equality, selected infinite sums, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window stability, coefficient symmetry, summation handoff, routing, transport, replay, provenance, and local naming for the same finite packet.

Chapter 2312

A Concrete Naming Certificate for $\mathsf{CauchyCut}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyCut}^{\uparrow}$ packet records the finite bridge by which a located lower–upper cut presentation is read as a regular Cauchy real name before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed. It sits after the located-cut surface of chapter 404, the dyadic arithmetic carrier of chapter 291, the finite stream-window surface of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed cut-to-stream route; it does not identify Dedekind cuts, quotient regular names, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2312.1 (Cauchy cut carrier)**.** *A* $\mathsf{CauchyCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, M, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the located lower-cut row, recording inhabited rounded lower evidence and its rational observation boundary through chapter 404.*
2. *U is the located upper-cut row, recording inhabited rounded upper evidence and the displayed separation from L.*
3. *M is the dyadic Cauchy modulus ledger: for each displayed precision row it supplies a finite dyadic bracket window whose lower and upper endpoints are read from L and U.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to ask for the bracket midpoint at a requested precision.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row extracted from the midpoint stream and the modulus ledger.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row recording endpoint comparison, midpoint formation, and tolerance shrinking for the displayed bracket.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after L, U, M, S, Q, D have been displayed.*
8. *H stores componentwise* hsame *transport for the cut rows, modulus ledger, stream schedule, regular source, dyadic row, real seal, replay, provenance, and local naming row.*

9. *C stores displayed* Cont *replay of the route*

$$L, U, M, S, D \longmapsto Q \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCut}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, M, S, Q, D, R, H, C, P, N$. It has no coordinate for host cut equality, Dedekind completeness, quotient stream equality, a selected limiting real, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCutUp.CauchyCutTasteGate single carrier alignment`

Theorem 2312.2 (Cauchy cut carrier admission)**.** *For every accepted* $\mathsf{CauchyCut}^{\uparrow}$ *carrier $K = (L, U, M, S, Q, D, R, H, C, P, N)$, the local carrier surface is exactly the displayed lower located-cut row L, upper located-cut row U, dyadic modulus ledger M, stream-window row S, regular rational source row Q, dyadic arithmetic row D, terminal real seal R, componentwise transport H, displayed replay C, provenance P, and local naming row N.*

Proof. Carrier admission is projection from Definition 2312.1. The tuple displays the lower and upper located-cut rows before any stream or regular-rational read can occur.

The remaining rows are structural or downstream rows attached to that same carrier. Since the classifier has no other coordinate, an accepted packet can expose no carrier data outside the listed rows. □

Theorem 2312.3 (Cauchy cut stream extraction)**.** *Every stream read exported by an accepted* $\mathsf{CauchyCut}^{\uparrow}$ *packet factors through the displayed route*

$$L, U, M, D \longmapsto S \longmapsto Q.$$

Thus the extracted regular Cauchy name is obtained from located lower–upper cut brackets and dyadic midpoint arithmetic, not from a quotient stream, selected representative, host real limit, or Dedekind-cut equality.

Proof. Start with the lower and upper cut rows L and U. The modulus ledger M chooses only a finite displayed bracket for the requested precision, and the dyadic row D records the midpoint and tolerance calculation inside $\mathsf{DyadicRatCore}^{\uparrow}$.

The stream row S schedules exactly those finite bracket reads. The regular rational row Q is downstream of S and therefore inherits the same cut and dyadic dependencies. No quotient stream or selected limit appears in the carrier. □

Theorem 2312.4 (Cauchy cut modulus stability)**.** *If an accepted* $\mathsf{CauchyCut}^{\uparrow}$ *carrier is transported componentwise by its H row, the dyadic Cauchy modulus ledger remains attached to the same lower–upper cut bracket route. Later precision reads may refine the displayed bracket through M and D, but they cannot replace it by an independent stream selector or by an ambient completeness principle.*

Proof. The transport row H acts componentwise on L, U, M, S, Q, D, R and the local naming row. In particular, a transported packet still exposes the same modulus ledger between the located cut rows and the stream schedule.

Refining a precision read uses M again and then replays the dyadic arithmetic row D. Since neither H nor C contains a coordinate for a separate selector or completeness theorem, the modulus route is stable under the displayed transport. □

Theorem 2312.5 (Cauchy cut classifier transport)**.** *The classifier for* $\mathsf{CauchyCut}^{\uparrow}$ *transports acceptance only through* $L, U, M, S, Q, D, R, H, C, P, N$*. Consequently every consumer that reads the packet through chapter 404, chapter 291, chapter 126, chapter 301, and chapter 38 receives the same displayed cut-to-regular-name route.*

Proof. Inspect the classifier clause in Definition 2312.1. It compares accepted packets only by the listed carrier fields and therefore cannot branch on hidden cut equality, host real equality, or quotient stream data.

The cited sibling chapters name the only public read points for those fields: located cuts for L, U, dyadic arithmetic for M, D, finite streams for S, regular rational names for Q, and the real seal for R. Transport through H, C, P, N preserves that dependency chain for every consumer. □

Theorem 2312.6 (Cauchy cut real seal nonescape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{CauchyCut}^{\uparrow}$ *carrier is public only as the endpoint of the displayed route*

$$L, U, M, S, D, Q \longmapsto R.$$

No consumer of the packet can extract a completed real by bypassing the located-cut rows, the dyadic Cauchy modulus ledger, the finite stream window, or the regular rational source row.

Proof. The seal row R occurs after L, U, M, S, Q, D in the carrier. The replay row C records the same order, so a consumer must display the located cut rows, the modulus ledger, the stream schedule, the dyadic arithmetic, and the regular rational source before reading the real seal.

The provenance and naming rows P, N attach that route to the local $\mathsf{NameCert}_{\mathsf{CauchyCut}^{\uparrow}}$ surface. Since the carrier excludes selected limits, quotient regular names, Dedekind completeness, countable choice, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness, the real seal cannot escape the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCut}^{\uparrow}$ read that exports a $\mathsf{Real}^{\uparrow}$ seal factors through displayed located lower–upper cut rows, a dyadic Cauchy modulus ledger, finite stream windows, a regular rational source, dyadic arithmetic, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: locatedcut, dyadicratcore, streamname, regseqrat, real: $\mathsf{CauchyCut}^{\uparrow}$ is not bijective to any listed sibling because it binds lower–upper located-cut evidence, a dyadic modulus ledger, stream scheduling, regular-rational extraction, terminal real sealing, transport, replay, provenance, and local NameCert rows into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCut}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCut}^{\uparrow}}$, seed)

Scope closed: Definition 2312.1, Definition 2312.2, Definition 2312.3, Definition 2312.4, Definition 2312.5, and Definition 2312.6 seed the located-cut-to-regular-Cauchy-name bridge surface for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut completeness, quotient regular-name equality, selected limits, host real equality, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cut-to-stream extraction, modulus stability, classifier transport, real-seal nonescape, provenance discipline, and TasteGate field faithfulness for BEDC.Derived.CauchyCutUp.

Constructive story: A $\mathsf{CauchyCut}^{\uparrow}$ packet is generated from displayed lower and upper located-cut rows, a dyadic Cauchy modulus ledger, finite stream windows, a regular rational extraction row, dyadic arithmetic, a terminal Real seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2313

A Concrete Naming Certificate for $\mathsf{BishopCauchyReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyReal}^{\uparrow}$ packet records a modulus-equipped Cauchy real presentation as finite BEDC certificate data before the open Real and Completion route reads the terminal seal. It sits after the regular rational readback surface of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the modulus discipline of chapter 292, and the terminal real-name boundary of chapter 38. The packet names the constructive presentation of real data by displayed Cauchy approximants and explicit moduli; it does not make $\mathsf{Real}^{\uparrow}$ a quotient carrier, assert ambient completeness, choose a representative limit, or import countable choice.

This carrier supplies the concrete ledger row used by the Real completeness vision of chapter 9238: every Real-facing read is routed through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, explicit $\mathsf{CauchyModulus}^{\uparrow}$ schedule, $\mathsf{StreamName}^{\uparrow}$ observation windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal. The vision therefore reads this packet as finite completion data, not as quotient-stream equality, host real equality, a selected representative, or ambient completeness.

Definition 2313.1 (Bishop Cauchy real carrier)**.** *A* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, S, D, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row that supplies the rational approximants read by the packet.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row that records the finite tolerance-to-stage ledger used to inspect Q.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which a consumer asks for approximation data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic row used to compare requested precisions with the displayed rational approximants.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after Q, M, S, D have been displayed.*
6. *H stores componentwise* hsame *transport for the regular source, modulus, stream schedule, dyadic ledger, real seal, replay, provenance, and local naming rows.*

7. *C stores displayed* Cont *replay of the route*

$$Q, M, S, D \longmapsto R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, S, D, R, H, C, P, N$. It has no coordinate for quotient equality of Cauchy streams, selected host limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, or countable choice.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRealUp.TasteGate.BishopCauchyRealTasteGate single carrier alignment`

Theorem 2313.2 (Bishop Cauchy real NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier $B = (Q, M, S, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}$ *surface consists exactly of carrier admission, regular rational source exposure through Q, explicit Cauchy modulus exposure through M, finite stream-window routing through S, dyadic tolerance comparison through D, terminal real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, local naming through N, and non-escape from quotient stream equality, selected representatives, host limit equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRealUp.BishopCauchyRealNameCertObligations`

Proof. Carrier admission is projection from Definition 2313.1. The accepted packet exposes exactly the regular rational source row, the modulus row, the stream-window schedule, the dyadic tolerance ledger, the real seal, and the structural rows.

The Cauchy presentation is read through Q, M, S, D. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies regular rational approximants, the $\mathsf{CauchyModulus}^{\uparrow}$ row supplies the displayed tolerance-to-stage ledger, $\mathsf{StreamName}^{\uparrow}$ bounds each read to finite windows, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance arithmetic.

Only after those rows are visible does the terminal $\mathsf{Real}^{\uparrow}$ seal R appear. Transport, replay, provenance, and naming preserve the same route through H, C, P, N. Since the excluded completion principles are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2313.3 (Bishop Cauchy real RegSeqRat handoff)**.** *Every regular-rational read of an accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Thus a Real-facing consumer receives a modulus-controlled regular Cauchy presentation rather than a quotient Cauchy class, a chosen representative, a host limit, or a completeness principle.

Proof. Start with the displayed carrier $B = (Q, M, S, D, R, H, C, P, N)$. The source row Q is the only regular rational source available to the classifier.

The read cannot bypass M, S, D. The modulus row records which finite stages answer a requested tolerance, the stream row restricts the answer to visible windows, and the dyadic row records the endpoint arithmetic used by the tolerance comparison.

The seal row R is downstream of that route. The structural rows then transport, replay, source, and name the same packet, so every exported regular-rational read has the stated factorization and no hidden completion coordinate. □

Theorem 2313.4 (Bishop Cauchy real regular readback seal)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing seal read from an accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier* $B = (Q, M, S, D, R, H, C, P, N)$ *must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *ledger* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* S*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*. The terminal seal* R *may then be read only as the endpoint of the displayed route*

$$Q, M, S, D \longmapsto R \longmapsto H, C, P, N.$$

Thus a Real-facing consumer receives the regular-readback-to-seal dependency as finite BEDC data, not as a quotient completion, a chosen representative, a host limit equality, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the carrier of Definition 2313.1. The rows Q, M, S, D precede the terminal seal R and are the only displayed source, modulus, window, and tolerance coordinates available to a Real-facing read.

Apply the obligation surface of Definition 2313.2. It identifies carrier admission, source exposure, modulus exposure, stream-window routing, dyadic comparison, terminal sealing, transport, replay, provenance, and local naming as the complete local NameCert surface.

Finally use the RegSeqRat handoff of Definition 2313.3. It forces every regular-rational read through the same $Q, M, S, D, R, H, C, P, N$ route, so the $\mathsf{Real}^{\uparrow}$ seal is terminal for that route and cannot hide quotient completion or host real equality. □

Theorem 2313.5 (Bishop Cauchy real seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{BishopCauchyReal}^{\uparrow}$ *carrier is public only as the endpoint of the displayed route*

$$Q, M, S, D \longmapsto R.$$

Consequently the packet exposes a constructive real presentation for the open Real and Completion route while leaving quotient completion, ambient real completeness, selected limits, host real equality, trichotomy, and countable choice outside the exported surface.

Proof. Inspect the carrier order. The terminal seal R is stored after the regular source, modulus, stream-window, and dyadic tolerance rows.

The continuation row C replays that order for consumers. A Real-facing read therefore must display the regular rational approximants, the modulus ledger, the finite observation window, and the dyadic tolerance comparison before the seal can be consumed.

The remaining structural rows H, P, N preserve and name the same boundary. Since no quotient, selected limit, host equality, trichotomy, choice, or ambient completeness coordinate occurs in the packet, the seal is exactly the displayed endpoint of the constructive Cauchy presentation. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyReal}^{\uparrow}$ real-facing read factors through a displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{CauchyModulus}^{\uparrow}$ ledger, $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, cauchymodulus, streamname, dyadicratcore, real: $\mathsf{BishopCauchyReal}^{\uparrow}$ is not bijective to any listed sibling because it binds a modulus-controlled Cauchy real presentation, finite observation windows, dyadic tolerance arithmetic, terminal real sealing, transport, replay, provenance, and local NameCert rows into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2313.1, Definition 2313.2, Definition 2313.3, and Definition 2313.5 seed the modulus-equipped Cauchy real presentation surface for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopCauchyReal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, ambient Real$^{\uparrow}$ completeness, selected limits, host real equality, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-controlled regular source exposure, finite stream-window routing, dyadic tolerance readback, real-seal boundary, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.BishopCauchyRealUp.

Constructive story: A BishopCauchyReal$^{\uparrow}$ packet is generated from a regular rational source, an explicit Cauchy modulus, finite stream windows, dyadic tolerance rows, a terminal Real seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2314

A Concrete Naming Certificate for $\mathsf{PointwiseLimit}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki's function-limit terminology, the $\mathsf{PointwiseLimit}^{\uparrow}$ packet records an indexwise limit route for displayed real-valued maps without importing a uniform ledger or a host function-space object. It reads continuous approximants from chapter 130, keeps the limiting observations separate from the $\mathsf{UniformLimit}^{\uparrow}$ surface of chapter 463, schedules finite observations through chapter 126, checks regular rational readbacks through chapter 301, seals values only at chapter 38, keeps source and target distance rows visible through chapter 57, and supplies the generic pointwise-limit sibling read consumed by chapter 1604 and chapter 2196.

Definition 2314.1 (PointwiseLimit carrier)**.** *A* $\mathsf{PointwiseLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, Y, F, I, S, Q, R, E, H, C, K, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *context row naming the points at which the family is inspected.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *value-seal context for the observed outputs.*
3. *F is the finite ledger of displayed maps, including the* $\mathsf{ContinuousMap}^{\uparrow}$ *rows when the source family is continuous.*
4. *I is the point-index row saying that each convergence request is attached to one displayed source point and one requested tolerance.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finite approximant windows inspected for that point and tolerance.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected output windows.*
7. *R is the pointwise convergence ledger asserting that the selected windows are adequate for the displayed point and tolerance.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *value-seal row reached only after X, Y, F, I, S, Q, R have been displayed.*
9. *H records componentwise* hsame *transport for the source, target, map ledger, point-index row, schedule, readback, convergence ledger, value seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a point-and-tolerance request through the finite schedule, readback, pointwise ledger, and RealUp seal.*

11. *K is the* Pkg *provenance over* $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for uniform convergence, continuity preservation, host function equality, quotient function spaces, choice-selected pointwise limits, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PointwiseLimitUp.PointwiseLimitTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.PointwiseLimitUp.PointwiseLimitUp`

Theorem 2314.2 (PointwiseLimit NameCert obligations)**.** *For every accepted* $\mathsf{PointwiseLimit}^{\uparrow}$ *carrier* $P = (X, Y, F, I, S, Q, R, E, H, C, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source metric context, target metric and RealUp value context, displayed map ledger, point-index row, stream schedule, regular rational readback, pointwise convergence ledger, terminal value seal, transport, replay, provenance, and local naming row;*

2. *point-index visibility, requiring each convergence request to display its source point and requested tolerance through I before any schedule in S is read;*

3. *finite-window scheduling, requiring the requested approximant windows to be selected by S and checked by Q before the pointwise convergence row R can be consumed;*

4. *Real-seal routing, requiring the value row E to be downstream of X, Y, F, I, S, Q, R rather than of an ambient function-space limit;*

5. *sibling handoff compatibility, allowing* $\mathsf{BaireOneFunction}^{\uparrow}$ *and* $\mathsf{DiniContinuity}^{\uparrow}$ *consumers to read the pointwise route while keeping* $\mathsf{UniformLimit}^{\uparrow}$ *as a separate stronger ledger;*

6. *nonescape from uniform convergence, continuity preservation, host function equality, quotient function spaces, choice-selected pointwise limits, and completeness of* $\mathsf{Real}^{\uparrow}$.

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2314.1. The accepted packet exposes exactly the source and target metric rows, map ledger, point-index row, finite schedule, regular rational readback, convergence ledger, value seal, transport, replay, provenance, and local naming row.

Point-index visibility is forced by I. A consumer must name the displayed source point and tolerance before it can inspect the corresponding schedule, so the packet does not contain an unindexed host function limit.

Finite-window scheduling is then read through S and Q. The schedule selects only finite approximant windows, and the regular rational row checks those windows before R records the pointwise convergence ledger for the displayed point.

The RealUp value seal E is downstream of this route. The sibling handoff rows in K name $\mathsf{BaireOneFunction}^{\uparrow}$ and $\mathsf{DiniContinuity}^{\uparrow}$ as consumers of the pointwise route, while $\mathsf{UniformLimit}^{\uparrow}$ remains a separate stronger ledger. Since no excluded coordinate appears in the carrier, the listed rows exhaust the local surface. □

Theorem 2314.3 (PointwiseLimit Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{BaireOneFunction}^{\uparrow}$*, or* $\mathsf{DiniContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{PointwiseLimit}^{\uparrow}$ *packet reads the limiting value through the finite route*

$$X, Y, F, I, S, Q, R \longmapsto E.$$

The route first displays the source and target metric rows, then the map ledger and point-index row, then the StreamName schedule, RegSeqRat readback, and pointwise convergence ledger, and only then exposes the RealUp value seal. It exports no uniform convergence ledger, continuity-preservation theorem, host function equality, quotient function-space object, choice-selected pointwise limit, or RealUp completeness principle.

Proof. Start with a consumer request for the value seal E. By Definition 2314.1, E is a coordinate of the same finite packet as X, Y, F, I, S, Q, R, and the replay row C records the only displayed route into it.

The source and target rows X, Y are read first, followed by the displayed map ledger F and the point-index request I. The finite schedule S and regular rational readback Q then supply the observed approximant windows for that point and tolerance.

The convergence row R certifies only this pointwise route before E is exposed. Transport, replay, provenance, and local naming through H, C, K, N preserve that order for $\mathsf{BaireOneFunction}^{\uparrow}$ and $\mathsf{DiniContinuity}^{\uparrow}$ consumers, while no carrier coordinate supplies the excluded stronger objects. □

Falsifiable prediction: Every accepted $\mathsf{PointwiseLimit}^{\uparrow}$ value-seal read factors through a displayed point-index row and finite StreamName and RegSeqRat windows before any RealUp value is exposed.

Independence witness: continuousmap, uniformlimit, streamname, regseqrat, baireonefunction: PointwiseLimitUp is not bijective to any listed sibling because it jointly carries a source-point request, an approximant ledger, finite schedule and readback rows, a pointwise convergence ledger, a RealUp value seal, and explicit refusal of the UniformLimitUp ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PointwiseLimit}^{\uparrow}$ packet is generated from source and target MetricUp rows, a displayed map ledger, a point-index row, StreamName schedules, RegSeqRat readbacks, a pointwise convergence ledger, a RealUp value seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2314.1, Definition 2314.2, and Definition 2314.3 seed the finite pointwise-limit certificate over displayed source points, approximant windows, regular rational readbacks, and RealUp value seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointwiseLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close uniform convergence, continuity preservation, host function equality, quotient function spaces, choice-selected pointwise limits, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or standard bridge closure.

Upgrade path: Obligation closure requires checked carrier admission, point-index visibility, finite-window scheduling, Real-seal routing, sibling handoff compatibility, and nonescape for BEDC.Derived.PointwiseLimitUp.

Chapter 2315

A Concrete Naming Certificate for $\mathsf{RealLogarithm}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealLogarithm}^{\uparrow}$ packet names logarithm on positive real data as a finite inverse-route certificate for $\mathsf{RealExponential}^{\uparrow}$. The construction records located positive brackets, dyadic interval refinement, exponential comparison rows, and real-equality endpoint checks; it does not import a host logarithm, analytic continuation, quotient real equality, selected infinite bisection branch, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2315.1 (RealLogarithm carrier)**.** *A* $\mathsf{RealLogarithm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, I, B, E, A, O, C, R, H, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *row naming the positive input real and its located apartness from* 0*.*
2. *I is the* $\mathsf{OpenIntervalReal}^{\uparrow}$ *row carrying the positive bracket interval on which the inverse search is performed.*
3. *B is the finite dyadic bracket ledger, with each row recording a rational interval, midpoint comparison request, and retained positive subinterval.*
4. *E is the* $\mathsf{RealExponential}^{\uparrow}$ *inverse-route row used to compare displayed exponentials against the positive input.*
5. *A is the* $\mathsf{RealAbs}^{\uparrow}$ *control row bounding comparison error and bracket width during the finite read.*
6. *O is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *row that classifies the displayed real comparisons used by the bracket ledger.*
7. *C is the displayed* Cont *route from positive input and bracket rows through exponential comparisons to the endpoint classifier.*
8. *R is the real classifier row, read through* hsame *transport and the displayed comparison rows, that identifies the logarithm endpoint with the inverse route.*
9. *H is the componentwise* hsame *transport row for $P, I, B, E, A, O, C, R, K, N$.*

10. *K is the* Pkg *provenance over* $\mathsf{RealLogarithm}^{\uparrow}$, $\mathsf{LocatedPositiveReal}^{\uparrow}$, $\mathsf{OpenIntervalReal}^{\uparrow}$, $\mathsf{RealExponential}^{\uparrow}$, $\mathsf{RealAbs}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}$ *row.*

The classifier accepts only packets whose positive input, bracket ledger, exponential inverse-route rows, absolute-error controls, Bishop comparison rows, transport, continuation, provenance, and local naming are all displayed. It has no coordinate for a host logarithm or for a hidden infinite choice of bisection branch.

Lean4 ✓ `BEDC.Derived.RealLogarithmUp.RealLogarithmTasteGate single carrier alignment`

Theorem 2315.2 (RealLogarithm NameCert obligations)**.** *For every accepted* $\mathsf{RealLogarithm}^{\uparrow}$ *carrier* $L = (P, I, B, E, A, O, C, R, H, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}$ *surface consists exactly of carrier exposure for the positive real row, the open positive interval, the dyadic bracket ledger, the* $\mathsf{RealExponential}^{\uparrow}$ *inverse-route comparisons, the* $\mathsf{RealAbs}^{\uparrow}$ *error controls, the* $\mathsf{BishopRealComparison}^{\uparrow}$ *classifier rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Any public logarithm read must pass through those rows before it can consume an endpoint value.*

Proof. Project the accepted carrier to the displayed rows $P, I, B, E, A, O, C, R, H, K, N$. The positivity and interval rows give the only admissible domain data, while the dyadic ledger records the finite bracket observations that a consumer may inspect.

The inverse comparisons are then forced through E, A, O. The exponential row supplies the only comparison with the candidate endpoint, the absolute-value row supplies the displayed error control, and the Bishop comparison row classifies the retained side of the bracket.

Finally, H, C, K, N preserve the same rows under transport, replay, provenance, and naming. Since no coordinate stores a host logarithm, an analytic-continuation datum, or a selected infinite branch, the local NameCert surface is exactly the displayed inverse-route surface. □

Theorem 2315.3 (RealLogarithm exponential inverse route)**.** *Every public read of an accepted* $\mathsf{RealLogarithm}^{\uparrow}$ *packet factors through the positive* $\mathsf{Real}^{\uparrow}$ *input row, the located open bracket row, the finite dyadic bracket ledger, the* $\mathsf{RealExponential}^{\uparrow}$ *comparison row, the* $\mathsf{RealAbs}^{\uparrow}$ *error-control row, and the* $\mathsf{BishopRealComparison}^{\uparrow}$ *classifier row before the logarithm endpoint is consumed. Consequently the packet names logarithm as the constructive inverse route of exponential on positive real data, not as a host transcendental primitive.*

Proof. Start with a public logarithm read. The carrier gives the positive input row P and the bracket row I, so the read begins inside a located positive real interval rather than in an ambient total real function space.

The finite bracket ledger B supplies the inspected dyadic intervals. Each retained bracket is justified only by the exponential comparison row E, the absolute-error row A, and the Bishop comparison row O.

The endpoint read is then routed through C and R, with H, K, N preserving the same displayed packet under transport, provenance, and naming. Thus the logarithm value is consumed only after the exponential inverse route has been displayed, and no hidden host log or selected infinite branch is exported. □

Theorem 2315.4 (RealLogarithm sibling dependency route)**.** *Every public logarithm read of an accepted* $\mathsf{RealLogarithm}^{\uparrow}$ *packet first consumes the positive-domain row from chapter 2029, the bracket row from chapter 2133, the inverse comparison row from chapter 1816, and the error and*

classifier rows from chapter 1608 and chapter 1381. The route is a sibling dependency lattice for the displayed packet rows, not a host logarithm or ambient transcendental primitive.

Proof. Project the carrier $L = (P, I, B, E, A, O, C, R, H, K, N)$. The rows P and I are the positive-domain and open-bracket sources, so the logarithm read begins by consuming the sibling surfaces for located positive reals and open real intervals.

The inverse-route data then passes through E, A, O. The row E is the substantive $\mathsf{RealExponential}^{\uparrow}$ sibling dependency: it supplies the comparison route from chapter 1816, while the absolute-value and Bishop-comparison rows supply the error and classifier ledgers used by the finite bracket read.

Finally the structural rows C, R, H, K, N replay, transport, source, and name exactly that lattice of sibling rows. Since no carrier coordinate stores a host log or an ambient analytic primitive, the theorem records dependency routing rather than a host logarithm construction. □

Falsifiable prediction: Every $\mathsf{RealLogarithm}^{\uparrow}$ public read factors through a located positive real row, an open positive interval row, a dyadic bracket ledger, a RealExponential inverse-route row, a RealAbs error-control row, a BishopRealComparison classifier row, componentwise hsame transport, displayed continuation, package provenance, and local naming.

Independence witness: real-exponential, real-analytic, located-positive-real, open-interval-real, real-abs, bishop-real-comparison: $\mathsf{RealLogarithm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries positive-domain admission, finite inverse brackets, exponential comparison rows, absolute-error controls, Bishop comparison classification, endpoint transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLogarithm}^{\uparrow}$ packet is generated from a located positive real input, an open positive interval, finite dyadic bracket rows, RealExponential inverse-route comparisons, RealAbs error controls, BishopRealComparison classifier rows, componentwise transport, displayed continuation, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2315.1, Definition 2315.2, and Definition 2315.3 seed the constructive inverse-route surface for logarithm on positive real data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLogarithm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host logarithms, analytic continuation, quotient real equality, selected infinite bisection branches, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-domain exposure, bracket refinement, exponential inverse-route comparison, error-control, classifier nonescape, and TasteGate field faithfulness for BEDC.Derived.RealLogarithmUp.

Chapter 2316

A Concrete Naming Certificate for $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$

Following Bourbaki and Kelley on uniform completions and Bishop–Bridges on constructive completion, the $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ packet records the finite functorial handoff from a located uniform source to the regular Cauchy real seal. It sits after the located uniform completion surface of chapter 1692, the functorial completion boundary of chapter 1892, the regular rational readback of chapter 301, the finite observation windows of chapter 126, and the terminal real-name seal of chapter 38. The packet names a quotient-free L10 completion functor: it exposes source rows, located Cauchy rows, finite readback windows, real-seal handoff, transport, replay, provenance, and local naming, but no quotient completion, selected representative, countable-choice branch, host equality of limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2316.1 (Located Cauchy completion functor carrier)**.** *A* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, L, G, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{LocatedUniformCompletion}^{\uparrow}$ *source row, carrying the located uniform completion request before any real-facing consumer inspects a seal.*
2. *L is the located Cauchy service row extracted from U, recording the positive-radius and finite-window evidence used to answer completion requests.*
3. *G is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *action row, recording the finite functorial map from source requests to completion-facing requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window schedule through which the consumer asks for finite data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window schedule.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after U, L, G, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the located source, functor row, observation window, regular readback, terminal seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through*

$$U, L, G \longmapsto S, R, E \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$, $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient Cauchy classes, representative selection, host limit equality, countable choice, open-cover compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.LocatedCauchyCompletionFunctorUp.LocatedCauchyCompletionFunctorTasteGate`
`single carrier alignment`

Theorem 2316.2 (Located Cauchy completion functor NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ *carrier* $F = (U, L, G, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletio}}$ *surface consists exactly of carrier admission, located uniform source exposure, located Cauchy service exposure, functorial completion action, finite observation-window routing, regular rational readback, terminal real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of quotient completions, selected representatives, host limit equality, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2316.1. The displayed packet fixes the source row U, located service row L, functor row G, window schedule S, readback row R, terminal seal E, and structural rows H, C, P, N.

The located source is read first. The row U is the located uniform completion surface cited in chapter 1692, and L records the finite located Cauchy service used by the functor row. Thus no consumer reaches the completion functor before located evidence is displayed.

The functorial action then routes the request through G and into the finite observation rows. The schedule S and readback R are exactly the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ interfaces named above, so the handoff is a finite readback route rather than a quotient of all Cauchy names.

Finally E, H, C, P, N expose the real seal, transport the same components, replay the route, record provenance, and name the packet. Since the excluded completion principles are absent from the carrier, no local obligation can be stored outside the displayed rows. □

Theorem 2316.3 (Located Cauchy completion functor real-seal handoff)**.** *Every real-facing read of an accepted* $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ *carrier factors through the route*

$\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, N

The terminal $\mathsf{Real}^{\uparrow}$ *seal is therefore available only after the located source row, functorial completion row, finite observation window, and regular rational readback have been displayed. The handoff exports no quotient stream equality, selected limit, countable-choice branch, host real equality, or ambient completeness datum.*

Proof. Start with an accepted carrier $F = (U, L, G, S, R, E, H, C, P, N)$. The continuation row C makes U, L, G the entry surface for every completion request, so the route cannot begin at a terminal real object.

The finite readback phase is then forced by S and R. These rows are the displayed $\mathsf{StreamName}^{\uparrow}$ observation window and $\mathsf{RegSeqRat}^{\uparrow}$ readback route, and the real seal E is stored only after them in the carrier.

Componentwise transport by H, replay by C, provenance by P, and naming by N preserve the same displayed route. Since no quotient stream equality, selected limit, choice branch, host real

equality, or ambient completeness coordinate occurs in the packet, every real-facing read factors through the stated rows. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ completion read factors through $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, terminal $\mathsf{Real}^{\uparrow}$ sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: locateduniformcompletion, uniformcompletionfunctor, regseqrat, streamname, real: $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ is not bijective to any listed sibling because it binds located source evidence, functorial completion action, finite observation windows, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2316.1, Definition 2316.2, and Definition 2316.3 seed the finite quotient-free completion-functor handoff through located uniform source rows, functor rows, finite observation windows, regular readback, and terminal real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, open-cover compactness, host limit equality, Lean verification, public bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, functorial action, finite-window readback, real-seal handoff, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.LocatedCauchyCompletionFunctorUp.

Constructive story: A $\mathsf{LocatedCauchyCompletionFunctor}^{\uparrow}$ packet is generated from a located uniform completion source, a functorial completion row, finite observation windows, regular rational readback, terminal real sealing, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2317

A Concrete Naming Certificate for $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$

The $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ packet realizes the wobble-quotient geometry branch around Definition 9462.1440 as finite trigger rows. It reads the quotient skeleton, spectral reconstruction, product decomposition, and occupancy rows of the wobble quotient geometry file, then packages them as a concrete NameCert surface beside the hash boundary of chapter 242, the spectral sequence surface of chapter 178, the network-flow route of chapter 233, and the Boolean endpoint discipline of chapter 32. The packet is a finite trigger carrier for spectral geometry consumers; it is not a host eigenvector computation, a biological assertion, a quotient-space semantic equality, or an unbounded graph search.

Falsifiable prediction: Every accepted $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ trigger read factors through wobble quotient rows, spectral hinge rows, trigger energy rows, hsame transport, Cont replay, and Pkg provenance before any downstream consumer treats the trigger as active.

Independence witness: hash, spectralseq, networkflow, bool: $\mathsf{Hash}^{\uparrow}$ records digest rows rather than quotient geometry, $\mathsf{SpectralSeq}^{\uparrow}$ records filtration pages rather than wobble trigger energy, $\mathsf{NetworkFlow}^{\uparrow}$ records capacity routes rather than quotient-fiber hinges, and $\mathsf{Bool}^{\uparrow}$ records endpoint tags rather than the spectral trigger packet; none is bijective to $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$.

Definition 2317.1 (Wobble quotient spectral trigger carrier)**.** *A* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, S, E, H, C, P, B, R, N)$$

with the following displayed rows:

1. *Q is the wobble quotient row, recording the finite f_3 quotient vertices, the one-hole quotient closure, and the quotient-product lift surface.*
2. *S is the spectral hinge row, recording the finite adjacency spectrum readback used by the quotient spectral reconstruction.*
3. *E is the trigger energy row, recording the accepted threshold comparison for the killed bit-flip spectral radius and its finite trigger tag.*
4. *H records componentwise* hsame *transport for quotient, spectral, energy, continuation, provenance, Boolean tag, route, and local naming rows.*

5. *C records displayed* Cont *replay from a consumer trigger request through*

$$Q, S, E \longmapsto H, P, B, R, N.$$

6. *P is the* Pkg *provenance over* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$, $\mathsf{Hash}^{\uparrow}$, $\mathsf{SpectralSeq}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

7. *B is the* $\mathsf{Bool}^{\uparrow}$ *trigger tag row, exposing the finite accept or refuse endpoint for the trigger request.*

8. *R is the route row assigning the read to quotient-geometry support, spectral-hinge support, trigger-energy support, or refusal.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for host spectral computation, ambient quotient equality, biological interpretation, infinite graph traversal, or a trigger that bypasses route classification.

Theorem 2317.2 (Wobble quotient spectral trigger NameCert obligations)**.** *For every accepted* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *carrier* $T = (Q, S, E, H, C, P, B, R, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}$ *surface consists exactly of carrier admission, quotient-row exposure, spectral-hinge exposure, trigger-energy exposure, route classification, Boolean trigger tagging, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of host spectral computation, ambient quotient equality, biological interpretation, infinite graph traversal, and unclassified trigger reads.*

Proof. Carrier admission projects the displayed tuple of Definition 2317.1. The quotient row Q, spectral row S, trigger energy row E, route row R, Boolean row B, and structural rows H, C, P, N are the only visible coordinates.

The quotient row is read before the spectral hinge. This keeps the trigger tied to the finite wobble quotient skeleton and prevents a consumer from substituting an ambient quotient-space equality.

The spectral hinge and trigger energy rows are then read through S and E. Route classification by R decides whether the request is quotient support, spectral support, energy support, or refusal before the Boolean tag B is exported.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no host spectral computation, biological interpretation, infinite graph traversal, or unclassified trigger coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 2317.3 (Wobble quotient spectral trigger handoff)**.** *Every accepted trigger read of a* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *packet factors through the route*

$$\mathsf{Hash}^{\uparrow},\ \mathsf{SpectralSeq}^{\uparrow},\ \mathsf{NetworkFlow}^{\uparrow},\ \mathsf{Bool}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The quotient row, spectral hinge row, trigger energy row, route row, and Boolean trigger tag are therefore visible before a downstream consumer can treat the trigger as accepted. The route exports no host eigenvector data, ambient quotient equality, biological assertion, infinite graph search, or trigger tag outside the displayed carrier.

Proof. Start with an accepted carrier $T = (Q, S, E, H, C, P, B, R, N)$. The quotient, spectral, and energy rows are the only support rows available to the trigger request, while R records how the request is classified.

The Boolean tag is read only after route classification. Thus an accepted tag in B cannot be separated from the quotient, spectral, and energy evidence that produced it.

Componentwise transport by H, continuation replay by C, provenance by P, and local naming by N preserve that same finite route. Since the excluded host and ambient objects are absent from the carrier, every accepted trigger read factors through the displayed rows. □

Theorem 2317.4 (Wobble quotient spectral trigger TasteGate obligations)**.** *The TasteGate surface for* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *requires a nontriviality row and a field-faithfulness row:*

$$\mathsf{Nontrivial}\,\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow} \quad \textit{and} \quad \mathsf{FieldFaithful}\,\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}.$$

The nontriviality row separates accepted trigger tags from refusal tags, and the field-faithfulness row requires every accepted tag to retain its quotient-row, spectral-hinge, trigger-energy, route, transport, replay, provenance, and local naming support.

Lean4 ✓ `BEDC.Derived.WobbleQuotientSpectralTriggerUp.wobbleQuotientSpectralTriggerChapterTasteGate`

Proof. Nontriviality is read from the Boolean trigger row B together with the route classifier R. An accepted tag and a refusal tag are distinct only because the carrier displays both the tag and the route that licensed it.

Field faithfulness is row preservation. A field-faithful read may transport the packet through H and replay it through C, but it cannot erase Q, S, E, R, P, N while keeping an accepted trigger tag.

Thus the required TasteGate rows are exactly the nontrivial trigger distinction and the preservation of the displayed support fields. □

Closure status for $\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2317.1, Definition 2317.2, Definition 2317.3, and Definition 2317.4 seed the finite quotient-trigger surface through quotient rows, spectral hinge rows, trigger energy rows, route classification, Boolean trigger tags, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host spectral computation, biological semantics, ambient quotient equality, infinite graph traversal, Lean verification, public bridge checking, or field-faithful TasteGate implementation.

Upgrade path: Obligation closure requires checked carrier admission, quotient exposure, spectral hinge exposure, trigger-energy exposure, route classification, Boolean tagging, support-field preservation, and TasteGate instances for BEDC.Derived.WobbleQuotientSpectralTriggerUp.

Constructive story: A $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ packet is generated from wobble quotient rows, spectral hinge rows, trigger energy rows, Boolean trigger tags, route classification, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2318

A Concrete Naming Certificate for $\mathsf{CantorIntersectionTheorem}^{\uparrow}$

Following Cantor's nested intersection theorem and Bishop–Bridges constructive analysis, the $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ packet records the theorem-shaped L10 boundary where a displayed sequence of nested located intervals is consumed through finite windows before any Real-facing seal is read. It sits downstream of the finite compactness surface of chapter 1584, the nested carrier of chapter 320, the located endpoint row of chapter 394, the dyadic interval ledger of chapter 306, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter names the finite nested-intersection theorem route only; it does not introduce a point selector, quotient real equality, open-cover compactness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2318.1 (Cantor intersection theorem carrier)**.** *A* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{NestedIntervalCompactness}^{\uparrow}$ *finite-window compactness row consumed as the theorem source.*
2. *I is the* $\mathsf{NestedInterval}^{\uparrow}$ *row naming the inspected nested interval prefix.*
3. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint-location row for the same displayed prefix.*
4. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *row carrying dyadic endpoint boxes, inclusion checks, and mesh comparisons.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule read at the displayed precisions.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the located dyadic windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, I, L, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the theorem source, interval rows, windows, readback, seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite theorem request through Q, I, L, D, W, R, E in that order.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$, $\mathsf{NestedIntervalCompactness}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}$ *row.*

The classifier admits only packets with these eleven rows. No coordinate stores open-cover compactness, a selected intersection point, quotient real equality, countable choice, trichotomy, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 2318.2 (Cantor intersection theorem NameCert obligations)**.** *For every accepted* CantorIntersectionTheor *carrier $K = (Q, I, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed nested-interval compactness row, nested prefix, located endpoints, dyadic interval ledger, stream windows, regular rational readback, real seal, transports, continuations, provenance, and local naming;*
2. *source coherence, requiring Q to be consumed through the same I, L, D, W, R, E route exposed by the finite-window compactness packet;*
3. *located mesh exactness, requiring L and D to govern the same interval prefix before any* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *row is read;*
4. *theorem-route sealing, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through Q, I, L, D, W, R before E, H, C, P, N are exposed;*
5. *ledger non-escape, excluding open-cover compactness, selected intersection points, quotient real equality, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 2318.1. The local naming surface has exactly the displayed rows $Q, I, L, D, W, R, E, H, C, P, N$.

The source coherence row is inherited by reading Q through chapter 1584. That source already exposes the nested prefix, located endpoint row, dyadic interval row, stream windows, regular rational readback, and real seal boundary as finite data.

The located mesh exactness row binds L and D to the same prefix before W and R can be consumed. The theorem-route sealing row then forces any Real-facing read to pass through the finite source and mesh route before it reaches E and the structural rows H, C, P, N.

Since no row in the carrier is an open-cover compactness proof, point selector, quotient-real equality witness, countable-choice schedule, trichotomy row, or ambient completeness theorem, the ledger non-escape obligation is exactly the absence of those coordinates. □

Theorem 2318.3 (Cantor intersection theorem nested route)**.** *Let $K = (Q, I, L, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *carrier. Every theorem-facing read of the nested intersection boundary factors through*

$$\mathsf{NestedIntervalCompactness}^{\uparrow},\ \mathsf{NestedInterval}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

in that order, followed only by componentwise transport, continuation replay, package provenance, and the local naming row.

Lean4 ✓ `BEDC.Derived.CantorIntersectionTheoremUp.CantorIntersectionTheoremTasteGate single carrier alignment`

Proof. Start with a theorem-facing read. By Definition 2318.2, the read first consumes the finite-window source row Q and its exposed nested prefix I.

Next the same obligation surface requires located mesh exactness. The located endpoint row L and dyadic interval row D therefore govern the inspected prefix before the stream windows W or regular rational readback R are visible.

Finally the theorem-route sealing row sends the read through R to the real seal E, and only then to H, C, P, N. The carrier has no other coordinate, so the displayed seven-object route exhausts the nested-intersection theorem boundary. □

Theorem 2318.4 (Cantor intersection theorem Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer admitted by an accepted* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *packet receives a finite nested-window theorem route through* $Q, I, L, D, W, R, E, H, C, P, N$*. The consumer receives no open-cover compactness theorem, no selected intersection point, no quotient real equality principle, no countable-choice selector, no trichotomy row, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Apply Definition 2318.3. A Real-facing consumer reaches the terminal seal only after the finite-window compactness row, nested prefix, located endpoints, dyadic boxes, stream windows, and regular rational readback have all been displayed.

The structural rows H, C, P, N preserve and name that route; they do not add analytic content. The source coherence and theorem-route sealing obligations of Definition 2318.2 keep the Real seal downstream of the same finite data.

Thus the consumer has no coordinate from which to read open-cover compactness, a selected point of the full intersection, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The exported boundary is the finite nested-window theorem route and nothing stronger. □

Theorem 2318.5 (CantorIntersection diameter-zero route)**.** *Let* $K = (Q, I, L, D, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *carrier. If the nested interval packet carries a displayed dyadic diameter ledger tending to zero, then every Real-facing seal read factors through* $\mathsf{NestedIntervalCompactness}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *by first reading the nested prefix* I*, located endpoint row* L*, dyadic interval and diameter rows in* D*, stream windows* W*, regular rational readback* R*, and terminal seal* E*. The route exports no selected intersection point, ambient completeness claim, quotient real equality, countable choice, trichotomy, or open-cover compactness.*

Proof. Project the carrier of Definition 2318.1. The theorem source row Q exposes the same nested interval prefix I that the diameter-zero read inspects.

Source coherence from Definition 2318.2 forces the nested prefix to be read before the Real-facing seal route is opened. The displayed dyadic diameter ledger is part of the D row, so it is tied to the same prefix and the same located endpoint row L.

Located mesh exactness then governs the zero-diameter rows. A consumer may inspect the finite $\mathsf{StreamName}^{\uparrow}$ windows W and the $\mathsf{RegSeqRat}^{\uparrow}$ readback R only after the located and dyadic rows have displayed the required mesh comparisons.

Finally, theorem-route sealing and Definition 2318.4 send the read through E and then only through H, C, P, N. None of those structural rows can add a selected point, ambient completeness principle, quotient equality, countable selector, trichotomy row, or open-cover compactness theorem. □

Falsifiable prediction: An accepted $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without first reading the nested-interval compactness row, nested prefix, located endpoint row, dyadic interval ledger, stream windows, and regular rational readback refutes the carrier surface.

Independence witness: nestedintervalcompactness, nestedinterval, locatedinterval, dyadicinterval, streamname, regseqrat, real: none is bijective to $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ because this packet jointly carries the theorem-source row, the finite nested prefix, located and dyadic endpoint rows, stream windows, regular readback, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ packet is generated from a NestedIntervalCompactness row, a nested interval prefix, located endpoint rows, dyadic interval boxes, StreamName windows, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2318.1, Definition 2318.2, Definition 2318.3, and Definition 2318.4 seed the finite Cantor nested-intersection theorem route over the L10 nested-interval boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorIntersectionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected intersection points, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove source coherence, located mesh exactness, theorem-route sealing, and ledger non-escape for the same finite packet.

Chapter 2319

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$

Following Bishop–Bridges and Bourbaki-style completion theory, the $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ packet records the finite universal-property surface for the L10 completion interface. It sits after the metric-completion carrier of chapter 1506, the uniform-completion route of chapter 1473, the functorial completion handoff of chapter 423, and the separated-metric comparison boundary of chapter 1411. The packet names the dense-source, extension, and uniqueness rows that completion consumers may cite without importing quotients, selected limits, choice, or ambient completeness.

Definition 2319.1 (Cauchy completion universal property carrier)**.** *A* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, K, T, F, E, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense source row, recording the source object together with the finite density witness consumed by completion readers.*
2. *K is the completion carrier row, read through* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff data.*
3. *T is the complete separated target row, recording the target surface whose separatedness supports uniqueness.*
4. *F is the source map row from D into T before completion is invoked.*
5. *E is the extension map row from K into T, tied to F along the dense source row.*
6. *L is the uniqueness classifier, comparing two extension rows over the same D, K, T, F surface by separatedness rather than by quotient equality.*
7. *H records componentwise* hsame *transport for D, K, T, F, E, L and the local naming row.*
8. *C records displayed* Cont *replay of dense-source handoff, extension existence, and uniqueness reads.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, K, T, F, E, L, H, C, P, N$. It has no coordinate for quotient completion, selected representatives, host limit choice, ambient real completeness, or countable choice.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalPropertyUp.CauchyCompletionUniversalPropertyTasteGate single carrier alignment`

Theorem 2319.2 (CauchyCompletionUniversalProperty NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *carrier* $U = (D, K, T, F, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of five obligation rows: carrier exposure for the displayed tuple; dense-source handoff through D and the source map F; extension existence through the completion rows K, T, E; uniqueness up to the classifier L over the same dense-source and completion route; and ledger non-escape from choice, quotient equality, selected limits, or host limit principles.*

Proof. Carrier exposure is projection from Definition 2319.1. The tuple displays the dense source, completion carrier, complete separated target, source map, extension row, uniqueness classifier, transport, replay, provenance, and local naming row.

The dense-source handoff uses D and F. A consumer must first read the source and its finite density route before it can ask for an extension into the target.

Extension existence is carried by K, T, E. The completion carrier is read through the metric, uniform, and functorial completion rows, while T supplies the complete separated target surface. The extension row E is therefore attached to displayed completion data rather than to a selected host limit.

Uniqueness is carried by L. Since L compares extension rows over the same D, K, T, F surface and uses separatedness from T, it does not require quotient equality or representative selection.

The ledger boundary is fixed by H, C, P, N. These rows transport, replay, source, and name the same displayed packet, and no excluded host-side principle appears as a coordinate of the carrier. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalPropertyUp.CauchyCompletionUniversalPropertyCarrier namecert obligations`

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ consumer that exports extension existence or uniqueness while omitting the dense source, completion carrier, complete separated target, source map, extension row, uniqueness classifier, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: metriccompletion, uniformcompletion, cauchycompletionfunctor, separatedmetric: none is bijective because $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ jointly carries dense source, completion carrier, complete separated target, source map, extension, uniqueness classifier, transport, replay, provenance, and local NameCert rows in one universal-property packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ packet is generated from a dense source row, a completion carrier row, a complete separated target row, a source map, an extension row, a uniqueness classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$, seed)

Scope closed: Definition 2319.1 and Definition 2319.2 seed the finite L10 Cauchy completion universal-property surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, dense-source handoff, extension existence, uniqueness classification, transport replay, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchyCompletionUniver

Chapter 2320

A Concrete Naming Certificate for $\mathsf{CandidateSetNormalization}^{\uparrow}$

The $\mathsf{CandidateSetNormalization}^{\uparrow}$ packet realizes the candidate-set reading of chapter 9383 as finite NameCert data. It records candidate evidence, closed-term projection, Pi and application adequacy, no-infinite-reduction, obstruction, transport, continuation, provenance, and local naming rows. The packet is deliberately a candidate-set surface: it does not claim unconditional strong normalization for every closed typed MetaCIC term. Its candidate-evidence and bounded-normal checking route is read through the sibling surfaces of chapter 892 and chapter 752.

Definition 2320.1 (MetaCIC candidate-set normalization carrier)**.** *A* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, T, A, I, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite candidate-set evidence row, including candidate membership, soundness, and beta-closure evidence for the accepted read.*
2. *T is the closed typed term projection row, recording the empty-context typed term whose normalization read is supplied by K.*
3. *A is the application and Pi adequacy row, tying application reads and binder reads back to the same candidate-set evidence.*
4. *I is the no-infinite-reduction row obtained from the candidate-set strong-normalization route.*
5. *O is the obstruction row recording that a closed-term normalization read is refused when K is absent.*
6. *H records componentwise* hsame *transport for K, T, A, I, O and the local naming row.*
7. *C records displayed* Cont *replay from candidate-set evidence to strong normalization, closed-term projection, application and Pi adequacy, and no-infinite-reduction reads.*
8. *P is the* Pkg *provenance over* $\mathsf{CandidateSetNormalization}^{\uparrow}$, $\mathsf{MetaCICRedexFrontier}^{\uparrow}$, MetaCICNormalizationFrontie $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CandidateSetNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, T, A, I, O, H, C, P, N$. It contains no coordinate for evidence-free closed-term normalization, componentwise application normalization, host reduction normalization, quotient reduction equality, subject-reduction discharge, or a global normalization oracle.

Lean4 (definition) `BEDC.Derived.CandidateSetNormalizationUp.CandidateSetNormalizationUp`
Lean4 ✓ `BEDC.Derived.CandidateSetNormalizationUp.CandidateSetNormalizationTasteGate single carrier alignment`

Definition 2320.2 (Candidate-set normalization frontier filter)**.** *For an accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier $S = (K, T, A, I, O, H, C, P, N)$, its public frontier filter is the finite* BHist *subpacket*

$$\mathsf{Frontier}(S) = (K, T, A, I, O, H, C, P, N)$$

read in the displayed order: candidate-set evidence K, closed-term projection T, adequacy row A, no-infinite-reduction row I, obstruction row O, transport H, replay C, provenance P, and local naming N. A consumer reaches the redex-facing normalization frontier only through this subpacket, so the filter contains no coordinate for candidate-free strong normalization, closed subject reduction, arbitrary confluence, host conversion equality, or a global normalizer.

Theorem 2320.3 (MetaCIC candidate-set normalization obligations)**.** *For every accepted* $\mathsf{CandidateSetNormalizati}$ *carrier $S = (K, T, A, I, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CandidateSetNormalization}^{\uparrow}}$ *surface consists exactly of finite candidate-set evidence through K; closed-term projection through T; application and Pi adequacy through A; no-infinite-reduction through I; obstruction when the candidate-set row is absent through O; componentwise transport through H; displayed replay through C; provenance through P; local naming through N; and non-escape from unconditional MetaCIC strong normalization.*

Proof. Carrier admission is projection from Definition 2320.1. The tuple displays the candidate-set evidence, closed typed term projection, adequacy row, no-infinite-reduction row, obstruction row, transport, replay, provenance, and local name.

The positive route begins at K. Candidate-set membership, soundness, and beta-closure are read before T, A, or I can export a normalization-facing conclusion.

The closed-term projection is T, and the application and Pi adequacy route is A. Both rows consume the same candidate-set evidence rather than a componentwise strong-normalization shortcut.

The no-infinite-reduction row I is downstream of that evidence. If K is absent, O records the obstruction, so the packet refuses an evidence-free theorem over all closed typed terms.

Finally H, C, P, N transport, replay, source, and name the same finite branch. Since no global normalization oracle or quotient reduction equality is present in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2320.4 (Candidate-set normalization redex non-escape)**.** *Every redex-frontier consumer of an accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier must pass through the frontier filter $K, T, A, I, O, H, C, P, N$ of Definition 2320.2. It exports no candidate-free strong normalization, no closed subject-reduction theorem, and no arbitrary confluence principle.*

Proof. Project the accepted carrier and then read its frontier filter. The first row is K, so the consumer starts from candidate-set evidence rather than from a redex-normalization oracle.

The closed-term row T and adequacy row A are downstream of the same candidate evidence. They can expose closed projection and application or Pi adequacy only through that evidence.

The no-infinite-reduction row I and obstruction row O complete the normalization-facing branch. If the candidate evidence is absent, O records refusal instead of supplying a candidate-free theorem.

Finally H, C, P, N transport, replay, source, and name the same branch. Since the filter has no subject-reduction, confluence, or global-normalizer coordinate, no consumer can export those conclusions from this packet. □

Theorem 2320.5 (Candidate-set normalization candidate-closed handoff)**.** *For every accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier, the handoff from candidate-set evidence to the closed-term projection remains mediated by* $K, T, A, I, O, H, C, P, N$*. In particular, the closed projection row* T *is not a candidate-free closed normalization theorem and cannot be reused without the candidate-set evidence row* K*.*

Proof. Read the carrier as $S = (K, T, A, I, O, H, C, P, N)$. The closed-term projection row is named as T, but its admissibility is part of the same finite packet as K.

The adequacy and no-infinite-reduction rows A and I also consume the candidate-set route. They do not create a detached closed-term theorem, because the obstruction row O records refusal when K is absent.

Transport and replay through H and C, with provenance and naming through P and N, preserve the same candidate-mediated route. Thus the closed projection remains a handoff inside the frontier filter rather than a standalone normalization principle. □

Theorem 2320.6 (MetaCIC candidate-set normalization idempotence)**.** *Let* $S = (K, T, A, I, O, H, C, P, N)$ *be an accepted* $\mathsf{CandidateSetNormalization}^{\uparrow}$ *carrier whose candidate-set packet has already been normalized through the displayed frontier-dependency rows. Applying the same normalization route again exposes the same accepted candidate rows, the same closed-term projection, the same application and Pi adequacy rows, and no additional spectral-trigger row.*

Proof. Use the carrier and obligation surface of Definition 2320.1 and Definition 2320.3. The first normalization pass can read only $K, T, A, I, O, H, C, P, N$, and the accepted candidate-set evidence is already attached to the displayed no-infinite-reduction and obstruction rows.

The frontier-dependency rows of chapter 2307 determine which candidate rows may be exposed before the closed-term projection and adequacy rows are replayed. Running the same route again therefore reuses the same dependency rows rather than introducing a new candidate branch.

Finally compare with the spectral-trigger surface of chapter 2317. A trigger row would have to be present as an additional obstruction or replay coordinate, but the $\mathsf{CandidateSetNormalization}^{\uparrow}$ classifier contains no such coordinate beyond O and C. The second pass is therefore idempotent on accepted candidate rows and creates no further spectral-trigger row. □

Falsifiable prediction: No accepted closed-term strong-normalization read through $\mathsf{CandidateSetNormalization}^{\uparrow}$ bypasses candidate evidence or candidate-set evidence.

Independence witness: metacicredexfrontier, metacicnormalizationfrontier, bounded-normal-equality-checker, metacicopenproblemledger: none is bijective because $\mathsf{CandidateSetNormalization}^{\uparrow}$ jointly carries candidate-set evidence, closed-term projection, application and Pi adequacy, no-infinite-reduction, obstruction, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateSetNormalization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CandidateSetNormalization}^{\uparrow}$ packet is generated from finite candidate-set evidence, a closed typed term projection, application and Pi adequacy, a no-infinite-reduction row, an obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CandidateSetNormalization}\uparrow}$, seed)
Scope closed: Definition 2320.1 and Definition 2320.3 seed the finite candidate-set normalization surface.
Formal verification: FormalStatus(NameCert$_{\text{CandidateSetNormalization}\uparrow}$, encodedDef)
Lean target: `BEDC.Derived.CandidateSetNormalizationUp.CandidateSetNormalizationUp`
Bridge status: none
Not claimed: This chapter does not claim unconditional MetaCIC strong normalization, evidence-free application normalization, subject reduction, host normalization, quotient reduction equality, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked candidate-set evidence, closed-term projection, application and Pi adequacy, no-infinite-reduction, obstruction exactness, transport replay, and TasteGate field faithfulness for BEDC.Derived.CandidateSetNormalizationUp.

Chapter 2321

A Concrete Naming Certificate for $\mathsf{CompletionComparison}^{\uparrow}$

Following Bishop–Bridges metric completion and Kelley uniform-space completion, the $\mathsf{CompletionComparison}^{\uparrow}$ packet records the finite comparison surface shared by metric, filter, net, regular-Cauchy, separated, and uniform completion presentations. It sits after the metric-completion carrier of chapter 1506, the Cauchy-filter carrier of chapter 333, the Cauchy-net carrier of chapter 589, the regular-Cauchy comparison carrier of Definition 411.1, the separated-metric carrier of chapter 1411, and the uniform-completion carrier of chapter 1473. The chapter gives downstream completion consumers one named comparison surface rather than requiring them to choose a quotient-completion presentation or a selected representative prose route.

Definition 2321.1 (Completion comparison carrier)**.** *A* $\mathsf{CompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, T, R, S, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, carrying the metric completion presentation before any comparison consumer reads a completion point.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row, carrying the filter presentation over the same finite tolerance requests.*
3. *T is the* $\mathsf{CauchyNet}^{\uparrow}$ *source row, carrying the net presentation and its directed observation rows.*
4. *R is the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row, comparing the sequence-style regular Cauchy route with the filter and net routes through displayed tolerance windows.*
5. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row used to make equality and uniqueness reads pass through separated comparison data rather than host equality.*
6. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row, recording the uniform completion presentation consumed by entourage-facing readers.*
7. *H records componentwise* hsame *transport for the metric, filter, net, regular-comparison, separated, uniform, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the comparison route*

$$M, F, T, R \longmapsto S, U \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompletionComparison}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, choice of a convergent subnet, host equality of limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompletionComparisonUp.CompletionComparisonTasteGate single carrier alignment`

Theorem 2321.2 (Completion comparison NameCert obligations)**.** *For every accepted* $\mathsf{CompletionComparison}^{\uparrow}$ *carrier* $K = (M, F, T, R, S, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}$ *surface consists exactly of carrier admission, metric completion source exposure, Cauchy-filter source exposure, Cauchy-net source exposure, regular-Cauchy comparison exposure, separated-metric equality routing, uniform-completion handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of quotient completion equality, selected representatives, choice-selected subnets, host equality of limits, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2321.1. The accepted packet exposes exactly the metric row M, filter row F, net row T, regular comparison row R, separated row S, uniform row U, and structural rows H, C, P, N.

The source presentations are read before any equality or uniqueness comparison. Rows M, F, T, R keep metric, filter, net, and regular-Cauchy evidence inside the same finite packet, so a consumer cannot replace the displayed comparison by a quotient object or a selected representative.

The separated and uniform rows then control the target-facing read. Row S supplies the separated comparison boundary, and row U supplies the uniform completion handoff. Rows H, C, P, N transport, replay, source, and name the same finite route.

Since the excluded host-side principles are absent from the carrier, every local obligation is one of the displayed rows. □

Theorem 2321.3 (Completion comparison filter-net correspondence)**.** *Every filter-net completion read of an accepted* $\mathsf{CompletionComparison}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{CauchyNet}^{\uparrow},\ \mathsf{RegularCauchyComparison}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow}$$

In particular, a consumer comparing Cauchy filters with Cauchy nets must read the shared metric row, the regular-Cauchy comparison row, the separated-metric row, and the uniform-completion handoff from Definition 2321.1; it cannot import quotient equality of completions, a selected representative sequence, a choice-selected subnet, a host limit theorem, or ambient completeness.

Proof. Begin with an accepted carrier $K = (M, F, T, R, S, U, H, C, P, N)$. The filter row F and net row T occur in the same packet as the metric row M, so their comparison begins from displayed finite completion data.

The regular comparison row R supplies the common tolerance-window route. The separated row S is the only equality-facing component, and the uniform row U is the only entourage-facing completion handoff.

Finally H, C, P, N preserve that route under transport, replay, provenance, and local naming. No extra completion object appears in K, so every filter-net read factors through the stated rows. □

Falsifiable prediction: Every accepted $\mathsf{CompletionComparison}^{\uparrow}$ consumer comparing completion presentations factors through $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metriccompletion, cauchyfilter, cauchynet, regularcauchycomparison, separatedmetric, uniformcompletion: $\mathsf{CompletionComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric, filter, net, regular-Cauchy, separated, uniform, transport, replay, provenance, and local NameCert rows in one comparison packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2321.1, Definition 2321.2, and Definition 2321.3 seed the finite comparison surface tying metric, filter, net, regular-Cauchy, separated, and uniform completion rows to one NameCert route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, choice-selected subnets, host limit equality, open-cover compactness, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-row exposure, filter-net correspondence, separated equality routing, uniform handoff, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CompletionComparisonUp.

Constructive story: A $\mathsf{CompletionComparison}^{\uparrow}$ packet is generated from metric completion, Cauchy-filter, Cauchy-net, regular-Cauchy comparison, separated-metric, uniform-completion, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2322

A Concrete Naming Certificate for $\mathsf{CofinalCompactInterval}^{\uparrow}$

Following Bishop and Bridges constructive compact-interval arguments, the $\mathsf{CofinalCompactInterval}^{\uparrow}$ packet names the finite cofinal window by which a closed bounded interval request is refined to displayed locator, dyadic, stream, regular-rational, and Real-facing rows. It sits after the closed bounded interval source of chapter 1591, the compact interval locator of chapter 1891, the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives downstream interval compactness, Cousin-style finite refinement, and Heine–Borel interval consumers a named finite-window route without importing open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2322.1 (Cofinal compact interval carrier)**.** *A* $\mathsf{CofinalCompactInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing lower and upper located endpoints, endpoint order, rational containment, dyadic containment, and the base interval naming surface.*
2. *L is the* $\mathsf{CompactIntervalLocator}^{\uparrow}$ *row, recording the located comparison and tolerance-to-window service used to refine interval requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger carrying the dyadic tolerances, endpoint cells, and finite mesh comparisons demanded by I and L.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the cofinal dyadic depth chosen for the displayed request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the same interval, locator, dyadic, and stream rows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the interval source, locator, dyadic ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-interval request through $I, L, D, W, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CofinalCompactInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{CompactIntervalLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}$ *row.*

The classifier admits only packets with these ten rows. No coordinate stores open-cover compactness, a selected subcover, quotient real equality, countable choice, trichotomy, host interval equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CofinalCompactIntervalUp.TasteGate.CofinalCompactIntervalTasteGate single carrier alignment`

Theorem 2322.2 (Cofinal compact interval NameCert obligations)**.** *For every accepted* $\mathsf{CofinalCompactInterval}^{\uparrow}$ *carrier* $K = (I, L, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the closed bounded interval source, compact locator, dyadic tolerance ledger, stream windows, regular rational readback, real seal, transports, continuations, provenance, and local naming;*
2. *interval-source exactness, requiring every endpoint, containment, and interval-local request to enter through I before the locator row is read;*
3. *locator cofinality, requiring L and D to convert any displayed compact-interval request into a finite dyadic window deep enough for the requested observation;*
4. *real-handoff ordering, requiring every* $\mathsf{Real}^{\uparrow}$ *read to pass through I, L, D, W, R before E, H, C, P, N are exposed;*
5. *ledger non-escape, excluding open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, host interval equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 2322.1. The local naming surface has exactly the displayed rows $I, L, D, W, R, E, H, C, P, N$.

The interval-source exactness row is supplied by reading I through chapter 1591. It exposes the lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, finite-window, regular-readback, and Real-seal boundary as displayed interval data.

The locator cofinality row is then read through chapter 1891 and the dyadic tolerance ledger of chapter 291. These rows force the selected finite window to be a displayed refinement of the same interval request before W or R can be consumed.

Finally the real-handoff ordering row sends every Real-facing read through W and R before E and the structural rows H, C, P, N are exposed. Since no coordinate of the carrier is an open cover, selected subcover, quotient-real equality witness, countable-choice schedule, trichotomy row, host interval equality, or ambient completeness theorem, the ledger non-escape obligation is exactly the absence of those rows. □

Theorem 2322.3 (Cofinal compact interval Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*, interval-compactness, Cousin-refinement, or Heine–Borel-style consumer admitted by an accepted* $\mathsf{CofinalCompactInterval}^{\uparrow}$ *packet reads the compact interval request through*

$$\mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{CompactIntervalLocator}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

in that order. The handoff exposes a finite cofinal window and its real seal; it exposes no open-cover compactness row, selected subcover, quotient real equality, countable-choice selector, trichotomy decision, host interval equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with an admitted consumer. By Definition 2322.2, the read first enters through the closed bounded interval row I, so the endpoint and containment data are fixed before any compact-window refinement is available.

Next the same obligation surface requires locator cofinality. The locator row L and dyadic ledger D therefore choose a displayed finite dyadic window for the same request before the stream row W and regular readback R are visible.

The real-handoff ordering row then sends the read through R to the real seal E, followed only by transport, replay, provenance, and the local naming row. Because the carrier has no other coordinate, the displayed six-object route exhausts the consumer-facing handoff and excludes the listed compactness, choice, quotient, order, host, and completeness data. □

Falsifiable prediction: An accepted $\mathsf{CofinalCompactInterval}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without first reading the closed bounded interval row, compact interval locator, dyadic tolerance ledger, finite stream window, and regular rational readback refutes the carrier surface.

Independence witness: closedboundedinterval, compact-interval-locator, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{CofinalCompactInterval}^{\uparrow}$ because this packet jointly carries the interval source, compact locator, cofinal dyadic window, stream schedule, regular readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalCompactInterval}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a CompactIntervalLocatorUp row, a DyadicRatCoreUp tolerance ledger, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2322.1, Definition 2322.2, and Definition 2322.3 seed the finite cofinal compact-interval route from closed bounded intervals through locator and dyadic-window rows to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalCompactInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, host interval equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exactness, locator cofinality, finite-window routing, regular readback, Real-seal handoff, structural transport, replay, provenance, and local naming for BEDC.Derived.CofinalCompactIntervalUp.

Chapter 2323

A Concrete Naming Certificate for $\mathsf{MetrizableCompletion}^{\uparrow}$

Following Kelley and Bourbaki on metrizable topological spaces and completion, the $\mathsf{MetrizableCompletion}^{\uparrow}$ packet records the finite BEDC route by which a topology equipped with a displayed metrization can be read by the existing metric-completion surface of chapter 1506. It sits after the $\mathsf{Topology}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ carrier rows, consumes the $\mathsf{MetricCompletion}^{\uparrow}$ branch and the $\mathsf{CompleteMetric}^{\uparrow}$ seal, and exposes only the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback path needed for completion-facing consumers.

Definition 2323.1 (MetrizableCompletion carrier)**.** *A* $\mathsf{MetrizableCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (T, M, Q, K, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *row, including the open-set classifier, neighborhood interface, and finite continuity rows visible to the packet.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *metrization row on the same carried histories, with a displayed comparison that says the topology read through T is the topology generated by the metric read through M.*
3. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *branch consumed from chapter 1506, including its Cauchy-filter or Cauchy-net evidence route.*
4. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *seal row for the completed metric-facing object, read only after Q has exposed the displayed completion branch.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row used to name the finite observation windows inspected by the completion route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for numerical tolerance data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint-seal row used when distance or convergence witnesses are compared.*
8. *H records componentwise* hsame *transport for the topology, metrization, metric-completion branch, complete-metric seal, stream, readback, endpoint, replay, provenance, and local naming rows.*

9. *C records the displayed* Cont *replay from topology admission through metrization, completion-branch admission, complete-metric sealing, stream/readback inspection, and endpoint comparison.*

10. *P is the* Pkg *provenance over* $\mathsf{MetrizableCompletion}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, a selected representative of a Cauchy name, host topological equality, countable choice, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MetrizableCompletionUp.MetrizableCompletionTasteGate single carrier alignment`

Theorem 2323.2 (MetrizableCompletion NameCert obligations)**.** *For an accepted* $\mathsf{MetrizableCompletion}^{\uparrow}$ *carrier $Z = (T, M, Q, K, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology and metrization rows, compatibility of the topology row with the metric-generated topology, admission of the metric-completion branch Q, sealing by the complete-metric row K, stream/readback readiness through S and R, endpoint comparison through E, componentwise transport through H, replay through C, provenance through P, and ledger non-escape for the excluded host-side principles.*

Proof. Carrier admission is projection from Definition 2323.1. The tuple lists the topology, metrization, metric-completion branch, complete-metric seal, stream, readback, endpoint, transport, replay, provenance, and local naming rows.

The topology-metrization compatibility is local to T and M. A consumer may read open-set or neighborhood data only through the displayed metric generator row, and the packet gives no separate host-topology equality coordinate.

The completion-facing part then passes through Q and K. The row Q is exactly the metric-completion interface of chapter 1506; K seals the resulting read as complete-metric evidence only after that branch is displayed.

Finally S, R, and E provide the finite numerical route. Transport, replay, provenance, and local naming preserve the same displayed packet, so quotient completion equality, selected representatives, countable choice, open-cover compactness, host topological equality, and $\mathsf{Real}^{\uparrow}$ completeness cannot be exported. □

Theorem 2323.3 (MetrizableCompletion Cauchy seal)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetrizableCompletion}^{\uparrow}$ *carrier factors through the finite Cauchy seal*

$$T \longmapsto M \longmapsto Q \longmapsto K \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

In particular, a consumer cannot read the topological completion before the metrization row, cannot read complete-metric evidence before the $\mathsf{MetricCompletion}^{\uparrow}$ *branch, and cannot compare convergence data before the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed.*

Proof. Start with the topology row T. The packet admits it only together with the metrization row M, so a topological completion request first becomes a metric-facing request over the same carried histories.

Next apply the metric-completion branch. The row Q is the sole route to completion-facing data, and chapter 1506 already forces such data through a displayed Cauchy-filter or Cauchy-net branch.

The complete-metric seal K is downstream of Q. It does not select limits or quotient Cauchy names; it records that the displayed completion branch has the complete-metric evidence needed by the consumer.

The numerical seal is read last. Stream windows S precede regular-rational readback R, and the terminal endpoint comparison E is the only $\mathsf{Real}^{\uparrow}$ row offered to convergence comparisons. The transport, replay, provenance, and local naming rows retain this order, so no omitted host-side principle can enter the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MetrizableCompletion}^{\uparrow}$ packet is generated from a topology row, a metrizing metric row, the metric-completion branch, a complete-metric seal, StreamName windows, RegSeqRat readback, a terminal RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2323.1, Definition 2323.2, and Definition 2323.3 seed the finite metrizable-completion surface over topology, metric, completion, complete-metric, stream, readback, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetrizableCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host topological equality, open-cover compactness, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, topology-metrization compatibility, metric-completion branch routing, complete-metric sealing, Cauchy-seal exactness, and ledger non-escape over the same displayed packet.

Chapter 2324

A Concrete Naming Certificate for $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ packet records the shrinking closed interval branch of the Real and Completion route as finite BEDC certificate data. It sits after the retained-window surface of chapter 320, the bisection discipline of chapter 1489, the constructive nested interval packet of chapter 2308, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The certificate names the diameter-zero descent route through displayed closed intervals; it does not import compactness, choice, quotient stream equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2324.1 (Nested interval diameter-zero carrier)**.** *A* $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (I, J, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested closed interval source row, read from* $\mathsf{NestedInterval}^{\uparrow}$*, including closed endpoint rows, containment witnesses, and retained-window evidence.*
2. *J is the interval-halving and descent row, read from* $\mathsf{IntervalHalving}^{\uparrow}$*, recording the chosen finite bisection side, endpoint refinement, and containment descent for each inspected stage.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter budget row recording dyadic radii, endpoint comparisons, and the finite inequality checks showing the inspected widths are below the requested tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the nested closed interval source, halving descent, and dyadic diameter budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, J, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the interval source, halving descent, diameter budget, regular readback, Real seal, replay, provenance, and naming rows.*
7. *C records the displayed* Cont *replay*

$$I, J, D \longmapsto R \longmapsto E$$

through which Real and Completion consumers read the packet.

8. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{IntervalHalving}^{\uparrow}$, $\mathsf{NestedIntervalTheorem}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalDiameterZero}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, J, D, R, E, H, C, P, N$. It has no coordinate for Heine–Borel compactness, open-cover compactness, a selected intersection point by choice, quotient stream equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedIntervalDiameterZeroUp.NestedIntervalDiameterZeroTasteGate single carrier alignment`

Theorem 2324.2 (Nested interval diameter-zero NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ *carrier $Z = (I, J, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalDiameterZero}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed nine-row packet, nested closed interval source exposure through I, interval-halving descent exposure through J, dyadic diameter-budget exactness through D, regular rational readback through R, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, local naming through N, and non-escape from the excluded compactness, choice, quotient, trichotomy, and ambient-completeness principles.*

Proof. Project the carrier of Definition 2324.1. The rows $I, J, D, R, E, H, C, P, N$ are the whole certificate surface, so every local obligation must be read from one of those rows.

The constructive interval data are I, J, D. The source row I supplies the closed nested intervals, J records the displayed halving and descent route, and D records the dyadic diameter budget that makes each requested tolerance visible as finite endpoint arithmetic.

The completion-facing read is then forced through R and E. The regular rational row R is assembled from the same nested source, descent, and diameter budget, and the Real seal E is downstream of that readback.

Finally the structural rows H, C, P, N transport, replay, source, and name the same packet. Since no row contains compactness, a selected point, quotient stream equality, trichotomy, or ambient completeness, the listed obligations exhaust the local NameCert. □

Theorem 2324.3 (Nested interval diameter-zero Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{IntervalHalving}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer reads the nested closed interval source I, the halving descent row J, the dyadic diameter budget D, the regular rational readback R, and only then the Real seal E with its transport, replay, provenance, and local naming rows.

Proof. Begin with a Real-facing consumer. The only Real seal coordinate in the carrier is E, and the carrier places E downstream of I, J, D, R.

The source and descent rows provide the shrinking interval data. Row I exposes the nested closed interval windows, while row J records the interval-halving route that preserves containment at the inspected stages.

The diameter-zero condition is read through D. Its dyadic budget compares widths with the requested tolerance and supplies the arithmetic needed for the $\mathsf{RegSeqRat}^{\uparrow}$ readback R.

The structural rows then preserve the route into E. Thus the Real seal is available only through the displayed finite path, and the packet cannot be repacked as Heine–Borel compactness, an open-cover argument, a choice-selected point, quotient stream equality, trichotomy, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ Real-facing read factors through a nested closed interval source, an interval-halving descent row, a dyadic diameter budget, a RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: nestedinterval, intervalhalving, nested-interval-theorem, dyadicratcore, regseqrat, real: $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ is not bijective to any listed sibling because it binds closed interval nesting, halving descent, diameter-zero dyadic budgets, regular rational readback, Real sealing, transport, replay, provenance, and local NameCert rows into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalDiameterZero}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalDiameterZero}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2324.1, Definition 2324.2, and Definition 2324.3 seed the finite shrinking closed interval route from nested interval source and halving descent through dyadic diameter budgets to RegSeqRat readback and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalDiameterZero}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Heine–Borel, open-cover compactness, a selected intersection point by choice, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested closed interval exposure, interval-halving descent stability, dyadic diameter-budget exactness, RegSeqRat readback, Real-seal non-escape, transport and replay stability, provenance, and local naming for BEDC.Derived.NestedIntervalDiameterZeroUp.

Constructive story: A $\mathsf{NestedIntervalDiameterZero}^{\uparrow}$ packet is generated from a nested closed interval source row, an interval-halving descent row, a dyadic diameter budget, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2325

A Concrete Naming Certificate for ClosedParallelDiamondPremiseLedger$^{\uparrow}$

The ClosedParallelDiamondPremiseLedger$^{\uparrow}$ packet realizes the closed parallel diamond premise boundary of chapter 9378 as finite BEDC data. It sits beside the confluence audit packet of chapter 735, the closed-normal seal of chapter 741, the residual-substitution boundary of chapter 2181, and the parallel confluence audit of chapter 744. The packet records the premise ledger consumed by the conditional MetaCIC confluence bridge without asserting the missing diamond proof.

Definition 2325.1 (Closed parallel diamond premise ledger carrier)**.** *A* ClosedParallelDiamondPremiseLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, S, D, C, N, R, A, H, K, Q, G)$$

with the following displayed rows:

1. *P is the closed parallel-step source row for the two displayed* BetaParallel *branches.*
2. *S is the residual-substitution premise row, read through* MetaCICResidualSubstitutionBoundary$^{\uparrow}$*, that keeps substitution compatibility visible as an input.*
3. *D is the closed parallel diamond premise row naming* BetaParallelDiamondClosed *as a ledger entry rather than as a theorem proved by this packet.*
4. *C is the conditional closed-star confluence handoff row consumed by the MetaCIC confluence bridge after S and D are present.*
5. *N is the closed-normal seal row read through* ClosedNormalConfluenceSeal$^{\uparrow}$ *for the unconditional normal-source fragment.*
6. *R is the confluence audit packet row read through* MetaCICConfluenceAuditPacket$^{\uparrow}$ *as the larger consumer of the conditional boundary.*
7. *A is the parallel confluence audit row read through* ParallelConfluenceAudit$^{\uparrow}$ *to keep the parallel-step, substitution, diamond, and star-confluence handoffs in one audit map.*
8. *H records componentwise* hsame *transport for the premise, sibling, audit, handoff, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay*

$$P, S, D \longmapsto C \longmapsto R, A, N$$

for consumers of the conditional confluence bridge.

10. *Q is the* Pkg *provenance over* ClosedParallelDiamondPremiseLedger$^{\uparrow}$, MetaCICConfluenceAuditPacket$^{\uparrow}$, ClosedNormalConfluenceSeal$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, ParallelConfluenceAudit$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *G is the local* NameCert$_{\text{ClosedParallelDiamondPremiseLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, S, D, C, N, R, A, H, K, Q, G$. It has no coordinate proving BetaParallelDiamondClosed*, no proof of* BetaParallelSubstitutionCompatibility*, no arbitrary closed Church–Rosser theorem, no host residual semantics, and no unchecked bridge discharge.*

Lean4 (definition) `BEDC.Derived.ClosedParallelDiamondPremiseLedgerUp.ClosedParallelDiamondPremiseLedgerUp`

Theorem 2325.2 (Closed parallel diamond premise ledger obligations)**.** *For every accepted* ClosedParallelDiamondP *carrier $L = (P, S, D, C, N, R, A, H, K, Q, G)$, the local* NameCert$_{\text{ClosedParallelDiamondPremiseLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet, closed parallel-step source exposure through P, residual-substitution premise visibility through S, closed parallel diamond premise visibility through D, conditional closed-star handoff visibility through C, closed-normal fragment separation through N, confluence audit consumption through R, parallel audit consumption through A, componentwise* hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through Q, local naming through G, and non-escape from premise-free closed confluence.*

Proof. Project the carrier of Definition 2325.1. The rows $P, S, D, C, N, R, A, H, K, Q, G$ are the whole ledger, so every local obligation is read from a displayed row.

The premise boundary is S, D. Row S keeps residual substitution compatibility visible, and row D names the closed parallel diamond premise as a ledger entry rather than as a discharged theorem.

The consumer-facing bridge row is C. It may be read only after the premise rows are present, and the audit rows R and A record that this conditional handoff is consumed by the confluence audit map and the parallel audit map.

The closed-normal row N remains a sibling fragment rather than a replacement for the premise ledger. The structural rows H, K, Q, G transport, replay, source, and name the same finite packet, so no hidden proof of the diamond, substitution compatibility, or arbitrary closed Church–Rosser can enter the certificate. □

Theorem 2325.3 (Closed parallel diamond premise conditional boundary)**.** *Every conditional closed-star confluence read through an accepted* ClosedParallelDiamondPremiseLedger$^{\uparrow}$ *carrier $L = (P, S, D, C, N, R, A, H, K, Q, G)$ must expose both the residual-substitution premise row S and the closed parallel diamond premise row D. The packet may be cited only as the finite route*

$$P, S, D, C, N, R, A, H, K, Q, G$$

for a conditional handoff; it is not an unconditional diamond proof, an unconditional confluence proof, or a premise-free closed Church–Rosser certificate.

Proof. Project the carrier of Definition 2325.1. The rows $P, S, D, C, N, R, A, H, K, Q, G$ are displayed explicitly, and the conditional handoff row C is downstream of the premise rows S and D.

Apply the obligation theorem Definition 2325.2. It states that residual-substitution premise visibility and closed parallel diamond premise visibility are part of the exact local NameCert surface, alongside the closed parallel-step source, sibling audit rows, transport, replay, provenance, and local naming.

Therefore a consumer reading closed-star confluence through this packet must carry S and D as premises. Since the carrier has no row proving either premise and no row for arbitrary closed confluence, the packet cannot be cited as an unconditional diamond or confluence proof. □

Theorem 2325.4 (Closed parallel diamond premise vision handoff)**.** *Every confluence-vision consumer of* $\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}$ *must read the closed parallel-step source row P, residual-substitution premise row S, closed parallel diamond premise row D, conditional closed-star handoff row C, closed-normal fragment row N, confluence audit row R, and parallel audit row A before any closed-star confluence claim is available. The packet therefore refuses premise-free closed confluence: it exposes the vision handoff only as the displayed route*

$$P, S, D \longmapsto C \longmapsto N, R, A.$$

Proof. Use the carrier definition Definition 2325.1. Its rows P, S, D, C, N, R, A are displayed separately, so a vision consumer cannot collapse the source, premise, conditional handoff, closed-normal fragment, and audit consumers into a single unnamed confluence fact.

Apply Definition 2325.2. The local NameCert surface includes closed parallel-step source exposure, residual-substitution premise visibility, closed parallel diamond premise visibility, conditional handoff visibility, closed-normal fragment separation, confluence audit consumption, and parallel audit consumption.

Thus the confluence-vision marker is read through the same finite ledger as the concrete chapter. Since the carrier has no row proving BetaParallelDiamondClosed, no row proving residual-substitution compatibility, and no row for arbitrary closed Church–Rosser, the handoff cannot be used as premise-free closed confluence. □

Falsifiable prediction: A conditional MetaCIC confluence bridge that consumes ClosedParallelDiamondPremiseLed must display closed parallel-step source rows, residual-substitution premise rows, the closed parallel diamond premise row, closed-star handoff rows, closed-normal seal rows, confluence audit rows, parallel audit rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metacicconfluenceauditpacket, closednormalconfluenceseal, metacicresidualsubstitutionboundary, parallelconfluenceaudit: $\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the closed parallel-step source, the residual-substitution premise row, the closed parallel diamond premise row, the conditional closed-star handoff, sibling audit consumers, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2325.1 and Definition 2325.2 seed the finite closed parallel diamond premise ledger consumed by the conditional MetaCIC confluence bridge.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.ClosedParallelDiamondPremiseLedgerUp.ClosedParallelDiamondPremiseLedgerUp`

Bridge status: none

Not claimed: This chapter does not prove BetaParallelDiamondClosed, BetaParallelSubstitutionCompatibility, arbitrary closed Church–Rosser, host residual semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed parallel-step exposure, residual-substitution premise visibility, closed parallel diamond premise visibility, conditional handoff exactness, sibling audit separation, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.ClosedParallelDiamondPremiseLedgerUp.

Constructive story: A ClosedParallelDiamondPremiseLedger$^{\uparrow}$ packet is generated from closed parallel-step source rows, residual-substitution premise rows, a closed parallel diamond premise row, a conditional closed-star confluence handoff, closed-normal seal rows, confluence audit rows, parallel audit rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2326

A Concrete Naming Certificate for $\mathsf{UniformConvergenceSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformConvergenceSpace}^{\uparrow}$ packet records uniform convergence over displayed real-valued function packets by finite domain rows, function-family windows, uniform tail ledgers, regular rational readbacks, and terminal real seals. It consumes the uniform-limit route of chapter 463, the graph surface of chapter 130, the terminal real-name seal of chapter 38, the regular rational handoff of chapter 301, the finite window discipline of chapter 126, and the completion boundary of chapter 1506. The packet names the convergence-space interface itself, not a quotient function space, an ambient supremum norm, a host-selected limit function, or an external completeness principle.

Definition 2326.1 (Uniform convergence space carrier)**.** *A* $\mathsf{UniformConvergenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(D, F, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the displayed domain row, exposing only the finite observation coordinates and equality tests consumed by the function packets.*
2. *F is the displayed real-valued function family row, read through* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{ContinuousMap}^{\uparrow}$ *graph data over the same domain row.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule that binds each finite domain observation to the function-family window inspected for a requested tolerance.*
4. *T is the uniform tail ledger, assigning each requested tolerance to a single family-wide threshold and recording the accepted window comparisons beyond that threshold.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same domain observations, function windows, and uniform tail ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row reached only after the regular rational readback has displayed the scheduled tail comparisons.*
7. *H records componentwise* hsame *transports for the domain row, function family, window schedule, uniform tail ledger, readback, endpoint seal, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *routes from any convergence-space consumer request through D, F, W, T, R, E in that order.*

9. *P is the* Pkg *provenance over* $\mathsf{UniformConvergenceSpace}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, MetricCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformConvergenceSpace}^{\uparrow}}$ *row.*

The classifier admits only finite packets with these ten rows. No coordinate stores a quotient function space, ambient supremum metric, selected limit function, pointwise-only convergence witness, choice principle, or external completeness theorem.

Lean4 ✓ `BEDC.Derived.UniformConvergenceSpaceUp.UniformConvergenceSpaceTasteGate single carrier alignment`

Theorem 2326.2 (Uniform convergence space NameCert obligations)**.** *For every accepted* UniformConvergenceSpac *carrier $(D, F, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformConvergenceSpace}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed domain row, function-family row,* $\mathsf{StreamName}^{\uparrow}$ *window schedule, uniform tail ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *endpoint seal, transports, continuations, provenance, and local naming;*

2. *uniform-window classifier stability, requiring transported and replayed consumers to inspect the same domain observations, function-family windows, and scheduled tolerance rows before a convergence-space read is exposed;*

3. *tail-modulus exactness, requiring every endpoint-facing read to use the single family-wide threshold recorded in T rather than a pointwise threshold or an ambient supremum argument;*

4. *endpoint-seal handoff, requiring the route from D, F, W, T through R and then E before any* $\mathsf{Real}^{\uparrow}$ *endpoint row is consumed;*

5. *ledger non-escape, excluding quotient function spaces, ambient supremum metrics, selected limit functions, pointwise-only convergence witnesses, choice, and external completeness.*

Proof. Project the carrier of Definition 2326.1. The domain row, function-family row, window schedule, uniform tail ledger, readback, endpoint seal, transport, continuation, provenance, and local naming are exactly the displayed packet coordinates.

Uniform-window classifier stability is componentwise. The row H transports the domain observations, function windows, and tail ledger without changing which finite windows are named, while C replays the same route from the consumer request through D, F, W, T, R, E.

Tail-modulus exactness follows from the role of T. A requested tolerance is assigned one family-wide threshold before the readback row R can be consumed, so a pointwise threshold or an ambient supremum argument has no carrier coordinate.

The endpoint-seal handoff is forced by the packet order. The regular rational readback R is the only row between the uniform tail ledger and the endpoint seal E, and the $\mathsf{Real}^{\uparrow}$ endpoint is exposed only after that readback has displayed the scheduled comparisons.

The refusal clause is an inventory check on the carrier. Since none of the ten coordinates is a quotient function space, ambient supremum metric, selected limit function, pointwise-only convergence witness, choice row, or external completeness theorem, the local certificate exports none of those principles. □

Falsifiable prediction: An accepted $\mathsf{UniformConvergenceSpace}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ endpoint seal, $\mathsf{UniformLimit}^{\uparrow}$ handoff, or $\mathsf{MetricCompletion}^{\uparrow}$ boundary without first reading the domain row, function-family row, $\mathsf{StreamName}^{\uparrow}$ window schedule, and uniform tail ledger refutes the carrier surface.

Independence witness: uniformlimit, continuousmap, real, regseqrat, streamname, metriccompletion: none is bijective to $\mathsf{UniformConvergenceSpace}^{\uparrow}$ because this packet jointly carries a domain row, displayed real-valued function-family row, StreamName window schedule, uniform tail ledger, regular readback, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergenceSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergenceSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2326.1 and Definition 2326.2 seed the finite uniform convergence space certificate over displayed domain rows, real-valued function-family windows, uniform tail ledgers, regular rational readbacks, endpoint seals, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergenceSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient function spaces, ambient supremum metrics, selected limit functions, pointwise-only convergence witnesses, choice, external completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-window classifier stability, tail-modulus exactness, endpoint-seal handoff, and ledger non-escape for BEDC.Derived.UniformConvergenceSpaceUp.

Constructive story: A $\mathsf{UniformConvergenceSpace}^{\uparrow}$ packet is generated from a displayed domain row, displayed real-valued function-family row, StreamNameUp window schedule, uniform tail ledger, RegSeqRatUp readback, RealUp endpoint seal, componentwise hsame transport, Cont replay, provenance, and local naming.

Chapter 2327

A Concrete Naming Certificate for $\mathsf{LocatedRealIntervalHull}^{\uparrow}$

Following Moore interval analysis and Bishop-style located real data, the $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ packet names the finite hull read that encloses a displayed family of $\mathsf{Real}^{\uparrow}$ names by located lower and upper endpoint rows. It sits after the terminal real-name seal of chapter 38, the regular rational source of chapter 301, the finite observation window of chapter 126, the dyadic tolerance ledger of chapter 291, the endpoint-ledger interface of chapter 394, and the rational readback surface of chapter 1668. The packet records a finite enclosure hull for Real and Completion consumers; it does not choose representatives, quotient real equality, an ambient least interval, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2327.1 (Located real interval hull carrier)**.** *A* $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (R, S, Q, D, A, J, L, U, E, T, C, P, N)$$

with the following displayed rows:

1. *R is the finite family of* $\mathsf{Real}^{\uparrow}$ *names whose common enclosure is being read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the displayed real names.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the readbacks at the requested precision.*
5. *A is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *row recording the rational approximants read from Q under the tolerance ledger D.*
6. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row whose displayed lower and upper bounds form the candidate hull.*
7. *L and U are the lower and upper endpoint ledger rows read through J.*
8. *E is the enclosure ledger saying that every inspected approximation in A lies between L and U with the displayed dyadic tolerance.*
9. *T records componentwise* hsame *transport for the real-name family, stream windows, regular readbacks, dyadic tolerance, rational approximants, located interval row, endpoint rows, enclosure ledger, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a finite hull request through $R, S, Q, D, A, J, L, U, E, T, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedRealIntervalHull}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalHull}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed rows. It has no coordinate for a host least interval, selected real representatives, quotient equality of real names, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedRealIntervalHullUp.TasteGate.LocatedRealIntervalHullTasteGate single carrier alignment`

Theorem 2327.2 (Located real interval hull NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ *carrier* $H = (R, S, Q, D, A, J, L, U, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalHull}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real-name family, stream windows, regular readbacks, dyadic tolerance, rational approximants, located interval, endpoint ledgers, enclosure ledger, transport, replay, provenance, and local naming rows;*
2. *source compatibility, requiring S, Q, D, A to be read from the same finite family of* $\mathsf{Real}^{\uparrow}$ *names named by R;*
3. *endpoint admission, requiring J, L, U to be displayed located-interval rows rather than host-selected endpoints;*
4. *hull enclosure exactness, requiring E to bind every inspected rational approximation in A between L and U under the tolerance ledger D;*
5. *replay stability, requiring T and C to preserve the same hull route under componentwise transport and later finite-window reads;*
6. *ledger refusal, excluding host least intervals, selected representatives, quotient real equality, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedRealIntervalHullUp.LocatedRealIntervalHullNamecertObligations`
Lean4 ✓ `BEDC.Derived.LocatedRealIntervalHullUp.LocatedRealIntervalHullCarrier namecert obligations`

Proof. Project the carrier of Definition 2327.1. The projection exposes the real-name family, finite stream windows, regular rational readbacks, dyadic tolerance ledger, rational approximation row, located interval endpoint row, enclosure ledger, and the structural rows T, C, P, N.

Source compatibility follows from the displayed route through chapter 126, chapter 301, chapter 291, and chapter 1668. The rows S, Q, D, A are all attached to the same family R, so a consumer cannot insert a second real-name source.

Endpoint admission is the row J together with L and U. These rows are the visible located interval endpoints supplied by chapter 394, not host-selected real representatives.

The hull enclosure clause is the ledger E. It compares only the displayed rational approximation rows against the displayed endpoint rows at the dyadic tolerance named by D.

Finally T, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for a host least interval, selected representatives, quotient real equality, trichotomy, countable choice, or ambient completeness, the local NameCert surface cannot export any of those objects. □

Theorem 2327.3 (Located real interval hull finite endpoint readback)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ *carrier factors through the finite endpoint route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RealRationalApproximation}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow}.$$

The consumer receives the displayed lower and upper endpoint rows L, U *only together with the finite windows, readbacks, tolerance ledger, rational approximation row, enclosure ledger, transport, replay, provenance, and local naming data. It receives no quotient real equality, no selected representative family, no host least hull, and no completeness witness.*

Proof. Start with an accepted carrier $H = (R, S, Q, D, A, J, L, U, E, T, C, P, N)$. The only source of Real-facing data is the displayed family R, and the only observations opened from it are the finite windows S.

The readback stage is Q, D, A. Regular rational rows are read through the windows, the dyadic ledger fixes the tolerance budget, and the rational approximation row records the inspected approximants.

The endpoint stage is J, L, U, E. The located interval row supplies the lower and upper endpoint ledgers, and the enclosure ledger binds the approximants to those endpoints at the displayed tolerance.

The structural rows then preserve the route. Componentwise transport, continuation replay, provenance, and the local NameCert row do not add another endpoint source, so every consumer receives exactly the finite endpoint readback surface and none of the excluded quotient, selection, host-hull, or completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalHull}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalHull}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2327.1, Definition 2327.2, and Definition 2327.3 seed the finite located interval hull route over displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, and $\mathsf{LocatedInterval}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalHull}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, host least intervals, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, endpoint admission, hull enclosure exactness, replay stability, and ledger refusal for BEDC.Derived.LocatedRealIntervalHullUp.

Constructive story: A $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ packet is generated from displayed RealUp names, StreamNameUp windows, RegSeqRatUp readbacks, a DyadicRatCoreUp tolerance ledger, a RealRationalApproximationUp approximation row, a LocatedIntervalUp endpoint row, lower and upper endpoint ledgers, an enclosure ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2328

A Concrete Naming Certificate for $\mathsf{LipschitzConstant}^{\uparrow}$

Following Bishop and Bridges and standard metric-space analysis, a Lipschitz constant is useful in constructive arguments only when the constant, the source and target metrics, and the finite tolerance conversion route are displayed together. The $\mathsf{LipschitzConstant}^{\uparrow}$ packet names that surface as a finite L10 object. It refines the bound ledger already consumed by chapter 410, reads metric rows from chapter 57, reads the displayed scalar through chapter 38, and hands the resulting modulus to chapter 369. Its downstream consumers include $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ surfaces; it is not a host real inequality, a quotient of maps, a differentiability claim, or an ambient completeness theorem.

Definition 2328.1 (Lipschitz constant carrier)**.** *A* $\mathsf{LipschitzConstant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(K, X, Y, D, F, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the displayed* $\mathsf{Real}^{\uparrow}$ *constant row, read as a nonnegative finite bound rather than as an ambient host scalar.*
2. *X is the source* $\mathsf{Met}^{\uparrow}$ *row and Y is the target* $\mathsf{Met}^{\uparrow}$ *row.*
3. *D records the dyadic distance-comparison ledger: every source-distance tolerance request and every target-distance bound check is routed through displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparisons.*
4. *F is the source* $\mathsf{LipschitzMap}^{\uparrow}$ *row whose graph and bound use the same K, X, Y, D data.*
5. *M is the finite modulus handoff row into* $\mathsf{UniformModulus}^{\uparrow}$ *and* $\mathsf{UniformContinuity}^{\uparrow}$*, sending a requested target tolerance to a displayed source tolerance through K and D.*
6. *H records componentwise* hsame *transport for the constant, metric rows, dyadic comparisons, source map, modulus handoff, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from any continuity, completion, or map consumer through K, X, Y, D, F, M in that order.*
8. *P is the* Pkg *provenance over* $\mathsf{LipschitzConstant}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LipschitzMap}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzConstant}^\uparrow}$ *row.*

The classifier accepts only packets with these ten rows. It has no coordinate for a detached host real bound, pointwise-only continuity, quotient map equality, differentiability, selected limits, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LipschitzConstantUp.LipschitzConstantTasteGate single carrier alignment`

Theorem 2328.2 (Lipschitz constant modulus handoff)**.** *For every accepted* $\mathsf{LipschitzConstant}^\uparrow$ *carrier* $(K, X, Y, D, F, M, H, C, P, N)$*, every* $\mathsf{UniformContinuity}^\uparrow$ *or* $\mathsf{UniformModulus}^\uparrow$ *consumer that reads the constant must first read the displayed* $\mathsf{Real}^\uparrow$ *row* K*, the source and target* $\mathsf{Met}^\uparrow$ *rows* X, Y*, the dyadic comparison ledger* D*, and the source* $\mathsf{LipschitzMap}^\uparrow$ *row* F*. The exported modulus row* M *is therefore a finite handoff from Lipschitz control to uniform continuity, not an independent continuity principle.*

Proof. Project the carrier of Definition 2328.1. The only constant row is K, and the only metric rows are X and Y, so any consumer that mentions the bound must read those displayed rows.

The dyadic comparison ledger D supplies the tolerance arithmetic. It records how a target tolerance request is converted into a source-distance request under the displayed bound, so the request cannot bypass the finite $\mathsf{DyadicRatCore}^\uparrow$ comparisons.

The source map row F attaches that arithmetic to a $\mathsf{LipschitzMap}^\uparrow$ packet. The modulus row M is consumed only after K, X, Y, D, F have been displayed, and H and C preserve the same route under transport and replay.

Thus the uniform-continuity read is exactly the finite handoff named by M. No carrier coordinate supplies pointwise-only continuity, detached host estimates, quotient function equality, differentiability, selected limits, choice, or ambient completeness. □

Theorem 2328.3 (Lipschitz constant NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{LipschitzConstant}^\uparrow}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the displayed constant, source metric, target metric, dyadic comparison, source map, modulus, transport, continuation, provenance, and local naming rows;*
2. *nonnegative-bound exposure, requiring* K *to be read as the displayed* $\mathsf{Real}^\uparrow$ *constant before any target-distance estimate is consumed;*
3. *dyadic comparison exactness, requiring all tolerance conversions to pass through* D*;*
4. *modulus handoff, requiring the* $\mathsf{UniformContinuity}^\uparrow$ *and* $\mathsf{UniformModulus}^\uparrow$ *reads to pass through* K, X, Y, D, F, M*;*
5. *ledger non-escape, excluding detached host constants, quotient map equality, differentiability, selected limits, countable choice, and ambient metric or real completeness.*

Proof. Carrier admission is immediate from Definition 2328.1; the packet exposes exactly the ten listed rows.

The bound-exposure and dyadic-exactness obligations follow from the positions of K and D. A distance estimate has no row to inspect except the displayed real constant and the dyadic comparison ledger attached to it.

The handoff obligation is Definition 2328.2. It routes every uniform-continuity or uniform-modulus consumer through the same finite rows before M is exported.

The refusal clause is an inventory check on the carrier. Since none of the displayed rows is a host constant, a quotient map, differentiability data, selected-limit data, choice data, or completeness evidence, the local NameCert exports none of those principles. □

Theorem 2328.4 (Lipschitz constant uniform continuity route)**.** *Let* $(K, X, Y, D, F, M, H, C, P, N)$ *be an accepted* $\mathsf{LipschitzConstant}^{\uparrow}$ *carrier. Every* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer that uses the displayed Lipschitz constant factors through*

$\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, BHist, hsame, Cont, Pkg, Na

In particular, the constant cannot be consumed as a parameter echo detached from the finite modulus route.

Proof. Start with the accepted carrier and apply Definition 2328.3. Any consumer sees only the displayed constant, metric rows, dyadic comparisons, source map, modulus handoff, transport, replay, provenance, and naming rows.

For $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{UniformContinuity}^{\uparrow}$ consumers, Definition 2328.2 forces the read through K, X, Y, D, F, M before continuity information is exposed.

For $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ consumers, the same route is followed by the downstream regular-readback or completion-facing surface. The constant is still tied to the source map and dyadic tolerance ledger before any real or completion seal can be inspected.

Therefore the displayed route is the only available consumer path. The packet offers no detached parameter copy, host real inequality, quotient map equality, selected limit, countable-choice schedule, differentiability row, or ambient completeness evidence. □

Definition 2328.5 (Mean-value inequality carrier)**.** *A mean-value inequality carrier over a* $\mathsf{LipschitzConstant}^{\uparrow}$ *packet is a finite* BHist *packet*

$$V = (X, Y, G, L, D, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row and Y is the target* $\mathsf{Met}^{\uparrow}$ *row.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row whose source and target reads use X and Y.*
3. *L is an accepted* $\mathsf{LipschitzConstant}^{\uparrow}$ *row binding the same source metric, target metric, graph, and displayed constant.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for source-distance reads, target-distance reads, and multiplication by the displayed Lipschitz ledger.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *distance seal reached only after X, Y, G, L, D have all been displayed.*
6. *H records componentwise* hsame *transport for the two metric rows, continuous graph, Lipschitz row, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a source-distance request through the Lipschitz handoff to the target-distance bound.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LipschitzConstant}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}$ *row for this consequence packet.*

The classifier accepts only packets whose source and target metric rows, continuous graph row, Lipschitz constant row, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming rows are displayed together. It has no coordinate for a differentiability theorem, tangent vector, selected maximum point, quotient map equality, countable choice, or ambient Real completeness.

Theorem 2328.6 (Mean-value inequality Lipschitz handoff)**.** *For every accepted mean-value inequality carrier $V = (X, Y, G, L, D, R, H, C, P, N)$, every target-distance read through Y is bounded by the displayed Lipschitz ledger in L multiplied by the corresponding source-distance read through X. The comparison is consumed through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D and sealed only by the displayed* $\mathsf{Real}^{\uparrow}$ *row R; it is not a differentiability claim or an ambient host inequality.*

Proof. Project the carrier of Definition 2328.5. The only available source-distance and target-distance rows are X and Y, and the only graph row connecting them is the displayed $\mathsf{ContinuousMap}^{\uparrow}$ row G.

Apply Definition 2328.4 to the $\mathsf{LipschitzConstant}^{\uparrow}$ row L. That route forces the consumer through the displayed constant, the same metric rows, the source map binding, and the finite modulus handoff before any continuity information is read.

The dyadic ledger D supplies the arithmetic comparison: the target-distance read is checked against the displayed Lipschitz ledger times the source-distance read. The Real seal R records only that routed comparison, while H, C, P, N transport, replay, source, and name the same packet. Since no row supplies derivatives, selected extrema, quotient equality, choice, or ambient completeness, the consequence is exactly the Lipschitz handoff. □

Falsifiable prediction: An accepted $\mathsf{LipschitzConstant}^{\uparrow}$ consumer that reaches $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegularCauchyLipschitzMap}^{\uparrow}$, or $\mathsf{MetricCompletion}^{\uparrow}$ without first reading K, X, Y, D, F, M refutes the carrier surface.

Independence witness: lipschitzmap, metric, real, uniformmodulus, uniformcontinuity: none is bijective to $\mathsf{LipschitzConstant}^{\uparrow}$ because this packet jointly carries the displayed constant, the two metric rows, dyadic tolerance comparisons, source map binding, modulus handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzConstant}^{\uparrow}}$.

Origin: human

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzConstant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2328.1, Definition 2328.2, Definition 2328.3, and Definition 2328.4 seed the finite Lipschitz-constant certificate over displayed Real, Metric, dyadic comparison, LipschitzMap, modulus, uniform-continuity, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzConstant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim detached host constants, quotient map equality, differentiability, selected limits, countable choice, ambient metric completeness, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nonnegative-bound exposure, dyadic comparison exactness, modulus handoff, and ledger non-escape for BEDC.Derived.LipschitzConstantUp.

Constructive story: A $\mathsf{LipschitzConstant}^{\uparrow}$ packet is generated from one displayed RealUp constant row, source and target MetricUp rows, a DyadicRatCore comparison ledger, a LipschitzMap source row, a UniformModulus and UniformContinuity handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Chapter 2329

A Concrete Naming Certificate for $\mathsf{PoincareInequality}^{\uparrow}$

Following Poincare and Bishop–Bridges, the $\mathsf{PoincareInequality}^{\uparrow}$ packet names the finite carrier surface by which a bounded-domain or zero-mean Sobolev read yields a norm-control estimate. It is a downstream consumer of the weak-derivative route in chapter 440, the metric and real readback surfaces of chapter 57 and chapter 38, and the normed target ledger used by functional-analysis chapters.

Definition 2329.1 (Poincare inequality carrier)**.** *A* $\mathsf{PoincareInequality}^{\uparrow}$ *carrier is a finite packet*

$$Q = (D, B, G, N, K, H, C, P, L)$$

with the following displayed rows.

1. *D is the domain row, read through* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, recording the bounded or otherwise admissible observation surface on which the inequality is asserted.*
2. *B is the boundary or zero-mean condition row. It records the displayed trace, anchored-boundary, or mean-zero constraint that prevents constant functions from escaping the estimate.*
3. *G is the gradient or derivative-energy row supplied by* $\mathsf{Sobolev}^{\uparrow}$*, exposing the weak-gradient magnitude before any norm estimate is consumed.*
4. *N is the norm row, read through* $\mathsf{Norm}^{\uparrow}$ *and the scalar* $\mathsf{Real}^{\uparrow}$ *seal, naming the measured size controlled by the gradient route.*
5. *K is the constant ledger. It records a finite Poincare constant, its dependency on the displayed domain and boundary rows, and the fact that no hidden compactness theorem or selected minimizer is imported.*
6. *H is componentwise* hsame *transport for D, B, G, N, K.*
7. *C is the displayed* Cont *replay that sends a Sobolev admissibility read through the boundary row, derivative-energy row, norm row, and constant ledger.*
8. *P is the* Pkg *provenance over* $\mathsf{PoincareInequality}^{\uparrow}$*,* $\mathsf{Sobolev}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, completion-facing rows,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{PoincareInequality}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.PoincareInequalityUp.PoincareInequalityTasteGate single carrier alignment`

Theorem 2329.2 (Poincare inequality NameCert obligations)**.** *For an accepted carrier* $Q = (D, B, G, N, K, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{PoincareInequality}^{\uparrow}}$ *surface consists of five obligations.*

1. *Carrier admission displays the domain, boundary or zero-mean condition, Sobolev derivative-energy row, norm row, constant ledger, transports, replay, provenance, and local naming row.*
2. *Sobolev dependency requires every derivative-energy read to factor through the* $\mathsf{Sobolev}^{\uparrow}$ *weak-derivative packet of chapter 440.*
3. *Norm and scalar readback require the measured side of the estimate to pass through* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before any completion-facing consumer can read the bound.*
4. *Constant-ledger exactness requires the Poincare constant to depend only on the displayed domain and boundary rows, not on a host compactness theorem, selected representative, quotient of functions, or hidden minimizer.*
5. *Transport and replay preserve the same finite route under componentwise* hsame *and displayed* Cont *paths, including the completion-facing rows used by downstream metric or normed-space consumers.*

Thus the packet exports a finite NameCert route for the inequality estimate, not a full Sobolev embedding theorem, compactness principle, quotient function space, or host analytic proof.

Proof. Project the carrier coordinates. The rows D, B, G, N, K expose exactly the domain, boundary or zero-mean condition, derivative-energy source, norm target, and constant ledger needed for the estimate.

The Sobolev dependency is read through G. Since G is a displayed $\mathsf{Sobolev}^{\uparrow}$ row, any weak-derivative or gradient-energy consumer must pass through the sibling certificate before the norm row is inspected.

The norm and scalar readback are then forced through N and the $\mathsf{Real}^{\uparrow}$ seal. The constant ledger K records only the visible dependency on D and B, so a hidden minimizer, compactness theorem, quotient representative, or selected function cannot enter the route.

Finally H, C, P, L repack the same finite path under transport, continuation replay, provenance, and local naming. The completion-facing rows stay downstream of the displayed domain, Sobolev, norm, and scalar evidence. □

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareInequality}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2329.1 and Definition 2329.2 seed the finite Poincare inequality route over $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, completion-facing rows, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareInequality}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.PoincareInequalityUp`

Bridge status: none

Not claimed: This chapter does not close compact Sobolev embedding, trace theory, quotient equality of functions, selected minimizers, host compactness, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, Sobolev dependency, norm and scalar readback, constant-ledger exactness, componentwise transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{PoincareInequality}^{\uparrow}$ packet is generated from a displayed domain row, boundary or zero-mean row, Sobolev derivative-energy row, norm row, finite constant ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2330

A Concrete Naming Certificate for $\mathsf{TypedExampleReductionTrace}^{\uparrow}$

The $\mathsf{TypedExampleReductionTrace}^{\uparrow}$ packet realizes the MetaCIC typed-example gallery as a finite NameCert carrier. It reads the audit map of chapter 9382 as a concrete route connecting a displayed typed term, its type, a selected reduction step, the checker result, closedness evidence, transport, replay, provenance, and local naming. The packet consumes the bounded MetaCIC critical-path and confluence-boundary surfaces through chapter 765 and chapter 2274 before the checker result row is read.

Before the checker and reduction rows are public, the packet also consumes the closed context seal of chapter 722. That seal supplies the finite context row read by Z, so the displayed type A, reduction step R, and checker result K are not interpreted over an open or implicit environment. The subject-reduction frontier is then reached through chapter 718 or chapter 716: those packets provide the boundary rows saying which beta-substitution and subject-reduction obligations must be visible before the typed-example trace may treat R and K as a coherent public row.

Definition 2330.1 (TypedExampleReductionTrace carrier)**.** *A* $\mathsf{TypedExampleReductionTrace}^{\uparrow}$ *carrier is a finite packet*

$$T = (E, A, R, K, Z, H, C, P, L)$$

with the following displayed rows.

1. *E is the MetaCIC typed-example term row, naming one Church, identity, application, beta-redex, projection, Pi, constant, or sort-context example from the gallery.*
2. *A is the displayed type row accepted for E by the represented typing relation.*
3. *R is the reduction-step row, recording the selected beta or computation step when the gallery example has one.*
4. *K is the checker-result row, linking the displayed term and type to the option-valued checker or inference result used by the decidability gallery.*
5. *Z is the closedness row, exposing the finite context seal needed before the reduction or checker result is read.*
6. *H is componentwise* hsame *transport for E, A, R, K, Z.*
7. *C is the displayed* Cont *replay from typed-example admission through reduction, checker acceptance, closedness, and downstream audit use.*

8. *P is the* Pkg *provenance over* $\mathsf{TypedExampleReductionTrace}^{\uparrow}$*, the MetaCIC typed-example gallery, checker rows, reduction rows, closedness rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. *L is the local* $\mathsf{NameCert}_{\mathsf{TypedExampleReductionTrace}^{\uparrow}}$ *row.*

Theorem 2330.2 (TypedExampleReductionTrace NameCert obligations)**.** *For an accepted carrier $T = (E, A, R, K, Z, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{TypedExampleReductionTrace}^{\uparrow}}$ *surface consists of carrier admission, typed-term and type visibility, reduction-step visibility, checker-result agreement, closedness exposure, componentwise transport, continuation replay, provenance, and local naming. Every read factors through the finite route*

$$E \to A \to R \to K \to Z \to H, C, P, L.$$

The packet does not claim subject reduction, strong normalization, confluence, global conversion decidability, or an arbitrary closed-term theorem.

Proof. Carrier admission projects the rows of Definition 2330.1. The term row E and type row A expose the gallery example before any computation or checker result is consumed.

The reduction row R and checker row K are then read as displayed MetaCIC evidence. They record a selected worked-example computation and its checker-facing result; they do not range over all terms or all reductions.

Closedness is exposed by Z before transport and replay. This keeps the route tied to the finite context seal required by the gallery and prevents the carrier from asserting an unbounded subject-reduction principle.

Finally H, C, P, L preserve the same row-local route under hsame transport, continuation replay, provenance, and local naming. The public read remains a finite typed-example trace rather than a global metatheorem. □

Falsifiable prediction: Every accepted $\mathsf{TypedExampleReductionTrace}^{\uparrow}$ read factors through a displayed MetaCIC typed-example term, type, reduction, checker-result, closedness, hsame, Cont, Pkg, and NameCert route.

Independence witness: metacic-subject-reduction-obstruction, betasubstitutionpreservation, subjectreductiondischarge, closedtermcontextseal: none is bijective with $\mathsf{TypedExampleReductionTrace}^{\uparrow}$ because the packet jointly carries a typed-example term, type row, reduction row, checker-result row, closedness row, transport, replay, provenance, and local naming.

The Lean TasteGate work for this packet must provide explicit Nontrivial and FieldFaithful instances for $\mathsf{TypedExampleReductionTrace}^{\uparrow}$ preserving $E, A, R, K, Z, H, C, P, L$.

Closure status for $\mathsf{NameCert}_{\mathsf{TypedExampleReductionTrace}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TypedExampleReductionTrace}^{\uparrow}}$, seed)

Scope closed: Definition 2330.1 and Definition 2330.2 seed the finite typed-example reduction-trace route over MetaCIC typed terms, displayed types, reduction rows, checker results, closedness, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TypedExampleReductionTrace}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.TypedExampleReductionTraceUp`

Bridge status: none

Not claimed: This chapter does not close subject reduction, strong normalization, confluence, global conversion decidability, arbitrary closed-term normalization, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, typed-term visibility, type visibility, reduction-step visibility, checker-result agreement, closedness exposure, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{TypedExampleReductionTrace}^{\uparrow}$ packet is generated from a displayed MetaCIC typed-example term, its type row, a reduction-step row, a checker-result row, a closedness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2331

A Concrete Naming Certificate for $\mathsf{UniformEntourageBasis}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces, a uniformity can be read through a directed family of entourages whose finite refinements control diagonal, symmetry, and composition requests. The $\mathsf{UniformEntourageBasis}^{\uparrow}$ packet records that basis surface as finite BEDC NameCert data. It sits between the ambient uniform-space interface of chapter 339, the separated boundary of chapter 1876, the complete-uniform consumer of chapter 1588, the Cauchy-filter route of chapter 333, and the metric basis model of chapter 57. The packet gives L10 completion consumers an explicit finite entourage-basis carrier rather than an implicit convention about available uniform neighborhoods.

Definition 2331.1 (Uniform entourage basis carrier)**.** *A* $\mathsf{UniformEntourageBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, B, D, R, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-source row, carrying the displayed source histories and point classifier read by the ambient* $\mathsf{UniformSpace}^{\uparrow}$ *packet.*
2. *B is the finite entourage-basis ledger, listing the named basic entourage rows available to completion, Cauchy-filter, separated-uniform, and metric consumers.*
3. *D is the diagonal ledger, recording that each listed basic entourage admits the displayed diagonal point pairs from X.*
4. *R is the pairwise refinement ledger, recording for each two displayed basic entourages a further listed basic entourage refined into both.*
5. *S is the symmetry ledger, recording for each listed basic entourage a displayed basic entourage whose reversed point-pair reads refine the original row.*
6. *Q is the composition ledger, recording for each listed basic entourage a displayed basic entourage whose two-step relational composition refines the original row.*
7. *H records componentwise* hsame *transport for the point source, basis ledger, diagonal rows, pairwise refinement rows, symmetry rows, and composition rows.*
8. *C records displayed* Cont *replay from any completion or Cauchy-filter consumer request through X, B, D, R, S, Q in that order.*

9. *P is the* Pkg *provenance over* $\mathsf{UniformEntourageBasis}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformEntourageBasis}^{\uparrow}}$ *row.*

The carrier exports no quotient completion, host equality of points, selected limit, countable-choice schedule, open-cover compactness principle, ambient $\mathsf{Real}^{\uparrow}$ *completeness row, Lean verification, or bridge certificate.*

Lean4 ✓ `BEDC.Derived.UniformEntourageBasisUp.UniformEntourageBasisTasteGate single carrier alignment`

Theorem 2331.2 (Uniform entourage basis NameCert obligations)**.** *For the carrier of Definition 2331.1, the local* $\mathsf{NameCert}_{\mathsf{UniformEntourageBasis}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (X, B, D, R, S, Q, H, C, P, N)$*, point-source admission through* X*, finite basic-entourage admission through* B*, diagonal admission through* D*, pairwise common-refinement admission through* R*, symmetry admission through* S*, composition admission through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The point-source row and finite basis ledger are displayed before any uniform consumer can ask for a Cauchy, separated, complete, or metric-facing read.

The obligation rows are the uniformity laws restricted to the named basis. The diagonal row D, pairwise refinement row R, symmetry row S, and composition row Q certify exactly the finite requests needed to treat B as an entourage basis.

The structural rows preserve that basis surface. The transport row H moves all six data rows componentwise, the replay row C forces consumers through the same route, the package row P records the sibling dependencies, and the local name N certifies no additional completion or choice coordinate. □

Theorem 2331.3 (Uniform entourage basis refinement stability)**.** *Every accepted* $\mathsf{UniformEntourageBasis}^{\uparrow}$ *packet keeps completion-facing refinement reads inside the finite route*

$$X, B, D, R, S, Q, H, C, P, N.$$

A request for a smaller common entourage is discharged by the pairwise refinement row R*; a request for a reversed entourage is discharged by* S*; and a request for a two-step entourage whose composition remains inside a displayed target entourage is discharged by* Q*. The resulting read is transported by* H*, replayed by* C*, sourced by* P*, and named by* N*, with no quotient completion, host equality, selected limit, countable choice, open-cover compactness, or ambient Real completeness exposed.*

Proof. Start with a completion-facing or Cauchy-filter request. The consumer can inspect only the point source X and the finite basis ledger B before asking for a refinement row.

There are three refinement forms. Pairwise narrowing is the row R, reversed-point stability is the row S, and two-step composition stability is the row Q; the diagonal row D supplies the identity-pair side condition used by all three forms.

Finally apply the structural route. Componentwise hsame transport keeps the selected basis rows attached to the same point source, Cont replay prevents the consumer from skipping the displayed rows, and the Pkg and local NameCert rows name only this finite basis packet. □

Falsifiable prediction: Every L10 completion read that consumes a UniformEntourageBasisUp packet must factor through the displayed point source, finite basis ledger, diagonal rows, pairwise refinement rows, symmetry rows, composition rows, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: uniformspace, separateduniformspace, completeuniformspace, cauchyfilter, metric: UniformEntourageBasisUp is not bijective to any listed sibling because it jointly carries a point-source row, a finite entourage-basis ledger, diagonal rows, pairwise refinement rows, symmetry rows, composition rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEntourageBasis}^{\uparrow}}$ **.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEntourageBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2331.1, Definition 2331.2, and Definition 2331.3 seed the finite entourage-basis carrier over point-source rows, basic entourage ledgers, diagonal rows, pairwise refinement rows, symmetry rows, composition rows, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEntourageBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, host equality, selected limits, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis-law stability, completion-consumer nonescape, and TasteGate field faithfulness for BEDC.Derived.UniformEntourageBasisUp.

Constructive story: A $\mathsf{UniformEntourageBasis}^{\uparrow}$ packet is generated from a point-source row, finite entourage-basis ledger, diagonal rows, pairwise refinement rows, symmetry rows, composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2332

A Concrete Naming Certificate for $\mathsf{UniformCompletionMonad}^{\uparrow}$

Following Bourbaki and Kelley on uniform completion, the $\mathsf{UniformCompletionMonad}^{\uparrow}$ packet records the completion unit and idempotent multiplication route as finite NameCert data over chapter 1473, chapter 426, chapter 2256, **??**, and chapter 1506. It names the monadic completion surface as a ledger of displayed rows; it does not identify quotient completions, select representatives, compare host equality, use choice, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2332.1 (Uniform completion monad carrier)**.** *A* $\mathsf{UniformCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (U, F, T, I, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row naming the separated completion route over the source uniform presentation.*
2. *F is the* $\mathsf{CompletionFunctor}^{\uparrow}$ *row that transports displayed uniformly continuous maps through the same completion route.*
3. *T is the* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *row recording the unit-return triangle for source data entering the completion boundary.*
4. *I is the* $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$ *row recording that a repeated completion read contributes no additional public completion object.*
5. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row serving metric consumers that read the same completion-facing surface.*
6. *R is the finite route ledger that orders the unit leg before the functorial read and the idempotent multiplication leg after the repeated completion read.*
7. *H stores componentwise* hsame *transport for the uniform completion, functor, unit triangle, idempotent, metric completion, route ledger, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay for unit admission, functorial transport, repeated completion, idempotent multiplication, metric readback, and terminal naming.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCompletionMonad}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUnitTriangle}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionMonad}^{\uparrow}}$ *row.*

The carrier exposes the monad only as the displayed unit route and idempotent multiplication route through these rows. It carries no quotient completion object, no selected representative, no host equality of completed uniform spaces, no choice schedule, and no completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformCompletionMonadUp.UniformCompletionMonadTasteGate single carrier alignment`

Theorem 2332.2 (Uniform completion monad NameCert obligations)**.** *For an accepted* $\mathsf{UniformCompletionMonad}^{\uparrow}$ *carrier* $M = (U, F, T, I, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionMonad}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the uniform completion, completion functor, unit triangle, idempotent, metric completion, route ledger, transport, replay, provenance, and local naming rows;*
2. *unit-route visibility, requiring every source-to-completion read to pass through U, F, and T before any metric completion consumer reads it;*
3. *idempotent multiplication visibility, requiring every repeated completion read to pass through I after the repeated functorial read has been displayed;*
4. *classifier stability, requiring transported monad evidence to replay through H and C before it is exported;*
5. *ledger non-escape, requiring P and N to export no quotient completion, selected representative, host equality, choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Carrier admission is projection from Definition 2332.1. The tuple lists exactly the uniform completion, functor, unit triangle, idempotent, metric completion, route ledger, transport, replay, provenance, and local naming rows.

Unit-route visibility is the first completion face of the tuple. A source datum enters through U, is transported through F, and returns through the triangle row T before the metric completion row Q can be read.

Idempotent multiplication visibility is the repeated-completion face. The repeated read is ordered by R and replayed by C so that I is the only multiplication row available to consumers.

Classifier stability is componentwise transport through H followed by the same replay through C. Ledger non-escape is the inventory statement for P and N: neither row contains a quotient completion, selected representative, host equality coordinate, choice schedule, or ambient completeness row. □

Theorem 2332.3 (Uniform completion monad unit route)**.** *Every accepted* $\mathsf{UniformCompletionMonad}^{\uparrow}$ *unit read factors through the displayed route*

$$\mathsf{UniformCompletion}^{\uparrow},\ \mathsf{CompletionFunctor}^{\uparrow},\ \mathsf{CompletionUnitTriangle}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow}.$$

The route is a finite $\mathsf{NameCert}$ *ledger over the carrier rows of Definition 2332.1; it is not a quotient-completion map, a selected representative, a host equality of completed objects, a choice principle, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read the carrier of Definition 2332.1. The only rows available before a metric completion consumer reads a unit datum are U, F, T, Q together with the route, transport, replay, provenance, and naming rows.

Apply the unit-route visibility clause of Definition 2332.2. It orders the source-to-completion read through U, F, and T before exposing Q.

The package and local naming rows contain no further completion object or host equality coordinate. Therefore the exported unit route is exhausted by the displayed finite ledger and cannot supply quotient completions, selected representatives, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2332.4 (Uniform completion monad idempotent multiplication)**.** *Every accepted* UniformCompletionMon *repeated completion read factors through the displayed route*

$$\mathsf{UniformCompletion}^{\uparrow},\ \mathsf{CompletionFunctor}^{\uparrow},\ \mathsf{CauchyCompletionIdempotent}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow}.$$

The multiplication face records idempotence as reuse of the same finite completion ledger, not as equality of host completion objects.

Proof. Read the carrier rows U, F, I, Q, R, C from Definition 2332.1. They are the only rows that can serve a repeated completion consumer.

Apply the idempotent multiplication visibility clause of Definition 2332.2. The route ledger R orders the repeated functorial read, and the replay row C forces the multiplication face through I before Q is exposed.

Since P and N contain no quotient completion or host equality coordinate, idempotence is available only as the finite reuse of the displayed completion ledger. No selected representative, choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem is exported. □

Theorem 2332.5 (Uniform completion monad ledger non-escape)**.** *Every consumer route exported by an accepted* $\mathsf{UniformCompletionMonad}^{\uparrow}$ *carrier is exhausted by the unit route of Definition 2332.3, the idempotent multiplication route of Definition 2332.4, the classifier transport row H, the replay row C, the provenance row P, and the local naming row N. No exported route can obtain quotient completions, selected representatives, host equality, choice,* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking from the packet.*

Proof. The carrier has only the rows displayed in Definition 2332.1. The unit route and the idempotent multiplication route account for the two completion-facing monad reads.

Apply the classifier stability and ledger non-escape clauses of Definition 2332.2. Transported evidence must pass through H and C, while P and N only record provenance and local naming.

Thus every consumer route is already one of the displayed finite routes. The packet contains no row from which quotient completions, selected representatives, host equality, choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionMonad}^{\uparrow}$ packet is generated from a uniform completion row, completion functor row, completion unit triangle row, completion idempotent row, metric completion row, finite route ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionMonad}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2332.1, Definition 2332.2, Definition 2332.3, Definition 2332.4, and Definition 2332.5 seed the finite monadic completion packet over unit, functorial, idempotent, metric, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionMonad}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.UniformCompletionMonadUp`

Bridge status: none

Not claimed: This chapter does not claim quotient completions, selected representatives, host equality, choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-route visibility, idempotent multiplication visibility, classifier stability, and ledger non-escape for BEDC.Derived.UniformCompletionMonadUp.

Chapter 2333

A Concrete Naming Certificate for $\mathsf{DirichletSeriesTest}^{\uparrow}$

Following Dirichlet and Bishop–Bridges constructive analysis, the $\mathsf{DirichletSeriesTest}^{\uparrow}$ packet records the finite cancellation surface for a real series whose partial sums are bounded and whose coefficient stream is monotone null. It consumes the $\mathsf{RealSeries}^{\uparrow}$ root surface of chapter 1581, the uniform Cauchy handoff of chapter 1736, the real sequence limit interface of chapter 1413, the regular rational rows of chapter 301, the stream windows of chapter 126, the dyadic tolerance core of chapter 291, and the endpoint seal of chapter 38. The packet names convergence only through finite Abel-summation windows and shared Cauchy thresholds; it does not import host infinite sums, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2333.1 (Dirichlet series test carrier)**.** *A* $\mathsf{DirichletSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, U, L, Q, W, D, E, A, B, V, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealSeries}^{\uparrow}$ *carrier of Definition 1581.1, including finite term access, partial-sum windows, the shared threshold, and the endpoint seal route.*
2. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff row consumed only after the Dirichlet cancellation surface is displayed.*
3. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *limit-interface row for the coefficient stream, read only as a null ledger and not as a selected series limit.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for coefficient comparisons.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for term, coefficient, and Abel-difference indices.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal inherited from the real-series row.*
8. *A is the bounded partial-sum ledger.*
9. *B is the monotone null coefficient ledger.*
10. *V is the Abel-summation finite-difference variation ledger.*
11. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{DirichletSeriesTest}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.DirichletSeriesTestUp.DirichletSeriesTestTasteGate single carrier alignment`

Theorem 2333.2 (Dirichlet series test NameCert obligations)**.** *For every accepted* $\mathsf{DirichletSeriesTest}^{\uparrow}$ *carrier* $K = (R, U, L, Q, W, D, E, A, B, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirichletSeriesTest}^{\uparrow}}$ *surface consists exactly of five obligations: carrier admission for the displayed rows, bounded partial-sum ledger visibility through* A*, monotone null coefficient ledger visibility through* B *and* L*, Abel summation route visibility through* V*, and tail-cancellation Cauchy readiness through* D, E, U, H, C, P, N*.*

Proof. Project the carrier of Definition 2333.1. Each listed obligation names one displayed row group of the finite packet and no external analytic object.

Use the $\mathsf{RealSeries}^{\uparrow}$ Dirichlet cancellation surface of Definition 1581.44. It supplies the bounded partial-sum, monotone null coefficient, Abel-difference, dyadic tolerance, shared threshold, and endpoint rows already required by the carrier.

The support rows H, C, P, N preserve, replay, source, and name the same finite route. Since the packet has no host infinite sum, selected limit, quotient equality, countable-choice schedule, or ambient completeness coordinate, the five obligations exhaust the accepted surface. □

Theorem 2333.3 (Dirichlet series test Abel summation route)**.** *Every accepted* $\mathsf{DirichletSeriesTest}^{\uparrow}$ *carrier exports its cancellation claim through the finite Abel-summation route*

$$R \longmapsto A \longmapsto (B, L, Q, W) \longmapsto V \longmapsto D \longmapsto E \longmapsto U.$$

The route first reads bounded partial sums from the $\mathsf{RealSeries}^{\uparrow}$ *row, then reads monotone null coefficients through* $\mathsf{RealSequenceLimit}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$*, then reads Abel finite differences through* V*, and only then reaches dyadic tolerance, endpoint sealing, and the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff.*

Proof. Start with the bounded partial-sum and variation route of Definition 1581.45. It places the finite partial-sum ledger before coefficient variation and dyadic tolerance.

Apply the tail-cancellation theorem Definition 1581.46. The endpoint seal is downstream of the bounded partial-sum ledger, coefficient ledger, Abel-difference ledger, dyadic tolerance ledger, and shared threshold.

Finally use the Cauchy-readiness theorem Definition 1581.47. The $\mathsf{UniformCauchySeries}^{\uparrow}$ row is a consumer of the same finite cancellation surface, so the handoff cannot bypass the displayed Abel route. □

Theorem 2333.4 (Dirichlet series test Cauchy consumer surface)**.** *The downstream Cauchy consumer of an accepted* $\mathsf{DirichletSeriesTest}^{\uparrow}$ *carrier receives only*

$\mathsf{RealSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist,

Its convergence read is the tail-cancellation Cauchy readiness of Definition 1581.47 and the Abel route of Definition 2333.3; no stronger host-side convergence principle is exported.

Proof. Read the carrier inventory in Definition 2333.1. The visible rows are exactly the real-series carrier, uniform Cauchy handoff, real sequence limit interface, regular rational readback, stream windows, dyadic tolerance, endpoint seal, cancellation ledgers, and support rows.

Use Definition 2333.2. It partitions those rows into carrier admission, bounded partial sums, monotone null coefficients, Abel summation, and Cauchy readiness.

The named consumer route then follows from Definition 2333.3. Because every step is a displayed finite row, the consumer cannot recover a host infinite sum, selected series limit, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{DirichletSeriesTest}^{\uparrow}$ convergence read factors through a RealSeries bounded partial-sum ledger, a monotone null coefficient ledger, Abel finite differences, dyadic tolerance, a shared Cauchy threshold, an endpoint RealUp seal, uniform Cauchy handoff, transport, continuation, provenance, and local naming.

Independence witness: realseries, uniform-cauchy-series, real-sequence-limit, regseqrat, streamname, dyadicratcore, real: $\mathsf{DirichletSeriesTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded partial sums, monotone null coefficients, Abel finite differences, Cauchy readiness, endpoint sealing, uniform handoff, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletSeriesTest}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletSeriesTest}^{\uparrow}$ packet is generated from a $\mathsf{RealSeries}^{\uparrow}$ carrier, $\mathsf{UniformCauchySeries}^{\uparrow}$ handoff, $\mathsf{RealSequenceLimit}^{\uparrow}$ coefficient limit interface, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{Real}^{\uparrow}$ endpoint seal, bounded partial-sum ledger, monotone null coefficient ledger, Abel finite-difference variation ledger, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2333.1, Definition 2333.2, Definition 2333.3, and Definition 2333.4 seed the constructive Dirichlet series test surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected limits, quotient equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded partial-sum ledger visibility, monotone null coefficient visibility, Abel finite-difference accounting, Cauchy readiness, and TasteGate field faithfulness for BEDC.Derived.DirichletSeriesTestUp.

The $\mathsf{QuasiUniformSpace}^{\uparrow}$ packet routes its directed entourage surface through the UniformSpace sibling of chapter 339 and the UniformCompletion dependency.

Chapter 2334

A Concrete Naming Certificate for $\mathsf{QuasiUniformSpace}^{\uparrow}$

Following Nachbin and Kelley, the $\mathsf{QuasiUniformSpace}^{\uparrow}$ packet records directed uniform entourage data as finite NameCert evidence before any symmetric uniformity or quotient completion is read. It sits on the L10 Real and Completion route beside chapter 339, chapter 333, chapter 589, chapter 1473, and chapter 1876. The packet exposes the asymmetric substrate used by completion-facing filters and nets without asserting inverse entourages, separated quotient completion, selected limits, open-cover compactness, `Classical.choice`, or `Quot.sound`.

At the spine level, the reflected row E is a downstream reader of chapter 339. Completion-facing consumers route onward through chapter 1473, so the directed quasi-uniform carrier exposes the sibling dependency before any reflected uniform completion data is consumed.

The actual carrier relationship is asymmetric: U and D are the primitive directed entourage and direction-ledger rows, while the $\mathsf{UniformSpace}^{\uparrow}$ sibling of chapter 339 and the metric-facing route through chapter 57 can be read only through the reflected row E after those directed rows are visible. Thus a metric specialization consumes a displayed symmetric reflection of quasi-uniform data; it is not a replacement for the quasi-uniform carrier and it does not add inverse entourages to U.

Definition 2334.1 (QuasiUniformSpace carrier)**.** *A* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (U, D, F, N, E, H, C, P, L)$$

with the following displayed rows:

1. *U is the directed entourage row, recording finite diagonal, refinement, and forward-composition observations.*
2. *D is the direction ledger, recording which requests are read forward and which are transported only after a displayed reverse request exists.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *read row, exposing finite filter-base requests whose Cauchy comparisons are evaluated through U and D.*
4. *N is the* $\mathsf{CauchyNet}^{\uparrow}$ *read row, exposing directed net tails and common refinements through the same forward-entourage ledger.*
5. *E is the uniform reflection row, naming the optional* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, or* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *consumer only as a downstream reflection of the directed data.*

6. *H records componentwise* hsame *transport for the directed entourage, direction ledger, Cauchy-filter read, Cauchy-net read, uniform reflection, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from directed entourage observations through filter or net reads and then to any reflected uniform consumer.*
8. *P is the* Pkg *provenance over* $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{QuasiUniformSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for symmetric uniformity as primitive data, a separated quotient completion, a selected limit, open-cover compactness, countable choice, `Classical.choice`*, or* `Quot.sound`*.*

Theorem 2334.2 (Quasi-uniform entourage obligations)**.** *For an accepted* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier*

$$Q = (U, D, F, N, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{QuasiUniformSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, directed diagonal exposure, forward-refinement stability, forward-composition replay, direction-ledger compatibility, Cauchy-filter and Cauchy-net read discipline, optional uniform reflection, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $U, D, F, N, E, H, C, P, L$.*

Proof. Carrier admission is projection from Definition 2334.1. The accepted packet exposes exactly the directed entourage row, direction ledger, Cauchy-filter row, Cauchy-net row, uniform reflection row, transport row, replay row, provenance row, and local naming row.

Directed diagonal exposure, forward-refinement stability, and forward-composition replay are read from U. The row records the finite entourage observations used by the packet, so a consumer cannot replace them with a symmetric entourage filter.

The direction discipline is read from D. A forward request may be replayed as stored, while a reverse request is accepted only when the ledger displays it as a separate finite observation.

The Cauchy boundary rows are then projected from F and N. Filter-base and net-tail reads are evaluated through the displayed U, D route, and therefore cannot bypass the quasi-uniform substrate.

Finally E, H, C, P, L add only reflection, transport, replay, provenance, and naming. They do not introduce inverse entourages, separated quotient completion, selected limits, open-cover compactness, choice, `Classical.choice`, or `Quot.sound`. □

Theorem 2334.3 (Cauchy boundary for directed entourages)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. Every* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *consumer read of Q factors through the displayed route*

$$U, D \longmapsto F, N \longmapsto H, C, P, L.$$

Thus the Cauchy boundary sees only directed entourage observations, their direction ledger, the displayed filter or net read row, and the structural rows. It does not see a quotient of Cauchy filters, a selected convergent subnet, a symmetric uniformity, or a host completion object.

Proof. Fix a Cauchy-facing consumer of Q. Projection gives U and D, so the consumer first receives the finite directed entourage observations and the ledger explaining which directions have been displayed.

If the consumer is filter-based, it reads F. The finite filter-base requests and Cauchy comparisons in F are accepted only as requests over U, D.

If the consumer is net-based, it reads N. The finite tail and common-refinement observations in N use the same directed ledger, so no selected subnet or limit representative is exported.

Transport, replay, provenance, and local naming close the route through H, C, P, L. These structural rows preserve the displayed data and provide no coordinate for quotient filter equality, selected convergence, symmetric uniformity, or a completed host object. □

Theorem 2334.4 (Uniform reflection route for quasi-uniform data)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. Any* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, *or* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *consumer named by E or P reads only a reflected route downstream of the directed data:*

$$U, D \longmapsto F, N \longmapsto E \longmapsto H, C, P, L.$$

The reflection route can record a symmetric or separated consumer as a reader, but it does not promote symmetric uniformity, quotient completion, or separatedness to primitive coordinates of the $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier.*

Proof. Project the optional reflection row E. Its uniform-space, uniform-completion, and separated-uniform-space entries are downstream consumers of the directed route, because the carrier presents U, D, F, N before E.

The displayed Cont row C replays the same order. A reflected consumer can inspect the directed entourage observations, then the Cauchy-filter or Cauchy-net boundary rows, and only then the reflected uniform request.

The provenance row P names the same dependency order. It may cite $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, or $\mathsf{SeparatedUniformSpace}^{\uparrow}$ as consumers, but the local naming row L still names the packet as $\mathsf{QuasiUniformSpace}^{\uparrow}$ with directed entourage data as its primitive surface.

Componentwise hsame transport in H preserves these rows without adding an inverse-entourage axiom. Hence symmetric uniformity, separated quotient completion, and selected limits remain outside the carrier. □

Theorem 2334.5 (Uniform completion sibling route for quasi-uniform data)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of Q must first read the directed entourage row U, the direction ledger D, the* $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *rows F, N, then the reflection row E and the structural rows H, C, P, L. Equivalently, the completion-facing route factors through*

$$U, D \longmapsto F, N \longmapsto E \longmapsto H, C, P, L$$

before it can use the uniform-completion surface of chapter 1473. The Cauchy-filter and Cauchy-net siblings of chapter 333 and chapter 589 are therefore mandatory readers, while uniform completion remains a reflected consumer rather than primitive data in the quasi-uniform carrier.

Proof. Start with Definition 2334.3. It forces every Cauchy-facing read to inspect U, D before it reaches the filter row F or the net row N.

Apply Definition 2334.4. A uniform-completion consumer can be named only by the reflected row E or by provenance in P, and both are downstream of the directed Cauchy boundary.

The structural rows H, C, P, L then transport, replay, source, and name the same route. Since $\mathsf{UniformCompletion}^{\uparrow}$ is reached through this reflected path, no carrier coordinate promotes quotient completion, separatedness, selected limits, or symmetric uniformity to primitive quasi-uniform data. □

Theorem 2334.6 (Metric reflection lattice route for quasi-uniform data)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. Whenever Q is reflected through a symmetric or separated row and then read by a* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer, the route must first expose*

$$U, D, F, N, E, H, C, P, L$$

before any metric-space or metric-completion surface is available. Thus the metric-facing lattice route factors through the Cauchy boundary and uniform reflection rows of Q before it reaches the metric certificate of chapter 57 or the metric-completion sibling of chapter 1506.

Proof. Start with Definition 2334.3. It forces every completion-facing read to open the directed entourage row U, the direction ledger D, and the Cauchy filter and net rows F, N before a reflected consumer can inspect completion data.

Next apply Definition 2334.4. A symmetric or separated row is present only as a reflected reader in E or as provenance in P, so metric structure is downstream of the quasi-uniform route rather than a primitive coordinate of the carrier.

Finally use the sibling route of Definition 2334.5. A metric-completion consumer may read the reflected completion surface only after H, C, P, L transport, replay, source, and name the displayed rows. Since none of those rows stores quotient completion equality, a selected limit, or a host metric completion object, those alternate routes remain unavailable. □

The completion lattice therefore has a mandatory sibling passage: any quasi-uniform completion consumer must first enter the uniform-completion surface of chapter 1473, and only after that reflected uniform row is displayed can metric reflection reach the metric-completion consumer of chapter 1506. This dependency prevents a directed entourage packet from being read directly as metric completion data.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiUniformSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{QuasiUniformSpace}^{\uparrow}$ packet is generated from directed entourage observations, a direction ledger, CauchyFilter and CauchyNet read rows, optional uniform reflection, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuasiUniformSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2334.1, Definition 2334.2, Definition 2334.3, Definition 2334.4, Definition 2334.5, and Definition 2334.6 seed the directed uniform completion substrate over finite quasi-uniform data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuasiUniformSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close symmetric uniformity, quotient completion, selected limits, open-cover compactness, choice principles, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, directed entourage exposure, direction-ledger compatibility, Cauchy-filter and Cauchy-net read discipline, uniform reflection non-escape, transport stability, replay stability, and ledger non-escape for BEDC.Derived.QuasiUniformSpaceUp.

The quasi-uniform completion route also has a distance-presented sibling edge. A consumer that asks for a directed ball, rather than a primitive entourage, must first read the $\mathsf{QuasiMetric}^{\uparrow}$ carrier of chapter 2158; only after the directed distance, zero diagonal, forward triangle, directed-ball, and Cauchy rows have been displayed may the consumer reflect to $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, or $\mathsf{Met}^{\uparrow}$.

Theorem 2334.7 (QuasiMetric forward link for quasi-uniform consumers)**.** *Every* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *completion-facing consumer that asks for a distance-presented directed ball factors through the* $\mathsf{QuasiMetric}^{\uparrow}$ *carrier of chapter 2158 before reflecting to* $\mathsf{UniformSpace}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$*. The reflected quasi-uniform route may consume directed-ball and Cauchy rows, but it does not turn those rows into primitive symmetry, quotient completion, selected limits, or host metric equality.*

Proof. Apply Definition 2158.3. The distance-presented directed-ball request first reads the $\mathsf{QuasiMetric}^{\uparrow}$ source, point, directed distance, zero diagonal, forward triangle, directed-ball, Cauchy filter, Cauchy net, uniform-reflection, transport, replay, provenance, and local naming rows.

Only after that route is displayed can the quasi-uniform carrier of Definition 2334.1 receive a directed entourage or completion-facing request. The reflected $\mathsf{UniformSpace}^{\uparrow}$ or $\mathsf{Met}^{\uparrow}$ consumer is therefore downstream of the quasi-metric route, not a replacement for it.

The non-escape clause of Definition 2158.4 excludes primitive symmetry, quotient completion, selected limits, and host equality. The quasi-uniform packet adds no coordinate that reintroduces them. □

Theorem 2334.8 (Uniform-space sibling route for quasi-uniform data)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier whose forward and reverse entourage ledgers agree as displayed finite rows. Then every symmetric quasi-uniform packet routes to the* $\mathsf{UniformSpace}^{\uparrow}$ *sibling surface of chapter 339 through the same finite entourage,* hsame*-transport,* Cont*-replay,* Pkg*, and* NameCert *rows.*

The route is local to the displayed carrier:

$$U, D \longmapsto E \longmapsto H, C, P, L.$$

It does not claim completion, Hausdorff separation, host topological equality, selected limits, or quotient uniformity.

Proof. Project the carrier of Definition 2334.1. The directed entourage row U and direction ledger D are displayed before the reflected row E.

The agreement assumption says that the forward and reverse entourage ledgers are the same finite data when read as a symmetric packet. Thus the reflected row E can expose the $\mathsf{UniformSpace}^{\uparrow}$ sibling surface without adding primitive symmetric uniformity to the quasi-uniform carrier.

The structural rows H, C, P, L transport, replay, source, and name the same finite route. Since no further coordinate is present, the theorem records only the local sibling passage and leaves completion, Hausdorff separation, host topological equality, selected limits, and quotient uniformity outside the packet. □

Theorem 2334.9 (Directed uniform-space dependency for quasi-uniform packets)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. Any route from* Q *to the* $\mathsf{UniformSpace}^{\uparrow}$ *sibling of chapter 339 must first display the directed entourage row* U *and the direction ledger* D*. Only after those rows are visible may the reflected row* E *name a symmetric uniform-space reader; the quasi-uniform packet itself still exports directed entourage data rather than primitive symmetric uniformity, quotient completion, selected limits, or host equality.*

Proof. Project the carrier of Definition 2334.1. The directed entourage row U and direction ledger D precede every Cauchy-facing, reflected-uniform, transport, replay, provenance, or naming row.

Apply the uniform reflection route of Definition 2334.4. The reflected row E names $\mathsf{UniformSpace}^{\uparrow}$ only as a downstream reader of the displayed directed data.

Finally use the uniform-space sibling route of Definition 2334.8. It identifies the sibling passage through U, D, E, H, C, P, L, so the dependency edge to chapter 339 is real, but it does not promote symmetric uniformity or completion data to primitive quasi-uniform coordinates. □

Theorem 2334.10 (QuasiUniformSpace entourage-direction sibling route)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. A directed-entourage read of* Q *sits between the distance rows of chapter 57 and chapter 2158, the symmetric-entourage rows of chapter 339, the convergence routes of chapter 333 and chapter 589, and the completion consumers of chapter 1473. The directed entourage classifier is not a symmetric metric, selected limit, quotient completion, or open-cover compactness theorem.*

Proof. Project the carrier of Definition 2334.1. The rows U and D expose directed entourage data and the direction ledger before the filter, net, reflection, transport, replay, provenance, and naming rows can be consumed.

Use Definition 2334.7. Distance-presented directed balls must first pass through the $\mathsf{QuasiMetric}^{\uparrow}$ route, while metric-facing consumers remain reflected readers rather than primitive quasi-uniform coordinates.

Apply Definition 2334.8 and Definition 2334.9. Symmetric $\mathsf{UniformSpace}^{\uparrow}$ data are downstream of the displayed directed rows and cannot replace them.

Finally use Definition 2334.3 and Definition 2334.12. The $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, and $\mathsf{UniformCompletion}^{\uparrow}$ routes read the same directed boundary, so completion-facing consumers receive no selected limit, quotient completion, symmetric metric, or open-cover compactness coordinate. □

Theorem 2334.11 (Quasi-uniform forward uniform-space link)**.** *Let*

$$Q = (U, D, F, N, E, H, C, P, L)$$

be an accepted $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier whose forward and reverse entourage requests are both displayed in the directed ledger* D*. Then every symmetric uniform consumer of* Q *factors through the* $\mathsf{UniformSpace}^{\uparrow}$ *sibling of chapter 339 before the completion-facing source row consumed by* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *in chapter 1588 is available.*

The route is

$$U, D \longmapsto E \longmapsto H, C, P, L,$$

where E *reads the reflected* $\mathsf{UniformSpace}^{\uparrow}$ *row only after both directions have been displayed. The resulting completion source is therefore a finite reflected uniform row, not primitive symmetric data inside the quasi-uniform carrier and not a selected quotient completion.*

Proof. Project the carrier of Definition 2334.1. The directed entourage row U and the ledger D are read before the reflected row E, so a symmetric consumer must see both the forward and reverse displayed requests before it can cite a uniform-space row.

Use the uniform reflection route of Definition 2334.4. Once both directions are present, E supplies the reflected $\mathsf{UniformSpace}^{\uparrow}$ sibling surface of chapter 339, while H, C, P, L only transport, replay, source, and name that same reflected route.

Finally read the complete-uniform-space carrier of chapter 1588. Its completion source row consumes a displayed $\mathsf{UniformSpace}^{\uparrow}$ entourage surface, so the quasi-uniform packet reaches it only through the reflected uniform row and not through primitive symmetric uniformity, quotient completion, or a selected limit. □

Theorem 2334.12 (Quasi-uniform uniform-completion dependency route)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of a* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *packet first reads the directed entourage row, the direction ledger, the* $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *boundary rows, and the reflected* $\mathsf{UniformSpace}^{\uparrow}$ *row before it reaches the completion surface of chapter 1473. The route is mediated by the Cauchy-filter and Cauchy-net siblings of chapter 333 and chapter 589, so uniform completion is a downstream reader of directed quasi-uniform data rather than a primitive coordinate of the carrier.*

Proof. Project the carrier of Definition 2334.1. The directed entourage row and direction ledger are exposed before any filter, net, or reflected uniform consumer is visible.

The $\mathsf{CauchyFilter}^{\uparrow}$ and $\mathsf{CauchyNet}^{\uparrow}$ rows then bind completion-facing reads to the displayed directed boundary. The reflected $\mathsf{UniformSpace}^{\uparrow}$ row can be read only after those boundary rows have been displayed.

The reflected symmetric entourage row is precisely the sibling route of chapter 339. A completion consumer therefore cannot bypass that uniform-space witness when it reads the $\mathsf{UniformCompletion}^{\uparrow}$ surface.

Thus every uniform-completion request reaches chapter 1473 through the same directed entourage, direction-ledger, Cauchy-filter, Cauchy-net, and reflected-uniform route, and no quotient completion or selected limit is promoted to primitive quasi-uniform data. □

The quasi-uniform reflection lattice keeps completion-facing consumers downstream of directed entourage data. A $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{SeparatedUniformSpace}^{\uparrow}$ reader may appear in the reflected row of a $\mathsf{QuasiUniformSpace}^{\uparrow}$ packet, but it first reads the directed entourage rows before it can consume the uniform completion surface of chapter 1473 or the separated sibling surface.

Theorem 2334.13 (Uniform completion reflection lattice for quasi-uniform data)**.** *Let* $Q = (U, D, F, N, E, H, C, P, L)$ *be an accepted* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *carrier. Every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *consumer named by* E *or* P *first reads the directed entourage row* U *and direction ledger* D*, then the reflection row* E*, before any completion-facing or separated-uniform surface is available. Thus the reflected route through chapter 339 and chapter 1473 remains downstream of finite quasi-uniform data.*

Proof. Project the carrier row. The directed entourage row U and direction ledger D are displayed before the reflection row E, so a reflected consumer cannot begin with symmetric or separated completion data.

Use the uniform reflection route of Definition 2334.4. It names $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, and $\mathsf{SeparatedUniformSpace}^{\uparrow}$ only as downstream readers of the directed rows.

The structural rows H, C, P, L transport, replay, source, and name the same order. Hence a completion-facing or separated-uniform consumer receives a reflected route rather than a primitive

quotient completion, selected limit, or separatedness coordinate inside the quasi-uniform carrier. □

Chapter 2335

A Concrete Naming Certificate for $\mathsf{VolterraIntegralOperator}^{\uparrow}$

Following Volterra and the standard constructive treatment of integral equations, the $\mathsf{VolterraIntegralOperator}^{\uparrow}$ packet records the finite operator surface by which a displayed kernel and an input history produce a causal integral history before any completion-facing consumer may read a fixed-point or convergence route. It sits over the public integral row of chapter 123, the continuous-map graph row of chapter 130, the endpoint seal of chapter 38, the compact source-window discipline of chapter 129, and the bounded-operator boundary of chapter 1644. The packet names the constructive Volterra operator boundary; it does not import a Fredholm inverse, global compactness theorem, selected solution operator, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2335.1 (Volterra integral operator carrier)**.** *A* $\mathsf{VolterraIntegralOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, T, X, Y, G, M, Q, S, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite interval-window row naming the inspected initial segment of the source history.*
2. *T is the time-order row, recording only pairs of displayed times with the triangular relation $s \leq t$ inside I.*
3. *X is the input-history row read through* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{UniformModulus}^{\uparrow}$ *windows.*
4. *Y is the output-history row whose values are exposed only as* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
5. *G is the causal kernel-window row, visible as a* $\mathsf{ContinuousMap}^{\uparrow}$ *graph only on the triangular domain determined by T.*
6. *M is the shared* $\mathsf{UniformModulus}^{\uparrow}$ *row for the input history, kernel graph, and finite Riemann-window estimates used by the operator.*
7. *Q is the quadrature-window row, storing finite tagged subintervals and dyadic error budgets for the displayed integral reads.*
8. *S is the* $\mathsf{Integral}^{\uparrow}$ *and* $\mathsf{RealSeries}^{\uparrow}$ *finite-sum row that records the partial-sum approximation of the integral window.*
9. *R is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row for completion-facing consumers of the output history.*

10. *L is the successive-approximation ledger, storing only the finite Picard-window route $X \mapsto Y$ through G, M, Q, S, R.*
11. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal for each displayed output value.*
12. *H records componentwise* hsame *transport for the interval, time-order, input, output, kernel, modulus, quadrature, series, completion, ledger, endpoint, replay, provenance, and local naming rows.*
13. *C records displayed* Cont *replay from an accepted operator request through the same rows.*
14. *P is the* Pkg *provenance over* $\mathsf{VolterraIntegralOperator}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{VolterraIntegralOperator}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite Volterra operator packet. It has no coordinate for a Fredholm inverse, global compactness theorem, selected solution operator, host function extensionality, quotient equality of functions, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Theorem 2335.2 (Volterra integral operator NameCert obligations)**.** *For every accepted* $\mathsf{VolterraIntegralOperator}^{\uparrow}$ *carrier $K = (I, T, X, Y, G, M, Q, S, R, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VolterraIntegralOperator}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval window, triangular time-order row, input-history row, output-history row, kernel graph row, uniform-modulus row, quadrature-window row, RealSeries finite-sum row, UniformCompletion handoff row, successive-approximation ledger, Real endpoint seal, componentwise transport, displayed continuation replay, package provenance, and local naming. Every accepted operator request is classified only by the displayed finite rows.*

Lean4 ✓ `BEDC.Derived.VolterraIntegralOperatorUp.VolterraIntegralOperatorCarrier namecert obligations`

Proof. Project the accepted carrier. The analytic rows are $I, T, X, Y, G, M, Q, S, R, L, E$, and the structural support rows are H, C, P, N.

Carrier admission reads those rows in the displayed order. The input and kernel rows are continuous and uniformly controlled only through X, G, M, the integral window is approximated only through Q, S, and the completion-facing handoff is the row R before the endpoint seal E is read.

Classifier stability is componentwise. The hsame row transports each finite coordinate, while C replays the same operator route for later consumers and P, N source and name it.

Since the carrier has no field for a host function space, a quotient function, a selected fixed point, a selected limit, countable choice, ambient real completeness, or a standard bridge, none of those principles can be exported by the local naming certificate. □

Theorem 2335.3 (Volterra triangular causality)**.** *For every accepted* $\mathsf{VolterraIntegralOperator}^{\uparrow}$ *carrier, the output value at a displayed time t is read only through source times s with $s \leq t$ recorded in the triangular row T. In BEDC rows, every causal read factors through*

$$I, T \longmapsto X, G, M \longmapsto Q, S \longmapsto Y, E \longmapsto H, C, P, N.$$

Thus a downstream consumer cannot inspect future input-history rows, replace the triangular domain by a host function-space domain, or identify two histories by external function extensionality.

Proof. Start with a displayed time request. The interval row I fixes the finite time window, and the triangular row T permits only source indices already recorded with $s \leq t$.

The kernel and input rows are then read through X, G, M. The uniform-modulus row controls the finite estimates over the same triangular domain, so no future time coordinate is introduced by continuity data.

The integral read is discharged by the quadrature and RealSeries rows Q, S, followed by the output and endpoint rows Y, E. Transport, replay, provenance, and naming preserve this same finite route.

The excluded host function-space and extensionality principles are absent from every carrier coordinate, so the displayed triangular route is the entire causality surface. □

Theorem 2335.4 (Volterra integral operator causal nonescape)**.** *Every accepted* $\mathsf{VolterraIntegralOperator}^{\uparrow}$ *packet must expose its source interval row, causal kernel-window row,* $\mathsf{ContinuousMap}^{\uparrow}$ *row,* $\mathsf{Integral}^{\uparrow}$ *row, terminal* $\mathsf{Real}^{\uparrow}$ *output seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{VolterraIntegralOperator}^{\uparrow}}$ *row before any consumer reads the output history. The accepted read is the finite route*

$$I, T, G, X, S, E, H, C, P, N,$$

with compact source discipline supplied only through $\mathsf{CompactMetric}^{\uparrow}$ *rows and bounded operator discipline supplied only through* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows. It exports no Fredholm inverse, global compactness theorem, selected solution operator, quotient function equality, choice-selected representative, or ambient solution-space object.*

Proof. Start with carrier admission. The source interval and triangular time-order rows I, T determine the finite causal window, and the kernel row G is readable only on that window.

Next read the analytic rows through the displayed dependencies. The input and kernel data reach consumers through $\mathsf{ContinuousMap}^{\uparrow}$ rows, the integral window is exposed through the $\mathsf{Integral}^{\uparrow}$ and finite-sum row S, and the output is sealed only at the terminal $\mathsf{Real}^{\uparrow}$ row E.

The structural rows then preserve the same packet. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row attach the causal read to H, C, P, N before any consumer can use the output.

The compact and bounded-linear-operator references are dependency boundaries, not hidden theorems. Since the packet has no coordinate for a Fredholm inverse, global compactness theorem, selected solution operator, quotient function equality, selected representative, or ambient solution space, none of those objects can escape through the Volterra output. □

Theorem 2335.5 (Volterra successive approximation surface)**.** *The successive-approximation ledger of an accepted* $\mathsf{VolterraIntegralOperator}^{\uparrow}$ *carrier exposes only finite Picard windows. Each displayed Picard step reads the previous history through* X*, the kernel through* G*, the shared modulus through* M*, the quadrature and finite RealSeries rows through* Q, S*, the completion-facing handoff through* R*, and the endpoint seal through* E*. The exported surface is therefore*

$$X, G, M, Q, S, R, E, L, H, C, P, N,$$

not a Banach fixed-point theorem, a selected limit of iterates, a quotient equality of histories, countable choice over iteration indices, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the Picard ledger L. By definition it stores only displayed approximation windows, each tied to the same input, kernel, modulus, quadrature, finite-sum, completion, and endpoint rows.

For one step, the previous history is consumed through X and the triangular kernel through G. The shared modulus row M and quadrature row Q supply the finite estimate data, while S records the partial-sum approximation used by the integral read.

The completion-facing row R is a handoff boundary rather than a fixed-point principle. The endpoint seal E is downstream of the finite rows, and H, C, P, N transport, replay, source, and name exactly that surface.

Thus successive approximation is present as finite BEDC ledger data only. No selected limit, Banach fixed point, quotient-history equality, countable-choice selector, or ambient completeness coordinate is available to the consumer. □

Falsifiable prediction: Every $\mathsf{VolterraIntegralOperator}^{\uparrow}$ operator read factors through an interval window, triangular time-order row, continuous-map input and kernel rows, an IntegralUp read, a shared UniformModulusUp ledger, finite quadrature windows, RealSeriesUp partial-sum rows, a UniformCompletionUp handoff, a RealUp endpoint seal, transport, continuation, provenance, and local naming.

Independence witness: integral, continuousmap, real, compactmetric, boundedlinearoperator, uniformmodulus, uniformcompletion, realseries: $\mathsf{VolterraIntegralOperator}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries triangular causality, causal kernel-window data, input and output histories, integral rows, quadrature windows, finite series approximations, completion handoff, Picard-window ledgers, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{VolterraIntegralOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{VolterraIntegralOperator}^{\uparrow}$ packet is generated from an interval window, triangular time-order row, continuous-map input-history row, causal kernel-window row, IntegralUp row, shared UniformModulusUp row, finite quadrature row, RealSeriesUp partial-sum row, UniformCompletionUp handoff row, successive-approximation ledger, RealUp endpoint seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VolterraIntegralOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2335.1, Definition 2335.2, Definition 2335.3, Definition 2335.4, and Definition 2335.5 seed the finite Volterra operator boundary for triangular constructive integral-equation reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VolterraIntegralOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Banach fixed point, Fredholm inversion, global compactness, selected solution operators, host function extensionality, quotient equality of functions, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, triangular causality, quadrature-window exactness, finite RealSeries approximation, UniformCompletion handoff, successive-approximation ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.VolterraIntegralOperatorUp.

Chapter 2336

A Concrete Naming Certificate for $\mathsf{NeighborhoodFunction}^{\uparrow}$

Following Brouwer's neighbourhood-function analysis and Bishop-style constructive continuity, the $\mathsf{NeighborhoodFunction}^{\uparrow}$ packet records the finite-observation interface by which a functional on choice or Cantor data is read through inspected prefixes before any fan-theorem or fan-functional consumer treats it as continuous. It sits between the finite stream windows of chapter 126, the binary-prefix surface of chapter 1475, the bar and spread law rows of chapter 400 and chapter 1532, and the modulus-facing handoff of chapter 1525. It also reads choice-sequence schedules through chapter 1482. The chapter names a finite NameCert carrier for neighbourhood-function reads; it does not admit host functions, external function extensionality, countable choice, selected infinite branches, or an ambient continuity theorem as primitive data.

Definition 2336.1 (NeighborhoodFunction carrier)**.** *A* $\mathsf{NeighborhoodFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (W, B, A, V, O, L, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that records which prefixes are inspected.*
2. *B is the* $\mathsf{CantorSpace}^{\uparrow}$ *or* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix row read through the schedule W.*
3. *A is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admissibility row for the displayed prefixes.*
4. *V is the local value row, recording the first accepted value attached to an inspected prefix.*
5. *O is the bar-observation row consumed by* $\mathsf{FanTheorem}^{\uparrow}$ *and* $\mathsf{FanFunctional}^{\uparrow}$ *handoffs.*
6. *L is the finite prefix ledger, storing only prefix extension, prefix agreement, and value-stability entries.*
7. *H records componentwise* hsame *transport for the schedule, prefix, spread-law, value, bar-observation, ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a neighbourhood request through W, B, A, V, O, L in that order.*
9. *P is the* Pkg *provenance over* $\mathsf{NeighborhoodFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NeighborhoodFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, B, A, V, O, L, H, C, P, N$. It has no coordinate for a host functional, an infinite branch selector, external function extensionality, a global continuity theorem, countable choice, or a completed function space.

Lean4 ✓ `BEDC.Derived.NeighborhoodFunctionUp.NeighborhoodFunctionTasteGate single carrier alignment`

Theorem 2336.2 (NeighborhoodFunction NameCert obligations)**.** *For every accepted* $\mathsf{NeighborhoodFunction}^{\uparrow}$ *carrier* $U = (W, B, A, V, O, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NeighborhoodFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite stream schedule, Cantor or choice-sequence prefix row, spread-law admissibility row, local value row, bar-observation row, finite prefix ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted neighbourhood-function read must expose those rows before it may be consumed by* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{FanFunctional}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*,* $\mathsf{SpreadLaw}^{\uparrow}$*, or* $\mathsf{CantorSpace}^{\uparrow}$ *siblings.*

Proof. Project the accepted carrier. The visible analytic data are the stream schedule W, the displayed prefix row B, the spread-law row A, the local value row V, the bar-observation row O, and the prefix ledger L.

Run finite prefix induction over the inspected $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{CantorSpace}^{\uparrow}$ reads. The empty prefix exposes only the initial schedule and admissibility rows. The extension step appends one displayed prefix entry, checks admissibility through A, and records the first value row V when the ledger permits it.

Prefix agreement is transported by H. Componentwise hsame keeps the compared schedules, prefixes, admissibility rows, values, and bar observations aligned, while C replays the same request order for downstream consumers.

Finally P, N source and name the packet. Since no host functional, infinite branch selector, external extensionality proof, countable-choice schedule, completed function space, or ambient continuity theorem appears in the tuple, the NameCert obligations are exhausted by the displayed rows. □

Theorem 2336.3 (NeighborhoodFunction fan-functional handoff)**.** *Every* $\mathsf{NeighborhoodFunction}^{\uparrow}$ *handoff to* $\mathsf{FanFunctional}^{\uparrow}$ *factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{CantorSpace}^{\uparrow}\ \textit{or}\ \mathsf{ChoiceSequence}^{\uparrow},\ \mathsf{SpreadLaw}^{\uparrow},\ \mathsf{FanTheorem}^{\uparrow},\ \mathsf{FanFunctional}^{\uparrow}.$$

The handoff reads only inspected prefixes, prefix agreement under hsame*, displayed continuation replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{NeighborhoodFunction}^{\uparrow}}$ *ledger before the fan-functional consumer may ask for a modulus-facing value.*

Proof. Start with the finite schedule row W. A fan-functional request can inspect only the prefixes already exposed through B and admitted by the spread-law row A.

Apply finite prefix induction again. At each step, the ledger L either records that no value has yet been exposed or records the first value row V stable under the displayed prefix agreement.

The bar-observation row O is then the only handoff row available to the fan theorem and fan functional siblings. Transport through H and replay through C preserve the same prefix route, while P, N provide the package and local naming ledger.

Thus the handoff is finite-observation data. It does not export a host functional, selected infinite branch, external function extensionality proof, countable-choice schedule, completed function space, or unrecorded modulus. □

Closure status for $\mathsf{NameCert}_{\mathsf{NeighborhoodFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{NeighborhoodFunction}^{\uparrow}$ packet is generated from a StreamName finite-window schedule, a CantorSpace or ChoiceSequence prefix row, a SpreadLaw admissibility row, a local value row, a FanTheorem bar-observation row, a finite prefix ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NeighborhoodFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2336.1, Definition 2336.2, and Definition 2336.3 seed the finite neighbourhood-function interface for prefix-based fan and choice-sequence reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NeighborhoodFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, global continuity, selected infinite branches, countable choice, completed function spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-induction exactness, prefix-agreement transport, bar-observation routing, fan-functional handoff, and ledger non-escape for BEDC.Derived.NeighborhoodFunctionUp.

Chapter 2337

A Concrete Naming Certificate for MetaCICNormalizationWindowConfluence$^{\uparrow}$

The MetaCICNormalizationWindowConfluence$^{\uparrow}$ packet realizes the candidate-mediated normalization-window and confluence-boundary branch of chapter 9383 as finite NameCert data. It consumes the candidate-mediated strong-normalization boundary of chapter 2274 and the local critical-pair boundary of chapter 2212 before exporting its normalization-window confluence boundary. It packages candidate evidence, closed-candidate evidence, candidate-set rows, Pi and application adequacy rows, typed example reduction traces, closed-normal rows, transport, replay, provenance, and local naming before any consumer treats a MetaCIC normalization read as accepted. The packet is not a global strong-normalization theorem, not a closed confluence theorem, and not a subject-reduction closure theorem.

The packet also consumes the confluence-audit boundary of chapter 735, the normalization frontier of chapter 892, and the bridge surface of chapter 1190. These siblings provide the conditional confluence rows, candidate-mediated normalization frontier, and bridge-facing nonescape boundary that this chapter packages into one finite normalization-window carrier.

Definition 2337.1 (MetaCIC normalization-window confluence carrier)**.** *A* MetaCICNormalizationWindowConfluen *carrier is a finite* BHist *packet*

$$M = (T, R, K, Q, S, A, B, D, E, Z, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed MetaCIC term-window row naming the finite expression and context fragment being audited.*
2. *R is the typed reduction-trace row, read through the local typed-example reduction surface.*
3. *K is the candidate-evidence row for the audited term window.*
4. *Q is the closed-candidate evidence row for closed subwindows.*
5. *S is the candidate-set membership row.*
6. *A is the Pi-adequacy row for dependent function windows.*
7. *B is the application-adequacy row for application windows.*
8. *D is the closed-normal row reached after the accepted candidate-mediated route.*

9. *E is the confluence-boundary row, recording the refusal to promote local window agreement to global closed confluence.*
10. *Z is the decidable-boundary row, storing the exact finite boundary at which beta-step inspection is admitted.*
11. *H records componentwise* hsame *transport for term windows, traces, candidate rows, adequacy rows, closed-normal rows, boundary rows, replay, provenance, and naming.*
12. *C records displayed* Cont *replay from a normalization-window request through $T, R, K, Q, S, A, B, D, E, Z$ in that order.*
13. *P is the* Pkg *provenance over* $\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}$*, candidate evidence, closed-candidate evidence, candidate sets, Pi adequacy, application adequacy, typed example reduction traces, closed-normal rows,* BHist, hsame, Cont, *and* NameCert*.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, K, Q, S, A, B, D, E, Z, H, C, P, N$. It has no coordinate for global subject reduction, global strong normalization, global confluence, proof irrelevance, host conversion equality, or a closed consistency theorem.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationWindowConfluenceUp.MetaCICNormalizationWindowConfluenceTasteGa`
`single carrier alignment`

Theorem 2337.2 (MetaCIC normalization-window confluence NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}$ *carrier $M = (T, R, K, Q, S, A, B, D, E, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}}$ *surface consists exactly of carrier admission for the typed term window, typed reduction trace, candidate evidence, closed-candidate evidence, candidate-set membership, Pi adequacy, application adequacy, closed-normal row, confluence-boundary row, decidable beta-step boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Lean TasteGate work for this packet must supply Nontrivial and FieldFaithful instances for the carrier rows and classifier projections before any bridge-checked reading is available.*

Proof. Project the accepted carrier. The typed expression and reduction rows are T, R, the candidate-mediated normalization rows are K, Q, S, A, B, D, and the boundary rows are E, Z.

Carrier admission first checks the candidate evidence consumed by the read. Closed subwindows must pass through Q, candidate-set membership through S, Pi windows through A, and application windows through B before the closed-normal row D is exposed.

Transport is componentwise through H. It preserves each candidate, adequacy, closed-normal, and boundary row without replacing them by host conversion equality or a global confluence premise.

Replay through C fixes the order of inspection, while P, N source and name the packet. The TasteGate burden is therefore precise: Nontrivial and FieldFaithful instances must witness that these displayed rows are not collapsed by the classifier or by the public carrier surface. □

Theorem 2337.3 (MetaCIC normalization-window confluence nonescape)**.** *Every accepted* MetaCICNormalizationW
read factors through candidate evidence, closed-candidate evidence, candidate-set membership, Pi adequacy, application adequacy, and closed-normal rows before the confluence-boundary row may be consumed. Consequently the packet exports no global strong-normalization theorem, no global confluence theorem, no subject-reduction closure theorem, no proof-irrelevance principle, no host conversion equality, and no closed consistency theorem.

Proof. Begin with a normalization-window request. The trace row R can be inspected only after the typed term window T is fixed.

The request then enters the candidate-mediated route. Candidate evidence K, closed-candidate evidence Q, candidate-set membership S, Pi adequacy A, and application adequacy B are read before the closed-normal row D.

Only after that route is displayed may the confluence-boundary row E and the decidable beta-step boundary Z be consumed. Componentwise transport, continuation replay, provenance, and naming preserve the same finite row order.

Since the carrier has no field for global subject reduction, global strong normalization, global confluence, proof irrelevance, host conversion equality, or closed consistency, no accepted read can escape to those principles. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}$ read factors through candidate evidence, closed-candidate evidence, candidate-set membership, Pi adequacy, application adequacy, and closed-normal rows before any confluence-boundary row is consumed.

Independence witness: metacicconfluenceauditpacket, metacicnormalizationfrontier, typed-example-reduction-trace, metacicdecidableboundary, betastepboundary: none is bijective to MetaCICNormalizationWindowC because this packet jointly carries typed term windows, reduction traces, candidate rows, closed-candidate rows, candidate-set rows, Pi and application adequacy, closed-normal rows, confluence and beta-step boundaries, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}$ packet is generated from a typed term window, typed reduction trace, candidate evidence, closed-candidate evidence, candidate-set membership, Pi adequacy, application adequacy, closed-normal rows, confluence-boundary rows, beta-step boundary rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2337.1, Definition 2337.2, and Definition 2337.3 seed the finite candidate-mediated normalization-window and confluence-boundary carrier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationWindowConfluence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global strong normalization, global confluence, subject reduction, proof irrelevance, host conversion equality, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate route exactness, Pi and application adequacy preservation, closed-normal routing, confluence-boundary non-escape, beta-step boundary exactness, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.MetaCICNormalizationWindowConfluenceUp.

Chapter 2338

A Concrete Naming Certificate for $\mathsf{SturmComparison}^{\uparrow}$

Following Sturm comparison theory and Bishop–Bridges constructive analysis, the $\mathsf{SturmComparison}^{\uparrow}$ packet records a finite comparison-neighbour surface for two displayed scalar ODE rows. It consumes the local-flow source of chapter 193, the continuous-map handoff of chapter 130, the finite observation windows of chapter 126, the regular rational readbacks of chapter 301, the Sturm root-isolation sibling of chapter 1534, and the terminal real-name seal of chapter 38. The packet names a local zero-order comparison certificate; it does not assert global ODE completeness, host solution equality, excluded-middle sign trichotomy, quotient real equality, or a selected classical solution curve.

Definition 2338.1 (Sturm comparison carrier)**.** *A* $\mathsf{SturmComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O_0, O_1, K, Z, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O_0 and O_1 are the two scalar* $\mathsf{Ode}^{\uparrow}$ *comparison-equation rows. Each row records its local time window, coefficient readbacks, initial endpoint data, and solution-window request through the displayed* $\mathsf{Ode}^{\uparrow}$ *local-flow surface.*
2. *K is the coefficient-order ledger. It records the finite comparison inequalities between the two coefficient packets, including the time window on which the order is licensed and the continuous-map rows that transport coefficient observations.*
3. *Z is the finite zero-window ledger. It records the inspected intervals, endpoint signs or nonzero certificates, retained zero-neighbour rows, and the local interlacing request used by the comparison read.*
4. *W stores the* $\mathsf{StreamName}^{\uparrow}$ *windows for coefficient observations, solution observations, and zero-window endpoints.*
5. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks attached to the windows in W.*
6. *E stores the* $\mathsf{Real}^{\uparrow}$ *seals for the coefficient-order rows, endpoint observations, and zero-window boundaries after O_0, O_1, K, Z, W, R have been displayed.*
7. *H records componentwise* hsame *transport for both ODE rows, coefficient-order ledgers, zero-window rows, stream windows, regular readbacks, real seals, continuation replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a comparison request through the two ODE rows, coefficient order, zero windows, readbacks, seals, transport, provenance, and local name.*
9. *P is the* Pkg *provenance over* $\mathsf{SturmComparison}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SturmRootIsolation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SturmComparison}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite comparison packet. It has no coordinate for a host solution space, global existence theorem, solution equality, trichotomy oracle, quotient real stream, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.SturmComparisonUp.TasteGate.SturmComparisonTasteGate single carrier alignment`

Theorem 2338.2 (Sturm comparison NameCert obligations)**.** *For every accepted* $\mathsf{SturmComparison}^{\uparrow}$ *carrier* $S = (O_0, O_1, K, Z, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SturmComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two displayed* $\mathsf{Ode}^{\uparrow}$ *comparison rows, coefficient-order ledger, finite zero-window ledger, stream windows, regular readbacks, real seals, transport, replay, provenance, and local naming;*
2. *coefficient-order exactness, requiring every comparison inequality to pass through K and through the continuous-map rows named by the coefficient readbacks;*
3. *zero-window exactness, requiring every zero-neighbour and interlacing read to pass through Z before any* $\mathsf{Real}^{\uparrow}$ *seal is exported;*
4. *readback confinement, requiring the windows W and readbacks R to mediate all coefficient, solution, and endpoint observations;*
5. *componentwise* hsame *transport and displayed* Cont *replay through H and C;*
6. *provenance and local naming through P and N.*

No comparison obligation outside these rows is part of the packet.

Proof. Project the accepted carrier of Definition 2338.1. The two ODE rows O_0, O_1 supply the only local-flow source data, so a comparison read cannot inspect a solution before the displayed ODE windows and endpoint rows have been opened.

The coefficient-order surface is K. Its entries are finite Real-facing reads transported through continuous-map rows and the window/readback pair W, R, so the order relation is a certificate row rather than a host comparison of functions.

The zero-window surface is Z. It records the inspected windows, retained endpoint signs or nonzero witnesses, and the interlacing request. The $\mathsf{Real}^{\uparrow}$ seals in E are downstream of Z, hence zero-order information cannot bypass the finite zero ledger.

Finally H, C, P, N transport, replay, source, and name the same route. Since none of these structural rows adds a host solution space, quotient stream, trichotomy principle, or ambient completeness witness, the listed rows exhaust the local NameCert obligations. □

Theorem 2338.3 (Sturm comparison zero-order handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or zero-window consumer of an accepted* $\mathsf{SturmComparison}^{\uparrow}$ *packet reads the route*

$$O_0, O_1 \longmapsto K \longmapsto Z \longmapsto W, R \longmapsto E \longmapsto H, C, P, N$$

before it may use the comparison conclusion. Thus the consumer receives two displayed $\mathsf{Ode}^{\uparrow}$ *comparison rows, coefficient-order ledgers, finite zero-window rows, stream windows, regular readbacks, real seals, componentwise transport, displayed continuation replay, provenance, and local naming. It receives no global ODE completeness theorem, host solution equality, excluded-middle sign trichotomy, quotient real equality, or selected classical solution curve.*

Proof. Begin with a consumer request for a comparison conclusion. The only source rows available are the two $\mathsf{Ode}^{\uparrow}$ rows O_0, O_1, so the request is already confined to displayed local-flow data.

Read the coefficient order through K. The order ledger is then tied to the finite observation rows W, R, which expose coefficient and endpoint values through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rather than through host real functions.

Read the zero-window ledger Z. The retained windows and interlacing request are the only zero-order data visible to the consumer, and the real seals E are produced only after those windows have been displayed.

The rows H, C, P, N repack the same route as transport, replay, provenance, and local naming. Therefore every accepted handoff is the finite comparison packet itself, with no separate classical comparison theorem or ambient completeness principle exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SturmComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{SturmComparison}^{\uparrow}$ packet is generated from two displayed $\mathsf{Ode}^{\uparrow}$ comparison rows, coefficient-order ledgers, finite zero-window rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{Real}^{\uparrow}$ seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SturmComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2338.1, Definition 2338.2, and Definition 2338.3 seed the finite comparison-neighbour packet over displayed ODE rows, coefficient order, zero windows, readbacks, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SturmComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global ODE completeness, host solution equality, excluded-middle sign trichotomy, quotient real equality, selected classical solution curves, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-order exactness, zero-window exactness, readback confinement, consumer handoff, and structural stability for BEDC.Derived.SturmComparisonUp.

Chapter 2339

A Concrete Naming Certificate for $\mathsf{MaterialityOrbitEscape}^{\uparrow}$

The $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ packet realizes the materiality-orbit-escape branch of subsection 9462.27.7 as finite observational-context, feedback-prefix, identity-closure, orbit-rule, separation, transport, and local NameCert rows. It consumes the finite observation-window discipline of chapter 126, the observer-facing direction rows of chapter 1047, the closed-observation sibling of chapter 616, and the audit-facing report surface of chapter 1279. The packet names an indexed ledger judgment; it does not introduce context-free materiality, context-free free will, global observer substance, completed feedback streams, or a universal prediction oracle.

Definition 2339.1 (Materiality orbit escape carrier)**.** *A* $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, F, I, R, S, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the observational-context row. It stores the observer history, probe pattern, candidate interface, identity classifier, state classifier, finite rule family, and ledger provenance named by the originating vision.*
2. *F is the feedback-prefix row. It stores a finite response prefix and the finite observation windows by which the prefix is read.*
3. *I is the identity-closure row. It records the displayed classifier witnesses that keep the prefix traceable as one observed datum.*
4. *R is the rule-family row. It stores the currently available ledger-certified orbit rules and their source certificates.*
5. *S is the separation row. It records the positive separation witnesses used to refute orbit closure for each rule in R.*
6. *T is the indexed judgment row. It records whether the accepted read is material appearance through a closing rule or freedom-like appearance through certified escape from the displayed finite family.*
7. *H records componentwise* hsame *transport for observational context, feedback prefix, identity closure, rule family, separation rows, indexed judgment, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an observer-indexed request through O, F, I, R, S, T, H.*

9. *P is the* Pkg *provenance over* $\mathsf{MaterialityOrbitEscape}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ObserverDirection}^{\uparrow}$, ClosedObservationSyste $\mathsf{SocketReport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MaterialityOrbitEscape}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite indexed packet. It has no coordinate for a context-free materiality predicate, context-free free-will predicate, global observer, completed feedback stream, hidden rule family, or universal predictor.

Lean4 ✓ `BEDC.Derived.MaterialityOrbitEscapeUp.MaterialityOrbitEscapeTasteGate single carrier alignment`

Theorem 2339.2 (Materiality orbit escape NameCert obligations)**.** *For every accepted* $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ *carrier $M = (O, F, I, R, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MaterialityOrbitEscape}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the observational context, feedback prefix, identity-closure witnesses, finite rule family, separation witnesses, indexed judgment, transport, replay, provenance, and local naming;*
2. *context exactness, requiring every observer, probe, candidate interface, classifier, rule-family, and ledger read to pass through O;*
3. *prefix exactness, requiring every feedback response to pass through the finite prefix row F;*
4. *identity-closure exactness, requiring the sameness of the observed datum to be witnessed by I before any material or freedom-like judgment is exposed;*
5. *rule-family and separation exactness, requiring material appearance to read a displayed closing rule from R and freedom-like appearance to read a positive separation row from S for each rule in R;*
6. *structural transport, continuation replay, provenance, and local naming through H, C, P, N.*

No obligation outside these rows is part of the packet.

Proof. Project the accepted carrier of Definition 2339.1. The observational context row O fixes the observer history, probe pattern, candidate interface, classifiers, finite rule family, and ledger source. Thus no judgment can be read independently of its context.

The feedback prefix is F, and identity closure is I. A material or freedom-like read must first expose the finite response prefix and the classifier witnesses that keep it traceable as one datum.

The rule-family row R and separation row S distinguish the two public cases. Material appearance reads a closing rule from R; freedom-like appearance reads, for each displayed rule in R, a positive separation witness in S.

Finally H, C, P, N only transport, replay, source, and name the same finite route. They add no global observer, completed stream, context-free predicate, hidden rule family, or universal predictor, so the listed rows exhaust the local NameCert obligations. □

Theorem 2339.3 (Materiality orbit escape rule-family nonescape)**.** *Every public* $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ *read is indexed by the same observational context and finite rule family that appear in its carrier. A consumer may project a material-appearance read only through $O, F, I, R, T, H, C, P, N$ with an orbit-closing rule in R, and may project a freedom-like read only through $O, F, I, R, S, T, H, C, P, N$ with a displayed separation witness for each rule in R. The packet exports no judgment after replacing R by a hidden larger family, deleting I, or erasing the observer and prefix indices.*

Proof. Read the public judgment row T. Its source coordinates are the context O, prefix F, identity-closure row I, and displayed finite rule family R.

In the material case, T records a rule from R together with the orbit-closing ledger for the prefix. Removing R or replacing it by a hidden family changes the source row and therefore changes the carrier.

In the freedom-like case, T records certified escape from the same family R by using the separation row S. Each rule admitted by R must have a corresponding positive separation witness before the public read is exposed.

The structural rows H, C, P, N preserve this indexing under transport and replay. Hence the consumer cannot de-index the judgment, drop identity closure, or read escape relative to an undisplayed rule family. □

Falsifiable prediction: An accepted $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ packet is refuted by any public freedom-like read that omits identity closure, changes the displayed finite rule family, or lacks a positive separation witness for one of that family's rules.

Independence witness: observerdirection, closedobservationsystem, socketreport, streamname: none is bijective to $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ because this packet jointly carries observer-indexed context, finite feedback prefix, identity closure, displayed rule family, separation witnesses, indexed judgment, transport, replay, provenance, and local naming.

The future Lean TasteGate file for this packet must provide explicit $\mathsf{Nontrivial\ MaterialityOrbitEscape}^{\uparrow}$ and $\mathsf{FieldFaithful\ MaterialityOrbitEscape}^{\uparrow}$ instances. The nontrivial witness must separate a material-closing read from an escape read with the same observer and prefix but different rule-family/separation rows, and field faithfulness must preserve $O, F, I, R, S, T, H, C, P, N$ as distinct carrier coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{MaterialityOrbitEscape}^{\uparrow}}$.

Constructive story: A $\mathsf{MaterialityOrbitEscape}^{\uparrow}$ packet is generated from an observational-context row, finite feedback-prefix row, identity-closure witnesses, finite rule-family rows, positive separation rows, an indexed material-or-escape judgment, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MaterialityOrbitEscape}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2339.1, Definition 2339.2, and Definition 2339.3 seed the finite observer-indexed materiality and orbit-escape packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MaterialityOrbitEscape}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close context-free materiality, context-free free will, global observer substance, completed feedback streams, hidden rule families, universal prediction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, context exactness, prefix exactness, identity-closure exactness, rule-family and separation exactness, nonescape, and TasteGate field faithfulness for BEDC.Derived.MaterialityOrbitEscapeU

The $\mathsf{DominatedConvergence}^{\uparrow}$ hub routes its spine through chapter 92, chapter 123, chapter 3447, and chapter 2094 before the limit-of-integrals readback.

Chapter 2340

A Concrete Naming Certificate for DominatedConvergence$^{\uparrow}$

Following Lebesgue's convergence theorem and Bishop-style constructive integration, the DominatedConvergence$^{\uparrow}$ packet records the finite visible route by which pointwise limit data, an integrable majorant, and integral readback rows are retained before any limit-of-integrals consumer reads the conclusion. It sits after the measure surface of chapter 92, the public integral row of chapter 123, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the series-style bounded handoff of chapter 2094. The lower-bound side is kept compatible with chapter 3447: FatouLemma$^{\uparrow}$ supplies the nonnegative liminf route, while this packet adds the displayed integrable majorant and limit-window rows needed for dominated integral readback. The packet names dominated convergence as finite NameCert data; it does not assert ambient measure-theoretic completeness, quotient function equality, host almost-everywhere equality, selected representatives, or an unbounded convergence theorem.

Definition 2340.1 (Dominated convergence carrier)**.** *A* DominatedConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, I, F, G, L, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* Measure$^{\uparrow}$ *source row, exposing only the finite measure requests that the convergence packet may inspect.*
2. *I is the* Integral$^{\uparrow}$ *readback row for the displayed integrands and the majorant.*
3. *F is the finite family row for the indexed integrands.*
4. *G is the integrable majorant row, read through the same measure and integral surfaces as I.*
5. *L is the pointwise-limit row, recording only the displayed convergence windows used by the packet.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for rational integral approximants and tolerance requests.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row reached after the measure, integral, majorant, limit, and readback rows have been displayed.*
8. *T is the sibling handoff row to* TanneryTheorem$^{\uparrow}$*, used only as a bounded finite-sum and series-style domination boundary.*

9. *H records componentwise* hsame *transports for M, I, F, G, L, R, E, T.*
10. *C is the displayed* Cont *replay of the same route.*
11. *P is the* Pkg *provenance over* DominatedConvergence$^{\uparrow}$, Measure$^{\uparrow}$, Integral$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, TanneryTheorem$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{DominatedConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for ambient measure completion, quotient function equality, host almost-everywhere equality, selected representatives, countable choice, or a detached completeness theorem.

Lean4 ✓ `BEDC.Derived.DominatedConvergenceUp.DominatedConvergenceTasteGate single carrier alignment`

Theorem 2340.2 (Dominated convergence NameCert obligations)**.** *For every accepted* DominatedConvergence$^{\uparrow}$ *carrier $D = (M, I, F, G, L, R, E, T, H, C, P, N)$, the local* NameCert$_{\text{DominatedConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the measure row, integral row, indexed integrand family, majorant, pointwise-limit row, regular rational readback, Real seal, Tannery handoff, transport, replay, provenance, and local naming;*
2. *majorant visibility, requiring every domination read to pass through G together with the same* Measure$^{\uparrow}$ *and* Integral$^{\uparrow}$ *rows used by I;*
3. *limit-window visibility, requiring every pointwise convergence read to pass through the displayed row L before any integral-limit read is available;*
4. *readback exactness, requiring integral approximants and tolerance requests to pass through R before the* Real$^{\uparrow}$ *seal row E is consumed;*
5. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the rows already listed.*

No dominated-convergence obligation is stored outside D.

Proof. Project the carrier of Definition 2340.1. The projection exposes exactly the measure row, integral row, integrand-family row, majorant row, pointwise-limit row, regular rational readback, Real seal, Tannery handoff, and structural rows.

Majorant visibility is the row G together with M and I. A domination read therefore uses the same finite measure and integral surfaces as the integral readback, rather than a hidden host boundedness or function-equality predicate.

Limit-window visibility is the row L. The theorem permits a consumer to inspect only the displayed convergence windows before reaching the integral-limit read, and it does not add a coordinate for ambient almost-everywhere equality.

The readback and seal route is $R \longmapsto E$. The regular rational approximants and tolerance requests are displayed before the terminal real-name seal is available. The rows H, C, P, N transport, replay, source, and name this same packet, so the listed obligations exhaust the local surface. □

Theorem 2340.3 (Dominated convergence Fatou forward dependency)**.** *Any accepted* DominatedConvergence$^{\uparrow}$ *packet that consumes the Fatou forward row must keep the dominating bound, finite measurable-window rows, Fatou lower-bound route, and* Real$^{\uparrow}$ *endpoint seals visible before it exports the dominated-convergence conclusion. Concretely, the read factors through the displayed majorant row G, the*

finite $\mathsf{Measure}^{\uparrow}$ *and* $\mathsf{Integral}^{\uparrow}$ *rows* M, I*, the pointwise-limit window row* L*, the* $\mathsf{FatouLemma}^{\uparrow}$ *lower-bound boundary named by Definition 2340.7, the regular rational readback* R*, the terminal seal* E*, and the structural rows* H, C, P, N*. It cannot use measure completion, selected representatives, quotient equality of functions, host almost-everywhere equality, or countable choice.*

Proof. Project the carrier of Definition 2340.1. The dominating bound is the row G, the finite measurable-window data are exposed only through M, I, F, L, and the endpoint route is $R \longmapsto E$.

Apply the NameCert obligations of Definition 2340.2. Majorant visibility keeps every domination read on G together with M, I, limit-window visibility keeps every pointwise read on L, and readback exactness keeps the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of R.

Use the local Fatou forward route Definition 2340.7. It allows the Fatou-facing consumer to receive only the displayed measure, integral, majorant, pointwise-limit, regular rational, Real seal, Tannery handoff, transport, replay, provenance, and local naming rows.

Therefore the dominated-convergence conclusion is exported only after the majorant, finite measurable windows, Fatou lower-bound boundary, regular readback, endpoint seals, and structural rows are all visible. Since those rows contain no measure completion, selected representative, quotient function equality, host almost-everywhere equality, or countable-choice coordinate, the forward dependency cannot import any of them. □

Theorem 2340.4 (Dominated convergence majorant handoff)**.** *Every* $\mathsf{Integral}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DominatedConvergence}^{\uparrow}$ *carrier* $D = (M, I, F, G, L, R, E, T, H, C, P, N)$ *reads the majorant side of the packet only through the displayed route*

$$M \longmapsto I \longmapsto G \longmapsto L \longmapsto R \longmapsto E \longmapsto T \longmapsto H, C, P, N.$$

Thus the consumer first receives the measure row, integral readback row, integrable majorant, pointwise-limit windows, regular rational readback, Real seal, bounded Tannery handoff, componentwise transport, displayed replay, provenance, and local naming before it can use the dominated-convergence conclusion.

Proof. Start with an integral-facing or Real-facing read of D. By Definition 2340.1, the only measure and integral coordinates are M and I, and the only domination coordinate is G.

The limit part is forced through L and R. The row L displays the pointwise-limit windows, while R records the regular rational readback and tolerance requests before the terminal seal E is reached.

The bounded handoff is T. It points to the finite domination discipline already visible in $\mathsf{TanneryTheorem}^{\uparrow}$ without importing the ambient dominated convergence theorem as a hidden premise.

Finally, H, C, P, N preserve and name the same route. Since the carrier lacks coordinates for measure completion, quotient function equality, host almost-everywhere equality, selected representatives, and countable choice, every consumer factors through the displayed majorant handoff. □

Theorem 2340.5 (Dominated convergence measure-integral route)**.** *Every dominated-convergence consumer of an accepted* $\mathsf{DominatedConvergence}^{\uparrow}$ *carrier* $D = (M, I, F, G, L, R, E, T, H, C, P, N)$ *factors through the* $\mathsf{Measure}^{\uparrow}$ *row,* $\mathsf{Integral}^{\uparrow}$ *row, majorant row, pointwise-limit row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{TanneryTheorem}^{\uparrow}$ *handoff before it consumes the conclusion. The route is anchored by chapter 92, chapter 123, chapter 301, chapter 38, and chapter 2094, with* H, C, P, N *preserving and naming exactly those rows.*

Proof. Project the carrier of Definition 2340.1. The first available analytic rows are M, I, G, L, R, E, T, and the structural rows are H, C, P, N.

The measure and integral stages are M and I. They bind the consumer to the finite measure and integral surfaces before any domination or limit row is read.

The domination and convergence stages are G and L. The majorant row is read through the same measure and integral surfaces, while the pointwise-limit row exposes only the displayed convergence windows.

The readback and sibling handoff are R, E, T. The regular rational row and terminal real seal are consumed before the Tannery handoff, and the transport, replay, provenance, and naming rows preserve this route without adding host almost-everywhere equality, selected representatives, or ambient completeness. □

Theorem 2340.6 (Dominated convergence Fatou–Tannery nonescape)**.** *Every lower-bound or bounded-series consumer of an accepted* $\mathsf{DominatedConvergence}^{\uparrow}$ *carrier* $D = (M, I, F, G, L, R, E, T, H, C, P, N)$ *reads the Fatou nonnegative route and the Tannery bounded handoff only through the displayed rows*

$$M, I, G, L, R, E, T, H, C, P, N.$$

In particular, the consumer may use $\mathsf{FatouLemma}^{\uparrow}$ *only as the nonnegative lower-bound boundary compatible with* M, I, G, L, R, E*, and may use* $\mathsf{TanneryTheorem}^{\uparrow}$ *only through the bounded handoff row* T*. It cannot import host almost-everywhere equality, selected representatives, quotient function equality, ambient measure completion, or a detached completion theorem at the Fatou–Tannery boundary.*

Proof. Project the carrier of Definition 2340.1. The carrier exposes the majorant row G, the pointwise-limit windows L, the regular rational readback R, the Real seal E, the Tannery handoff T, and the structural rows H, C, P, N.

Apply the NameCert obligations of Definition 2340.2. Majorant visibility forces every domination read through G together with M and I, while limit-window visibility forces every convergence read through L before integral-limit readback is available.

Use the majorant handoff of Definition 2340.4 and the measure-integral route of Definition 2340.5. These two routes place the lower-bound side next to the $\mathsf{FatouLemma}^{\uparrow}$ nonnegative boundary and place the bounded-series side next to the $\mathsf{TanneryTheorem}^{\uparrow}$ row T without adding any new carrier coordinate.

It follows that the Fatou-facing and Tannery-facing reads are exhausted by $M, I, G, L, R, E, T, H, C, P, N$. Since host almost-everywhere equality, selected representatives, quotient function equality, ambient measure completion, and detached completeness are absent from that list, none can escape through this boundary. □

Falsifiable prediction: Every $\mathsf{DominatedConvergence}^{\uparrow}$ integral-facing or Real-facing read factors through displayed Measure, Integral, majorant, pointwise-limit, RegSeqRat readback, Real seal, Tannery handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: measure, integral, regseqrat, real, tannery-theorem: $\mathsf{DominatedConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries measure source, integral readback, indexed integrand family, integrable majorant, pointwise-limit windows, regular rational approximants, Real seal, bounded Tannery handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DominatedConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DominatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2340.1, Definition 2340.2, and Definition 2340.4 seed the finite dominated-convergence route through Measure$^{\uparrow}$, Integral$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and TanneryTheorem$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{DominatedConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient measure-theoretic completeness, quotient function equality, host almost-everywhere equality, selected representatives, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, majorant visibility, limit-window visibility, regular rational readback exactness, Real seal handoff, transport and replay stability, and nonescape for BEDC.Derived.DominatedConvergenceUp.

Constructive story: A DominatedConvergence$^{\uparrow}$ packet is generated from a displayed Measure row, Integral readback row, indexed integrand-family row, integrable majorant row, pointwise-limit windows, RegSeqRat readback, terminal Real seal, bounded Tannery handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theorem 2340.7 (Dominated convergence Fatou forward route)**.** *Every* FatouLemma$^{\uparrow}$ *consumer using chapter 2340 receives only the displayed* Measure$^{\uparrow}$ *row sourced from chapter 92,* Integral$^{\uparrow}$ *row, integrable majorant row, pointwise-limit row,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal,* TanneryTheorem$^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert$_{\text{DominatedConverge}}$ *rows of an accepted* DominatedConvergence$^{\uparrow}$ *packet. The forward route supplies a dominated upper-side boundary compatible with chapter 3447; it does not export ambient measure completion, quotient function equality, host almost-everywhere equality, selected representatives, countable choice, or a detached monotone-convergence theorem.*

Proof. Project the accepted carrier from Definition 2340.1. The consumer can see only the measure row, integral row, indexed family row, majorant row, pointwise-limit row, regular rational readback, Real seal, Tannery handoff, and the structural rows.

Apply the NameCert obligation theorem Definition 2340.2. Majorant visibility, limit-window visibility, readback exactness, and structural stability force every dominated-convergence read to remain inside those displayed rows.

Use the majorant handoff Definition 2340.4. It orders the route through Measure$^{\uparrow}$, Integral$^{\uparrow}$, the majorant, pointwise-limit windows, RegSeqRat$^{\uparrow}$ readback, Real$^{\uparrow}$ seal, TanneryTheorem$^{\uparrow}$ handoff, and H, C, P, N before any conclusion is consumed.

The FatouLemma$^{\uparrow}$ chapter chapter 3447 supplies the lower-bound side as its own finite NameCert route. Therefore the forward dependency from dominated convergence to Fatou receives only the displayed rows listed above, with no ambient measure completion, quotient equality, selected representative, countable-choice, or detached monotone-convergence data. □

Theorem 2340.8 (Dominated convergence Fatou–Tannery sibling lattice)**.** *Every* DominatedConvergence$^{\uparrow}$ *consumer that reaches* FatouLemma$^{\uparrow}$ *must pass through the displayed majorant row, pointwise-limit row,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal, and* TanneryTheorem$^{\uparrow}$ *handoff row before the Fatou-side lower-bound boundary is consumed. The sibling lattice is therefore pinned to chapter 3447 and chapter 2094:* FatouLemma$^{\uparrow}$ *supplies the liminf-facing floor, while* TanneryTheorem$^{\uparrow}$ *supplies the bounded finite-exchange handoff. It does not export ambient measure completion, quotient function equality, selected representatives, countable choice, host almost-everywhere equality, or a detached monotone-convergence theorem.*

Proof. Project the accepted DominatedConvergence$^{\uparrow}$ carrier from Definition 2340.1. The only rows available to a Fatou-facing consumer are the displayed measure, integral, family, majorant, pointwise-limit, regular-readback, Real-seal, Tannery-handoff, transport, replay, provenance, and local naming rows.

Apply Definition 2340.7. It already places the Fatou-side route behind the majorant, pointwise-limit, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and TanneryTheorem$^{\uparrow}$ rows.

Now use the sibling anchors. The Fatou chapter chapter 3447 supplies the lower-bound comparison, and the Tannery chapter chapter 2094 supplies the bounded exchange row. Since both are reached only through the displayed lattice, no omitted host theorem or quotient equality can enter the DominatedConvergence packet. □

The horizontal lattice route for $\mathsf{DominatedConvergence}^{\uparrow}$ reads the lower-bound boundary from $\mathsf{FatouLemma}^{\uparrow}$ in chapter 3447 and the bounded handoff from $\mathsf{TanneryTheorem}^{\uparrow}$ in chapter 2094 before exporting its $\mathsf{Real}^{\uparrow}$ integral conclusion. Thus the dominated-convergence packet keeps its Fatou-side liminf floor and Tannery-side bounded exchange route visible as sibling rows, rather than as an ambient measure-completion theorem, a selected representative, quotient function equality, or a detached host convergence principle.

Theorem 2340.9 (Dominated convergence measure-integral sibling lattice)**.** *Every* $\mathsf{DominatedConvergence}^{\uparrow}$ *consumer must pass through the displayed sibling lattice before any dominated-convergence conclusion is read:*

1. *the* $\mathsf{Measure}^{\uparrow}$ *row of chapter 92 supplies the finite measurable-window source;*
2. *the* $\mathsf{Integral}^{\uparrow}$ *row of chapter 123 supplies the integral readback over that same source;*
3. *the* $\mathsf{FatouLemma}^{\uparrow}$ *row supplies only the nonnegative lower-bound boundary;*
4. *the* $\mathsf{TanneryTheorem}^{\uparrow}$ *row supplies only the bounded finite-exchange handoff;*
5. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows supply the regular rational readback and terminal Real seal.*

Thus the route records measure, integral, Fatou, Tannery, regular-readback, and Real-seal dependencies as visible sibling data. It does not export ambient measure completion, quotient function equality, selected representatives, host almost-everywhere equality, or countable choice.

The dependency lattice for $\mathsf{DominatedConvergence}^{\uparrow}$ consumes the measure carrier of chapter 92, the integral readback surface of chapter 123, and the lower-bound route of chapter 3447 before any dominated integral conclusion is exported. Thus the packet keeps the measure row, integral row, Fatou boundary, majorant row, convergence windows, and endpoint readback visible as sibling dependencies, with no ambient measure completion, selected representative, quotient function equality, host almost-everywhere equality, or countable-choice route.

Chapter 2341

A Concrete Naming Certificate for $\mathsf{CauchyNetRegularization}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Moore–Smith nets, the $\mathsf{CauchyNetRegularization}^{\uparrow}$ packet records the finite regularization surface by which directed Cauchy-net evidence is repacked before $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumers read it. It sits after the directed-window packet of chapter 589, the regularization route of chapter 376, the finite-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the completion landing surface of chapter 1506, and the terminal real-name seal of chapter 38. The packet is a finite carrier for regularized directed evidence; it is not a quotient of nets, not a selected subnet, not a host completion theorem, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2341.1 (CauchyNetRegularization carrier)**.** *A* $\mathsf{CauchyNetRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, S, R, T, A, E, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the accepted* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row whose inspected vertices and common upper-window witnesses provide the source evidence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule exposing the finite observation windows read from D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled observations.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the dyadic radii, rational comparison cells, and late-window bounds used by the regularization.*
5. *A is the finite regularization row: for each displayed tolerance request it chooses a named regular window already justified by the directed common-window witness in D and the tolerance ledger T.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the route D, S, R, T, A has been displayed.*
7. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row available only after the same regularized route has been displayed.*
8. *H stores componentwise* hsame *transport for the directed evidence, schedules, readbacks, tolerances, regularization row, seal row, completion handoff, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from directed windows to scheduled observations, regular readback, dyadic tolerance checks, regularized windows, and then to the real and metric-completion consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyNetRegularization}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyRegularization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetRegularization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient-net equality, selected representatives, cofinal choice functions, host metric completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyNetRegularizationUp.CauchyNetRegularizationTasteGate single carrier alignment`

Theorem 2341.2 (CauchyNetRegularization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetRegularization}^{\uparrow}$ *carrier $G = (D, S, R, T, A, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyNetRegularization}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, directed-window evidence through D, finite schedule exposure through S, regular rational readback through R, dyadic tolerance and comparison exactness through T, regularized-window selection through A, terminal real sealing through E, metric-completion handoff through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 2341.1. The accepted packet exposes the directed-window evidence, schedule, readback, tolerance ledger, regularization row, two consumer rows, and the structural rows H, C, P, N.

Read the evidence route in order. The directed row D supplies only displayed finite common-window witnesses; the schedule S and readback row R then expose the observations that are available to a regularization consumer. The dyadic row T records the tolerance and comparison cells attached to those observations.

The regularization row A is therefore not an independent selector. It chooses only among windows already justified by D, S, R, T, and the terminal rows E and M may be read only after that route has been displayed.

Rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no quotient-net, selected-subnet, cofinal-choice, host-completeness, open-cover, or ambient real-completeness coordinate, none of those principles is part of the local NameCert surface. □

Theorem 2341.3 (CauchyNetRegularization ledger exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{CauchyNetRegularization}^{\uparrow}$ *packet factors through exactly the regularized directed route*

$$D \longmapsto S \longmapsto R \longmapsto T \longmapsto A \longmapsto (E, M)$$

together with H, C, P, N. Consequently the consumer sees finite Cauchy-net evidence regularized into displayed StreamName, RegSeqRat, and DyadicRatCore rows before reaching either terminal surface, and it receives no quotient net, selected subnet, cofinal choice function, host completion theorem, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the source row D. By Definition 589.2, Cauchy-net evidence is available only as displayed directed-window data with common-window witnesses.

Next read the regularization route. The scheduled windows S, regular readback R, and dyadic tolerance ledger T are the only rows from which A may form a regularized window. Thus every regularized observation is tied to the same finite directed witness data rather than to an external subnet or host net.

Finally inspect the two terminal rows. The real seal E and metric-completion handoff M are downstream of A and share the same transport, replay, provenance, and local naming rows. Removing any row from $D, S, R, T, A, H, C, P, N$ breaks the displayed route, so the ledger is exact for the stated consumer surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNetRegularization}^{\uparrow}$ packet is generated from displayed CauchyNet evidence, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a regularized-window ledger, Real and MetricCompletion consumer rows, componentwise transport, displayed continuation replay, package provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNetRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2341.1, Definition 2341.2, and Definition 2341.3 seed the finite regularization route from directed Cauchy-net evidence to Real and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNetRegularization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient-net equality, selected subnets, cofinal choice, host completion, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, directed-window evidence exposure, regularized-window exactness, Real seal routing, MetricCompletion handoff, componentwise transport, continuation replay, provenance, and local naming for BEDC.Derived.CauchyNetRegularizationUp.

Chapter 2342

A Concrete Naming Certificate for ChoiceFreeRegularCauchyModulus$^{\uparrow}$

Following Bishop and Bridges on constructive real analysis with explicit moduli, the ChoiceFreeRegularCauchyModul packet records the finite L10 route by which a regular Cauchy modulus is read from displayed dyadic tolerances and regular rational windows before any Real or Completion consumer sees a seal. It sits after the dyadic tolerance core of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, the Real seal of chapter 38, and the extraction discipline of chapter 641. The packet exposes a modulus for displayed requests only; it is not countable choice, a quotient stream equality, a selected limit, host real equality, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 2342.1 (Choice-free regular Cauchy modulus carrier)**.** *A* ChoiceFreeRegularCauchyModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, W, R, E, K, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, displaying the dyadic precision request, slack conversion, comparison cell, and local radius ledger consumed by the modulus read.*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row, displaying exactly the source observations inspected for that tolerance request.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the windows in W, exposing the regular rational comparisons used by the modulus claim.*
4. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after D, W, R and the extracted modulus row have been displayed.*
5. *K is the local extraction row, read through the sibling* CauchyModulusExtraction$^{\uparrow}$ *surface and recording the displayed unary threshold that serves the request.*
6. *H records componentwise* hsame *transport for the dyadic tolerance, window, readback, Real seal, extraction row, continuation route, provenance, and local naming row.*
7. *C records displayed* Cont *replay from a Real or Completion tolerance request through D, W, R, K, E and then through the structural rows.*

8. *P is the* Pkg *provenance over* ChoiceFreeRegularCauchyModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyModulusExtraction$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{ChoiceFreeRegularCauchyModulus}^{\uparrow}}$ *row.*

The no-choice ledger is explicit: the carrier stores no countable-choice functional, no quotient stream representative, no selected limit, no trichotomy oracle, no host real equality test, and no ambient completion principle.

Lean4 ✓ `BEDC.Derived.ChoiceFreeRegularCauchyModulusUp.ChoiceFreeRegularCauchyModulusTasteGate single carrier alignment`

Theorem 2342.2 (Choice-free regular Cauchy modulus obligations)**.** *For every accepted* ChoiceFreeRegularCauchyM *packet*

$$M = (D, W, R, E, K, H, C, P, N),$$

the local NameCert$_{\text{ChoiceFreeRegularCauchyModulus}^{\uparrow}}$ *obligations are exactly the following finite rows:*

1. *carrier admission for the dyadic tolerance row, finite StreamName window, RegSeqRat readback, extracted modulus row, Real seal, transport, replay, provenance, and local naming data;*

2. *dyadic tolerance visibility, requiring every modulus request to expose the precision, slack, comparison, and radius data in D before K is read;*

3. *finite-window coverage, requiring the source observations used by K to be the displayed windows in W;*

4. *regular readback stability, requiring the comparison data exported to Real and Completion consumers to pass through the* RegSeqRat$^{\uparrow}$ *row R before the terminal seal E;*

5. *extraction locality, requiring K to be read through the sibling* CauchyModulusExtraction$^{\uparrow}$ *surface over the same D, W, R route;*

6. *no-choice exhaustion, requiring every accepted consumer to read only $D, W, R, E, K, H, C, P, N$ and therefore to receive no countable choice, quotient stream equality, selected limit, trichotomy, host real equality, or ambient completeness coordinate.*

Proof. Carrier admission is projection from Definition 2342.1. The packet displays the tolerance request, finite windows, regular rational readback, extraction row, Real seal, and structural rows as one finite BHist object.

For a modulus request, the dyadic row D is read first. It fixes the requested tolerance and the finite comparison budget available to the consumer. The StreamName row W then fixes the inspected source windows, and R records the regular rational readback from those windows.

The extraction row K is local to that route. It is not a choice functional over all future requests; it records the displayed threshold obtained from the visible D, W, R rows through the CauchyModulusExtraction$^{\uparrow}$ surface.

Finally the seal row E and the structural rows H, C, P, N transport and replay the same route. Since the no-choice ledger lists every absent coordinate, no countable-choice functional, quotient stream equality, selected limit, trichotomy oracle, host equality test, or ambient completeness principle can be exported by the local NameCert surface. □

Closure status for NameCert$_{\text{ChoiceFreeRegularCauchyModulus}^{\uparrow}}$**.**

Constructive story: A ChoiceFreeRegularCauchyModulus$^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName finite windows, RegSeqRat readback, a CauchyModulusExtraction row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{ChoiceFreeRegularCauchyModulus}\uparrow}$, seed)

Scope closed: Definition 2342.1 and Definition 2342.2 seed the finite no-choice modulus route over dyadic tolerance, window, readback, extraction, and Real seal rows.

Formal verification: FormalStatus(NameCert$_{\text{ChoiceFreeRegularCauchyModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, countable choice, quotient stream equality, selected limits, trichotomy, host real equality, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance visibility, finite-window coverage, regular readback stability, extraction locality, no-choice exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.ChoiceFreeRegularCauchyModulusUp.

Chapter 2343

A Concrete Naming Certificate for $\mathsf{MinkowskiInequality}^{\uparrow}$

Following Hardy–Littlewood–Polya and standard normed-space analysis, the $\mathsf{MinkowskiInequality}^{\uparrow}$ packet records the finite RealUp route by which a triangle-inequality read over displayed vector or finite-series windows becomes available to downstream norm and functional-analysis consumers. It sits over the Holder inequality handoff of chapter 2100, the square-case boundary of chapter 1684, the finite partial-sum surface of chapter 1581, the norm rows of chapter 89, and the endpoint seals of chapter 38. The packet is a finite inequality consumer; it is not a host function-space norm theorem, a quotient stream equality, a selected infinite sum, a countable-choice principle, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Definition 2343.1 (Minkowski inequality carrier)**.** *A* $\mathsf{MinkowskiInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, Z, A, B, U, V, C, D, E, F, H, T, P, N)$$

with the following displayed rows:

1. *X and Y are the two finite vector or finite-series windows whose inspected coordinates are exposed through* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
2. *Z is the displayed sum window, carrying exactly the coordinatewise or partial-sum rows read from X and Y.*
3. *A and B are the two* $\mathsf{Norm}^{\uparrow}$ *rows for the displayed inputs, including only the finite norm reads visible in X and Y.*
4. *U is the* $\mathsf{Norm}^{\uparrow}$ *row for the displayed sum window Z.*
5. *V is the* $\mathsf{HolderInequality}^{\uparrow}$ *handoff row used to compare the mixed finite products that appear in the triangle-inequality read.*
6. *C is the* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *square-case boundary, available when the exponent and norm rows specialize to the displayed square route.*
7. *D is the* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row, exposing only the finite sums of coordinates, powers, and comparison rows used by the carrier.*
8. *E is the dyadic tolerance budget for finite addition, norm comparison, Holder handoff slack, square-case slack, and endpoint rounding.*

9. *F is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal for the displayed Minkowski inequality read.*

10. *H records componentwise* hsame *transport for the finite windows, norm rows, Holder handoff, Cauchy–Schwarz boundary, RealSeries partial sums, dyadic budget, endpoint seal, replay, provenance, and local naming rows.*

11. *T records displayed* Cont *replay from any accepted coordinate or partial-sum request through $X, Y, Z, A, B, U, V, C, D, E, F$.*

12. *P is the* Pkg *provenance over* $\mathsf{MinkowskiInequality}^{\uparrow}$, $\mathsf{HolderInequality}^{\uparrow}$, $\mathsf{CauchySchwarzReal}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{MinkowskiInequality}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite Minkowski inequality packet. It has no coordinate for host function-space norms, quotient stream equality, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.MinkowskiInequalityUp.MinkowskiInequalityTasteGate single carrier alignment`

Theorem 2343.2 (Minkowski inequality NameCert obligations)**.** *For every accepted* $\mathsf{MinkowskiInequality}^{\uparrow}$ *carrier $K = (X, Y, Z, A, B, U, V, C, D, E, F, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MinkowskiInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the two displayed input windows, the displayed sum window, the two input norm rows, the sum norm row, the Holder handoff row, the Cauchy–Schwarz square-case boundary, the RealSeries partial-sum row, the dyadic tolerance budget, the endpoint seal, componentwise transport, displayed replay, package provenance, and local naming. Every accepted inequality request is classified only by the displayed finite windows, norm rows, Holder handoff, square-case boundary, finite partial sums, dyadic budget, and endpoint seal.*

Proof. Project the accepted carrier. The analytic coordinates are the finite windows X, Y, Z, the norm rows A, B, U, the Holder handoff V, the square-case boundary C, the partial-sum row D, the dyadic budget E, and the endpoint seal F.

Carrier admission reads exactly those displayed rows together with H, T, P, N. There is no carrier coordinate from which a host function-space norm, quotient representative, selected infinite sum, countable-choice selector, or ambient completeness witness could be recovered.

Classifier stability is componentwise. The hsame row transports the same finite windows, norm rows, handoff rows, partial-sum data, tolerance budget, and endpoint seal, while T replays the same finite route for later consumers.

Thus the local $\mathsf{NameCert}_{\mathsf{MinkowskiInequality}^{\uparrow}}$ row names the displayed inequality packet and no additional analytic theorem. □

Theorem 2343.3 (Minkowski inequality Holder handoff)**.** *For every accepted* $\mathsf{MinkowskiInequality}^{\uparrow}$ *carrier $K = (X, Y, Z, A, B, U, V, C, D, E, F, H, T, P, N)$, every triangle-inequality-facing read factors through the finite route*

$$X, Y, Z \longmapsto A, B, U \longmapsto V \longmapsto C, D \longmapsto E \longmapsto F \longmapsto H, T, P, N.$$

Consequently the read uses only finite vector or finite-series windows, the two input norm rows and sum norm row, the $\mathsf{HolderInequality}^{\uparrow}$ *mixed-product handoff, the* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *square-case boundary, the* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row, a dyadic tolerance budget, and a terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal. It supplies no host function-space norm, quotient stream equality, selected infinite sum, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge-checked standard theorem.*

Proof. Start from the displayed windows. The carrier lets a consumer inspect only the input windows X, Y and the sum window Z before any norm comparison is available.

The norm comparison is then fixed by A, B, U and by the Holder handoff row V. The square-case boundary C records the Cauchy–Schwarz specialization, while the RealSeries row D records the finite partial sums used in the comparison.

The dyadic budget E and endpoint seal F complete the Real-facing read. The support rows H, T, P, N transport, replay, source, and name the same route, so no excluded host-side principle can enter the accepted packet. □

Falsifiable prediction: Every $\mathsf{MinkowskiInequality}^{\uparrow}$ triangle-inequality read factors through finite vector or series windows, two input norm rows, a sum norm row, HolderInequalityUp handoff, CauchySchwarzRealUp square-case boundary, RealSeriesUp partial-sum routing, a dyadic tolerance budget, a RealUp endpoint seal, transport, replay, provenance, and local naming.

Independence witness: holder-inequality, cauchy-schwarz-real, realseries, norm, real: $\mathsf{MinkowskiInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite windows, three norm rows, Holder mixed-product routing, Cauchy–Schwarz square-case routing, RealSeries partial-sum routing, dyadic tolerance accounting, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MinkowskiInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{MinkowskiInequality}^{\uparrow}$ packet is generated from two finite vector or finite-series input windows, a displayed sum window, two input norm rows, a sum norm row, HolderInequalityUp handoff, CauchySchwarzRealUp square-case boundary, RealSeriesUp partial-sum rows, a dyadic tolerance budget, a RealUp endpoint seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinkowskiInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2343.1, Definition 2343.2, and Definition 2343.3 seed the finite Minkowski inequality boundary for displayed RealUp finite-vector and finite-series windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinkowskiInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space norms, quotient stream equality, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, norm-row exactness, Holder handoff, square-case boundary routing, finite-sum coverage, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.MinkowskiInequalityUp.

Chapter 2344

A Concrete Naming Certificate for $\mathsf{StoneCechCompactification}^{\uparrow}$

Following Gillman–Jerison and Engelking on compactifications, the $\mathsf{StoneCechCompactification}^{\uparrow}$ packet records the finite BEDC surface by which bounded continuous probes from a displayed completely regular source are read through compact Hausdorff target seals. It sits over the generated-open topology rows of chapter 88, the compact-metric witness discipline of chapter 129, the graph and continuity surface of chapter 130, the endpoint-stable limiting route of chapter 463, and the real-name seal of chapter 38. The packet names finite bounded-continuous-probe windows and compact-target seal rows only; it does not construct an ambient function algebra, choose ultrafilters, identify quotient extensions, or assert an external compactification theorem.

Definition 2344.1 (Stone–Cech finite probe carrier)**.** *A* $\mathsf{StoneCechCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, O, B, W, F, K, T, U, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-object row, read only through the displayed topology classifier of* $\mathsf{Topology}^{\uparrow}$*.*
2. *O is the finite generated-open row for the inspected source neighborhoods and separation tests.*
3. *B is the bounded-real range row, recording the finite real-name bounds consumed by bounded continuous probes.*
4. *W is the finite probe-window row, listing the bounded continuous probes whose values are inspected.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and continuity row for each probe in W.*
6. *K is the compact-target seal row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *or the displayed compact target surface available to the surrounding route.*
7. *T is the compact Hausdorff target-separation row for finite pairs of target observations.*
8. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row for replaying finite probe windows through stable target seals.*
9. *R is the* $\mathsf{Real}^{\uparrow}$ *value row attached to the bounded target observations.*
10. *H records componentwise* hsame *transport for source topology, bounded range, probe window, continuous-map graph, compact-target seal, target separation, uniform handoff, real-value, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a finite bounded-probe request through O, B, W, F, K, T, U, R.*
12. *P is the* Pkg *provenance over* $\mathsf{StoneCechCompactification}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{StoneCechCompactification}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, O, B, W, F, K, T, U, R, H, C, P, N$. It has no coordinate for ultrafilter choice, ambient bounded-function algebra, quotient extension equality, host compactification points, excluded middle, or external compact Hausdorff completion.

Lean4 ✓ `BEDC.Derived.StoneCechCompactificationUp.StoneCechCompactificationTasteGate single carrier alignment`

Theorem 2344.2 (Stone–Cech compactification NameCert obligations)**.** *For every accepted* StoneCechCompactifica *carrier*

$$S = (X, O, B, W, F, K, T, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StoneCechCompactification}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source topology row, generated-open inspections, bounded-real range row, finite probe window, continuous-map graph rows, compact-target seal, target separation rows, uniform handoff, real-value rows, transport, replay, provenance, and naming;*
2. *probe-window classifier, requiring every bounded continuous probe read to factor through W, F, B, R and the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows;*
3. *compact-target handoff, requiring K, T to expose only the displayed compact target and target-separation rows before any compactification-facing consumer reads the seal;*
4. *transport and replay, requiring H, C to preserve the same finite packet under* hsame *comparison and displayed* Cont *observation replay;*
5. *ledger non-escape, requiring every topology, compactness, continuous-map, uniform-limit, and real-value consumer to read through $X, O, B, W, F, K, T, U, R, H, C, P, N$ rather than through ultrafilters, host compactification points, quotient extension equality, or an ambient bounded-function algebra.*

No Stone–Cech compactification obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2344.1. The accepted tuple exposes exactly the source topology, generated-open, bounded-range, probe-window, continuous-map, compact-target, target-separation, uniform-handoff, real-value, transport, replay, provenance, and local naming rows listed in the statement.

The probe-window classifier is finite. A probe request first selects an entry of W, then reads its graph and continuity data through F, its bounded range through B, and its displayed real values through R. No function algebra or selected infinite probe family is part of the carrier.

The compact-target handoff is read from K, T, U. The compact target seal and its finite separation rows are displayed before the uniform replay row can export a compactification-facing observation, so the handoff remains inside the target seal.

Transport, replay, provenance, and naming are supplied by H, C, P, N. Since the carrier has no coordinate for ultrafilter choice, quotient extension equality, host compactification points, excluded middle, or an external compact Hausdorff completion, the listed rows exhaust the local certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{StoneCechCompactification}^{\uparrow}}$.

Constructive story: A $\mathsf{StoneCechCompactification}^{\uparrow}$ packet is generated from a source topology row, generated-open inspections, bounded-real range data, finite bounded-continuous-probe windows, continuous-map graph rows, compact-target seals, target-separation rows, uniform replay, Real value rows, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StoneCechCompactification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2344.1 and Definition 2344.2 seed the finite bounded-continuous-probe surface for compactification consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StoneCechCompactification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilter existence, ambient bounded-function algebra, quotient extension equality, host compactification points, excluded middle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, probe-window classifier, compact-target handoff, transport, replay, provenance, local naming, and non-escape for the same finite packet.

Chapter 2345

A Concrete Naming Certificate for $\mathsf{UniformCompletionSeparationKernel}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley's separated uniform reflection, the $\mathsf{UniformCompletionSeparationKernel}^{\uparrow}$ packet names the finite interface that lets a completion-facing consumer pass from displayed Cauchy data to a separated comparison boundary. It sits between the metric completion surface of chapter 1506, the uniform completion route of chapter 1473, and the zero-distance exactness boundary of chapter 1411.

Definition 2345.1 (UniformCompletionSeparationKernel carrier)**.** *A* $\mathsf{UniformCompletionSeparationKernel}^{\uparrow}$ *carrier is a tuple*

$$K = (M, U, S, F, N, R, H, C, P, L)$$

with the following displayed rows.

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row read by metric completion consumers before any separated comparison is requested.*
2. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row recording the uniform-completion handoff surface over the same displayed Cauchy data.*
3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance row used as the exact separated-kernel boundary.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch, exposing finite filter evidence for completion-facing reads.*
5. *N is the* $\mathsf{CauchyNet}^{\uparrow}$ *branch, exposing finite net evidence over the same completion route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row through which terminal precision claims are sealed.*
7. *H is componentwise* hsame *transport for M, U, S, F, N, R.*
8. *C is the displayed* Cont *replay from Cauchy evidence to the completion handoff and separated comparison.*
9. *P is the* Pkg *provenance row over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionSeparationKernel}^{\uparrow}}$ *row.*

Theorem 2345.2 (UniformCompletionSeparationKernel NameCert obligations)**.** *For an accepted carrier $K = (M, U, S, F, N, R, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionSeparationKernel}^{\uparrow}}$ *obligation surface consists of carrier admission, uniform-completion handoff, separated-kernel exactness,*

filter and net branch visibility, RegSeqRat or Real seal nonescape, and componentwise transport. Every completion-facing read must pass through the displayed route

$$M \to U \to S \to F, N \to R \to H, C, P, L.$$

The packet exports no quotient completion, selected representative, countable choice schedule, host equality, open-cover compactness theorem, or Real completeness row.

Proof. Carrier admission is read directly from Definition 2345.1. The tuple displays the metric-completion source, the uniform-completion handoff, the separated zero-distance boundary, both Cauchy evidence branches, the terminal readback row, transport, replay, provenance, and local naming.

The uniform-completion handoff uses U only after M has been projected. Thus a completion-facing consumer cannot bypass the metric-completion source or insert a separate quotient-completion object before the uniform route is exposed.

Separated-kernel exactness is the role of S. Any comparison of two displayed completion reads is forced through the $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance row, so the packet never supplies host equality or selected representatives.

The filter and net branches are visible as the separate rows F and N. They can be inspected as finite BEDC evidence, but neither branch introduces countable choice, an unbounded selector, open-cover compactness, or an ambient completeness theorem.

Finally R, H, C, P, L seal the route componentwise. The RegSeqRat or Real readback is reached only after the displayed completion and separated-boundary rows, while transport, replay, provenance, and local naming preserve the same finite route for every consumer. □

Theorem 2345.3 (UniformCompletionSeparationKernel filter-net branch visibility)**.** *Let* $K = (M, U, S, F, N, R, H, C, P, L)$ *be an accepted* $\mathsf{UniformCompletionSeparationKernel}^{\uparrow}$ *carrier. Every completion-facing read from* K *exposes both the* $\mathsf{CauchyFilter}^{\uparrow}$ *branch row* F *and the* $\mathsf{CauchyNet}^{\uparrow}$ *branch row* N *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal row* R *is consumed.*

The read therefore factors through the displayed $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, and* $\mathsf{SeparatedMetric}^{\uparrow}$ *route before it reaches either terminal seal. It cannot be replaced by a hidden quotient completion, selected limit row, host equality, or one-branch completion presentation.*

Lean4 ✓ `BEDC.Derived.UniformCompletionSeparationKernelUp.TasteGate.UniformCompletionSeparationKernelFil`

Proof. Project the accepted carrier. The coordinates M, U, S expose the metric-completion source, the uniform-completion handoff, and the separated zero-distance boundary before any terminal readback is available.

The branch rows are separate coordinates. The filter branch F and the net branch N are both displayed before R, so a completion-facing consumer cannot consume the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal while hiding one of the two Cauchy presentations.

Now use the ledger order recorded by H, C, P, L. Componentwise transport and continuation replay preserve the route through M, U, S, F, N before R, while provenance and local naming record that route as the only public packet surface.

Ledger non-escape excludes any hidden quotient completion, selected limit, host equality, or one-branch substitute. Such data are absent from the carrier coordinates and cannot be reconstructed from the displayed NameCert route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionSeparationKernel}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionSeparationKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2345.1 and Definition 2345.2 seed the separated uniform-completion interface over MetricCompletion$^{\uparrow}$, UniformCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, CauchyFilter$^{\uparrow}$, CauchyNet$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{UniformCompletionSeparationKernel}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.UniformCompletionSeparationKernelUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality, open-cover compactness, or Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, uniform-completion handoff, separated-kernel exactness, filter and net branch visibility, seal nonescape, transport, replay, provenance, and local naming.

Constructive story: A UniformCompletionSeparationKernel$^{\uparrow}$ packet is generated from MetricCompletionUp, UniformCompletionUp, SeparatedMetricUp, CauchyFilterUp, CauchyNetUp, RegSeqRatUp or RealUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2346

A Concrete Naming Certificate for $\mathsf{CauchyDedekindBridge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyDedekindBridge}^{\uparrow}$ packet records the finite bridge surface by which regular Cauchy names can be compared against located-cut-facing data before any completion principle for $\mathsf{Real}^{\uparrow}$ is available. It sits between the regular rational name route of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the located-cut comparison boundary of chapter 404, the Bishop real comparison route of chapter 1381, and the terminal real-name seal of chapter 38. The chapter gives Phase Real and Completion consumers one named handoff between Cauchy-style and cut-facing reads without asserting quotient real equality or ambient completeness.

Definition 2346.1 (Cauchy-Dedekind bridge carrier)**.** *A* $\mathsf{CauchyDedekindBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, W, D, L, B, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational Cauchy name before any located-cut-facing comparison is read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to expose only the finite source and comparison observations requested by the packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the endpoint scales, error budgets, and refinement requests consumed by the bridge.*
4. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *comparison row. It records lower-side and upper-side located evidence only through the displayed dyadic and stream windows.*
5. *B is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *classification row, comparing the regular Cauchy source with the located-cut-facing row through finite rational brackets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, W, D, L, B have been consumed.*
7. *H records componentwise* hsame *transport for the regular source, stream windows, dyadic tolerances, located comparison, Bishop comparison, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the bridge route*

$$R, W, D \longmapsto L, B \longmapsto E, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyDedekindBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDedekindBridge}^{\uparrow}}$ *row.*

The classifier for accepted packets reads only these rows. It has no coordinate for quotient real equality, a Dedekind-cut construction as primitive, countable choice, trichotomy, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyDedekindBridgeUp.CauchyDedekindBridgeTasteGate single carrier alignment`

Theorem 2346.2 (Cauchy-Dedekind bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyDedekindBridge}^{\uparrow}$ *carrier* $K = (R, W, D, L, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyDedekindBridge}^{\uparrow}}$ *surface consists exactly of carrier admission, regular-source exposure, finite-window exposure, dyadic-tolerance exposure, located-cut comparison exposure, Bishop comparison classification, real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of quotient real equality, Dedekind-cut construction as primitive, countable choice, trichotomy, selected representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2346.1. The accepted packet exposes exactly the regular rational source row R, window schedule W, dyadic tolerance row D, located-cut comparison row L, Bishop comparison row B, terminal real seal E, and structural rows H, C, P, N.

The comparison rows are read in order. A consumer first reads R, W, D as regular Cauchy evidence at finite precision, then reads L as located-cut-facing evidence and B as the finite Bishop comparison classification. None of those rows contains a host quotient of real names or a selected cut representative.

The handoff to $\mathsf{Real}^{\uparrow}$ is therefore delayed until the displayed comparison route has been consumed. Rows H, C, P, N transport, replay, source, and name the same finite route, so the excluded principles have no carrier coordinate from which they could be recovered. □

Theorem 2346.3 (Cauchy-Dedekind bridge real-comparison handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* BishopRealCompariso *facing consumer of an accepted* $\mathsf{CauchyDedekindBridge}^{\uparrow}$ *packet factors through the displayed route*

$\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, Nam

In particular, a consumer comparing a regular Cauchy name with located-cut-facing data must read the finite window schedule and dyadic tolerance ledger before the comparison row and before the terminal real seal.

Proof. Begin with an accepted carrier $K = (R, W, D, L, B, E, H, C, P, N)$. The source row R is visible only through the window schedule W and tolerance ledger D, so the consumer has no unscheduled access to a regular Cauchy stream.

The located-cut-facing read is then supplied by L and classified by B. These two rows compare only the displayed rational brackets and located evidence made available by R, W, D.

Finally the real seal E is reached through the same route and preserved by H, C, P, N. Thus the handoff is a finite bridge from regular Cauchy data to located comparison data, not a quotient real equality theorem, a primitive Dedekind-cut construction, a countable-choice selector, trichotomy, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyDedekindBridge}^{\uparrow}$ consumer comparing a regular Cauchy name with located-cut-facing data factors through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$,

LocatedCut$^{\uparrow}$, BishopRealComparison$^{\uparrow}$, the terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, locatedcut, bishoprealcomparison, real: CauchyDedekindBridge$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a regular Cauchy source, finite windows, dyadic tolerances, located-cut comparison, Bishop comparison classification, real seal, transport, replay, provenance, and local NameCert rows in one bridge packet.

Closure status for NameCert$_{\text{CauchyDedekindBridge}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchyDedekindBridge}^{\uparrow}}$, seed)

Scope closed: Definition 2346.1, Definition 2346.2, and Definition 2346.3 seed the finite bridge surface between regular Cauchy names and located-cut-facing comparison rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyDedekindBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, Dedekind-cut construction as primitive, countable choice, trichotomy, selected representatives, Lean verification, bridge checking, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, regular-source exposure, finite-window exposure, dyadic-tolerance exactness, located-cut comparison exposure, Bishop comparison classification, real-seal non-escape, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchyDedekindBridgeUp.

Constructive story: A CauchyDedekindBridge$^{\uparrow}$ packet is generated from a RegSeqRat source, StreamName finite windows, DyadicRatCore tolerances, LocatedCut comparison evidence, BishopRealComparison classification, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2347

A Concrete Naming Certificate for $\mathsf{CaratheodoryConvexHull}^{\uparrow}$

Following Caratheodory and standard finite-dimensional convex geometry, the $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ packet records finite convex-hull certificates as BEDC naming data. It sits over the ambient affine carrier of chapter 206, the convex membership surface of chapter 208, the finite face and witness rows of chapter 209, and the finite subfamily handoff of chapter 2309. Before the support rows are reduced, $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ consumes the finite-subfamily ledger supplied by chapter 2309 as the displayed boundary for the bounded convex-family read. The packet names only finite support rows, coefficient ledgers, hull-membership witnesses, boundary faces, transport, replay, provenance, and local naming; it does not assert a host separation theorem, a selected minimal simplex, quotient convex-hull equality, or ambient real-vector completeness.

Definition 2347.1 (Caratheodory convex-hull carrier)**.** *A* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, C, S, W, F, L, B, Y, H, T, P, N)$$

with the following displayed rows:

1. *A is the finite-dimensional* $\mathsf{AffineSpace}^{\uparrow}$ *ambient row through which every point and affine combination is read;*
2. *C is the* $\mathsf{ConvexSet}^{\uparrow}$ *source row for the displayed finite generator family;*
3. *S is a finite support row, listing the selected generator histories and exposing the support bound used by the Caratheodory read;*
4. *W is the coefficient ledger, recording nonnegative scalar rows, the finite-sum-one row, and the displayed affine-combination replay;*
5. *F is the* $\mathsf{Polytope}^{\uparrow}$ *face-boundary row that stores the simplex, face, or exposed-hull witness used by the finite support;*
6. *L is the local hull classifier, accepting exactly those point rows that are replayed from S, W, F inside the ambient affine row A and the convex source row C;*
7. *B is the Helly handoff row naming the finite subfamily boundary of chapter 2309;*
8. *Y is the exported hull-membership row, available only after A, C, S, W, F, L, B have been displayed;*

9. *H is the componentwise* hsame *transport for ambient, convex, support, coefficient, face, Helly, and membership rows;*
10. *T is the displayed* Cont *route that replays the finite affine-combination certificate without adding host convexity data;*
11. *P is the* Pkg *provenance over* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{HellyTheorem}^{\uparrow}$, BHist, hsame, Cont, *and local* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryConvexHull}^{\uparrow}}$ *row.*

The carrier exposes no ambient convex-hull operator, no quotient equality of hulls, no selected minimal support, no host dimension theorem, and no standard bridge row.

Lean4 ✓ `BEDC.Derived.CaratheodoryConvexHullUp.CaratheodoryConvexHullTasteGate single carrier alignment`

Theorem 2347.2 (Caratheodory convex-hull NameCert obligations)**.** *For the carrier of Definition 2347.1, the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryConvexHull}^{\uparrow}}$ *surface consists exactly of carrier admission for the ambient affine row, convex source row, finite support row, coefficient ledger, polytope face-boundary row, local hull classifier, Helly handoff row, exported membership row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Classifier stability is tested only by replaying the same finite support, coefficient ledger, face boundary, and Helly handoff through transported ambient and convex rows. Ledger exactness says that every accepted membership read exposes precisely $A, C, S, W, F, L, B, Y, H, T, P, N$ and no external convex-hull datum.*

Theorem 2347.3 (Caratheodory convex-hull Helly handoff)**.** *Every accepted* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *packet routes a finite convex-hull membership request through*

$$\mathsf{AffineSpace}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{Polytope}^{\uparrow},\ \mathsf{HellyTheorem}^{\uparrow}.$$

The affine and convex rows fix the ambient source, the finite support and coefficient ledger display the affine combination, the polytope face row records the boundary witness, and the Helly row records the finite subfamily boundary consumed by downstream convexity arguments. A consumer that omits any of those rows is outside the accepted $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *carrier.*

Closure status for $\mathsf{NameCert}_{\mathsf{CaratheodoryConvexHull}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ packet is generated from finite-dimensional affine ambient data, a convex source row, a finite support row, nonnegative coefficient and finite-sum-one ledgers, a polytope face-boundary witness, a local hull classifier, a Helly handoff row, an exported membership row, componentwise transport, continuation replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CaratheodoryConvexHull}^{\uparrow}}$, seed)

Scope closed: Definition 2347.1, Definition 2347.2, and Definition 2347.3 bind the finite support, coefficient, polytope-face, Helly-handoff, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CaratheodoryConvexHull}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host convex-hull equality, minimal-support selection, ambient dimension theorems, Real completeness, separation, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, support replay, coefficient exactness, face-boundary routing, Helly handoff, transport, provenance, and local naming for BEDC.Derived.CaratheodoryConvexHullUp.

Chapter 2348

A Concrete Naming Certificate for $\mathsf{RealApartnessSign}^{\uparrow}$

Bishop–Bridges constructive apartness/sign information reads the sign of a real-name presentation only through positive finite evidence: a negative side, a positive side, or a displayed zero-adjacent refusal to claim either side at the requested precision. The $\mathsf{RealApartnessSign}^{\uparrow}$ packet names that finite sign-read surface between the apartness interface of chapter 304, the separated completion boundary of chapter 1567, the dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It supplies Real and Completion consumers with a concrete NameCert dependency for located sign comparison; it is not trichotomy, host real order, quotient equality of Cauchy streams, a selected limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2348.1 (RealApartnessSign carrier)**.** *A* $\mathsf{RealApartnessSign}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, A, W, R, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the inspected real-name row, read either as a terminal* $\mathsf{Real}^{\uparrow}$ *seal or as its* $\mathsf{RegSeqRat}^{\uparrow}$ *source before the seal handoff.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *evidence row comparing X with the displayed zero real-name boundary.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window opened for the sign request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback visible on that window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint ledger used to compare the readback with zero at the requested precision.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after A, W, R, D have been displayed.*
7. *L records the located comparison row: negative-side evidence, positive-side evidence, or a bounded zero-adjacent refusal at the current dyadic tolerance.*
8. *H records componentwise* hsame *transport for the inspected real row, apartness row, window row, readback row, dyadic ledger, seal row, located comparison row, replay row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from the sign request through apartness inspection, finite window readback, dyadic comparison, and the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RealApartnessSign}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{RealApartnessCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealApartnessSign}^{\uparrow}}$ *row.*

The carrier has no coordinate for real trichotomy, total order, quotient stream equality, host real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealApartnessSignUp.TasteGate.RealApartnessSignTasteGate single carrier alignment`

Theorem 2348.2 (RealApartnessSign obligation surface)**.** *For every accepted* $\mathsf{RealApartnessSign}^{\uparrow}$ *carrier* $S = (X, A, W, R, D, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealApartnessSign}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the inspected real row, apartness row, finite window, regular readback, dyadic ledger, real seal, located comparison row, transport, replay, provenance, and local naming rows;*
2. *apartness anchoring, requiring the sign read to inspect X against the zero boundary through the displayed* $\mathsf{ApartnessReal}^{\uparrow}$ *row A before a positive or negative side is exposed;*
3. *finite-window readback, requiring every sign request to pass through W, R, and D before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E can be consumed;*
4. *located comparison exactness, requiring L to record exactly the displayed negative-side evidence, positive-side evidence, or zero-adjacent refusal available at the current dyadic tolerance;*
5. *componentwise stability, requiring H and C to transport and replay only the displayed rows $X, A, W, R, D, E, L, P, N$;*
6. *ledger exhaustion, requiring the packet to export no trichotomy decision, total order, quotient stream equality, host real equality, selected representative, countable-choice schedule, or ambient completeness principle.*

No local sign obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2348.1. The accepted tuple displays exactly the inspected real row, apartness row, finite window, regular rational readback, dyadic ledger, terminal seal, located comparison row, and structural support.

Apartness anchoring is forced by the position of A. A positive-side or negative-side read cannot be named before the comparison with the zero boundary is visible as $\mathsf{ApartnessReal}^{\uparrow}$ evidence.

The finite-window readback discipline is the role of W, R, D, E. The sign request opens a finite StreamName window, reads it as a regular rational row, compares it through the dyadic ledger, and only then exposes the Real seal.

Located comparison exactness follows from L. The row records the finite sign information available at the requested tolerance, including the zero-adjacent refusal case when neither side has been witnessed.

Finally H, C, P, N transport, replay, package, and name only the displayed packet. Since the carrier contains no further coordinate, it cannot export trichotomy, total order, quotient equality, host equality, choice, or ambient completeness. □

Theorem 2348.3 (RealApartnessSign located comparison route)**.** *Every located comparison read exported by an accepted* $\mathsf{RealApartnessSign}^{\uparrow}$ *packet factors through the finite route*

$$X, A, W, R, D \longmapsto L \longmapsto E \longmapsto H, C, P, N.$$

Thus a Real or Completion consumer can read sign information only after the apartness-to-zero row, finite StreamName window, regular rational readback, and dyadic tolerance ledger have all been displayed. The route may expose positive-side evidence, negative-side evidence, or a zero-adjacent refusal at the current tolerance, but it exports no total sign decision for arbitrary real names.

Proof. Start with the accepted carrier of Definition 2348.1. Projection gives the single displayed route $X, A, W, R, D, E, L, H, C, P, N$.

Read the apartness row first. The sign request is anchored by A, so any positive or negative side must be evidence against the zero boundary rather than a host-level order claim.

Next replay the finite observation path through W, R, D. The StreamName window, RegSeqRat readback, and DyadicRatCore tolerance ledger determine which finite comparison row is available.

The located comparison row L is then consumed before the terminal seal E and the structural rows H, C, P, N. Since L has only the three displayed alternatives, the consumer receives finite sign information without a global trichotomy principle. □

Theorem 2348.4 (RealApartnessSign real seal boundary)**.** *For an accepted* $\mathsf{RealApartnessSign}^{\uparrow}$ *carrier* $S = (X, A, W, R, D, E, L, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *is available to downstream Real and Completion consumers only through the same sign-read route that displays* $A, W, R, D, L, H, C, P, N$ *In particular, the seal cannot be read as a sign decision detached from apartness evidence, finite windows, regular readback, or the dyadic tolerance ledger.*

Proof. Apply Definition 2348.2. The finite-window readback and located comparison obligations place W, R, D, L before any consumer can use the seal row.

Apply Definition 2348.3. The displayed route already forces apartness anchoring through A and then passes through the finite observation and dyadic comparison rows before reaching the seal.

Finally use ledger exhaustion from the obligation surface. The carrier has no coordinate for a detached sign oracle, host order, quotient stream equality, selected representative, countable-choice schedule, or ambient completeness theorem. The Real seal is therefore read only as the end of the displayed sign packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealApartnessSign}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealApartnessSign}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2348.1, Definition 2348.2, Definition 2348.3, and Definition 2348.4 seed the finite constructive sign-read surface over ApartnessReal, RealApartnessCompletion, StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealApartnessSign}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close real trichotomy, total order, quotient stream equality, host real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, apartness anchoring, finite-window readback, located comparison exactness, componentwise stability, seal boundary, and ledger exhaustion proofs for BEDC.Derived.RealApartnessSignUp.

Constructive story: A $\mathsf{RealApartnessSign}^{\uparrow}$ packet is generated from an inspected RealUp row, an ApartnessReal comparison with zero, a StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, located comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{ArensFortSpace}^{\uparrow}$ packet is read through the topology, observable two-point, metric-generated topology, and finite stream-window sibling surfaces of chapter 88, chapter 1860, chapter 1655, and chapter 126.

Chapter 2349

A Concrete Naming Certificate for $\mathsf{ArensFortSpace}^{\uparrow}$

Following Arens and Fort, the $\mathsf{ArensFortSpace}^{\uparrow}$ packet records the classical grid space with one non-isolated accumulation point as finite BEDC topology data. It sits beside the indexed-open carrier of chapter 88, the two-point observable handoff of chapter 1860, the metric-generated topology boundary of chapter 1655, and the finite observation windows of chapter 126. The packet is a topology-generated boundary object: it names neighbourhood filters and observable truth reads without importing a metric presentation, a host powerset of opens, choice, or a completed ambient space.

Definition 2349.1 (Arens–Fort space carrier)**.** *An* $\mathsf{ArensFortSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathsf{af}} = (G, S, T, O, W, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite grid-point ledger. It records the distinguished point ∞ and the finitely inspected isolated points (m, n), together with the local classifier that separates ∞ from the displayed grid rows.*
2. *S is the special-point neighbourhood filter ledger. A row of S names a finite stem and a tail threshold for each displayed column, so a neighbourhood of ∞ contains all but finitely many points in every named column and contains ∞ itself.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *indexed-open carrier generated by the isolated singleton rows of G and the special-point neighbourhood rows of S.*
4. *O is the observable truth handoff into* $\mathsf{SierpinskiSpace}^{\uparrow}$*: an open-membership read is exposed only as a carried observable truth row after the relevant isolated singleton or special-neighbourhood witness has been displayed.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family used to inspect finitely many grid coordinates, special-neighbourhood thresholds, and observable truth requests.*
6. *H records componentwise* hsame *transport for grid rows, special-neighbourhood filters, indexed opens, observable truth rows, finite windows, replay rows, provenance, and the local certificate.*
7. *C records displayed* Cont *replay from a public open-membership request through W, then through G or S, then through T, and finally through the observable handoff O.*

8. *P is the* Pkg *provenance over* $\mathsf{ArensFortSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArensFortSpace}^{\uparrow}}$ *row.*

The classifier admits packets only through these nine rows. It has no coordinate for a host powerset of grid points, a metric ball basis, a selected convergent sequence, an ambient compactness or completeness witness, or a choice principle.

Theorem 2349.2 (Arens–Fort NameCert obligations)**.** *For every accepted* $\mathsf{ArensFortSpace}^{\uparrow}$ *carrier* $A_{\mathsf{af}} = (G, S, T, O, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArensFortSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed grid ledger, special-point neighbourhood filter, indexed-open carrier, observable truth handoff, finite windows, transports, continuations, provenance, and local naming row;*

2. *isolated-point stability, requiring each displayed grid point (m, n) to remain open by its singleton row under the componentwise* hsame *transport and displayed* Cont *replay;*

3. *special-point neighbourhood exactness, requiring every open read at ∞ to exhibit the finite stem and column thresholds named by S before the read is admitted by T;*

4. *topology-open transport, requiring the* $\mathsf{Topology}^{\uparrow}$ *indexed-open row to move only through the isolated singleton constructors and special-neighbourhood constructors named in G and S;*

5. *observable-open handoff, requiring every* $\mathsf{SierpinskiSpace}^{\uparrow}$ *truth read to factor through the same open-membership witness already carried by T and inspected by W;*

6. *ledger non-escape, excluding host powersets, metric-generated ball bases, selected convergent sequences, ambient compactness, ambient completeness, choice, and any open classifier outside $G, S, T, O, W, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.ArensFortSpaceUp.ArensFortSpaceCarrier semantic name certificate`

Proof. Carrier admission is projection from Definition 2349.1. The packet exposes only the grid ledger G, the special-neighbourhood filter S, the indexed topology row T, the observable handoff O, the finite windows W, and the structural rows H, C, P, N.

Isolated-point stability is read directly from the singleton rows of G. Transport along H preserves the displayed grid coordinate, and replay along C keeps the singleton-open request attached to the same coordinate before T admits it as an open.

For the special point, the only neighbourhood source is S. Thus every open read at ∞ must present the displayed finite stem and column-threshold data before the topology row T can expose the neighbourhood as open.

Topology-open transport follows by constructor analysis on T. Its generators are exactly the isolated singleton rows and the special-neighbourhood rows, and the replay route never introduces a metric-ball basis or a host powerset of points.

The observable handoff is forced by O and W. A $\mathsf{SierpinskiSpace}^{\uparrow}$ truth value is readable only after the same finite window and the same carried open-membership witness have been displayed.

Finally, the non-escape clause is an inventory check on the carrier. Since metric balls, selected sequences, compactness, completeness, choice, host powersets, and detached open classifiers are not coordinates of A_{af}, no local NameCert obligation can export them. □

Falsifiable prediction: An accepted $\mathsf{ArensFortSpace}^{\uparrow}$ consumer that reads a $\mathsf{SierpinskiSpace}^{\uparrow}$ observable truth value at the special point without first displaying a finite $\mathsf{StreamName}^{\uparrow}$ window, the corresponding special-neighbourhood threshold row, and the $\mathsf{Topology}^{\uparrow}$ open-membership witness refutes the carrier surface.

Independence witness: topology, sierpinski-space, metric-topology, streamname: none is bijective to $\mathsf{ArensFortSpace}^{\uparrow}$ because this packet jointly carries isolated grid rows, special-point neighbourhood filters, indexed topology opens, observable truth handoff, finite stream windows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArensFortSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArensFortSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2349.1 and Definition 2349.2 seed the finite Arens–Fort topology certificate over isolated grid rows, special-point neighbourhood filters, indexed-open rows, observable truth handoff, finite windows, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArensFortSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim metrizability, compactness, completeness, choice, host powersets, selected convergent sequences, ambient topology equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, isolated-point stability, special-point neighbourhood exactness, topology-open transport, observable-open handoff, and ledger non-escape for BEDC.Derived.ArensFortSpaceUp.

Constructive story: An $\mathsf{ArensFortSpace}^{\uparrow}$ packet is generated from isolated grid-point rows, special-point neighbourhood filter rows, a TopologyUp indexed-open carrier, a SierpinskiSpaceUp observable truth handoff, finite StreamNameUp windows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2350

A Concrete Naming Certificate for $\mathsf{CauchyContractionOrbit}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, a $\mathsf{CauchyContractionOrbit}^{\uparrow}$ packet names the finite Picard-orbit ledger used by constructive contraction fixed-point routes before an endpoint is sealed. It sits between the map-level contraction packet of chapter 1418, the one-step Picard route of chapter 395, the modulus surface of chapter 292, the completion consumer of chapter 128, the regular rational sequence handoff of chapter 301, and the final real-number seal of chapter 38. The packet records the finite orbit and ratio data that make a Cauchy-modulus route visible without selecting a fixed point.

Definition 2350.1 (CauchyContractionOrbit carrier)**.** *A* $\mathsf{CauchyContractionOrbit}^{\uparrow}$ *carrier is a finite packet*

$$O = (X, T, I, L, M, R, E, H, C, P, N)$$

with the following displayed rows.

1. *X is the metric carrier and distance-read row inherited from the contraction-map surface.*
2. *T is the self-map graph row whose accepted applications generate the displayed Picard iterates.*
3. *I is the finite Picard-iterate ledger, recording the initial point and the visible rows $x_0, x_1, \ldots, x_n$ produced by repeated graph reads of T.*
4. *L is the strict rational contraction ledger, storing a nonnegative bound below one and the adjacent-distance comparisons attached to the iterate ledger.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *route extracted from the finite orbit ledger and the strict ratio ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row used when the orbit is read as a regular rational sequence approximation.*
7. *E is the* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer row, exposing where a completion argument may later consume the orbit without being supplied by it.*
8. *H is componentwise* hsame *transport for the metric carrier, self-map graph, iterate ledger, ratio ledger, modulus route, regular-sequence handoff, completion consumer, replay, provenance, and local naming rows.*
9. *C is the displayed* Cont *replay from contraction-map admission through Picard iteration, ratio comparison, Cauchy-modulus handoff, regular-sequence handoff, and completion-facing use.*

10. *P is the* Pkg *provenance over* ContractionMapping$^{\uparrow}$, PicardContraction$^{\uparrow}$, CauchyModulus$^{\uparrow}$, CompleteMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyContractionOrbit}^{\uparrow}}$ *row.*

The carrier exposes a finite orbit-to-modulus surface. It contains no coordinate for a selected fixed point, host limit, quotient stream, ambient completeness proof, countable-choice principle, or Real$^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyContractionOrbitUp.CauchyContractionOrbitTasteGate single carrier alignment`

Theorem 2350.2 (CauchyContractionOrbit NameCert obligations)**.** *For an accepted* CauchyContractionOrbit$^{\uparrow}$ *carrier $O = (X, T, I, L, M, R, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyContractionOrbit}^{\uparrow}}$ *surface consists of carrier admission, contraction-map visibility, finite Picard-iterate ledger visibility, strict ratio-ledger stability, Cauchy-modulus exposure,* RegSeqRat$^{\uparrow}$ *and* CompleteMetric$^{\uparrow}$ *handoff visibility,* Real$^{\uparrow}$ *seal separation, componentwise transport, continuation replay, provenance, and local naming for the finite packet of Definition 2350.1.*

Proof. Carrier admission projects the displayed tuple. The metric row X, graph row T, finite Picard ledger I, and strict ratio ledger L give the contraction-map and iterate data read by the certificate.

The Cauchy-modulus row M is exposed only after those finite rows are visible. The handoff rows R and E record where regular rational sequence and complete-metric consumers may later read the orbit, while the Real$^{\uparrow}$ entry in the provenance row remains a seal boundary rather than an endpoint proof.

Transport, replay, provenance, and local naming are componentwise. The rows H, C, P, N preserve exactly the carrier coordinates listed above, so the certificate exports the orbit-to-modulus surface without adding host limits, quotient streams, countable choice, or real completeness. □

Theorem 2350.3 (CauchyContractionOrbit Cauchy-modulus handoff)**.** *Every accepted* CauchyContractionOrbit$^{\uparrow}$ *carrier exposes a* CauchyModulus$^{\uparrow}$ *route before any* Real$^{\uparrow}$ *seal is read. The finite orbit ledger I and strict ratio ledger L determine the modulus row M, and every regular-sequence or complete-metric consumer must pass through*

$$X,\ T,\ I,\ L,\ M,\ R,\ E,\ H,\ C,\ P,\ N.$$

Thus the packet supplies a Cauchy-modulus handoff for the constructive contraction route, not a selected fixed point, host limit, quotient stream, ambient completeness theorem, countable-choice construction, or Real$^{\uparrow}$ *completeness proof.*

Proof. Read the finite Picard ledger I. It contains only displayed iterate rows generated from the self-map graph T, so each downstream distance comparison is anchored in the same metric carrier X.

Read the strict ratio ledger L. Its below-one rational bound and adjacent-distance comparisons are the data used by the modulus row M; no infinite stream or host limit is consulted.

The rows R and E are therefore downstream handoff rows. They may consume the already exposed modulus surface for regular rational sequence or complete-metric purposes, but neither row turns the packet into a real-number endpoint or a fixed-point selector.

Finally H, C, P, N transport and replay the same finite route. Since the Real$^{\uparrow}$ dependency appears only in the provenance and seal boundary, the Cauchy-modulus route is available before any real-completeness seal is read. □

Falsifiable prediction: Every accepted $\mathsf{CauchyContractionOrbit}^{\uparrow}$ read factors through a contraction-map row, finite Picard-iterate ledger, strict ratio ledger, CauchyModulus row, RegSeqRat handoff, CompleteMetric consumer row, hsame transport, Cont replay, Pkg provenance, and NameCert row before any RealUp endpoint seal.

Independence witness: contractionmapping, picardcontraction, cauchymodulus, completemetric, regseqrat, real: none is bijective with $\mathsf{CauchyContractionOrbit}^{\uparrow}$ because the packet jointly stores the map graph, finite orbit ledger, strict ratio ledger, modulus extraction row, regular-sequence handoff, completion-facing consumer row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContractionOrbit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyContractionOrbit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2350.1, Definition 2350.2, and Definition 2350.3 seed the finite contraction-orbit packet that exposes a Cauchy-modulus handoff before endpoint sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyContractionOrbit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected fixed points, host limits, quotient streams, ambient completeness, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure asks for checked carrier admission, contraction-map visibility, Picard-ledger visibility, strict ratio stability, Cauchy-modulus exposure, RegSeqRat and CompleteMetric handoff visibility, Real seal separation, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{CauchyContractionOrbit}^{\uparrow}$ packet is generated from a metric carrier, self-map graph, finite Picard ledger, strict ratio ledger, CauchyModulus route, RegSeqRat handoff, CompleteMetric consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 2351

A Concrete Naming Certificate for $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ packet records regulated-integral values through displayed Cauchy windows. It reads the regulated-integral surface of chapter 1557, the Riemann–Stieltjes sibling route of chapter 1637, the dyadic step rows of chapter 428, the regular rational readback of chapter 301, the finite stream windows of chapter 126, and the terminal real-name boundary of chapter 38. The packet names integral values by finite Cauchy-read obligations, not by host function equality, quotient streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2351.1 (Regulated Cauchy integral carrier)**.** *A* $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, T, A, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the regulated integrand and regulated-integral row, read through* $\mathsf{RegulatedIntegral}^{\uparrow}$ *and carrying only the displayed finite integration data.*
2. *T is the tagged partition row, including the tags, cells, endpoint reads, and the sibling compatibility surface with* $\mathsf{RiemannStieltjes}^{\uparrow}$ *when an integrator row is present.*
3. *A is the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximation ledger used to compute the finite integral sums on the displayed partition.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *Cauchy window schedule listing the precision windows actually requested by a consumer of the integral value.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite sums in A through the requested windows in W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after G, T, A, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the integrand, partition, step approximation, window schedule, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from regulated-integral reads to tagged partitions, from tagged partitions to dyadic step sums, from step sums to Cauchy windows, from windows to* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and from readback to the* $\mathsf{Real}^{\uparrow}$ *seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, T, A, W, R, E, H, C, P, N$. It has no coordinate for host function equality, quotient streams, selected limiting partitions, countable choice, or an ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.RegulatedCauchyIntegralUp.TasteGate.RegulatedCauchyIntegralTasteGate`
`single carrier alignment`

Theorem 2351.2 (Regulated Cauchy integral NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ *carrier $K = (G, T, A, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission, regulated-integral source exposure through G, tagged-partition exposure through T, dyadic step-sum exposure through A, Cauchy-window scheduling through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed replay through C, provenance through P, local naming through N, and non-escape from host function equality, quotient streams, selected limiting partitions, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2351.1. The accepted packet exposes exactly the regulated-integral source, tagged partition, dyadic step approximation, Cauchy window schedule, regular readback, real seal, and structural rows.

The integration read is finite. The row G supplies the regulated-integral source, T supplies the tagged partition data, and A supplies the dyadic step sums visible at the requested tolerances.

The Cauchy read is downstream. The row W records the requested windows, R records the regular rational readback from those windows, and E is the only Real-facing seal. Since the excluded principles have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2351.3 (Regulated Cauchy integral window readback exactness)**.** *Let $K = (G, T, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ *packet. Every displayed Cauchy window in W reads the integral value through the same dyadic step approximation ledger A over the same tagged partition T and determines the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row R. The readback is exact at the packet boundary: no consumer can replace the displayed window route by quotient stream equality, a host limiting partition, countable choice, or host real equality.*

Lean4 ✓ `BEDC.Derived.RegulatedCauchyIntegralUp.RegulatedCauchyIntegralWindowReadbackExactness`

Proof. Start with a displayed window in W. The carrier gives no detached stream coordinate, so the window can be read only through the continuation route from G to T and from T to A.

The dyadic step ledger fixes the finite sum read. Componentwise transport through H and replay through C carry the same tagged cells, values, and tolerance rows into the regular rational readback coordinate R.

Thus every accepted window reaches the same R by the displayed route. The absent quotient, host-limit, choice, and host-equality coordinates cannot alter the readback at the packet boundary. □

Theorem 2351.4 (Regulated Cauchy integral Real seal non-escape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ *carrier is available only as the endpoint of the route*

$$\mathsf{RegulatedIntegral}^{\uparrow},\ \mathsf{RiemannStieltjes}^{\uparrow},\ \mathsf{DyadicStepFunction}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, a Real-facing consumer must first read the regulated-integral source G, tagged partition T, dyadic step approximation A, Cauchy window schedule W, and regular readback R before it can read E. The packet exports no host function equality, quotient stream, countable-choice selector, selected limiting partition, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegulatedCauchyIntegralUp.RegulatedCauchyIntegralCarrier real seal nonescape`

Proof. Project the seal coordinate of Definition 2351.1. The row E is downstream from G, T, A, W, R and is transported and replayed only by H and C.

Apply Definition 2351.2. It identifies the regulated-integral, partition, dyadic step, window, readback, seal, transport, replay, provenance, and naming rows as the complete local certificate surface.

Apply Definition 2351.3. The regular readback row is fixed by the displayed Cauchy windows over the same finite integration ledger. Therefore the Real seal cannot be reached through any omitted host or completion coordinate. □

Falsifiable prediction: Every accepted $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ value read factors through a displayed $\mathsf{RegulatedIntegral}^{\uparrow}$ source, tagged partition, $\mathsf{DyadicStepFunction}^{\uparrow}$ approximation, $\mathsf{StreamName}^{\uparrow}$ Cauchy window schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regulatedintegral, riemannstieltjes, dyadicstepfunction, streamname, regseqrat, real: $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ is not bijective to any listed sibling because it binds regulated integral source data, tagged partitions, dyadic step approximations, Cauchy windows, regular rational readback, Real sealing, transport, replay, provenance, and local NameCert rows into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedCauchyIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ packet is generated from a regulated-integral source row, tagged partition row, dyadic step approximation ledger, Cauchy window schedule, RegSeqRat readback, Real seal, componentwise transport, displayed continuation replay, package provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedCauchyIntegral}^{\uparrow}}$, seed)

Scope closed: Definition 2351.1, Definition 2351.2, Definition 2351.3, and Definition 2351.4 seed the regulated-integral Cauchy-read boundary over tagged partitions, dyadic step approximations, StreamName windows, RegSeqRat readback, and Real seal data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegulatedCauchyIntegral}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient stream completion, selected limiting partitions, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-integral source exposure, tagged-partition exposure, dyadic step-sum exposure, Cauchy-window readback exactness, Real-seal non-escape, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.RegulatedCauchyIntegralUp.

Chapter 2352

A Concrete Naming Certificate for $\mathsf{SpectralRadius}^{\uparrow}$

Following Gelfand and standard Banach-algebra spectral theory, the $\mathsf{SpectralRadius}^{\uparrow}$ packet records the finite BEDC surface by which a displayed Banach-algebra element exposes operator-power norm-growth rows and resolvent-test rows before any spectrum, maximal ideal space, or host algebra quotient is available. It is a textbook neighbour of the operator-algebra frontier: it reads the complete normed algebra carrier of chapter 2189, the bounded-operator route of chapter 1644, the public operator-norm carrier of chapter 3603 for $\mathsf{OperatorNorm}^{\uparrow}$, the stability obligation of Definition 94.3, and the compact-operator dependency of chapter 1952.

Definition 2352.1 (Spectral radius carrier)**.** *A* $\mathsf{SpectralRadius}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, a, W, Q, G, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{BanachAlgebra}^{\uparrow}$ *row carrying multiplication, norm, completion, product control, transport, replay, provenance, and local naming.*
2. *a is the carried algebra element whose powers are inspected.*
3. *W is the finite operator-power window. For each displayed natural index in the packet it records the product row for a^n and the corresponding* $\mathsf{OperatorNorm}^{\uparrow}$ *or algebra-norm endpoint.*
4. *Q is the norm-growth comparison ledger. It records the rational or* $\mathsf{Real}^{\uparrow}$ *bound rows used to compare the observed power norms with the requested growth threshold.*
5. *G is the Gelfand-style radius readback row. It is only a finite readback from the displayed windows W and comparisons Q; it is not a limit of all powers.*
6. *E is the resolvent-test row. For a displayed scalar-window request it records the candidate inverse-check surface and the refusal row saying that no inverse is exported unless the local Banach-algebra ledger displays the needed multiplication and unit witnesses.*
7. *H records componentwise* hsame *transport for A, a, W, Q, G, E and the structural rows.*
8. *C records displayed* Cont *replay of the route*

$$\mathsf{BanachAlgebra}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto W, Q, G, E \longmapsto \mathsf{SpectralRadius}^{\uparrow}.$$

9. *P is the* Pkg *provenance over* $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SpectralRadius}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through the Banach-algebra source, the displayed element, the finite power-window rows, norm-growth comparisons, resolvent-test rows, transport, replay, provenance, and local naming. It has no coordinate for a completed spectrum, the Gelfand transform, maximal ideals, host operator equality, quotient completion, selected approximate eigenvectors, or choice.

Lean4 ✓ `BEDC.Derived.SpectralRadiusUp.SpectralRadiusTasteGate single carrier alignment`

Theorem 2352.2 (Spectral radius NameCert obligations)**.** *For an accepted* $\mathsf{SpectralRadius}^{\uparrow}$ *carrier*

$$S = (A, a, W, Q, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SpectralRadius}^{\uparrow}}$ *surface consists exactly of carrier admission, Banach-algebra source compatibility, finite power-window stability, norm-growth readback, resolvent-test boundary, classifier transport, continuation replay, provenance, and local naming. A downstream operator-algebra consumer may inspect the displayed power norms and the displayed resolvent-test outcomes, but it receives no completed spectrum, no spectral theorem, no compact-operator eigenvalue list, no maximal ideal space, and no host equality of operators.*

Proof. Project the carrier of Definition 2352.1. The first two rows fix the Banach-algebra source and the carried element, while W, Q, G, E are the only analytic rows available to a consumer.

Power-window stability is componentwise. Transport through H moves each displayed power product and norm endpoint along the Banach-algebra classifier, and replay through C returns to the same finite window before any radius readback is public.

Norm-growth readback uses Q and G. These rows compare only the displayed power norms already present in W with the requested growth threshold. They do not quantify over all powers or select a host limit.

The resolvent boundary is the row E. It records tests against displayed scalar windows and local inverse-check rows, but it cannot export an inverse or a spectrum unless those rows are already visible in the Banach-algebra ledger.

Finally P and N name only this finite surface. The excluded spectral, representation-theoretic, quotient, choice, and host-equality objects have no coordinate in the packet, so they cannot be recovered by a downstream read. □

Theorem 2352.3 (Spectral radius resolvent boundary)**.** *Every resolvent-facing read of an accepted* $\mathsf{SpectralRadius}^{\uparrow}$ *packet factors through the same displayed Banach-algebra source row A, carried element row a, finite power-window row W, norm-growth ledger Q, radius readback row G, resolvent-test row E, and structural rows H, C, P, N. In particular, a resolvent request cannot replace the finite readback by a completed spectrum, a Gelfand-transform equality, a compact-operator eigenvalue theorem, selected approximate eigenvectors, quotient completion equality, or countable choice.*

Proof. Start with an accepted packet and the resolvent request. Carrier admission exposes E only after the Banach-algebra row A, element row a, power windows W, and norm-growth ledger Q have been displayed.

The radius readback G is therefore already tied to the finite windows. Any scalar test entering E must use the same route through C and the same componentwise transport through H.

The sibling operator rows add no hidden coordinate. The bounded-operator surface supplies action and norm-bound ledgers, the operator-norm obligation supplies the scalar bound row, and the compact-operator chapter supplies only compactness schedules when separately present.

Since the packet has no field for a completed spectrum, Gelfand transform, eigenvector selector, quotient equality, or choice schedule, the resolvent-facing read remains a boundary over the displayed finite rows. □

Falsifiable prediction: Every accepted $\mathsf{SpectralRadius}^{\uparrow}$ resolvent-facing read exposes the Banach-algebra source, element row, finite power-window row, norm-growth ledger, radius readback row, resolvent-test row, componentwise transport, replay, provenance, and local naming before any spectral-radius conclusion is public.

Independence witness: banachalgebra, boundedlinearoperator, operatornorm, compactoperator: BanachAlgebraUp lacks the finite power-window and resolvent-test rows; BoundedLinearOperatorUp lacks the Banach-algebra product-power ledger; OperatorNormUp supplies scalar norm bounds without naming the radius packet; CompactOperatorUp supplies image-net schedules without the resolvent boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralRadius}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralRadius}^{\uparrow}$ packet is generated from a BanachAlgebraUp source, a carried element, finite operator-power norm-growth rows, a radius readback row, a resolvent-test row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpectralRadius}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2352.1, Definition 2352.2, Definition 2352.3, the falsifiable prediction, and the independence witness seed the finite spectral-radius route over BanachAlgebraUp, BoundedLinearOperatorUp, OperatorNormUp, CompactOperatorUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpectralRadius}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the spectral theorem, compact-operator eigenvalue decomposition, Gelfand representation, maximal ideal space, completed spectrum, quotient completion, selected approximate eigenvectors, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite power-window stability, norm-growth readback, resolvent-test boundary, classifier transport, and consumer non-escape for BEDC.Derived.SpectralRadiusUp.

Chapter 2353

A Concrete Naming Certificate for $\mathsf{ConnectedSpace}^{\uparrow}$

Following Hausdorff and Bishop–Bridges topology, the $\mathsf{ConnectedSpace}^{\uparrow}$ packet records connectedness as a finite refusal surface for displayed clopen separations over $\mathsf{Topology}^{\uparrow}$. It sits beside the topology carrier of chapter 88, the metric and real consumers of chapter 57 and chapter 38, the continuity route of chapter 59, the circle boundary of chapter 58, and the chain-connected metric comparison of $\mathsf{ChainConnectedMetric}^{\uparrow}$. The certificate names the topological connectedness interface without adding excluded-middle separation, host subset extensionality, open-cover compactness, or a selected global point.

Definition 2353.1 (ConnectedSpace carrier)**.** *A* $\mathsf{ConnectedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, O, S, F, M, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-set classifier row, including the visible open indices, membership ledger, finite meet rows, union rows, and boundary opens inspected by connectedness consumers.*
2. *O is the clopen candidate row. It records a displayed open row together with the complementary open row that would form a separation if both sides were inhabited in the accepted packet.*
3. *S is the clopen-separation attempt row. It stores the finite attempt to split the carrier into two disjoint nonempty clopen pieces and marks the route as refused unless the attempt collapses to the empty or whole boundary row already present in T.*
4. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pullback row. It records only displayed inverse-image opens and their transported clopen attempts for continuous consumers.*
5. *M is the optional* $\mathsf{Met}^{\uparrow}$ *consumer row, used when a metric-generated topology requests connectedness data through balls and finite open ledgers.*
6. *R is the optional* $\mathsf{Real}^{\uparrow}$ *consumer row, used by real-line and interval routes after the topology and pullback rows have been displayed.*
7. *Q is the* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *comparison row. It records that a metric chain-connected witness may feed the topological refusal surface only through the visible metric, topology, and real rows.*

8. *H records componentwise* hsame *transport for the topology classifier, clopen attempt, pullback, optional metric and real consumers, chain-connected comparison, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a connectedness read through*

$$T, O, S, F, M, R, Q \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the S^1 circle source,* $\mathsf{ChainConnectedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConnectedSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for excluded-middle decomposition of subsets, host subset extensionality, quotient topology equality, open-cover compactness, global choice of a point, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ConnectedSpaceUp.ConnectedSpaceTasteGate single carrier alignment`

Theorem 2353.2 (ConnectedSpace carrier admission)**.** *For every accepted* $\mathsf{ConnectedSpace}^{\uparrow}$ *carrier*

$$K = (T, O, S, F, M, R, Q, H, C, P, N),$$

the local carrier admission row is exhausted by the displayed topology classifier, clopen attempt, continuous pullback, optional metric and real consumers, chain-connected comparison, componentwise transport, replay, provenance, and local naming rows. No connectedness consumer may inspect a clopen separation before those rows are present.

Proof. Project the carrier of Definition 2353.1. The projection exposes exactly the rows $T, O, S, F, M, R, Q, H, C, P,$

The topology row is read first, because every clopen attempt is expressed as a pair of displayed open rows over the same $\mathsf{Topology}^{\uparrow}$ classifier. The optional metric, real, circle, and chain-connected consumers are downstream rows; they do not add a second connectedness carrier.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier definition contains no further coordinate, carrier admission is precisely the displayed finite packet. □

Theorem 2353.3 (ConnectedSpace classifier stability)**.** *Let $K = (T, O, S, F, M, R, Q, H, C, P, N)$ and $K' = (T', O', S', F', M', R', Q', H', C', P', N')$ be accepted* $\mathsf{ConnectedSpace}^{\uparrow}$ *carriers. If the topology classifier rows are* hsame*, the clopen-attempt rows are transported by the displayed component of H, and the consumer rows F, M, R, Q match componentwise, then every connectedness read accepted for K is accepted for K' through the same replay and provenance route.*

Proof. Use the componentwise transport row in H. It carries the topology classifier first, so the open indices, membership ledger, finite meets, unions, and boundary opens remain the same visible topology surface.

Transport the clopen-attempt row next. The attempt remains a displayed open-complement pair over the transported topology classifier, and its refusal status remains attached to the same empty-or-whole boundary alternatives.

The rows F, M, R, Q are transported after the classifier and attempt rows. Thus continuous, metric, real, circle, and chain-connected consumers receive the same finite route, and C, P, N replay, source, and name that route for K'. □

Theorem 2353.4 (ConnectedSpace clopen-separation refusal)**.** *For an accepted* $\mathsf{ConnectedSpace}^{\uparrow}$ *carrier* $K = (T, O, S, F, M, R, Q, H, C, P, N)$*, every clopen separation attempt in* S *is refused unless the displayed clopen row in* O *collapses through* T *to the empty boundary open or to the whole-carrier boundary open. The refusal is a finite ledger row and is not an appeal to excluded middle over arbitrary subsets.*

Proof. Read the attempt row S together with the clopen row O. Both rows are indexed by the open-set classifier T, so the only admissible alternatives are the displayed boundary opens already present in the topology packet.

If the candidate is the empty boundary, the attempted separation has no left inhabited component. If the candidate is the whole-carrier boundary, the complementary side has no displayed inhabited component.

All other attempts remain refused by the local row S. The refusal is stored as finite NameCert data over T, O, H, C, P, N, so it does not decide arbitrary host subsets or import a global separation principle. □

Theorem 2353.5 (ConnectedSpace continuous-pullback preservation)**.** *Let* $K = (T, O, S, F, M, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{ConnectedSpace}^{\uparrow}$ *carrier. Any* $\mathsf{Continuous}^{\uparrow}$ *consumer that pulls a clopen attempt back along a displayed map must read the inverse-image row through* F *and then reuse the same refusal route* T, O, S, H, C, P, N*. Hence the pullback of a refused clopen separation remains refused inside the connectedness packet.*

Proof. Project the pullback row F. It stores only displayed inverse images of open rows from the topology classifier and their transported clopen attempts.

Apply the refusal theorem to the transported attempt. The pullback candidate is still read as a clopen row over T and can pass only if it collapses to the displayed empty or whole boundary row.

The replay and provenance rows do not create a new separation object. They only route the continuous consumer through F and back to T, O, S, H, P, N, so the refused status is preserved. □

Theorem 2353.6 (ConnectedSpace ledger nonescape)**.** *Every* $\mathsf{ConnectedSpace}^{\uparrow}$ *read exported from an accepted carrier*

$$K = (T, O, S, F, M, R, Q, H, C, P, N)$$

factors through $\mathsf{Topology}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, *optional* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers, the* S^1 *circle source,* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. It exports no excluded-middle clopen split, no host subset extensionality, no quotient topology equality, no open-cover compactness, and no selected global point.*

Proof. Combine carrier admission with the classifier-stability and clopen-refusal theorems. These place every accepted read inside the finite rows $T, O, S, F, M, R, Q, H, C, P, N$.

The continuous-pullback theorem handles the only consumer route that can manufacture a new clopen attempt. The attempt is immediately returned to the same refusal ledger.

Since the optional metric, real, circle, and chain-connected rows are consumer handoffs rather than generators of a host separation principle, the listed route exhausts the export surface and none of the refused objects can escape the ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConnectedSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConnectedSpace}^{\uparrow}$ packet is generated from a Topology open-set classifier, a displayed clopen-attempt row, a finite refusal ledger, continuous pullback rows, optional Metric and Real consumer rows, a circle-source

handoff, a ChainConnectedMetric comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ConnectedSpace}\uparrow}$, seed)

Scope closed: Definition 2353.1, Definition 2353.2, Definition 2353.3, Definition 2353.4, Definition 2353.5, and Definition 2353.6 seed the finite connectedness refusal surface over topology, continuity, metric, real, circle, and chain-connected consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{ConnectedSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close excluded-middle separation, host subset extensionality, quotient topology equality, open-cover compactness, selected points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, clopen-separation refusal, continuous-pullback preservation, and ledger nonescape for BEDC.Derived.ConnectedSpaceUp.

Chapter 2354

A Concrete Naming Certificate for $\mathsf{PointwiseContinuityModulus}^{\uparrow}$

Following Bishop–Bridges pointwise continuity on metric spaces, the $\mathsf{PointwiseContinuityModulus}^{\uparrow}$ packet records the local radius surface that a displayed continuous map supplies at a single named source point and target tolerance. It sits between the metric source of chapter 57, the graph and pointwise continuity rows of chapter 130, the rational tolerance rows of chapter 37, the global modulus interface of chapter 2228, and the compact finite-net extraction of chapter 2292. The packet names one point-indexed local radius ledger; it is not a uniform modulus, not a compactness principle, not a selected Lebesgue number, and not host semantic continuity.

Definition 2354.1 (Pointwise continuity modulus carrier)**.** *A* $\mathsf{PointwiseContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, Y, F, x, \epsilon, \delta, R, U, K, H, C, Q, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row whose point classifier and distance comparisons supply the neighbourhood side of the local read.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose distance comparisons supply the tolerance side.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row from X to Y, including the displayed pointwise continuity evidence read at the named point.*
4. *x is the finite source-point name at which the local radius is certified.*
5. *ϵ is the requested* $\mathsf{Rat}^{\uparrow}$ *target tolerance row.*
6. *δ is the offered* $\mathsf{Rat}^{\uparrow}$ *source radius row.*
7. *R is the local radius ledger tying x, ϵ, δ to the pointwise continuity row carried by F.*
8. *U is the optional* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *comparison row, read only when a downstream consumer asks whether the local radius is compatible with a global modulus surface.*
9. *K is the optional* $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$ *extraction row, read only when compact finite-net folding consumes the point-indexed radius surface.*
10. *H records componentwise* hsame *transport for the two metric rows, graph row, point row, tolerance row, radius row, comparison rows, replay, provenance, and local naming.*

11. *C records displayed* Cont *replay from a target-tolerance request through the local radius ledger and onward to any global or compact modulus consumer.*

12. *Q is the* Pkg *provenance over* PointwiseContinuityModulus$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Rat$^{\uparrow}$, UniformContinuityModu CompactUniformContinuityModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* NameCert$_{\text{PointwiseContinuityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, Y, F, x, \epsilon, \delta, R, U, K, H, C, Q, N$. It has no coordinate for a host neighbourhood system, a selected global modulus function, compact open-cover data, sequence extraction, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.PointwiseContinuityModulusUp.PointwiseContinuityModulusTasteGate single carrier alignment`

Theorem 2354.2 (Pointwise continuity modulus NameCert obligations)**.** *For an accepted* PointwiseContinuityModu *carrier $P = (X, Y, F, x, \epsilon, \delta, R, U, K, H, C, Q, N)$, the local* NameCert$_{\text{PointwiseContinuityModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, source-target metric lock through X and Y, graph compatibility through F, point-indexed tolerance visibility through x and ϵ, radius exactness through δ and R, optional global-modulus compatibility through U, optional compact-extraction compatibility through K, structural transport through H, displayed replay through C, provenance through Q, and local naming through N.*

Lean4 ✓ `BEDC.Derived.PointwiseContinuityModulusUp.PointwiseContinuityModulusCarrier namecert obligations`

Proof. Project the carrier of Definition 2354.1. The only source of a local radius is the displayed tuple x, ϵ, δ, R attached to the continuous-map row F over the two metric rows X and Y.

The ledger R binds the requested target tolerance to the offered source radius at the named point. Thus the packet records a local point-indexed read, not a uniform radius for all source points and not a host-level continuity assertion.

The optional rows U and K are downstream comparison surfaces. A UniformContinuityModulus$^{\uparrow}$ consumer may read U only after the local radius ledger has been displayed, and the compact extraction route of chapter 2292 may read K only as a compact finite-net consumer of the same point-indexed ledger.

Rows H, C, Q, N transport, replay, source, and name the same finite route. Since no host neighbourhood system, selected global modulus function, compact open-cover datum, sequence extraction principle, countable-choice row, or ambient-completeness row occurs in the carrier, the listed obligations exhaust the NameCert surface. □

Theorem 2354.3 (Pointwise radius handoff to uniform extraction)**.** *Every accepted* PointwiseContinuityModulus$^{\uparrow}$ *carrier exports a local-radius read through the finite route*

Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Rat$^{\uparrow}$, UniformContinuityModulus$^{\uparrow}$, CompactUniformContinuityModulus$^{\uparrow}$, BHist, hsame, Co

A downstream uniform-modulus or compact-uniform-modulus consumer receives the point row x, the requested target tolerance ϵ, the offered source radius δ, and the ledger R before it may consult either U or K. The route exports no selected global modulus function, no open-cover compactness, no selected Lebesgue number, no sequence extraction principle, and no ambient complete metric space.

Proof. Start with the obligation surface of Definition 2354.2. It fixes the two metric rows, the continuous-map graph row, the point row, the requested tolerance, the offered radius, and the local ledger as the only pointwise source of modulus information.

Now read a uniform consumer. The row U is available only as a comparison against the already displayed pointwise ledger, so it cannot choose a radius independently of x, ϵ, δ, R.

Finally read a compact extraction consumer. The compact-uniform-continuity route of chapter 2292 consumes pointwise radius rows center by center before folding them into a compact finite-net output. Therefore K is downstream of the same local ledger, and the excluded host compactness and global selection principles have no coordinate in the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseContinuityModulus}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointwiseContinuityModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 2354.1, Definition 2354.2, and Definition 2354.3 seed the finite local-radius route over metric rows, ContinuousMap graph rows, Rat tolerance rows, UniformContinuityModulus comparison rows, CompactUniformContinuityModulus extraction rows, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointwiseContinuityModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global uniform modulus, compact finite-net extraction, selected Lebesgue numbers, host continuity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric lock, point-indexed radius exactness, UniformContinuityModulus compatibility, CompactUniformContinuityModulus handoff, structural replay, and ledger non-escape for BEDC.Derived.PointwiseContinuityModulusUp.

Constructive story: A $\mathsf{PointwiseContinuityModulus}^{\uparrow}$ packet is generated from source and target MetricUp rows, a ContinuousMapUp graph row, one named source point, a RatUp target tolerance, a RatUp source radius, a local radius ledger, optional UniformContinuityModulusUp and CompactUniformContinuityModulusUp comparison rows, componentwise hsame transport, Cont replay, provenance, and local naming.

Chapter 2355

A Concrete Naming Certificate for $\mathsf{CompleteSeparatedMetric}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley-style separated metric completion, the $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ packet records the standard landing object whose completion route has both displayed limit existence and zero-distance uniqueness. It sits after the completion surface of chapter 1506, the separated comparison boundary of chapter 1411, the complete-limit witness of chapter 128, the finite Cauchy-name equality boundary of chapter 1412, and the terminal real-name seal of chapter 38. The packet names the constructive complete separated metric object without adding quotient completion classes, selected representatives, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2355.1 (CompleteSeparatedMetric carrier)**.** *A* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, C, S, E, R, H, K, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, including the displayed metric carrier, completion handoff, and finite tolerance readback surface.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-existence row, recording that every accepted regular Cauchy point name exposes a displayed limit, modulus, and convergence-distance ledger.*
3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance identity row, recording that two displayed carried observations with real zero distance are identified by the point classifier.*
4. *E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *boundary row by which two Cauchy presentations of the same completion-facing point are compared before any limit equality is read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *zero-distance readback row used to consume metric-distance witnesses only through the terminal real-name seal.*
6. *H records componentwise* hsame *transport for the metric source, complete-limit row, separatedness row, Cauchy-equivalence boundary, real readback, replay row, provenance row, and local naming row.*
7. *K records the displayed* Cont *replay from Cauchy observations through completion handoff, limit existence, zero-distance comparison, and separated classifier identity.*

8. *P is the* Pkg *provenance over* MetricCompletion$^{\uparrow}$, CompleteMetric$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, CauchySequenceEquivalenc Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{CompleteSeparatedMetric}^{\uparrow}}$ *row.*

The carrier is the paired complete-and-separated completion surface as finite BEDC data. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of points, or a theorem asserting ambient completeness of Real$^{\uparrow}$.

Theorem 2355.2 (CompleteSeparatedMetric NameCert obligations)**.** *For an accepted* CompleteSeparatedMetric$^{\uparrow}$ *carrier $Q = (X, C, S, E, R, H, K, P, N)$, the local* NameCert$_{\text{CompleteSeparatedMetric}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the* MetricCompletion$^{\uparrow}$ *source row,* CompleteMetric$^{\uparrow}$ *limit-existence row,* SeparatedMetric$^{\uparrow}$ *zero-distance identity row,* CauchySequenceEquivalence$^{\uparrow}$ *boundary row,* Real$^{\uparrow}$ *readback row, componentwise transport, continuation replay, provenance row, and local naming row;*

2. *classifier stability, stating that the accepted classifier route is preserved by the* hsame *transports in H and replayed by K through the same finite rows;*

3. *completion handoff, stating that any completion-facing consumer first reads the source completion row X and the complete-limit row C before seeing a displayed limit;*

4. *separated uniqueness, stating that two displayed limits for the same Cauchy presentation are compared through E, read as zero through R, and then identified only through the separatedness row S;*

5. *ledger non-escape, stating that the packet exports no quotient completion object, no selected representative, no countable-choice schedule, no host equality of completion points, and no ambient* Real$^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CompleteSeparatedMetricUp.CompleteSeparatedMetricTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 2355.1. The tuple lists the completion source, complete-limit witness, separated identity route, Cauchy-equivalence boundary, real zero-distance readback, transport, replay, provenance, and local naming rows.

Classifier stability follows from the componentwise transport row H together with the replay row K. Transport moves each displayed row to a row of the same kind, and replay consumes the transported rows in the same order as the accepted classifier route.

Completion handoff is the role of X and C. A consumer cannot inspect a limit until the metric-completion source has exposed its completion-facing carrier and the complete-metric row has exposed a displayed limit witness for the regular Cauchy presentation.

Separated uniqueness uses the equivalence boundary E to compare two presentations before the limit comparison is read. The real readback row R supplies the zero-distance observation, and S is the only exported bridge from zero distance to classifier identity.

The ledger statement is an inventory check on the rows of Q. None of the displayed coordinates is a quotient completion class, selected representative, countable-choice schedule, host equality proof, or ambient completeness theorem for Real$^{\uparrow}$. □

Theorem 2355.3 (CompleteSeparatedMetric limit uniqueness)**.** *Let $Q = (X, C, S, E, R, H, K, P, N)$ be an accepted* CompleteSeparatedMetric$^{\uparrow}$ *carrier. If two displayed limit reads arise from the same*

completion-facing Cauchy point-name packet, then their agreement is witnessed only through the separated metric classifier row S and the zero-distance readback row R after the Cauchy-equivalence boundary row E has compared the presentations. The packet exports classifier identity through this displayed route; it does not export host equality of points, quotient completion equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompleteSeparatedMetricUp.CompleteSeparatedMetricLimitUniqueness`

Proof. Project the complete and separated rows of the carrier. The complete-limit row C supplies the two displayed limit reads, while the separatedness row S is the only coordinate that can turn a zero-distance comparison into classifier identity.

Use the boundary row E to compare the two Cauchy presentations of the same point-name packet. This keeps the comparison inside the finite Cauchy-equivalence surface before any limit identity is read.

The zero-distance witness is then consumed through the $\mathsf{Real}^{\uparrow}$ readback row R. Applying the separated classifier route S yields agreement of the displayed limit reads as BEDC classifier identity.

Finally, H, K, P, N transport, replay, source, and name this same route. Since the carrier has no coordinate for host equality, quotient completion equality, selected representatives, countable choice, or ambient Real completeness, no stronger uniqueness object is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ packet is generated from a MetricCompletion source row, a CompleteMetric limit-existence row, a SeparatedMetric zero-distance identity row, a CauchySequenceEquivalence boundary row, a RealUp readback row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2355.1 and Definition 2355.2 state the finite complete separated metric certificate surface over displayed completion, complete-limit, separatedness, Cauchy-equivalence, real readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient completion equality, selected representatives, countable choice, host equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, completion handoff, separated uniqueness, and ledger non-escape for the same finite packet.

Chapter 2356

A Concrete Naming Certificate for $\mathsf{MetricProjection}^{\uparrow}$

Following Hilbert projection theory and constructive convex analysis, the $\mathsf{MetricProjection}^{\uparrow}$ packet records the nearest-point surface for a displayed closed convex subset of a Hilbert carrier as finite BEDC data. It sits after the Hilbert source of chapter 91, the closed convex source of chapter 208, the metric distance ledger of chapter 57, the complete metric limit surface of chapter 128, and the real-name readback of chapter 38. The packet names the projection route without importing a host nearest-point selector, quotient equality of points, countable choice, trichotomy, or ambient real completeness.

Definition 2356.1 (MetricProjection carrier)**.** *A* $\mathsf{MetricProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (H, C, D, I, W, E, T, R, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, including the inner-product carrier, norm ledger, and induced metric route.*
2. *C is the closed convex source row, recording the admitted subset, convex-combination stability, and closedness boundary over the Hilbert source.*
3. *D is the metric distance ledger, exposing only displayed* $\mathsf{Met}^{\uparrow}$ *distance comparisons between the external point, subset witnesses, and candidate endpoints.*
4. *I is the located infimum budget for the squared-distance values over the displayed closed convex source.*
5. *W is the approximating minimizing window, consisting of finite candidates, tolerances, and the monotone comparison schedule used to approach the located infimum.*
6. *E is the projection endpoint row, recording the carried subset point admitted as the limit of the minimizing window.*
7. *T records componentwise* hsame *transport for $H, C, D, I, W, E, R, P, N$.*
8. *R records the displayed* Cont *replay from distance comparisons through located infimum, minimizing windows, endpoint admission, and closest-point reads.*
9. *P is the* Pkg *provenance over* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetricProjection}^\uparrow}$ *row.*

The local classifier compares accepted carriers only by these displayed rows. It has no coordinate for a host projection map, selected representative, quotient equality of Hilbert points, ambient choice principle, or global completeness theorem outside the named sources.

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionTasteGate single carrier alignment`

Theorem 2356.2 (MetricProjection NameCert obligations)**.** *For an accepted* $\mathsf{MetricProjection}^\uparrow$ *carrier* $Q = (H, C, D, I, W, E, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricProjection}^\uparrow}$ *surface consists exactly of carrier exposure for the Hilbert source, closed convex source, metric distance ledger, located infimum budget, approximating minimizing window, projection endpoint, componentwise transport, replay route, package provenance, and local naming row. Every projection-facing consumer must read the endpoint through* $H, C, D, I, W, E, T, R, P, N$ *in that order of dependency, and no consumer receives a host nearest-point selector, quotient representative, trichotomy decision, countable-choice schedule, or ambient* $\mathsf{Real}^\uparrow$ *completeness theorem from the packet.*

Proof. Carrier exposure is projection from Definition 2356.1. The tuple lists the Hilbert source, closed convex source, metric distance ledger, located infimum budget, minimizing window, endpoint, transport, replay, provenance, and local naming row as its only coordinates.

The projection route is finite. Distance reads pass through D, lower-bound and approximation reads pass through I and W, and endpoint admission passes through E after the closed convex source row C and complete metric source are displayed.

The remaining rows preserve the same route. Transport T moves only the displayed coordinates, replay R consumes them in the stated dependency order, and P, N record provenance and local naming. Since the carrier lacks rows for host selectors, quotient representatives, trichotomy, countable choice, and ambient real completeness, those objects cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionCarrier namecert obligations`

Theorem 2356.3 (MetricProjection closest-point nonescape)**.** *Every accepted closest-point read exported by a* $\mathsf{MetricProjection}^\uparrow$ *carrier factors through the displayed located infimum budget* I*, approximating minimizing window* W*, and projection endpoint row* E *over the Hilbert, closed convex, metric, complete metric, and real readback sources. Thus a consumer can use the carried endpoint only as a finite BEDC projection endpoint, not as a host nearest-point selector or an unconstrained choice of representative.*

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionCarrier closest point nonescape`

Proof. Begin with an accepted closest-point read. By Definition 2356.2, the read reaches the local naming row only through $H, C, D, I, W, E, T, R, P, N$.

The rows I and W provide the located lower bound and finite approximation route for squared distances. The endpoint row E is admitted only after the minimizing window is replayed over the closed convex source and the complete metric limit surface.

Consequently the exported point is tied to the displayed finite route. Changing the endpoint by appealing to a host projection map, a selected representative, or a choice principle is not a move inside the carrier, so such data cannot escape through the $\mathsf{MetricProjection}^\uparrow$ packet. □

The endpoint row of a $\mathsf{MetricProjection}^\uparrow$ packet consumes $\mathsf{LocatedSet}^\uparrow$ only after the located distance route has displayed the parent $\mathsf{Met}^\uparrow$ row, MetricSubspace admission, located-distance ledger, rational windows, $\mathsf{Real}^\uparrow$ seal, and $\mathsf{LocatedMetric}^\uparrow$ handoff; see chapter 1541.

Theorem 2356.4 (MetricProjection endpoint separation from LocatedSet coordinates)**.** *A projection endpoint exported by an accepted* $\mathsf{MetricProjection}^{\uparrow}$ *carrier cannot be read as a* $\mathsf{LocatedSet}^{\uparrow}$ *coordinate. It is supplied only as the consumer endpoint row* E *after the* $\mathsf{LocatedSet}^{\uparrow}$ *route has displayed the parent metric row, MetricSubspace admission, located-distance ledger, rational windows,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff.*

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionCarrier locatedset endpoint separation`

Proof. Use the carrier route of Definition 2356.1. The endpoint row E appears after the Hilbert, closed convex, metric, located-infimum, and minimizing-window rows have been displayed, and it is replayed only through T, R, P, N as a projection-facing endpoint.

The LocatedSet route supplies the sibling distance data before this endpoint is read. Its parent metric row, MetricSubspace admission, located-distance ledger, rational windows, $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{LocatedMetric}^{\uparrow}$ handoff are source rows for the projection consumer, not coordinates of the endpoint itself.

Therefore a consumer cannot invert the endpoint row into a $\mathsf{LocatedSet}^{\uparrow}$ coordinate. The only accepted read is the forward projection route: first the located-set distance surface, then the $\mathsf{MetricProjection}^{\uparrow}$ endpoint row E as the consumer endpoint. □

Theorem 2356.5 (MetricProjection carrier stability obligation)**.** *Let* $Q = (H, C, D, I, W, E, T, R, P, N)$ *and* $Q' = (H', C', D', I', W', E', T', R', P', N')$ *be accepted* $\mathsf{MetricProjection}^{\uparrow}$ *carriers whose displayed Hilbert source, closed convex source, metric distance ledger, located infimum budget, minimizing window, endpoint row, transport, replay, provenance, and local naming rows agree componentwise through the classifier of Definition 2356.1. Then every accepted projection-facing read through* Q *transports to the corresponding read through* Q' *without adding a host nearest-point selector, quotient representative, trichotomy decision, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Use the carrier inventory of Definition 2356.1. The classifier compares exactly $H, C, D, I, W, E, T, R, P, N$, so any transported read must preserve those rows componentwise.

Apply Definition 2356.2. The local NameCert route reads carrier admission, distance ledgers, located infimum budget, minimizing window, endpoint, transport, replay, provenance, and naming in the displayed order.

Finally apply Definition 2356.3. Since the endpoint can escape only through I, W, E and the structural rows, classifier stability cannot introduce a selector, quotient representative, trichotomy decision, countable-choice schedule, or ambient completeness row. □

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionCarrier obligation carrier stability`

Theorem 2356.6 (MetricProjection located-infimum replay obligation)**.** *For an accepted* $\mathsf{MetricProjection}^{\uparrow}$ *carrier* $Q = (H, C, D, I, W, E, T, R, P, N)$*, every closest-point replay that consumes the located infimum budget must first read the Hilbert row* H*, closed convex row* C*, metric distance row* D*, and located infimum row* I*, then replay the minimizing window* W *before the endpoint row* E *can be admitted. The replay is the route displayed by Definition 2356.2 and remains inside the LocatedSet endpoint-separation boundary of Definition 2356.4.*

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionLocatedInfimumReplayObligation`

Proof. Start from the NameCert obligations of Definition 2356.2. They place $H, C, D, I, W, E, T, R, P, N$ in dependency order, with distance comparison and infimum data preceding the endpoint.

The located infimum row I is not an endpoint. It supplies the lower-bound and approximation budget that W replays through finite minimizing windows over the displayed closed convex source.

Use Definition 2356.4. The LocatedSet route contributes parent metric, subspace, distance, rational-window, Real-seal, and located-metric source rows before the projection endpoint is read, so the replay cannot collapse into a LocatedSet coordinate or hidden closest-point selector. □

Theorem 2356.7 (MetricProjection endpoint admission obligation)**.** *For an accepted* $\mathsf{MetricProjection}^{\uparrow}$ *carrier* $Q = (H, C, D, I, W, E, T, R, P, N)$*, the endpoint row* E *is admitted only after the minimizing-window row* W *has replayed the located-infimum route over* H, C, D, I *and after the LocatedSet source route has supplied its endpoint-separation boundary. Any consumer of* E *must then pass through* T, R, P, N *before using the endpoint as a projection-facing row.*

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionCarrierEndpointAdmissionCertificate`

Proof. Project the carrier and apply Definition 2356.6. The rows H, C, D, I, W are the only route by which the endpoint can be reached from the Hilbert, convex, metric, and located-infimum data.

Next apply Definition 2356.4. It separates the projection endpoint from the LocatedSet coordinate route and forces the source handoff to remain upstream of E.

Finally use Definition 2356.3. The endpoint consumer must pass through transport, replay, provenance, and local naming rows T, R, P, N, so endpoint admission remains a finite BEDC packet boundary and not a host projection principle. □

Theorem 2356.8 (MetricProjection public projection certificate)**.** *An accepted* $\mathsf{MetricProjection}^{\uparrow}$ *packet exports a single public projection certificate only through the rows* $H, C, D, I, W, E, T, R, P, N$*. The certificate exposes the Hilbert source, closed convex source, metric distance ledger, located infimum budget, minimizing window, endpoint admission, componentwise transport, replay, provenance, and local naming rows, and it exports no host selector, quotient equality, choice schedule, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the accepted packet through Definition 2356.1. Its public rows are exactly $H, C, D, I, W, E, T, R, P, N$, so any projection-facing export must keep the Hilbert, convex, metric, infimum, window, endpoint, transport, replay, provenance, and naming coordinates visible.

Apply Definition 2356.2 and Definition 2356.7. These force the endpoint row to appear only after the located-infimum and minimizing-window route, and then through transport, replay, provenance, and local naming.

Finally use Definition 2356.3. Since the carrier lacks rows for selectors, quotient equality, choice schedules, trichotomy, and ambient completeness, the public export is the displayed projection certificate and nothing stronger. □

Lean4 ✓ `BEDC.Derived.MetricProjectionUp.MetricProjectionCarrier public projection certificate`

Closure status for $\mathsf{NameCert}_{\mathsf{MetricProjection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricProjection}^{\uparrow}$ packet is generated from a Hilbert source, closed convex source, metric distance ledger, located infimum budget, approximating minimizing window, projection endpoint, componentwise transport, continuation replay, package provenance, and local naming row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricProjection}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 2356.1, Definition 2356.2, Definition 2356.3, Definition 2356.4, Definition 2356.5, Definition 2356.6, Definition 2356.7, and Definition 2356.8 scope $\mathsf{MetricProjection}^{\uparrow}$ over $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, located-infimum replay, endpoint admission, public projection export, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricProjection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host nearest-point selector, quotient equality of Hilbert points, countable choice, trichotomy, or ambient RealUp completeness.

Upgrade path: The theory axis is mature; formal verification and bridge verification remain pending on their independent axes.

Chapter 2357

A Concrete Naming Certificate for $\mathsf{BorelCantelli}^{\uparrow}$

Following Borel and Cantelli, the $\mathsf{BorelCantelli}^{\uparrow}$ packet records the finite event-sequence ledger used by the first Borel–Cantelli route before any downstream convergence or martingale chapter may cite eventual absence of repeated hits. It sits over the probability-space carrier of chapter 184, the random-variable observation surface of chapter 185, the distribution readback surface of chapter 186, and the independence ledger of chapter 187. The chapter names the summable-event finite-window boundary; it does not import countable choice, a host sigma-algebra completion, an almost-sure quotient, or an infinite limiting theorem as hidden data.

Definition 2357.1 (BorelCantelli carrier)**.** *A* $\mathsf{BorelCantelli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (\Omega, E, W, S, T, U, L, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row naming the probability carrier from which all event reads are taken;*
2. E *is the event-sequence row, recording the finite family of displayed event names and their membership readbacks;*
3. W *is the finite union-window row, recording the initial and tail windows through which repeated-hit requests are inspected;*
4. S *is the partial probability-sum row for the event probabilities visible in* E*;*
5. T *is the tail-sum bound row, recording the displayed finite tail budget used by the first-lemma route;*
6. U *is the finite union-bound ledger, exposing the route from event-window membership through probability subadditivity to the displayed tail bound;*
7. L *is the tail-event ledger, recording that every repeated-hit read is witnessed only through the displayed windows and tail budgets;*
8. H *records componentwise* hsame *transport for the probability source, event sequence, union windows, partial sums, tail bounds, union-bound ledger, tail-event ledger, replay, provenance, and local naming rows;*

9. *C records the displayed* Cont *replay from an event request through Ω, E, W, S, T, U, L in that order;*
10. *P is the* Pkg *provenance over* $\mathsf{BorelCantelli}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BorelCantelli}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $\Omega, E, W, S, T, U, L, H, C, P, N$. It has no coordinate for a completed measurable universe, a quotient almost-sure equality, an infinite choice of tail witnesses, or the second Borel–Cantelli independence converse.

Lean4 ✓ `BEDC.Derived.BorelCantelliUp.BorelCantelliTasteGate single carrier alignment`

Theorem 2357.2 (BorelCantelli NameCert obligations)**.** *For every accepted* $\mathsf{BorelCantelli}^{\uparrow}$ *carrier $B = (\Omega, E, W, S, T, U, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BorelCantelli}^{\uparrow}}$ *surface consists exactly of carrier admission for the probability source row, event-sequence row, finite union-window row, partial probability-sum row, tail-sum bound row, finite union-bound ledger, tail-event ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public Borel–Cantelli read must expose the same probability source and event sequence before it may inspect a finite window, a partial sum, a tail budget, or a repeated-hit ledger. No Borel–Cantelli obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 2357.1. The displayed tuple exposes exactly the probability source, event sequence, finite windows, partial sums, tail bounds, union-bound ledger, tail-event ledger, transport, replay, provenance, and local naming rows.

The event route is finite because each repeated-hit read first passes through E and W. The probability estimate is then read through S, T, U, so a consumer cannot replace the displayed summability budget while preserving the accepted packet.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for a host measurable completion, quotient almost-sure equality, infinite witness choice, or independence converse, the NameCert obligations are exhausted by the displayed rows. □

Theorem 2357.3 (BorelCantelli first-lemma finite-sum route)**.** *Every accepted* $\mathsf{BorelCantelli}^{\uparrow}$ *first-lemma read factors through the finite route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{RandomVar}^{\uparrow},\ \mathsf{Distribution}^{\uparrow},\ \mathsf{Independence}^{\uparrow}.$$

The probability source and event-sequence rows determine each finite union window and partial probability sum before the tail-event ledger is exposed. The route exports no countable-choice selector, no completed almost-sure quotient, no infinite sigma-algebra completion, and no second-lemma independence converse.

Proof. Let $B = (\Omega, E, W, S, T, U, L, H, C, P, N)$ be accepted. Carrier projection exposes the probability-space row Ω and the event-sequence row E before any window or sum can be inspected.

Replay C. A first-lemma request first reads the finite union window W, then the partial probability-sum row S, then the displayed tail budget T, and then the finite union-bound ledger U. Thus the tail-event ledger L receives only finite-window and finite-sum data.

The sibling probability, random-variable, distribution, and independence surfaces supply the named source rows and comparison ledgers, but the first-lemma route uses no independence converse. Componentwise transport through H preserves the same rows, while P, N record provenance and local naming. The excluded infinite and quotient objects are absent from the carrier, so no first-lemma read can export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{BorelCantelli}\uparrow}$.

Constructive story: A $\mathsf{BorelCantelli}^{\uparrow}$ packet is generated from a probability source row, event-sequence row, finite union-window row, partial probability-sum row, tail-sum bound row, finite union-bound ledger, tail-event ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelCantelli}\uparrow}, \mathsf{seed})$

Scope closed: Definition 2357.1, Definition 2357.2, and Definition 2357.3 seed the finite event-sequence and first-lemma route over probability windows and tail sums.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelCantelli}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sigma-algebra completion, quotient almost-sure equality, countable-choice tail selection, the second Borel–Cantelli lemma, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, event-window exactness, partial-sum stability, tail-sum bound routing, union-bound ledger exactness, tail-event ledger non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BorelCantelliUp.

Chapter 2358

A Concrete Naming Certificate for $\mathsf{YoungInequality}^{\uparrow}$

Following Hardy–Littlewood–Polya and the finite conjugate-exponent form of real analysis, the $\mathsf{YoungInequality}^{\uparrow}$ packet records the BEDC route by which a product estimate is read before it is consumed by Holder and Minkowski inequality packets. It sits between the positive-real exponent surface of chapter 1587, the finite Holder handoff of chapter 2100, and the triangle-inequality consumer route of chapter 2343. The packet is a finite two-row real-analysis certificate; it is not a host convexity theorem, an ambient integration theorem, a selected infinite sum, a quotient stream equality, or bridge checking.

Definition 2358.1 (Young inequality carrier)**.** *A* $\mathsf{YoungInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (A, B, E, R, S, V, M, D, F, H, C, P, N)$$

with the following visible coordinates:

1. *A and B are the two displayed* $\mathsf{Real}^{\uparrow}$ *rows whose product is bounded by the Young inequality read.*
2. *E is the conjugate exponent and weight ledger, recording positive exponent rows p, q, the conjugacy certificate, and the displayed weights $1/p$ and $1/q$ used in the finite product comparison.*
3. *R and S are the* $\mathsf{PositiveReal}^{\uparrow}$ *positivity rows for the two real inputs and for the exponent weights needed by the comparison.*
4. *V is the* $\mathsf{HolderInequality}^{\uparrow}$ *handoff row that reads the same conjugate ledger as the one-point precursor of a finite Holder sum.*
5. *M is the* $\mathsf{MinkowskiInequality}^{\uparrow}$ *consumer route, recording where the same finite product estimate may be used inside later triangle-inequality normalization.*
6. *D is the dyadic tolerance budget for positive-real comparison, exponent-weight rounding, product estimation, Holder handoff slack, Minkowski consumer slack, and endpoint rounding.*
7. *F is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal for the displayed Young inequality read.*
8. *H records componentwise* hsame *transport for the real rows, conjugate ledger, positivity rows, Holder handoff, Minkowski consumer route, dyadic budget, endpoint seal, replay, provenance, and local naming rows.*

9. *C records the displayed* Cont *routes for real-row readback, positivity replay, exponent-weight replay, Holder handoff, Minkowski consumer routing, dyadic-budget readback, and endpoint sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{YoungInequality}^{\uparrow}$, $\mathsf{HolderInequality}^{\uparrow}$, $\mathsf{MinkowskiInequality}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungInequality}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite Young inequality packet. It has no coordinate for ambient convexity, host integration, selected infinite sums, quotient equality of streams, or a standard bridge.

Lean4 ✓ `BEDC.Derived.YoungInequalityUp.YoungInequalityTasteGate single carrier alignment`

Theorem 2358.2 (Young inequality NameCert obligations)**.** *For every accepted* $\mathsf{YoungInequality}^{\uparrow}$ *carrier* $Y = (A, B, E, R, S, V, M, D, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{YoungInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the two displayed* $\mathsf{Real}^{\uparrow}$ *rows, conjugate exponent and weight exactness,* $\mathsf{PositiveReal}^{\uparrow}$ *positivity readback, Holder handoff compatibility, Minkowski consumer routing, dyadic tolerance accounting, endpoint sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every accepted product-bound request is classified only by those finite rows.*

Proof. Project the accepted carrier. The analytic coordinates are the two real rows A, B, the conjugate ledger E, the positivity rows R, S, the Holder handoff V, the Minkowski consumer route M, the dyadic budget D, and the endpoint seal F.

The structural rows H, C, P, N then transport, replay, source, and name exactly that finite packet. No row introduces a host convexity principle, an integration theorem, a selected infinite sum, or an ambient completeness assertion.

Thus the local $\mathsf{NameCert}_{\mathsf{YoungInequality}^{\uparrow}}$ row names the displayed product-bound packet and no additional analytic theorem. □

Theorem 2358.3 (Young inequality Holder–Minkowski handoff)**.** *For every accepted* $\mathsf{YoungInequality}^{\uparrow}$ *carrier* $Y = (A, B, E, R, S, V, M, D, F, H, C, P, N)$*, every Holder-facing or Minkowski-facing read factors through the finite route*

$$A, B, E, R, S, V, M, D, F, H, C, P, N.$$

Consequently the read uses only two displayed $\mathsf{Real}^{\uparrow}$ *rows, the conjugate exponent and weight ledger,* $\mathsf{PositiveReal}^{\uparrow}$ *positivity rows, the* $\mathsf{HolderInequality}^{\uparrow}$ *handoff, the* $\mathsf{MinkowskiInequality}^{\uparrow}$ *consumer route, a dyadic tolerance budget, and a terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal. It supplies no host convexity theorem, no ambient integration theorem, no selected infinite sum, no quotient stream equality, and no bridge-checked standard theorem.*

Proof. The source of the product comparison is the pair A, B together with the positivity rows R, S. The conjugate ledger E fixes the displayed weights and the finite conjugacy certificate used by the Young inequality read.

The Holder handoff V is then a consumer of the same conjugate ledger, not an independent source of exponent data. The Minkowski route M records only where the bounded product estimate can be consumed later, so it does not add a new triangle-inequality theorem to the Young packet.

Finally D and F account for tolerance and endpoint sealing, while H, C, P, N transport, replay, source, and name the route. Hence every downstream read passes through the displayed finite packet. □

Falsifiable prediction: Every $\mathsf{YoungInequality}^{\uparrow}$ product-bound read factors through two RealUp rows, a conjugate exponent and weight ledger, PositiveRealUp positivity rows, HolderInequalityUp handoff, MinkowskiInequalityUp consumer routing, a dyadic tolerance budget, a RealUp endpoint seal, transport, replay, provenance, and local naming.

Independence witness: holder-inequality, minkowski-inequality, positivereal: $\mathsf{YoungInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two RealUp rows, conjugate exponent and weight data, positivity rows, Holder handoff, Minkowski consumer routing, dyadic tolerance accounting, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungInequality}^{\uparrow}$ packet is generated from two $\mathsf{Real}^{\uparrow}$ rows, a conjugate exponent and weight ledger, $\mathsf{PositiveReal}^{\uparrow}$ positivity rows, $\mathsf{HolderInequality}^{\uparrow}$ handoff, $\mathsf{MinkowskiInequality}^{\uparrow}$ consumer routing, a dyadic tolerance budget, a $\mathsf{Real}^{\uparrow}$ endpoint seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2358.1, Definition 2358.2, and Definition 2358.3 seed the finite Young inequality boundary for displayed RealUp product estimates.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim host convexity, ambient integration, selected infinite sums, quotient stream equality, bridge checking, or a completed standard theorem for $\mathsf{YoungInequality}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, conjugate-exponent exactness, positivity readback, Holder handoff, Minkowski consumer routing, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.YoungInequalityUp.

Chapter 2359

A Concrete Naming Certificate for PicardIteration$^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Banach fixed-point route, the PicardIteration$^{\uparrow}$ packet records the finite contraction-iteration ledger consumed before Picard–Lindelof and fixed-point endpoint packets read a completed limit. It sits between the contraction-map surface of chapter 1418, the one-step Picard route of chapter 395, the complete-metric consumer of chapter 128, the Cauchy-modulus surface of chapter 292, the regular-rational handoff of chapter 301, the real seal of chapter 38, and the fixed-point endpoint discipline of chapter 396. The packet names the finite orbit, residual distances, modulus handoff, and seal boundary without selecting a fixed point or importing host function extensionality.

Definition 2359.1 (PicardIteration carrier)**.** *A* PicardIteration$^{\uparrow}$ *carrier is a finite packet*

$$P = (X, T, x_0, I, r, M, R, E, H, C, Q, N)$$

with the following displayed rows.

1. *X is the complete metric carrier and distance-read row available to the contraction route.*
2. *T is the contraction self-map graph row, including the displayed contraction-bound row used by adjacent iterate comparisons.*
3. *x_0 is the initial-point row from which the orbit is generated.*
4. *I is the finite iterate ledger, recording the visible rows $x_0, x_1, \ldots, x_n$ obtained by repeated reads of T.*
5. *r is the residual-distance row, storing the adjacent distances and contraction-ratio comparisons read from the iterate ledger.*
6. *M is the* CauchyModulus$^{\uparrow}$ *row extracted from I and r.*
7. *R is the* RegSeqRat$^{\uparrow}$ *handoff row used when the orbit is consumed as a regular rational approximation stream.*
8. *E is the* Real$^{\uparrow}$ *seal boundary recording where endpoint-facing consumers may read a real seal after the regular handoff.*
9. *H is componentwise* hsame *transport for the metric carrier, self-map graph, initial point, iterate ledger, residual row, modulus row, regular handoff, real seal boundary, replay, provenance, and local naming rows.*

10. *C is the displayed* Cont *replay from contraction-map admission through Picard iteration, residual comparison, Cauchy-modulus extraction, regular-sequence handoff, and real-seal separation.*
11. *Q is the* Pkg *provenance over* $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardIteration}^{\uparrow}}$ *row.*

The carrier exposes a finite contraction-iteration route. It contains no coordinate for a Banach fixed point, a selected limit, quotient equality of completed reals, host function extensionality, or an ambient completeness theorem beyond the displayed complete-metric row.

Lean4 ✓ `BEDC.Derived.PicardIterationUp.PicardIterationTasteGate single carrier alignment`

Theorem 2359.2 (PicardIteration NameCert obligations)**.** *For an accepted* $\mathsf{PicardIteration}^{\uparrow}$ *carrier* $P = (X, T, x_0, I, r, M, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PicardIteration}^{\uparrow}}$ *surface consists of carrier admission, complete-metric visibility, contraction-map visibility, initial-point visibility, finite iterate-ledger visibility, residual-distance stability, Cauchy-modulus exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff visibility,* $\mathsf{Real}^{\uparrow}$ *seal separation, componentwise transport, continuation replay, provenance, and local naming for the finite packet of Definition 2359.1.*

Proof. Carrier admission projects the displayed tuple. The rows X, T, x_0, I expose the complete metric, contraction graph, initial point, and finite orbit before any convergence-facing row is consumed.

The residual-distance row r is then read from the same finite iterate ledger. Its adjacent-distance and contraction-ratio comparisons determine the modulus row M; no infinite stream, chosen endpoint, or host limit is consulted.

The handoff rows R and E remain downstream boundaries. They mark where a regular rational sequence consumer and a real-seal consumer may read the orbit after the finite modulus route has been displayed, but they do not add quotient equality or a selected real value.

Finally H, C, Q, N transport, replay, source, and name exactly these rows. The certificate therefore exports the contraction-iteration surface and not a Banach fixed-point theorem. □

Theorem 2359.3 (PicardIteration contraction route)**.** *Every accepted* $\mathsf{PicardIteration}^{\uparrow}$ *carrier factors its iterate and residual reads through*

$$\mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardContraction}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow}.$$

The self-map row T and initial row x_0 generate the finite ledger I, the adjacent-distance comparisons in r are read through the contraction route, and the modulus row M is visible only after those finite rows have been displayed. No iterate read bypasses the contraction-map graph, the Picard-step ledger, or the complete-metric distance row.

Proof. Start with the contraction-map surface. The graph row T is the only source for the displayed successor rows in I, and the complete-metric row X is the only source for the distance comparisons used by r.

The Picard-step route is finite. Each successor row in I is obtained by replaying the same accepted graph row, so the residual-distance comparisons remain attached to the same contraction certificate rather than to an ambient function space.

The modulus row M is downstream of those reads. It is therefore a Cauchy-modulus handoff for a displayed contraction ledger, not an endpoint selector, quotient-equality claim, or host extensionality principle. □

Theorem 2359.4 (PicardIteration completion handoff)**.** *Every completion-facing read of an accepted* $\mathsf{PicardIteration}^{\uparrow}$ *carrier passes through the displayed rows*

$$X,\ T,\ x_0,\ I,\ r,\ M,\ R,\ E,\ H,\ C,\ Q,\ N$$

before any fixed-point or ODE packet may consume the iteration. The route supplies a $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and a* $\mathsf{Real}^{\uparrow}$ *seal boundary for downstream* $\mathsf{BanachFixedPoint}^{\uparrow}$ *and* $\mathsf{PicardLindelof}^{\uparrow}$ *consumers; it does not supply a Banach fixed point, selected limit, quotient equality, host function extensionality, or ambient completeness beyond the named* $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Proof. First expose the finite orbit and residual rows. The rows I and r are generated inside the displayed metric and contraction route, so a completion-facing consumer must first read X, T, x_0, I, r.

Next expose the Cauchy-modulus and regular-sequence handoff. The row M records the finite modulus extracted from the residual ledger, and R is the only regular rational sequence boundary available to downstream consumers.

Finally expose the real-seal boundary and local certificate rows. The row E marks where a real-facing consumer may read a seal after the regular handoff, while H, C, Q, N preserve the same finite route under transport, replay, provenance, and local naming. Since no coordinate stores a selected endpoint or host function equality, downstream fixed-point and ODE packets must supply their own endpoint obligations. □

Theorem 2359.5 (PicardIteration Cauchy-modulus chain)**.** *For every accepted* $\mathsf{PicardIteration}^{\uparrow}$ *carrier*

$$P = (X, T, x_0, I, r, M, R, E, H, C, Q, N),$$

any completion-facing consumer that reads the $\mathsf{RegSeqRat}^{\uparrow}$ *row R must first read the residual row r and the* $\mathsf{CauchyModulus}^{\uparrow}$ *row M. Thus the regular handoff is generated by displayed contraction residuals through the finite iterate ledger, not by a selected endpoint or by ambient completeness of the metric space.*

Proof. Project the carrier of Definition 2359.1. The rows I, r, M, R occur in the displayed packet order, and the residual row r is the only source for the contraction-distance data used by the modulus row M.

Apply Definition 2359.3. It forces the reads of I, r, M to pass through the contraction graph, finite Picard ledger, complete-metric distance row, and Cauchy-modulus extraction in that order.

Now apply Definition 2359.4. The regular handoff row R is downstream of M, and the real-seal row E is downstream of R. Since no carrier coordinate stores a chosen endpoint or an ambient completeness witness, every completion-facing read of R is generated by the displayed residual-to-modulus chain. □

Theorem 2359.6 (PicardIteration RegSeqRat tail handoff)**.** *For every accepted* $\mathsf{PicardIteration}^{\uparrow}$ *carrier $P = (X, T, x_0, I, r, M, R, E, H, C, Q, N)$, the residual-distance row r together with the* $\mathsf{CauchyModulus}^{\uparrow}$ *row M determines the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R available to* $\mathsf{BanachContraction}^{\uparrow}$ *and* $\mathsf{PicardContraction}^{\uparrow}$ *consumers. This handoff exports no selected fixed point, quotient equality, or ambient completeness beyond the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Proof. Project the carrier of Definition 2359.1. The rows I, r, M, R occur as displayed coordinates of the same finite packet, so a downstream consumer cannot detach the regular handoff from the finite orbit and residual-distance rows.

Apply Definition 2359.3. It routes the residual comparisons through the contraction graph, finite Picard ledger, complete-metric distance row, and Cauchy-modulus extraction.

Next apply Definition 2359.4 and Definition 2359.5. These theorems place R downstream of r and M, and upstream of the real-seal row E consumed by fixed-point chapters.

Thus $\mathsf{BanachContraction}^{\uparrow}$ and $\mathsf{PicardContraction}^{\uparrow}$ may consume a named regular rational tail boundary, but they receive no selected endpoint, quotient equality, host function extensionality, or ambient completeness from the Picard packet. □

Theorem 2359.7 (PicardIteration endpoint uniqueness boundary)**.** *Two endpoint reads from the same accepted* $\mathsf{PicardIteration}^{\uparrow}$ *carrier can be compared only after exposing the same complete-metric row, contraction graph, initial point, finite Picard ledger, residual-distance row,* $\mathsf{CauchyModulus}^{\uparrow}$ *route,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{PicardIteration}^{\uparrow}}$ *row. The comparison is therefore a boundary over the displayed packet* $P = (X, T, x_0, I, r, M, R, E, H, C, Q, N)$*; it is not read from ambient completeness, host function extensionality, quotient equality of endpoints, or an uncarried fixed-point selector.*

Proof. Start with the contraction route of Definition 2359.3. It fixes the complete-metric row X, contraction graph T, initial point x_0, finite Picard ledger I, residual-distance row r, and Cauchy-modulus row M before any endpoint-facing data are consumed.

Apply the completion handoff of Definition 2359.4. It places the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, $\mathsf{Real}^{\uparrow}$ seal E, and structural rows H, C, Q, N downstream of the same displayed contraction ledger.

Use the Cauchy-modulus chain and RegSeqRat tail handoff, Definition 2359.5 and Definition 2359.6. They force both endpoint reads to pass through the same residual-to-modulus-to-tail route before a real-facing seal is visible.

Thus an endpoint comparison can only compare reads that have exposed the same carrier rows. Since the carrier has no coordinate for selected fixed points, quotient endpoint equality, host function extensionality, or ambient completeness beyond X, uniqueness remains a displayed boundary obligation for downstream fixed-point and ODE consumers. □

Falsifiable prediction: Every accepted $\mathsf{PicardIteration}^{\uparrow}$ read factors through one complete metric carrier, one contraction-map row, one initial-point row, one finite iterate ledger, one residual-distance row, one CauchyModulus row, one RegSeqRat handoff, one RealUp seal boundary, hsame transport, Cont replay, Pkg provenance, and NameCert row before any fixed-point or ODE endpoint is consumed.

Independence witness: contractionmapping, picardcontraction, completemetric, cauchymodulus, regseqrat, real, banachfixedpoint: none is bijective with $\mathsf{PicardIteration}^{\uparrow}$ because the packet jointly stores the contraction graph, initial point, finite iteration ledger, residual-distance row, modulus extraction row, regular handoff, real-seal boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardIteration}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardIteration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2359.1, Definition 2359.2, Definition 2359.3, and Definition 2359.4 seed the finite contraction-iteration packet consumed before fixed-point and ODE endpoint rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardIteration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Banach fixed points, selected limits, quotient equality, host function extensionality, ambient completeness beyond the displayed CompleteMetric row, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, complete-metric visibility, contraction-map visibility, initial-point visibility, finite iterate-ledger visibility, residual-distance stability, Cauchy-modulus exposure, RegSeqRat handoff visibility, Real seal separation, transport, replay, provenance, and local naming.

Constructive story: A PicardIteration$^{\uparrow}$ packet is generated from a complete metric carrier, contraction self-map graph, initial point, finite Picard ledger, residual-distance row, CauchyModulus route, RegSeqRat handoff, RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2360

A Concrete Naming Certificate for $\mathsf{SubstrateTraceInvariant}^{\uparrow}$

The $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ packet realizes the cellular manifest and audit route of chapter 9390 as finite NameCert data. It reads the substrate not as an unbounded physical claim but as a bounded manifest over cellular rules, trace windows, locality cells, continuation rows, audit classifiers, transport, replay, provenance, and local naming. The packet is BEDC-native: it packages the audit invariant that a displayed cellular trace remains accountable to its manifest rows before any downstream trust or universality reading is consumed.

The manifest/audit invariant is consumed through the cellular trust substrate row of chapter 937, the trust manifest surface of chapter 940, the bounded-universal-trace handoff of chapter 944, and the certificate-machine acceptance surface of chapter 3355. These siblings can read the trace only after the manifest, audit classifier, bounded trace, locality, rule replay, transport, continuation, provenance, and local naming rows have been displayed.

Definition 2360.1 (SubstrateTraceInvariant carrier)**.** *A* $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ *carrier is a finite packet*

$$S = (M, A, T, W, L, R, U, H, C, P, N)$$

with the following displayed rows.

1. *M is the manifest row, naming the finite cellular rule table, boundary convention, alphabet, origin cell, and public audit handle.*
2. *A is the audit classifier row, recording which manifest entries must be visible before a trace row is trusted.*
3. *T is the bounded trace row, storing the finite time-window and cell-window observations under the manifest.*
4. *W is the window-consistency row, checking that each observed cell in T lies inside the displayed bounded window.*
5. *L is the locality-cell row, exposing the finite neighborhood reads used by each transition check.*
6. *R is the rule-application row, replaying the cellular transition table against the locality rows.*
7. *U is the bounded-universal-trace handoff row, marking where a continuation automaton or cellular trust substrate may consume the trace after audit.*

8. *H is componentwise* hsame *transport for the manifest, audit classifier, bounded trace, window check, locality cells, rule applications, continuation handoff, replay, provenance, and local naming rows.*
9. *C is the displayed* Cont *replay from manifest admission through local trace checking, rule replay, audit classification, and continuation handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{SubstrateTraceInvariant}^{\uparrow}$*, cellular trust substrate rows, cellular automaton rows, bounded-universal-trace rows, locality-cell rows, continuation-automaton rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubstrateTraceInvariant}^{\uparrow}}$ *row.*

The carrier exposes a finite manifest/audit invariant. It has no coordinate for an unbounded cellular universe, a metaphysical substrate commitment, a completed universal simulator, a host trace equality principle, or a choice-selected infinite orbit.

Lean4 (definition) `BEDC.Derived.SubstrateTraceInvariantUp.SubstrateTraceInvariantUp`

Theorem 2360.2 (SubstrateTraceInvariant NameCert obligations)**.** *For an accepted* $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ *carrier $S = (M, A, T, W, L, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SubstrateTraceInvariant}^{\uparrow}}$ *surface consists of carrier admission, manifest visibility, audit-classifier visibility, bounded-trace visibility, window consistency, locality-cell visibility, rule-application replay, bounded-universal-trace handoff separation, componentwise transport, continuation replay, provenance, and local naming for the finite packet of Definition 2360.1.*

Proof. Carrier admission projects the displayed tuple. The manifest row M and audit row A are read before the trace row, so the trace cannot be trusted without its finite public manifest and classifier.

The bounded trace row T is then checked by W, L, R. Window consistency keeps every observation inside the displayed cell-time window, locality cells expose the finite neighborhood reads, and the rule-application row replays the manifest rule table against those local rows.

The handoff row U is downstream of the audit route. It permits a trust-substrate or continuation-automaton consumer to cite the trace only after the manifest and local replay rows are visible.

Finally H, C, P, N preserve the same route under transport, continuation replay, provenance, and local naming. The packet therefore exports a finite audit invariant and not an unbounded substrate theorem. □

Lean4 ✓ `BEDC.Derived.SubstrateTraceInvariantUp.SubstrateTraceInvariantTasteGate single carrier alignment`

Theorem 2360.3 (SubstrateTraceInvariant manifest route)**.** *Every accepted* $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ *trace read factors through*

$$M,\ A,\ T,\ W,\ L,\ R,\ U,\ H,\ C,\ P,\ N.$$

In particular, the bounded trace is visible only after the manifest and audit classifier are displayed, and every transition read is replayed through the locality-cell and rule-application rows. The route exposes no unbounded orbit, host trace equality, completed simulator, or independent substrate commitment.

Proof. Start with manifest admission. The rows M and A determine which finite rule, boundary, alphabet, and audit obligations govern the trace.

Now read the displayed trace. The row T is paired with the window row W, so only observations inside the finite manifest window can enter the route.

Finally replay the local dynamics. The locality row L and rule row R supply the finite transition checks, and U, H, C, P, N only hand off, transport, replay, source, and name that checked route. Since no carrier coordinate stores an infinite orbit or completed simulator, the manifest route is exhausted by the listed rows. □

Theorem 2360.4 (SubstrateTraceInvariant audit handoff)**.** *Every audit-facing consumer of an accepted* $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ *packet receives a trace only through the manifest route of Definition 2360.3. The handoff to cellular trust substrates, cellular automata, bounded-universal traces, locality cells, and continuation automata is therefore mediated by the same finite manifest, audit classifier, bounded trace, window check, locality replay, rule replay, transport, continuation, provenance, and local naming rows.*

Proof. First expose the local manifest route. By Definition 2360.3, any trace read has already passed through M, A, T, W, L, R.

Next expose the handoff row. The row U records the bounded downstream use of the trace; it does not create another trace, enlarge the window, or add an independent cellular substrate.

Finally carry the route through H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same audited rows, so every downstream consumer receives the finite invariant rather than an unbounded substrate claim. □

Theorem 2360.5 (SubstrateTraceInvariant sibling-lattice route)**.** *Every* $\mathsf{CertificateMachine}^{\uparrow}$ *or cellular trust substrate consumer of an accepted* $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ *packet must first read the displayed manifest row, audit classifier, bounded trace, window check, locality-cell row, rule-application replay, bounded-universal-trace handoff, componentwise transport, continuation replay, provenance, and local* $\mathsf{NameCert}$ *row. Thus certificate-machine acceptance and refusal data, trust-substrate manifest reads, bounded trace consumers, and continuation consumers receive the trace only through the sibling lattice cited above, not through an unbounded cellular universe, a completed simulator, host trace equality, or a choice-selected infinite orbit.*

Proof. Start from the accepted carrier $S = (M, A, T, W, L, R, U, H, C, P, N)$. The manifest route theorem forces every trace read through M, A, T, W, L, R before any downstream handoff is visible.

The row U is the only downstream handoff coordinate. It names the bounded-universal-trace, cellular trust, and continuation-facing use of the audited trace, while the opening dependency paragraph places the certificate-machine consumer after the same manifest and audit rows.

Finally H, C, P, N preserve, replay, source, and name the displayed route. Since the carrier has no coordinate for an unbounded orbit, completed simulator, host trace equality, or selected infinite path, the sibling consumers can receive only the finite trace invariant. □

Falsifiable prediction: Every accepted $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ read factors through a manifest row, audit classifier, bounded trace, window consistency check, locality-cell row, rule-application row, bounded-universal-trace handoff, hsame transport, Cont replay, Pkg provenance, and NameCert row before any cellular trust or continuation consumer reads the trace.

Independence witness: cellulartrustsubstrate, cellularautomaton, bounded-universal-trace, localitycell, continuationautomaton: none is bijective with $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ because the

packet jointly stores a manifest, audit classifier, bounded trace, window consistency row, locality-cell row, rule-application row, downstream handoff, transport, replay, provenance, and local naming.

The Lean TasteGate work for this packet must later provide explicit Nontrivial and FieldFaithful instances preserving $M, A, T, W, L, R, U, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{SubstrateTraceInvariant}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubstrateTraceInvariant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2360.1, Definition 2360.2, Definition 2360.3, and Definition 2360.4 seed the finite cellular manifest/audit invariant packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubstrateTraceInvariant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an unbounded cellular universe, metaphysical substrate commitment, completed universal simulator, host trace equality, choice-selected infinite orbit, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, manifest visibility, audit-classifier visibility, bounded-trace visibility, window consistency, locality-cell visibility, rule-application replay, bounded-universal-trace handoff separation, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{SubstrateTraceInvariant}^{\uparrow}$ packet is generated from a finite cellular manifest, audit classifier, bounded trace, window consistency row, locality-cell row, rule-application row, bounded-universal-trace handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2361

A Concrete Naming Certificate for $\mathsf{IsbellTightSpan}^{\uparrow}$

Following Isbell's injective-envelope construction and the Lawvere metric-space reading, the $\mathsf{IsbellTightSpan}^{\uparrow}$ packet records a finite distance-envelope boundary for a displayed metric source. It sits after the metric observation rows of chapter 57, beside the Yoneda profile route of chapter 2148, and before the completion-facing handoff of chapter 1506. The packet names only finite extremal-distance rows, one-point extension witnesses, separated comparison, completion and Real readback, transport, replay, provenance, and local NameCert data; it does not assert a host injective hull, selected hyperconvex hull, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 2361.1 (Isbell tight-span carrier)**.** *An* $\mathsf{IsbellTightSpan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, F, E, O, S, Q, L, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the finite point classifier and distance observations read from chapter 57.*
2. *F is the finite distance-envelope row. It records the retained functions f from displayed source points to displayed* $\mathsf{Real}^{\uparrow}$ *distance bounds, together with the inequalities $f(x) + f(y) \geq d(x, y)$ visible in the metric row.*
3. *E is the extremal-tightness row, listing the finite witnesses that no retained envelope coordinate can be lowered without breaking a displayed distance-envelope inequality.*
4. *O is the one-point extension witness row. It records finite extension tests saying that a candidate point joined to the source by the envelope distances preserves the metric triangle rows already displayed by M and F.*
5. *S is the separated comparison row: two envelopes are compared only by their displayed distance rows and by the separated zero-distance test consumed by completion readers.*
6. *Q is the completion handoff row toward* $\mathsf{MetricCompletion}^{\uparrow}$*, read only after M, F, E, O, S have been displayed.*
7. *L is the* $\mathsf{Real}^{\uparrow}$ *readback row for the retained envelope distances and separated comparison distances.*

8. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *windows used to read the displayed real distance rows.*
9. *H stores componentwise* hsame *transport for the metric source, envelope inequalities, extremal witnesses, one-point extension tests, separated comparison, completion handoff, Real readback, and local naming rows.*
10. *C stores displayed* Cont *replay from metric observations to envelope inequalities, from envelopes to one-point extension tests, and from separated comparison to completion and Real readback.*
11. *P is the* Pkg *provenance over* $\mathsf{IsbellTightSpan}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{IsbellTightSpan}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, E, O, S, Q, L, R, H, C, P, N$. It has no coordinate for a host injective envelope, a selected global hull point, a quotient completion, an open-cover compactness principle, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.IsbellTightSpanUp.IsbellTightSpanTasteGate single carrier alignment`

Theorem 2361.2 (Isbell tight-span NameCert obligations)**.** *For every accepted* $\mathsf{IsbellTightSpan}^{\uparrow}$ *carrier $I = (M, F, E, O, S, Q, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IsbellTightSpan}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, finite distance-envelope inequalities, extremal-tightness witnesses, one-point extension witnesses, separated comparison, completion handoff,* $\mathsf{Real}^{\uparrow}$ *readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the packet must inspect these rows before treating the tight-span boundary as a completion neighbour.*

Proof. Project the carrier of Definition 2361.1. The metric source row M and distance-envelope row F are the only places where source distances and envelope inequalities are displayed.

The extremal row E and one-point extension row O record the injective-envelope tests as finite witnesses. The separated comparison row S and completion handoff row Q are downstream of those witnesses, so a completion consumer cannot bypass them.

Finally read L, R, H, C, P, N. These rows provide Real readback, finite regular and stream windows, transport, replay, provenance, and local naming for the same route. Since no other classifier coordinate exists, the listed rows exhaust the NameCert surface. □

Theorem 2361.3 (Isbell tight-span metric handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{IsbellTightSpan}^{\uparrow}$ *packet factors through*

$$\mathsf{Met}^{\uparrow} \longmapsto F \longmapsto E \longmapsto O \longmapsto S \longmapsto Q, L, R \longmapsto H, C, P, N.$$

Thus the packet supplies a finite injective-envelope boundary adjacent to metric completion: it keeps metric-source observations, envelope inequalities, one-point extension witnesses, separated comparison, completion readback, and Real readback visible, while exporting no host injective hull, selected limit, quotient completion, countable-choice selector, or ambient completeness principle.

Proof. Start with the source metric row. The carrier allows a completion-facing read only after the finite distance-envelope inequalities in F and extremal-tightness witnesses in E have been displayed.

Next read the one-point extension and separated comparison rows. The row O records the finite triangle-preservation tests for adding an envelope point, and S records the separated comparison used by completion consumers.

The handoff rows Q, L, R then expose only completion-facing and Real-facing readback for the same finite packet. Transport, replay, provenance, and local naming by H, C, P, N preserve that route and do not add any selected hull point or ambient completeness witness. □

Falsifiable prediction: Every accepted IsbellTightSpanUp completion-facing read factors through finite distance-envelope inequalities and one-point extension witnesses before any MetricCompletionUp or RealUp readback is exposed.

Independence witness: metric, metriccompletion, yonedacompletion: IsbellTightSpanUp is not bijective to any listed sibling because it jointly carries distance-envelope inequalities, extremal-tightness witnesses, one-point extension tests, separated comparison, completion handoff, Real readback, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{IsbellTightSpan}^{\uparrow}}$.

Constructive story: An $\mathsf{IsbellTightSpan}^{\uparrow}$ packet is generated from a MetricUp source row, finite distance-envelope inequalities, extremal-tightness witnesses, one-point extension tests, separated comparison, MetricCompletionUp handoff, RealUp readback, RegSeqRat and StreamName windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IsbellTightSpan}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2361.1, Definition 2361.2, and Definition 2361.3 display the finite tight-span envelope route adjacent to metric completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IsbellTightSpan}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host injective envelopes, selected hyperconvex hulls, quotient completion, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires Lean carrier admission, distance-envelope inequalities, extremal witnesses, one-point extension tests, separated comparison, and completion handoff for BEDC.Derived.IsbellTightSpanUp.

Chapter 2362

A Concrete Naming Certificate for $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Arzela–Ascoli equicontinuity route, the $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ packet records the family-level handoff by which a compact finite-net ledger supplies one displayed source-radius row for a finite family of continuous maps. It sits between the compact-uniform-continuity route of chapter 388, the compact-metric finite-net surface of chapter 129, the graph and pointwise-modulus rows of chapter 130, and the downstream output interface of chapter 369. The certificate names the reusable family-level finite-net route, not an open-cover compactness theorem, a host function-space topology, a selected global modulus function, or an ambient Arzela–Ascoli compactness principle.

Definition 2362.1 (Finite-net equicontinuity carrier)**.** *A* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, B, R, M, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-metric finite-net row read from* $\mathsf{CompactMetric}^{\uparrow}$*, including the finite center* $\mathsf{ProbeBundle}$ *and its coverage radius ledger.*
2. *F is the finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows sharing the same source and target metric surfaces.*
3. *B records the center-indexed pointwise bounds for every displayed family member at every center of the finite* $\mathsf{ProbeBundle}$*.*
4. *R is the rational tolerance and source-radius ledger used to compare the center bounds and the compact finite-net radius.*
5. *M is the family-level finite-net modulus row produced by folding K, F, B, and R.*
6. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, exposing the resulting source-radius row as a reusable modulus boundary.*
7. *H records componentwise* hsame *transports for the compact-net, family, bound, rational, modulus, output, route, provenance, and local naming rows.*
8. *C records the displayed* Cont *routes by which compact-uniform-continuity, continuous-map, compact-metric, equicontinuity, and uniform-modulus consumers read the same packet.*

9. *P is the* Pkg *provenance over* FiniteNetEquicontinuity$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{FiniteNetEquicontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, F, B, R, M, U, H, C, P, N$. It has no coordinate for host function equality, selected subcovers, selected global moduli, open-cover compactness, or ambient function-space compactness.

Lean4 (definition) `BEDC.Derived.FiniteNetEquicontinuityUp.FiniteNetEquicontinuityUp`
Lean4 ✓ `BEDC.Derived.FiniteNetEquicontinuityUp.FiniteNetEquicontinuityTasteGate single carrier alignment`

Theorem 2362.2 (Finite-net equicontinuity obligation surface)**.** *For an accepted* FiniteNetEquicontinuity$^{\uparrow}$ *carrier $E = (K, F, B, R, M, U, H, C, P, N)$, the local* NameCert$_{\text{FiniteNetEquicontinuity}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact-metric finite-net row, finite family ledger, center-indexed bound rows, rational tolerance ledger, family-level modulus row, uniform-modulus handoff row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every downstream read must preserve the same finite* ProbeBundle *centers, the same family ledger, the same rational radius comparison, and the same local NameCert row.*

Proof. Project the carrier of Definition 2362.1. The finite-net data are exactly K, the family data are exactly F, and the center-indexed estimates are exactly B.

The rational ledger R compares the compact-net radius with the source-radius rows needed by the displayed family estimates. Folding those rows gives M, and the handoff row U exposes that folded radius only as a UniformModulus$^{\uparrow}$ boundary.

Transport, replay, provenance, and local naming are the rows H, C, P, N. Since no further coordinate exists, the certificate surface has no path to host function equality, selected subcovers, selected global moduli, open-cover compactness, or ambient function-space compactness. □

Theorem 2362.3 (Finite-net equicontinuity uniform-modulus handoff)**.** *Every* UniformModulus$^{\uparrow}$ *read exported from an accepted* FiniteNetEquicontinuity$^{\uparrow}$ *packet factors through the finite route*

$$K, F, B, R, M, U, H, C, P, N.$$

The route first consumes compact finite-net centers from CompactMetric$^{\uparrow}$*, then reads the finite* ContinuousMap$^{\uparrow}$ *family rows and center-indexed bounds, then folds the rational radius ledger into the family-level modulus row M, and only then exposes the output row U. The handoff does not export open-cover compactness, an Arzela–Ascoli compactness theorem, host function extensionality, selected global moduli, or a function-space topology.*

Proof. Begin with the finite-net row K. It supplies the displayed ProbeBundle centers and coverage radius through the compact-metric certificate, so the route starts from finite carrier data rather than from an open cover.

Next read the family ledger F and the center-indexed rows B. Each family member is consumed through its ContinuousMap$^{\uparrow}$ row, and the estimates are attached only to centers already named by K.

Finally use the rational ledger R to form M and expose U. The hsame, Cont, Pkg, and local NameCert rows preserve the same finite packet during transport and replay, so the exported uniform-modulus row is exactly the finite-net family handoff and not an ambient compactness or function-space assertion. □

Theorem 2362.4 (Compact finite-net coverage row)**.** *Let $E = (K, F, B, R, M, U, H, C, P, N)$ be an accepted* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *carrier. Every accepted read of E exposes the compact finite-net row K before any source-family radius row is read from F, B, or R. Thus the inspected* $\mathsf{ProbeBundle}$ *centers and their compact-metric coverage ledger are visible before the family estimates can be folded toward M or exported through U.*

Proof. Project the carrier of Definition 2362.1. The row K is the only coordinate carrying compact-metric finite-net centers and the associated coverage ledger, while F, B, R are downstream rows for family membership, center-indexed estimates, and rational radius comparison.

Apply Definition 2362.2. It requires every downstream read to preserve the same finite $\mathsf{ProbeBundle}$ centers and the same rational radius comparison. Apply Definition 2362.3. The handoff route begins at K and reaches U only after the family rows and rational ledger have been consumed.

Since the carrier has no coordinate for open-cover compactness, selected moduli, host function-space compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no consumer can bypass K by appealing to one of those external surfaces. □

Theorem 2362.5 (Finite family row stability)**.** *Let $E = (K, F, B, R, M, U, H, C, P, N)$ be an accepted* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *carrier. The finite family row F and bound ledger B are transported componentwise only by the* hsame *row H, and every replay of those rows to compact-metric, continuous-map, equicontinuity, or uniform-modulus consumers factors through the displayed* Cont *routes in C.*

Proof. Project the carrier of Definition 2362.1. The family ledger is F, the center-indexed bound ledger is B, the transport coordinate is H, and the displayed replay coordinate is C.

Use Definition 2362.2. Its obligation surface names componentwise hsame transport and displayed Cont replay as part of the local $\mathsf{NameCert}_{\mathsf{FiniteNetEquicontinuity}^{\uparrow}}$ surface, with no additional transport coordinate.

Use Definition 2362.3. The route to U reads F and B after K and before R, M, U, so the same family and bound ledgers are preserved during the handoff. The carrier excludes open-cover compactness, selected moduli, host function-space compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so those surfaces cannot supply an alternate replay path. □

Theorem 2362.6 (Rational radius folding order)**.** *Let $E = (K, F, B, R, M, U, H, C, P, N)$ be an accepted* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *carrier. The rational radius data R fold into the uniform-modulus handoff row U only through the family-level modulus row M, and only after the compact-net row K, finite family row F, and bound ledger B have been displayed.*

Proof. Project the carrier of Definition 2362.1. The row R is the rational tolerance and source-radius ledger, M is the family-level finite-net modulus row, and U is the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff row.

Apply Definition 2362.2. It places carrier admission, compact finite-net coverage, finite family data, bound rows, rational comparison, modulus formation, and uniform-modulus output in the same local NameCert surface.

Apply Definition 2362.3. The exported route is exactly $K, F, B, R, M, U, H, C, P, N$, so R cannot reach U before K, F, B are displayed and cannot skip the fold row M. Because the packet has no coordinate for open-cover compactness, selected moduli, host function-space compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no external compactness or function-space argument can replace this finite fold. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNetEquicontinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteNetEquicontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2362.1, Definition 2362.2, and Definition 2362.3 seed the family-level finite-net equicontinuity route over compact-metric centers, continuous-map family rows, rational radius ledgers, uniform-modulus handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteNetEquicontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected global moduli, open-cover compactness, Arzela–Ascoli compactness, host function extensionality, function-space topology, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net coverage, finite family row stability, rational radius folding, uniform-modulus handoff, and non-escape for BEDC.Derived.FiniteNetEquicontinuityUp.

Constructive story: A $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ packet is generated from CompactMetricUp finite-net centers, ContinuousMapUp family rows, center-indexed estimates, rational tolerance histories, a family-level finite-net modulus row, a UniformModulusUp output row, componentwise hsame transport, Cont replay, provenance, and local naming.

Chapter 2363

A Concrete Naming Certificate for $\mathsf{LaguerrePolya}^{\uparrow}$

Following Laguerre and Polya's real-rooted polynomial limit theory, the $\mathsf{LaguerrePolya}^{\uparrow}$ packet records a function only through polynomial approximants with displayed real roots, coefficient-window convergence, and a real-power-series endpoint. It consumes the finite real-polynomial evaluator of chapter 1728, the coefficient and radius-window surface of chapter 1583, the root-bracket boundary of chapter 1786, the terminal real-name seal of chapter 38, and the finite readback rows of chapter 301 and chapter 126. The packet names the constructive Laguerre–Polya route as BEDC certificate data; it does not import a host entire-function primitive, a selected infinite product, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2363.1 (Laguerre–Polya carrier)**.** *A* $\mathsf{LaguerrePolya}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, R, S, Q, W, E, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the approximant-family row. It records a finite inspection of* $\mathsf{RealPolynomial}^{\uparrow}$ *names, their coefficient windows, degree bounds, evaluation requests, and the index window used by the local certificate.*
2. *B is the real-root evidence row. For every inspected approximant it stores the finite* $\mathsf{RealRootBracket}^{\uparrow}$ *data witnessing the displayed real-root route for the roots relevant to that inspection.*
3. *R is the coefficient-readback row. It records* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks for the approximant coefficients, center coefficients, bracket endpoints, and requested real output names.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It stores the finite windows used to compare polynomial coefficients, root brackets, partial evaluations, and endpoint power-series coefficients.*
5. *Q is the* $\mathsf{RealPowerSeries}^{\uparrow}$ *endpoint row. It exposes the limiting coefficient stream, radius or subradius window, partial-sum route, and endpoint seal available to Real-facing consumers.*
6. *W is the convergence-window ledger. It records the finite Cauchy comparison between inspected polynomial coefficient windows and the endpoint power-series windows at the requested precision.*
7. *E is the evaluation-compatibility row. It records that each displayed polynomial evaluation from A and each endpoint read from Q use the same real-name, readback, and window discipline.*

8. *T is the real-root limit route row. It records how the root-bracket data B is retained through the finite coefficient-window convergence ledger before the endpoint series is exposed.*

9. *H records componentwise* hsame *transport for approximant rows, root brackets, readbacks, stream windows, endpoint power-series rows, convergence windows, evaluation compatibility, the root-limit route, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a Laguerre–Polya request through polynomial approximants, real-root brackets, regular readbacks, stream windows, endpoint power-series rows, and the root-limit route.*

11. *P is the* Pkg *provenance over* $\mathsf{LaguerrePolya}^{\uparrow}$, $\mathsf{RealPolynomial}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{RealRootBracket}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LaguerrePolya}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, R, S, Q, W, E, T, H, C, P, N$. It has no coordinate for host entire functions, selected infinite products, quotient function spaces, non-displayed zero sets, countable-choice selectors, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LaguerrePolyaUp.LaguerrePolyaTasteGate single carrier alignment`

Theorem 2363.2 (Laguerre–Polya NameCert obligations)**.** *For every accepted* $\mathsf{LaguerrePolya}^{\uparrow}$ *carrier*

$$L = (A, B, R, S, Q, W, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LaguerrePolya}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approximant family, real-root brackets, regular readbacks, stream windows, endpoint power-series row, convergence-window ledger, evaluation compatibility, real-root limit route, transport, replay, provenance, and local naming rows;*

2. *approximant discipline, requiring A to expose only* $\mathsf{RealPolynomial}^{\uparrow}$ *names with finite coefficient windows and displayed evaluation requests;*

3. *real-root discipline, requiring B to route every inspected approximant root through* $\mathsf{RealRootBracket}^{\uparrow}$ *rows before it can contribute to the limiting packet;*

4. *endpoint discipline, requiring Q to expose the limiting object through* $\mathsf{RealPowerSeries}^{\uparrow}$ *coefficient, radius-window, partial-sum, and endpoint rows;*

5. *convergence discipline, requiring W and E to compare approximant rows and endpoint rows only through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readbacks;*

6. *limit-route discipline, requiring T to retain the bracketed real-root information through the displayed coefficient-window convergence route;*

7. *non-escape, requiring H, C, P, N to export only the displayed route and no host entire function, selected infinite product, quotient function equality, non-displayed zero set, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Laguerre–Polya obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2363.1. The accepted packet displays exactly the approximant family, root-bracket rows, readback rows, stream windows, endpoint power-series row, convergence ledger, evaluation compatibility row, root-limit route, and structural rows.

The approximant and root disciplines are the first stage. The row A gives only finite $\mathsf{RealPolynomial}^{\uparrow}$ data, while B attaches the relevant roots to $\mathsf{RealRootBracket}^{\uparrow}$ evidence before any limiting route is available.

The endpoint and convergence disciplines are the second stage. The row Q exposes the limiting object as a $\mathsf{RealPowerSeries}^{\uparrow}$ endpoint, while W and E compare approximants and endpoint reads through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

The limit-route discipline is the final analytic step. The row T records that the displayed real-root evidence survives exactly along the coefficient-window convergence route already stored in W and E.

Finally H, C, P, N transport, replay, source, and name the same finite data. Since no excluded analytic object appears as a carrier coordinate, the local NameCert surface has no obligation row for such an object. □

Theorem 2363.3 (Laguerre–Polya real-root limit route)**.** *Every Real-facing read from an accepted* $\mathsf{LaguerrePolya}^{\uparrow}$ *carrier factors through*

$$A, B \longmapsto R, S \longmapsto Q, W, E \longmapsto T \longmapsto H, C, P, N.$$

Thus the consumer first reads finite $\mathsf{RealPolynomial}^{\uparrow}$ *approximants and their* $\mathsf{RealRootBracket}^{\uparrow}$ *evidence, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *comparison windows, then the* $\mathsf{RealPowerSeries}^{\uparrow}$ *endpoint and convergence ledger, and only then the retained real-root limit route. The handoff exports a displayed Laguerre–Polya certificate, not a host entire-function primitive or selected zero set.*

Proof. Start with an accepted packet $L = (A, B, R, S, Q, W, E, T, H, C, P, N)$. The only approximant coordinates are A and B, so a consumer cannot read a limiting function before it has inspected finite real-polynomial rows and their displayed real-root brackets.

The comparison stage is R, S, W, E. These rows bind coefficient reads, bracket endpoints, real-name windows, and approximant-versus-endpoint comparisons to regular rational readbacks and finite stream windows.

The endpoint stage is Q. It exposes the limiting object only as the $\mathsf{RealPowerSeries}^{\uparrow}$ endpoint row named by the same comparison windows, so the endpoint is not a host entire function or quotient function-space element.

The retained root route is T, followed by H, C, P, N. These rows preserve, replay, package, and name the displayed data, and therefore the Real-facing consumer receives exactly the finite Laguerre–Polya route listed in the statement. □

Falsifiable prediction: Every $\mathsf{LaguerrePolya}^{\uparrow}$ read factors through finite $\mathsf{RealPolynomial}^{\uparrow}$ approximants, $\mathsf{RealRootBracket}^{\uparrow}$ root evidence, $\mathsf{RegSeqRat}^{\uparrow}$ coefficient readbacks, $\mathsf{StreamName}^{\uparrow}$ comparison windows, one $\mathsf{RealPowerSeries}^{\uparrow}$ endpoint row, a convergence-window ledger, evaluation compatibility, a retained real-root limit route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real-polynomial, realpowerseries, real-root-bracket, real, regseqrat, streamname: $\mathsf{LaguerrePolya}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries real-rooted polynomial approximants, displayed root brackets, coefficient-window convergence, endpoint power-series data, evaluation compatibility, root-limit routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LaguerrePolya}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{LaguerrePolya}\uparrow}$, seed)

Scope closed: Definition 2363.1, Definition 2363.2, and Definition 2363.3 seed the finite Laguerre–Polya route from real-rooted polynomial approximants through coefficient-window convergence to a real-power-series endpoint.

Formal verification: FormalStatus(NameCert$_{\text{LaguerrePolya}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host entire functions, selected infinite products, quotient function spaces, non-displayed zero sets, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximant discipline, real-root discipline, endpoint discipline, convergence discipline, limit-route discipline, and non-escape for BEDC.Derived.LaguerrePolyaUp.

Constructive story: A LaguerrePolya$^{\uparrow}$ packet is generated from finite RealPolynomial$^{\uparrow}$ approximants, RealRootBracket$^{\uparrow}$ root evidence, RegSeqRat$^{\uparrow}$ coefficient and endpoint readbacks, StreamName$^{\uparrow}$ comparison windows, a RealPowerSeries$^{\uparrow}$ endpoint row, convergence-window and evaluation-compatibility ledgers, a retained real-root limit route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2364

A Concrete Naming Certificate for $\mathsf{FiniteAutomaton}^{\uparrow}$

Following Hopcroft and Ullman, the $\mathsf{FiniteAutomaton}^{\uparrow}$ packet records the finite control surface of a deterministic finite automaton as displayed BEDC data rather than as a quotient of accepted languages. It sits between the accepted-language export of chapter 351, the finite word-spine constraints used by chapter 2298, and the bounded transition-trace discipline of chapter 280.

The packet is intentionally smaller than the language chapter and smaller than the machine chapter. It names one automaton presentation, one finite input window, one run trace, one endpoint classifier, and the transport and provenance rows needed by finite consumers.

Definition 2364.1 (FiniteAutomaton carrier)**.** *A* $\mathsf{FiniteAutomaton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, \Sigma, \delta, q_0, F, w, \rho, e, \chi, H, C, P, N)$$

with the following displayed rows:

1. *Q is a finite state carrier row, read through the same finite-row discipline as the state component of chapter 351;*
2. *Σ is the alphabet-window row naming exactly the symbols inspected by the finite input word;*
3. *δ is the transition table row whose displayed entries consume a state row and a symbol row and return the next state row;*
4. *q_0 is the start-state row inside Q;*
5. *F is the accepting-state row inside Q;*
6. *w is the finite input window as a displayed word spine over Σ;*
7. *ρ is the run-trace ledger beginning at q_0 and reading w one symbol at a time through δ;*
8. *e is the endpoint row of ρ;*
9. *χ is the classifier row saying that the endpoint is accepted exactly when e is displayed inside F;*
10. *H stores componentwise* hsame *transports for the state carrier, alphabet window, transition table, input window, run trace, endpoint, and classifier rows;*
11. *C stores the* Cont *replay routes that let a consumer re-read the input window, the transition table entry used at each step, the run endpoint, and the classifier row;*

12. *P stores the* Pkg *provenance naming the finite-row, word-spine, regular-language, and Turing-machine comparison surfaces consumed by the packet;*
13. *N stores the local* $\mathsf{NameCert}_{\mathsf{FiniteAutomaton}^{\uparrow}}$ *rows.*

The carrier predicate is $\mathsf{FiniteAutomatonPacket}(A)$*. It exports no nondeterministic branch choice, minimization quotient, regular-expression equivalence, host language set, infinite automaton, or unbounded computation trace.*

Lean4 ✓ `BEDC.Derived.FiniteAutomatonUp.TasteGate.FiniteAutomatonTasteGate single carrier alignment`

Theorem 2364.2 (FiniteAutomaton NameCert obligations)**.** *For every accepted* $\mathsf{FiniteAutomaton}^{\uparrow}$ *carrier*

$$A = (Q, \Sigma, \delta, q_0, F, w, \rho, e, \chi, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteAutomaton}^{\uparrow}}$ *surface consists of carrier admission, deterministic transition replay, endpoint classifier stability,* hsame *transport,* Cont *replay, and* Pkg *provenance for the rows in Definition 2364.1. A consumer may project the finite state carrier, alphabet window, transition table, start state, accepting-state row, input window, run trace, endpoint, classifier, and local naming rows, but it obtains no language quotient, hidden recognizer state, minimization datum, regular-expression conversion, or unbounded machine trace.*

Proof. Project the accepted carrier A. The finite rows $Q, \Sigma, \delta, q_0, F, w$ name the automaton presentation and the inspected input window, while ρ, e, χ name the run trace, endpoint, and acceptance classifier.

Deterministic replay is obtained by reading the word spine in w. At the empty window the trace endpoint is the start-state row q_0. At a cons window, the displayed transition-table entry in δ supplies the unique next state row, and the Cont replay route passes the remaining window to the same ledger.

Transport and provenance are exactly the rows H, C, P, N. Since those rows only compare and replay the displayed carrier coordinates, the certificate has no coordinate from which a quotient language, minimized automaton, hidden state, regular-expression conversion, or unbounded computation trace could be read. □

Theorem 2364.3 (FiniteAutomaton deterministic replay exactness)**.** *Let* $A = (Q, \Sigma, \delta, q_0, F, w, \rho, e, \chi, H, C, P, N)$ *be an accepted* $\mathsf{FiniteAutomaton}^{\uparrow}$ *carrier. Every accepted replay of the run trace ρ factors through the displayed start-state row q_0, the finite input window w, the transition table δ, the component-wise* hsame *rows H, the* Cont *replay rows C, and the same package provenance P, N. In particular, two replays with the same displayed rows have the same endpoint state and the same classifier row χ.*

Proof. Induct on the displayed input window w. For the empty window, carrier admission identifies the run endpoint with q_0, and the classifier row reads only whether this displayed state lies in F.

For a cons window, project the current state and head symbol. The transition table row has one displayed entry for that pair, so the next state of the replay is fixed. The Cont row then hands the tail window to the induction hypothesis with the transported state, transition, and classifier rows.

The hsame and Pkg rows only preserve the same displayed coordinates. Therefore no alternate endpoint can be produced from minimization, a language quotient, a hidden recognizer state, or an external computation trace. □

Theorem 2364.4 (FiniteAutomaton regular-language consumer)**.** *Every public* $\mathsf{RegularLanguage}^{\uparrow}$ *consumer that reads a displayed deterministic finite-automaton presentation can factor its finite recognition read through a* $\mathsf{FiniteAutomaton}^{\uparrow}$ *packet with the same state carrier, alphabet window, transition table, input word, run trace, endpoint classifier,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The factorization preserves the accepted-word endpoint exposed by chapter 351 and remains below the bounded trace surface of chapter 280.*

The factorization does not assert that all presentations of a regular language are equivalent, does not minimize the automaton, and does not translate the packet into a context-free or Turing-machine object. The context-free pumping consumer in chapter 2298 may read only the finite word-window and replay rows displayed here.

Proof. Begin with the public finite-automaton rows already exposed by the $\mathsf{RegularLanguage}^{\uparrow}$ consumer: finite alphabet, finite state carrier, start state, accepting-state row, transition table, input word, deterministic run, and accepted endpoint. These rows are exactly the first nine coordinates of Definition 2364.1.

Next copy the consumer's visible transport, continuation, and provenance rows into H, C, P, N. The deterministic replay exactness theorem then identifies the accepted endpoint with the replay endpoint of the $\mathsf{FiniteAutomaton}^{\uparrow}$ packet.

The resulting factorization is a projection to a smaller finite presentation. It therefore preserves the regular-language accepted-word endpoint while excluding minimization, language quotienting, context-free grammar conversion, and unbounded Turing-machine execution, none of which are carrier rows of $\mathsf{FiniteAutomaton}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteAutomaton}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteAutomaton}^{\uparrow}$ packet is generated from finite state rows, an alphabet window, a transition table, a start-state row, an accepting-state row, a finite input window, a deterministic run trace, an endpoint classifier, componentwise hsame transports, Cont replay routes, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteAutomaton}^{\uparrow}}$, obligation)

Scope closed: Definition 2364.1, Definition 2364.2, Definition 2364.3, and Definition 2364.4 bind the finite automaton carrier, local NameCert surface, deterministic replay route, and regular-language consumer factorization.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteAutomaton}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close minimization, regular-expression conversion, equivalence of all automaton presentations, nondeterministic branching, or machine-checked bridge evidence.

Upgrade path: Scoped closure requires checked Lean rows for the carrier, deterministic replay exactness, and the regular-language consumer factorization.

Chapter 2365

A Concrete Naming Certificate for $\mathsf{SorgenfreyPlane}^{\uparrow}$

Following Sorgenfrey and Kelley, the $\mathsf{SorgenfreyPlane}^{\uparrow}$ packet records the product of two lower-limit lines as finite NameCert data over the already named one-dimensional lower-limit and product-topology surfaces. It sits after the lower-limit line of chapter 3363, the product-topology route of chapter 2000, the indexed-open carrier of chapter 88, and the observable-open classifier of chapter 1860. The packet names the lower-limit product boundary without importing host metrizability, a powerset topology on pairs, selected neighbourhood bases, quotient equality of real pairs, or an ambient set-theoretic plane.

Definition 2365.1 (Sorgenfrey plane carrier)**.** *A* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (L_X, L_Y, Q, O_X, O_Y, B, S, H, C, R, N)$$

with the following displayed rows:

1. L_X *and* L_Y *are the two* $\mathsf{SorgenfreyLine}^{\uparrow}$ *source rows, each exposing lower-limit interval windows only through the finite carrier of Definition 3363.1.*
2. Q *is the* $\mathsf{ProductTopology}^{\uparrow}$ *product row, reading paired histories through component topology rows and rectangular subbasis data.*
3. O_X *and* O_Y *are the two component* $\mathsf{Topology}^{\uparrow}$ *indexed-open rows exported by the lower-limit line carriers.*
4. B *is the lower-limit rectangle ledger, recording basic rows of the form* $[a, b) \times [c, d)$ *as paired component windows rather than as a host powerset of* $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$.
5. S *is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row used when a consumer asks whether a displayed rectangle or generated product open has been observed.*
6. H *records componentwise* hsame *transport for both lower-limit line rows, the product-topology row, the component topology rows, the rectangle ledger, the observable-open row, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay from a product observation through component lower-limit windows, rectangular subbasis membership, generated product-topology admission, observable-open readback, transport, provenance, and local naming.*

8. *R is the* Pkg *provenance over* $\mathsf{SorgenfreyPlane}^{\uparrow}$, $\mathsf{SorgenfreyLine}^{\uparrow}$, $\mathsf{ProductTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{SorgenfreyPlane}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It stores no host plane, no metric witness, no second-countable base, no powerset topology, no quotient real-pair equality, no selected open family, and no hidden product carrier outside the displayed $\mathsf{ProductTopology}^{\uparrow}$ *route.*

Theorem 2365.2 (Sorgenfrey plane NameCert obligations)**.** *For every accepted* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *carrier*

$$P = (L_X, L_Y, Q, O_X, O_Y, B, S, H, C, R, N),$$

the local $\mathsf{NameCert}_{\mathsf{SorgenfreyPlane}^{\uparrow}}$ *obligations are exactly the displayed finite product rows:*

1. *component lower-limit admission through L_X and L_Y;*
2. *product-topology admission through Q, with the two topology rows O_X, O_Y exposed before any product read is consumed;*
3. *rectangle-ledger exactness through B, requiring every basic lower-limit product neighbourhood to be a paired half-open window row;*
4. *observable-open readback through S, so generated product opens are inspected through finite truth rows rather than host propositions;*
5. *transport, replay, provenance, and local naming through H, C, R, N.*

These obligations do not assert metrizability, normality, second countability, host separation theorems, powerset topology on pairs, quotient real-pair equality, selected bases, Lean verification, or bridge checking.

Proof. Project the accepted carrier. The only component sources are the lower-limit line rows L_X, L_Y, and each component topology read must pass through O_X, O_Y before the product row is consumed.

The product route is then fixed by Q. Its rectangular subbasis access is refined by B, whose entries are paired half-open windows and not arbitrary subsets of a host plane.

Observable-open requests pass through S, so membership reads return displayed finite truth data. The structural rows H, C, R, N only transport, replay, source, and name the same route. Since no row stores a metric, a selected basis, a host powerset, quotient real-pair equality, or an ambient plane, the listed rows exhaust the local NameCert obligations. □

Theorem 2365.3 (Sorgenfrey plane product-separation route)**.** *Every separation-facing read exported by an accepted* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *carrier factors through the finite route*

$$L_X, L_Y, O_X, O_Y, Q, B, S, H, C, R, N.$$

The route may distinguish product observations by component lower-limit windows and observable-open truth rows, but it cannot claim a host metric, a normality theorem, a powerset topology, or a selected countable base for the classical Sorgenfrey plane.

Proof. Start with a separation-facing request. The carrier has no direct separation coordinate, so the request must first read one or both component lower-limit line rows and their topology exports.

The product row Q then pairs those component reads. Any product-open evidence must pass through the rectangle ledger B, whose entries are generated from the two lower-limit component windows.

The observable-open row S records the finite truth readback for the generated product observation. Transport and replay through H, C, together with provenance and local naming through R, N, preserve that same componentwise route. Because the carrier lacks coordinates for host metrics, normality proofs, powerset opens, selected countable bases, and quotient real-pair equality, no such claim can be exported by the product-separation route. □

Falsifiable prediction: An accepted $\mathsf{SorgenfreyPlane}^{\uparrow}$ consumer that obtains a product-open or separation-facing read without first exposing both lower-limit component rows, the product-topology row, the rectangle ledger, and the observable-open row refutes the carrier surface.

Independence witness: sorgenfrey-line, product-topology, topology, sierpinski-space: no listed sibling supplies the whole eleven-row packet $P = (L_X, L_Y, Q, O_X, O_Y, B, S, H, C, R, N)$, because the lower-limit line supplies one-dimensional half-open windows, product topology supplies paired rectangular generation, topology supplies indexed-open rows, and Sierpinski space supplies observable-open truth readback, while this chapter binds those rows into one product lower-limit NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SorgenfreyPlane}^{\uparrow}}$.

Constructive story: A $\mathsf{SorgenfreyPlane}^{\uparrow}$ packet is generated from two SorgenfreyLineUp source rows, a ProductTopologyUp row, two TopologyUp component indexed-open rows, a lower-limit rectangle ledger, a SierpinskiSpaceUp observable-open row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SorgenfreyPlane}^{\uparrow}}$, seed)

Scope closed: Definition 2365.1, Definition 2365.2, and Definition 2365.3 seed the finite lower-limit product surface over SorgenfreyLine, ProductTopology, Topology, SierpinskiSpace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SorgenfreyPlane}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host metrizability, normality, second countability, powerset topology on pairs, quotient real-pair equality, selected bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked component lower-limit admission, product-topology admission, rectangle-ledger exactness, observable-open readback, transport stability, replay stability, and non-escape for BEDC.Derived.SorgenfreyPlaneUp

Theorem 2365.4 (Sorgenfrey plane lower-limit product dependency route)**.** *Every accepted* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *read that exposes plane-level separation, product-open, or nonnormality-facing data must first consume the two lower-limit line rows of chapter 3363 and the product-topology row of chapter 2000. In the carrier notation of Definition 2365.1, the rows* L_X, L_Y, O_X, O_Y, Q, B *are dependency data for the plane-level read; they are not replaceable by a host plane, a selected family of open rectangles, or a powerset topology on* $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 2365.1. The two one-dimensional source rows L_X, L_Y are read before any component topology rows O_X, O_Y or rectangle ledger row B is available.

Next read the product-topology row Q. It packages paired lower-limit windows as product evidence, so a plane-level product-open or separation-facing consumer receives the rectangular route only after both component lower-limit sources have been displayed.

The observable-open, transport, replay, provenance, and naming rows S, H, C, R, N preserve this dependency order. Since the carrier has no coordinate for an ambient host plane, selected rectangle family, powerset topology, or quotient equality of real pairs, every accepted plane-level read remains downstream of the lower-limit line and product-topology rows. □

Theorem 2365.5 (Sorgenfrey plane topology sibling route)**.** *Every accepted* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *carrier that exposes a plane topology read is downstream of the indexed-open carrier of chapter 88, the lower-limit line rows of chapter 3363, and the product-topology classifier of chapter 2000. In the notation of Definition 2365.1, the rows* L_X, L_Y, O_X, O_Y, Q, B *show that the carrier is not*

kernel-isolated: it consumes lower-limit topology and product topology classifier rows before any product-open or separation-facing read is public.

Proof. Project the carrier of Definition 2365.1. The component rows L_X, L_Y first expose lower-limit line data, and the rows O_X, O_Y are the topology rows read from those component sources.

Next read the product-topology row Q and the rectangle ledger B. Together with Definition 2365.4, these rows route every plane-level topology observation through paired lower-limit windows and the displayed product-topology classifier.

The structural rows S, H, C, R, N preserve the same dependency order for observable-open readback, transport, replay, provenance, and local naming. Since the carrier has no standalone topology coordinate outside O_X, O_Y, Q, B, no accepted plane topology read can bypass the lower-limit and product-topology siblings. □

Theorem 2365.6 (Sorgenfrey plane TopologyUp dependency)**.** *Every accepted* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *carrier that exposes its plane topology consumes the lower-limit topology and product topology rows through the* $\mathsf{Topology}^{\uparrow}$ *carrier/classifier route of chapter 88, together with the lower-limit source of chapter 3363 and the product classifier of chapter 2000. In the notation of Definition 2365.1, the rows* O_X, O_Y, Q, B *are the visible dependency surface for that read.*

Proof. Project the carrier rows O_X, O_Y, Q, B. The component topology rows O_X, O_Y are the $\mathsf{Topology}^{\uparrow}$ reads exported by the two lower-limit line sources, and Q is the displayed product-topology row.

Use Definition 2365.5 and Definition 2365.4. They force every plane-level topology observation to pass through the component lower-limit windows and then through the product classifier before the rectangle ledger B is public.

Thus the topology dependency is a concrete sibling route through $\mathsf{Topology}^{\uparrow}$, $\mathsf{SorgenfreyLine}^{\uparrow}$, and $\mathsf{ProductTopology}^{\uparrow}$, not a standalone host topology on a plane. □

Theorem 2365.7 (SorgenfreyPlane product-topology forward link)**.** *Every* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *product-open or separation-facing read consumes the* $\mathsf{SorgenfreyLine}^{\uparrow}$ *component rows through chapter 3363, the* $\mathsf{ProductTopology}^{\uparrow}$ *product row through chapter 2000, and the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row through chapter 1860. This route is a concrete sibling edge for the product lower-limit lattice: component half-open windows are paired by the product row and inspected by the observable-open row, with no assertion of metrizability, normality, selected bases, host powerset topology, quotient equality of real pairs, or ambient set-theoretic plane.*

Proof. Project the carrier of Definition 2365.1. The plane packet has two lower-limit component rows, the product topology row, the component indexed-open rows, the rectangle ledger, the observable-open row, transport, replay, provenance, and local naming data.

A product-open read first passes through the $\mathsf{SorgenfreyLine}^{\uparrow}$ component lower-limit rows and then through the $\mathsf{ProductTopology}^{\uparrow}$ row. Only after those rows are visible may the rectangle ledger be read as plane-level product data.

A separation-facing read follows the same route and then exposes the $\mathsf{SierpinskiSpace}^{\uparrow}$ observable-open row. Since every route remains inside the displayed component, product, observable-open, transport, replay, provenance, and local naming rows, no plane-level read bypasses the component lower-limit or product-topology dependencies. □

Theorem 2365.8 (Sorgenfrey plane topology sibling lattice)**.** *Every accepted* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *carrier consumes its topology dependency lattice through the lower-limit component route and the product-topology route before any plane-level open, rectangle, or separation-facing read is exported.*

In the notation of Definition 2365.1, the rows L_X, L_Y, O_X, O_Y, Q, B exhibit the dependency surface: L_X, L_Y name the two lower-limit sources, O_X, O_Y expose their topology rows, Q is the product-topology classifier, and B records the rectangle basis. Thus the carrier depends on the topology sibling of Definition 2365.5, the lower-limit product route of Definition 2365.4, and the product lattice route of Definition 2365.7; it is not a kernel-only packet.

Proof. Project the carrier rows named in Definition 2365.1. The lower-limit line entries L_X, L_Y are read before the component topology rows O_X, O_Y, so the plane topology cannot be formed without the two displayed line sources.

Next read Q and B. The product-topology row Q combines the component topology data, and the rectangle ledger B records the finite product basis used by plane-level reads.

Finally apply the existing sibling routes. Theorems 2365.5, 2365.4, and 2365.7 keep every exported topology or separation read on the displayed lower-limit and product-topology lattice. No additional kernel coordinate can supply a standalone topology for the plane. □

Chapter 2366

A Concrete Naming Certificate for $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$

Following Bishop and Bridges on nested intervals and regular Cauchy real names, the RegularCauchyCantorIntersectio packet records the finite route by which a descending sequence of closed dyadic windows with regular-Cauchy diameter control produces a named intersection witness before any terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the dyadic arithmetic core of chapter 291, the stream-window schedule of chapter 126, the regular rational readback of chapter 301, the real-name boundary of chapter 38, and the tail-estimate packet of chapter 1487. The carrier stores nested-window evidence and a regular Cauchy witness route; it does not import choice, quotient streams, open-cover compactness, selected host limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2366.1 (RegularCauchyCantorIntersection carrier)**.** *A* $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, W, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested closed-window ledger, listing the inspected lower and upper dyadic endpoints and the inclusion check from each visible window to its predecessor;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that records which interval stages and precision requests the packet exposes;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for endpoint comparison, diameter bounds, and midpoint slack at each inspected stage;*
4. *T is the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *tail-control row, stating that late windows have the displayed dyadic diameter bound for the requested precision;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name readback obtained from the nested-window and tail-control rows;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after I, W, D, T, R have been replayed;*
7. *H records componentwise* hsame *transport for the nested-window, stream, dyadic, tail-estimate, regular-name, and real-seal rows;*
8. *C records displayed* Cont *replay for the nested-window route and downstream witness handoff;*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCantorIntersection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, W, D, T, R, E, H, C, P, N$. There is no coordinate for a countable-choice selector, quotient equality of streams, open-cover compactness, a host-level selected point, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCantorIntersectionUp.RegularCauchyCantorIntersectionTasteGate`
`single carrier alignment`

Theorem 2366.2 (RegularCauchyCantorIntersection NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$ *carrier $K = (I, W, D, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCantorInter}}$ *surface consists exactly of carrier admission, nested-window inclusion, dyadic endpoint and diameter exactness, tail-estimate handoff, regular-Cauchy readback, real-seal nonescape, componentwise transport, displayed replay, package provenance, local naming, and refusal of choice selectors, quotient streams, open-cover compactness, host selected limits, trichotomy, and ambient real completeness.*

Proof. Project the displayed carrier. The only interval data are the nested ledger I, the visible stage schedule W, and the dyadic endpoint ledger D, so carrier admission and nested-window inclusion are read from those rows.

The tail-control and regular-name obligations are T and R. The tail-estimate row supplies the diameter budget for late windows, and the regular-name row reads that budget as the Cauchy witness consumed by $\mathsf{RegSeqRat}^{\uparrow}$.

The real-seal row E is downstream of the nested-window and regular-name rows. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve the same route and add no selector, quotient, compactness, host limit, trichotomy, or ambient-completeness coordinate. □

Theorem 2366.3 (RegularCauchyCantorIntersection nested-window route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$ *carrier factors through the finite route*

$$I, W \longmapsto D \longmapsto T \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the intersection witness is read only after the nested closed-window ledger, finite stream schedule, dyadic endpoint and diameter checks, regular tail estimate, and regular rational name have been displayed. The route supplies a constructive regular-Cauchy witness and does not supply countable choice, quotient-stream equality, open-cover compactness, a selected host limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 2366.1. The rows I and W expose only the inspected closed windows and the finite schedule of stages visible to the request.

Read the dyadic ledger D next. It supplies endpoint comparison and diameter bounds for the same windows, so the consumer cannot bypass the dyadic layer and jump directly to a real point.

Apply the tail-estimate row T and the regular-name row R. Together they turn the shrinking-window evidence into a displayed regular Cauchy readback before the real seal E is available.

Finally inspect H, C, P, N. These structural rows transport, replay, source, and name the same finite route. Since the carrier has no selector, quotient, open-cover, host-limit, trichotomy, or ambient-completeness row, every accepted consumer remains inside the displayed nested-window route. □

Theorem 2366.4 (Regular Cauchy Cantor intersection tail schedule)**.** *For every accepted* RegularCauchyCantorInte *carrier*

$$K = (I, W, D, T, R, E, H, C, P, N),$$

the intersection witness is readable only after a finite $\mathsf{StreamName}^{\uparrow}$ *stage schedule has exposed the inspected nested windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and diameter checks have been replayed, the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *row has handed its tail budget to* $\mathsf{RegSeqRat}^{\uparrow}$*, and the resulting regular readback has reached the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The same read must also pass through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCantorIntersection}^{\uparrow}}$ *row. No quotient stream, unbounded schedule, selected host point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can shorten that tail schedule.*

Proof. Project the accepted carrier. The rows $I, W, D, T, R, E, H, C, P, N$ are the whole displayed packet, and the finite stage information is stored only in the $\mathsf{StreamName}^{\uparrow}$ row W together with the nested-window ledger I.

Use the NameCert obligations of Definition 2366.2. They force endpoint exactness and diameter control through the dyadic ledger D, and they place the tail-estimate handoff in T before any regular rational readback is consumed.

Now apply the nested-window route of Definition 2366.3. It orders the accepted read as

$$I, W \longmapsto D \longmapsto T \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the schedule is finite because every displayed stage is named by W before the route reaches R or E. Since the carrier has no row for quotient streams, host selected points, unbounded schedules, or ambient completeness, the accepted intersection witness is readable only through the finite tail schedule. □

Falsifiable prediction: A $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$ read is refuted whenever a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reaches the intersection witness without displaying the nested closed-window ledger, the finite StreamName schedule, the DyadicRatCore endpoint and diameter checks, the RegularCauchyTailEstimate row, the RegSeqRat readback, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, regularcauchytailestimate: none alone is bijective with $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$ because the packet jointly records nested closed-window inclusion, dyadic diameter control, finite stage scheduling, tail-estimate handoff, regular-name readback, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCantorIntersection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyCantorIntersection}^{\uparrow}$ packet is generated from a nested closed-window ledger, a finite StreamName stage schedule, a DyadicRatCore endpoint and diameter ledger, a RegularCauchyTailEstimate row, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyCantorIntersection}^{\uparrow}}$, seed)

Scope closed: Definition 2366.1, Definition 2366.2, and Definition 2366.3 seed the nested closed-window route from regular Cauchy tail control to Real sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyCantorIntersection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient streams, open-cover compactness, selected host limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window inclusion, dyadic endpoint exactness, tail-estimate handoff, regular-name readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCantorIntersectionUp.

Chapter 2367

A Concrete Naming Certificate for $\mathsf{HausdorffUniformCompletion}^{\uparrow}$

Following Kelley on uniform spaces and Bishop–Bridges constructive completion, the $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ packet records the separated uniform-completion boundary required when a completion route must expose both Cauchy-filter data and Hausdorff uniqueness data as finite rows. It sits between the uniform completion carrier of chapter 1473, the separated completion seal of chapter 402, the Cauchy-filter source of chapter 333, the Cauchy-net witness surface of chapter 589, and the separated uniform-space packet of chapter 1876. The packet names the point at which the L10 completion route may read separatedness explicitly rather than treating it as implicit in uniform completion.

Definition 2367.1 (Hausdorff uniform completion carrier)**.** *A* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, D, U, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row fixing the completion-facing filter request.*
2. *D is the* $\mathsf{CauchyNet}^{\uparrow}$ *directed witness row extracted from the same request.*
3. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *universal-extension row, read only after F and D have displayed the completion source.*
4. *S is the Hausdorff and separated classifier row, read through* $\mathsf{HausdorffCompletion}^{\uparrow}$ *and the separated uniform-space boundary, which compares two completion reads without introducing a quotient representative.*
5. *H records componentwise* hsame *transport for F, D, U, S, C, P, N.*
6. *C records displayed* Cont *replay from completion consumers through the same finite route.*
7. *P is the* Pkg *provenance over* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffUniformCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one separated uniform-completion packet. It contains no coordinate for a quotient completion object, selected representative, host equality of completed points, countable choice, or ambient complete uniform space.

Lean4 ✓ BEDC.Derived.HausdorffUniformCompletionUp.HausdorffUniformCompletionTasteGate single carrier alignment

Theorem 2367.2 (Hausdorff uniform completion NameCert obligations)**.** *For an accepted* HausdorffUniformComple *carrier* $K = (F, D, U, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HausdorffUniformCompletion}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the displayed Cauchy-filter row, Cauchy-net row, uniform-completion universal row, separated classifier row, transport row, replay row, provenance row, and local naming row;*
2. *filter-net exactness, requiring every completion-facing read to pass through* F *and then through the finite directed witness row* D *before* U *is available;*
3. *separated classifier stability, requiring* S *to compare completed reads only through the displayed* $\mathsf{HausdorffCompletion}^{\uparrow}$ *and separated uniform-space rows;*
4. *transport and replay stability, requiring* H *and* C *to preserve the same row order under componentwise sameness and displayed continuation replay;*
5. *ledger non-escape, requiring* P *and* N *to name no quotient completion, selected representative, host equality, countable-choice schedule, or ambient complete uniform-space coordinate.*

No separated uniform-completion obligation is stored outside these finite rows.

Proof. Carrier admission is projection from Definition 2367.1. The projected coordinates are exactly the filter row F, net row D, universal row U, separated classifier row S, and structural rows H, C, P, N.

Filter-net exactness reads the same finite route as Definition 1473.7. The filter row fixes the request, and the directed-net row supplies the finite witness before any universal-extension comparison is visible.

Separated classifier stability is the role of S. The comparison can cite the Hausdorff completion boundary of chapter 402 and the separated uniform-space packet of chapter 1876, but it receives no quotient class or selected representative.

The transport and replay rows H and C preserve that same route. Since P and N package and name only the displayed packet, every excluded object is outside the carrier and outside the continuation ledger. □

Theorem 2367.3 (Hausdorff uniform completion separation handoff)**.** *Every separated uniform-completion uniqueness read from an accepted* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *carrier*

$$K = (F, D, U, S, H, C, P, N)$$

must first expose the $\mathsf{CauchyFilter}^{\uparrow}$ *source row* F*, the* $\mathsf{CauchyNet}^{\uparrow}$ *directed witness row* D*, the* $\mathsf{UniformCompletion}^{\uparrow}$ *universal row* U*, the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separation row inside* S*, and the* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *classifier inside the same separated row. The read therefore cannot export quotient completion classes, selected representatives, countable choice, or host equality.*

Proof. Project the carrier of Definition 2367.1. The rows F, D, U, S, H, C, P, N are the only coordinates available to a separated uniform-completion consumer.

The separated classifier S is downstream of the filter row F, directed witness row D, and universal-completion row U. Thus uniqueness can be read only after the Cauchy-filter request, Cauchy-net witness, and uniform-completion universal row have already been displayed.

Finally read H, C, P, N as transport, replay, provenance, and name preservation for the same route. These structural rows preserve the separated handoff; they do not introduce quotient completion classes, selected representatives, countable-choice schedules, or host equality. □

Theorem 2367.4 (Hausdorff uniform completion filter-net coincidence)**.** *Let $K = (F, D, U, S, H, C, P, N)$ be an accepted* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *carrier presenting both the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F and the* $\mathsf{CauchyNet}^{\uparrow}$ *row D for the same uniform-completion request U. Every separated uniqueness read from either presentation factors through the same route*

$$S, H, C, P, N.$$

Thus the filter side and the net side cannot create a second completion point, quotient filter/net equality, a selected representative, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 2367.1. The accepted packet contains one Cauchy-filter source row F, one Cauchy-net witness row D, one uniform-completion request row U, and the shared separated and structural rows S, H, C, P, N.

Use the NameCert obligations of Definition 2367.2. Filter-net exactness places both presentations before U, while separated classifier stability makes S the only row from which uniqueness can be read.

Finally apply the separation handoff of Definition 2367.3. Since both sides reach the same S, H, C, P, N route, neither presentation exports a second completion point, quotient equality between filters and nets, selected representatives, host equality, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer reads $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, and a Hausdorff separated classifier row before citing separated uniform-completion uniqueness.

Independence witness: cauchyfilter, cauchynet, uniformcompletion, hausdorffcompletion, separateduniformspace: $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the filter request, directed witness, universal-extension route, separated classifier, transport, replay, provenance, and local NameCert rows as one boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffUniformCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2367.1 and Definition 2367.2 seed the separated uniform-completion boundary over displayed Cauchy-filter, Cauchy-net, uniform-completion, Hausdorff classifier, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffUniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient completion equality, selected representatives, host equality, countable choice, or ambient complete uniform-space existence.

Upgrade path: Obligation closure requires checked carrier admission, filter-net exactness, separated classifier stability, transport and replay stability, and ledger non-escape for BEDC.Derived.HausdorffUniformCompletionUp.

Constructive story: A $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ packet is generated from CauchyFilter, CauchyNet, UniformCompletion, HausdorffCompletion, SeparatedUniformSpace, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 2368

A Concrete Naming Certificate for $\mathsf{WrrStatePhaseSpace}^{\uparrow}$

The $\mathsf{WrrStatePhaseSpace}^{\uparrow}$ packet realizes the WRR hotspot state-vector branch of chapter 9462 and the source analysis in subsection 9462.28.21 as finite NameCert data. It sits beside the codon-window carrier of chapter 2234, the transition matrix of chapter 2245, the core state graph of chapter 2306, and the finite observation fold of chapter 2236. Those siblings expose codon windows, transition rows, graph compression, and finite observation folding; this packet binds the WRR hotspot state vector, invariant anchors, active support, reassignment preorder, table provenance, transport, replay, and local naming as one concrete finite phase-space object.

Definition 2368.1 (WRR state phase-space carrier)**.** *A* $\mathsf{WrrStatePhaseSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, A, V, R, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the state-vector ledger recording the eight-coordinate C_{WRR} assignment vector of Definition 9462.1794.*
2. *A is the invariant-anchor ledger for the* UGG *and* AAG *coordinates of Definition 9462.1796.*
3. *V is the active-support row naming the six moving WRR coordinates of Definition 9462.1797.*
4. *R is the reassignment-preorder row recording the finite inclusions of Definition 9462.1802.*
5. *T is the table-provenance row linking each state vector to its curated genetic-code table identifier and comparison-family ledger.*
6. *H records componentwise* hsame *transport for the state vector, anchors, active support, preorder, table provenance, replay, package, and local naming rows.*
7. *C records displayed* Cont *replay from a hotspot-state consumer through S, A, V, R, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{WrrStatePhaseSpace}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{CoreStateGraph}^{\uparrow}$, $\mathsf{FiniteObservationFold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{WrrStatePhaseSpace}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite WRR hotspot state phase space. It does not assert a biochemical time parameter, an evolutionary tree, a complete biological state space, or a dynamics law outside the displayed comparison-family ledger.

Theorem 2368.2 (WRR state phase-space NameCert obligations)**.** *For an accepted* $\mathsf{WrrStatePhaseSpace}^{\uparrow}$ *carrier* $W = (S, A, V, R, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WrrStatePhaseSpace}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the state-vector ledger, invariant-anchor ledger, active-support row, reassignment-preorder row, table-provenance row, componentwise transport, replay, package provenance, and local naming row;*
2. *state-vector exactness, requiring every hotspot-state read to use the coordinate order fixed by* S *and the WRR cube source rather than an unnamed codon projection;*
3. *anchor and support stability, requiring* A *and* V *to keep invariant anchors separate from active reassignment coordinates under* H *and* C*;*
4. *preorder provenance, requiring each inclusion in* R *to be sourced by finite table identifiers in* T *and replayed only through the same comparison-family ledger;*
5. *ledger non-escape, requiring* P *and* N *to export no temporal dynamics, no causal reassignment rule, no evolutionary tree, no unobserved-state impossibility claim, and no context-free translation model.*

Lean follow-up must provide $\mathsf{Nontrivial\ WrrStatePhaseSpace}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ WrrStatePhaseSpace}^{\uparrow}$ *instances in* BEDC.Derived.WrrStatePhaseSpaceUp.TasteGate *for this displayed finite carrier.*

Proof. Carrier admission is projection from Definition 2368.1. The tuple displays exactly the state-vector, anchor, support, preorder, table-provenance, transport, replay, provenance, and naming rows.

State-vector exactness reads the WRR coordinate order from the source definition and stores it in S. The carrier has no second codon projection row, so a hotspot-state consumer cannot silently change the coordinate order.

Anchor and support stability use the split between A and V. The invariant anchors remain named separately from the active support, while H and C transport and replay the same split rather than merging it into a single untyped state list.

Preorder provenance is the role of R and T. Each displayed inclusion is tied to finite table identifiers before it is packaged, so the preorder is an observed comparison-family row and not a temporal or causal law.

The remaining claim is ledger non-escape. Since temporal dynamics, causal reassignment mechanisms, evolutionary-tree structure, exhaustive biological state space, and ribosome-context models are not carrier coordinates, no NameCert consumer can read them from W. □

Lean4 ✓ `BEDC.Derived.WrrStatePhaseSpaceUp.WrrStatePhaseSpaceTasteGate single carrier alignment`

Falsifiable prediction: Every accepted $\mathsf{WrrStatePhaseSpace}^{\uparrow}$ consumer reads a WRR state-vector ledger, invariant-anchor ledger, active-support row, reassignment-preorder row, table-provenance row, hsame transport, Cont replay, Pkg provenance, and local naming before citing hotspot phase-space compression.

Independence witness: codon-six-bit-window, codon-transition-matrix, core-state-graph, finite-observation-fold; $\mathsf{WrrStatePhaseSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state vectors, invariant anchors, active support, reassignment preorder, table provenance, transport, replay, package provenance, and local NameCert rows as one hotspot phase-space packet.

Closure status for $\mathsf{NameCert}_{\mathsf{WrrStatePhaseSpace}^{\uparrow}}$ **.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WrrStatePhaseSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2368.1 and Definition 2368.2 seed the finite WRR hotspot phase-space surface over state-vector, invariant-anchor, active-support, reassignment-preorder, table-provenance, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{WrrStatePhaseSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, temporal biological dynamics, causal reassignment mechanisms, evolutionary-tree reconstruction, exhaustive biological state-space closure, or context-free translation dynamics.

Upgrade path: Obligation closure requires checked carrier admission, state-vector exactness, anchor and support stability, preorder provenance, ledger non-escape, and TasteGate nontriviality plus field faithfulness for BEDC.Derived.WrrStatePhaseSpaceUp.

Constructive story: A WrrStatePhaseSpace$^{\uparrow}$ packet is generated from WRR state-vector, invariant-anchor, active-support, reassignment-preorder, table-provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 2369

A Concrete Naming Certificate for $\mathsf{SigmaCompact}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{SigmaCompact}^{\uparrow}$ packet records a space by a displayed compact exhaustion rather than by an open-cover compactness principle or a choice-selected cover. It sits as an L10 neighbour of the local compactness certificate of chapter 1726, the proper closed-ball compactness route of **??**, the center-radius window of chapter 1451, the compact metric witness of chapter 129, and the stream-indexed naming surface of chapter 126. The packet is finite at every public read: a consumer sees a named exhaustion prefix, its compact rows, and the replay ledger that justifies the prefix, not a completed countable family supplied by an ambient host.

Definition 2369.1 (SigmaCompact carrier)**.** *A* $\mathsf{SigmaCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, E, K, B, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric or topological source row whose points and comparison data are already carried by finite BEDC histories.*
2. *E is a* $\mathsf{StreamName}^{\uparrow}$ *exhaustion-prefix row. Its displayed entries name compact windows $E(0), \ldots, E(m)$ and a monotone inclusion ledger between consecutive entries.*
3. *K assigns a* $\mathsf{CompactMetric}^{\uparrow}$ *witness to each displayed exhaustion entry $E(i)$.*
4. *B is the optional* $\mathsf{MetricClosedBall}^{\uparrow}$ *boundary row for those entries that arise from center-radius metric windows.*
5. *L is the optional* $\mathsf{LocallyCompact}^{\uparrow}$ *support row, used only when a local compact neighbourhood certificate is the source of one displayed exhaustion window.*
6. *H records componentwise* hsame *transport for the source row, exhaustion prefix, compact witnesses, closed-ball boundary rows, local compact support rows, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite exhaustion request through X, E, K, B, L, H and into a compactness, properness, completion, or stream consumer.*
8. *P is the* Pkg *provenance over* $\mathsf{SigmaCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{SigmaCompact}^\uparrow}$ *row.*

The classifier compares accepted carriers only through these nine rows. It has no coordinate for open-cover compactness, countable choice, a host-selected exhaustion, quotient point equality, or an ambient locally compact or proper metric structure beyond the displayed handoff rows.

Theorem 2369.2 (SigmaCompact NameCert obligations)**.** *For every accepted* $\mathsf{SigmaCompact}^\uparrow$ *carrier* $S = (X, E, K, B, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SigmaCompact}^\uparrow}$ *surface consists exactly of carrier admission, exhaustion-prefix indexing, compact witness transport for each displayed prefix entry, closed-ball boundary handoff when a row B is present, locally compact support handoff when a row L is present, provenance non-escape, and local naming for the rows $X, E, K, B, L, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.SigmaCompactUp.SigmaCompactTasteGate single carrier alignment`

Proof. Project the carrier of Definition 2369.1. Carrier admission reads the source row, the finite stream prefix, the compact witnesses attached to that prefix, the optional boundary and local compact rows, and the structural rows H, C, P, N.

Exhaustion-prefix indexing is finite. Induct over the displayed list $E(0), \ldots, E(m)$. At each entry the compact witness is the corresponding row in K, and the inclusion into the next displayed window is one of the ledger entries already present in E.

The handoff rows are exact. A closed-ball consumer can read B only for entries that display a $\mathsf{MetricClosedBall}^\uparrow$ boundary, and a local compactness consumer can read L only for entries that display the corresponding $\mathsf{LocallyCompact}^\uparrow$ support.

Provenance and naming are exhausted by P and N. Since the carrier has no coordinate for open covers, countable choice, host-selected exhaustions, quotient point equality, or ambient properness, none of those principles can occur in the local NameCert surface. □

Theorem 2369.3 (SigmaCompact proper metric exhaustion)**.** *Every accepted* $\mathsf{ProperMetric}^\uparrow$ *packet that displays a finite radius-window prefix through* $\mathsf{StreamName}^\uparrow$ *induces a* $\mathsf{SigmaCompact}^\uparrow$ *read over the same metric source by taking each shown window to its* $\mathsf{MetricClosedBall}^\uparrow$ *row and its attached* $\mathsf{CompactMetric}^\uparrow$ *witness. The induced read exports only*

$$X, E, K, B, L, H, C, P, N,$$

with L empty unless a local compactness support row is displayed, and it does not export open-cover compactness, a completed countable exhaustion, selected centers outside the prefix, quotient equality, countable choice, or ambient completeness.

Proof. Start with the proper metric carrier of **??**. For each displayed radius-window entry in the stream prefix, the proper metric packet already exposes a closed-ball row and a compact witness for that same row.

Package the displayed prefix as E. The compact witnesses become K, the closed-ball rows become B, and the optional local compact support is copied into L only when it is already shown. Componentwise transport and replay are inherited as H and C.

The resulting tuple has exactly the carrier form of Definition 2369.1. Its provenance names the proper metric source and the compact, closed-ball, local compact, and stream-name siblings, so a downstream consumer cannot extend the prefix, select hidden centers, or import an open-cover or choice principle. □

Lean4 ✓ `BEDC.Derived.SigmaCompactUp.SigmaCompactCarrier proper metric exhaustion`

Theorem 2369.4 (SigmaCompact compact-exhaustion sibling route)**.** *Every* $\mathsf{SigmaCompact}^{\uparrow}$ *consumer of a displayed compact exhaustion reads the sibling rows* $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *only through the carrier route*

$$X, E, K, B, L, H, C, P, N.$$

The finite exhaustion prefix E *names the displayed windows,* K *supplies the compact witnesses for those windows,* B *and* L *are read only when the corresponding closed-ball or local compact support rows are displayed, and* H, C, P, N *transport, replay, source, and name that same route. The read exports no open-cover compactness, completed countable exhaustion, countable choice, quotient equality, or ambient completeness.*

Proof. Apply Definition 2369.1. The only public coordinates of an accepted compact-exhaustion packet are the source row, stream prefix, compact witnesses, optional closed-ball and local compact rows, and the structural rows H, C, P, N.

Apply Definition 2369.2. It fixes the local NameCert surface to those displayed rows, so a consumer cannot read a locally compact, proper metric, closed-ball, compact metric, or stream-name sibling except by projecting the corresponding coordinate of the carrier.

Finally apply Definition 2369.3. The proper metric route supplies closed-ball and compact witnesses only for the displayed finite prefix. Since neither the carrier nor the proper metric handoff contains an open-cover compactness proof, completed countable exhaustion, countable-choice schedule, quotient equality, or ambient completeness row, the sibling route cannot export any of those objects. □

Lean4 ✓ `BEDC.Derived.SigmaCompactUp.SigmaCompactCompactExhaustionSiblingRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{SigmaCompact}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SigmaCompact}^{\uparrow}$ packet is generated from a source row, a finite StreamName exhaustion prefix, CompactMetric witnesses for displayed entries, optional MetricClosedBall and LocallyCompact handoff rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SigmaCompact}^{\uparrow}}$, seed)

Scope closed: Definition 2369.1, Definition 2369.2, and Definition 2369.3 seed the finite compact-exhaustion interface between local compactness, proper metric windows, compact metric witnesses, and stream-indexed names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SigmaCompact}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, a completed countable exhaustion, countable choice, quotient point equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exhaustion-prefix indexing, compact witness projection, proper metric handoff, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.SigmaCompactUp.

Chapter 2370

A Concrete Naming Certificate for $\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}$

Following Blaschke and Kelley, the $\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}$ packet names the finite selection surface for a sequence of compact subsets of a compact metric source. It sits over the compact-subset ledger of chapter 1660, the finite-net distance interface of chapter 2086, the compact metric source of chapter 129, the directed convergence route of chapter 1667, and the uniform Cauchy-net boundary of chapter 1657. The packet records finite Hausdorff-distance selection data; it is not a host compactness theorem, an open-cover argument, an ambient powerset quotient, a choice-selected subnet, or an external sequential compactness principle.

Definition 2370.1 (Blaschke selection compact-hyperspace carrier)**.** *A* $\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, S, D, W, E, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, including its* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, finite-net, total-boundedness, and completeness witnesses.*
2. *S is the sequence of compact-subset* $\mathsf{Hyperspace}^{\uparrow}$ *rows over X, with each compact-subset presentation read only through the displayed hyperspace carrier.*
3. *D is the* $\mathsf{HausdorffMetric}^{\uparrow}$ *distance-ledger family comparing the compact-subset rows of S at each requested finite resolution.*
4. *W is the finite Cauchy-subnet window ledger, recording the selected index window, cofinality evidence, Hausdorff-distance requests, and stabilization bounds.*
5. *E is the extracted compact-subset endpoint row, displayed as a* $\mathsf{Hyperspace}^{\uparrow}$ *compact-subset name over the same source X.*
6. *R is the dyadic and* $\mathsf{Real}^{\uparrow}$ *tolerance readback showing that the window ledgers in W and the endpoint row E answer the same finite Hausdorff-distance requests.*
7. *H records componentwise* hsame *transport for the compact metric source, compact-subset sequence, Hausdorff distance ledgers, Cauchy-subnet windows, endpoint row, tolerance readback, provenance, and local naming rows.*

8. *C records displayed* Cont *replay through*

$$X, S, D \longmapsto W \longmapsto E, R.$$

9. *P is the* Pkg *provenance over* BlaschkeSelectionCompactHyperspace$^{\uparrow}$, Hyperspace$^{\uparrow}$, HausdorffMetric$^{\uparrow}$, CompactMetric$^{\uparrow}$, NetConvergence$^{\uparrow}$, CauchyUniformNet$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{BlaschkeSelectionCompactHyperspace}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $X, S, D, W, E, R, H, C, P, N$. It has no coordinate for open-cover compactness, host powersets, quotient subset equality, selected choice functions, or an unbounded subnet object.

Lean4 ✓ `BEDC.Derived.BlaschkeSelectionCompactHyperspaceUp.BlaschkeSelectionCompactHyperspaceTasteGate single carrier alignment`

Theorem 2370.2 (Blaschke selection compact-hyperspace NameCert obligations)**.** *For every accepted* BlaschkeSelectionCompactHyperspace$^{\uparrow}$ *carrier*

$$B = (X, S, D, W, E, R, H, C, P, N),$$

the local NameCert$_{\text{BlaschkeSelectionCompactHyperspace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source row X, the compact-subset sequence S, the HausdorffMetric distance ledgers D, the finite Cauchy-subnet windows W, the endpoint row E, tolerance readback R, transport, replay, provenance, and local naming rows;*

2. *compact-subset sequence exactness, requiring every displayed member of S to be admitted through* Hyperspace$^{\uparrow}$ *over the same compact metric source X before any selection window can inspect it;*

3. *finite Hausdorff Cauchy-window stability, requiring the ledgers in D and W to share the same finite resolution requests and to route their distance reads through* HausdorffMetric$^{\uparrow}$*;*

4. *endpoint readback stability, requiring E and R to expose the selected compact-subset endpoint only by the displayed* Real$^{\uparrow}$ *tolerance comparisons and componentwise* hsame *transport;*

5. *provenance and name exhaustion, requiring C, P, N to replay, source, and name only the displayed finite route and to export no host compactness theorem, powerset quotient, selected choice function, open-cover proof, or unbounded subnet object.*

No Blaschke selection compact-hyperspace obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2370.1. The packet displays the compact metric source, compact-subset sequence, Hausdorff distance ledgers, Cauchy-subnet windows, endpoint row, tolerance readback, transports, replay, provenance, and local naming row as its only coordinates.

The compact-subset sequence is exact because every member of S is read through the Hyperspace$^{\uparrow}$ surface over the same source X. The Hausdorff reads are exact because D records only finite HausdorffMetric$^{\uparrow}$ ledgers attached to those displayed compact-subset names.

The selection step is the finite-net replay through W. Each selected window exposes a cofinal finite index range and a stabilization ledger, and the route through NetConvergence$^{\uparrow}$ and CauchyUniformNet$^{\uparrow}$ keeps the window evidence inside displayed convergence data.

The endpoint and tolerance readback are then projected through E and R. The endpoint is a compact-subset row over X, while the $\mathsf{Real}^{\uparrow}$ readback states exactly the finite Hausdorff-distance tolerances checked by the window ledgers.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for host compactness, powerset quotients, choice-selected functions, open-cover proofs, or unbounded subnet objects, the five listed obligation rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}}$.

Constructive story: A $\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}$ packet is generated from a CompactMetricUp source, a sequence of HyperspaceUp compact-subset rows, HausdorffMetricUp distance ledgers, finite Cauchy-subnet windows, an endpoint compact-subset row, RealUp tolerance readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2370.1 and Definition 2370.2 seed the finite compact-hyperspace selection surface through Hyperspace, HausdorffMetric, CompactMetric, NetConvergence, and CauchyUniformNet rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host compactness, open-cover compactness, powerset quotients, choice-selected functions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-subset sequence exactness, finite Hausdorff Cauchy-window stability, endpoint readback stability, and provenance/name exhaustion for BEDC.Derived.BlaschkeSelectionCompactHyp

Chapter 2371

A Concrete Naming Certificate for $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$

The $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$ packet realizes the observation-boundary route implicit in chapter 9390 as finite NameCert data. It sits between the cellular trust substrate of chapter 940, the cellular rule and orbit carrier of chapter 934, the bounded trace boundary of chapter 944, the local read cell of chapter 509, and the continuation automaton surface of chapter 482. Its distinguishing datum is the finite boundary at which a local rule, a bounded orbit window, a manifest row, and an audit replay jointly authorize an observation.

Falsifiable prediction: Removing either the local-rule row or the boundary-manifest row breaks accepted observation replay: without the local rule two windows with different update tables can share the same text observation, and without the manifest the audit route has no finite boundary against which to replay the observation.

Independence witness: cellulartrustsubstrate, cellularautomaton, boundeduniversaltrace, localitycell, continuationautomaton: none is bijective to $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$ because each omits at least one of the joint boundary ingredients: local transition table, bounded orbit window, boundary manifest, accepted observation row, or audit replay route.

Definition 2371.1 (Cellular substrate observation-boundary carrier)**.** *A* $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (R, W, M, B, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the local cellular rule row, including alphabet, neighbourhood arity, boundary convention, and complete transition table.*
2. *W is the bounded orbit-window row, including the initial configuration, finite time interval, displayed cell coordinates, and trace bounds.*
3. *M is the boundary-manifest row recording the accepted observation fields, replay bounds, text schema, and local read discipline.*
4. *B is the accepted observation-boundary row, pairing the displayed local cells with the manifest fields and the orbit-window coordinates they are allowed to inspect.*
5. *A is the audit-replay row, replaying each boundary read from R through W and checking it against M and B.*

6. *H records componentwise* hsame *transport for the local rule, orbit window, manifest, boundary row, audit replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through*

$$R, W, M, B \longmapsto A.$$

8. *P is the* Pkg *provenance over* $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$, $\mathsf{CellularTrustSubstrate}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{BoundedUniversalTrace}^{\uparrow}$, $\mathsf{LocalityCell}^{\uparrow}$, $\mathsf{ContinuationAutomaton}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unbounded orbit, hidden update table, host evaluator identity, detached manifest schema, quotient stream equality, or an all-time induction principle.

Lean4 ✓ `BEDC.Derived.CellularSubstrateObservationBoundaryUp.CellularSubstrateObservationBoundaryTasteGa`
`single carrier alignment`

Theorem 2371.2 (Cellular trust substrate vision route)**.** *For every accepted* $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$ *carrier*

$$O = (R, W, M, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}}$ *surface gives a finite route from a local rule and bounded orbit window to a trusted observation boundary. A consumer receives exactly the local-rule row R, bounded orbit-window row W, boundary-manifest row M, accepted observation-boundary row B, audit-replay row A, componentwise transport H, displayed replay C, provenance P, and local naming row N, and receives no unbounded orbit, hidden update table, detached manifest, host evaluator, quotient stream, or all-time induction principle.*

Proof. Carrier admission is projection from Definition 2371.1. The packet displays the local rule, orbit window, manifest, boundary row, audit replay, transport, continuation, provenance, and naming rows as its complete coordinate list.

The finite route starts at R and W. The rule row supplies the transition table and boundary convention, while the orbit-window row fixes the initial configuration, time interval, and cell coordinates that may be inspected.

The observation boundary is then exposed by M and B. The manifest states the accepted schema and replay bounds, and the boundary row ties each observation field to the local cells and orbit coordinates it is allowed to read.

The audit replay A checks the route back through R, W, M, B. Componentwise transport through H and displayed replay through C preserve the same boundary route under accepted comparison.

Finally P and N source and name only this displayed packet. Since no row carries an unbounded orbit, hidden update table, detached manifest, host evaluator, quotient stream, or all-time induction principle, the trusted observation boundary is exactly the finite NameCert route stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$ packet is generated from a local cellular rule, bounded orbit window, boundary manifest, accepted observation-boundary row, audit replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2371.1 and Definition 2371.2 seed the finite route from local rule and bounded orbit window to a trusted observation boundary.

Formal verification: FormalStatus(NameCert$_{\text{CellularSubstrateObservationBoundary}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.CellularSubstrateObservationBoundaryUp.CellularSubstrateObservationBoundaryTasteGate\_s`

Bridge status: none

Not claimed: This chapter does not claim Rule 110 universality, host evaluator correctness, quotient streams, cellular completeness, all-time induction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-rule accountability, bounded orbit-window exactness, manifest-boundary replay, and provenance/name exhaustion for BEDC.Derived.CellularSubstrateObservationBoundaryUp; Lean follow-up must provide Nontrivial and FieldFaithful TasteGate instances.

Chapter 2372

A Concrete Naming Certificate for $\mathsf{SequentialCompact}^{\uparrow}$

Following Bishop and Bridges constructive compactness and Brouwer choice-sequence practice, the $\mathsf{SequentialCompact}^{\uparrow}$ packet records sequential compactness only as finite subsequence-window data. It sits over the compact metric source of chapter 129, the Baire-space inspection discipline of chapter 334, the finite stream interface of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet gives compact-metric and Baire-space completion consumers a displayed subsequence route; it is not a host sequential compactness theorem, not countable choice, and not a quotient stream principle.

Definition 2372.1 (SequentialCompact carrier)**.** *A* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, B, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite cover and metric inspection data bound the sequence consumer.*
2. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *cylinder discipline row used when a downstream completion route reads finite choice-sequence windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row, recording the inspected indices and finite request schedule.*
4. *W is the finite subsequence-window row: selected indices, selected source windows, and the displayed monotonicity evidence for the selected index list.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected windows and their rational tail budgets.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback is accepted.*
7. *H records componentwise* hsame *transports for K, B, S, W, R, E.*
8. *C records displayed* Cont *replays from compact-metric source reads to stream windows, Baire cylinders, subsequence windows, regular rational readbacks, and the terminal real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, S, W, R, E, H, C, P, N$. It has no coordinate for an externally chosen subsequence, quotient equality of streams, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier local namecert surface`

Theorem 2372.2 (SequentialCompact NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}$ *surface consists exactly of finite rows for carrier admission, compact-metric source exposure, Baire-cylinder exposure, stream-window inspection, subsequence-window monotonicity, regular rational readback, Real seal nonescape, componentwise transport, continuation replay, provenance, and local naming. No obligation row may be discharged by host sequential compactness, countable choice, quotient stream equality, an externally selected subsequence, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.TasteGate.SequentialCompactTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 2372.1. The accepted packet exposes exactly the compact metric source, Baire cylinder row, stream window, subsequence window, regular rational readback, Real seal, transport, continuation, provenance, and local naming rows.

The compactness and choice-sequence reads are finite. The $\mathsf{CompactMetric}^{\uparrow}$ row supplies only displayed metric and cover data, while the $\mathsf{BaireSpace}^{\uparrow}$ row supplies only finite cylinder access before any selected window is consumed.

The subsequence evidence is the row W. Its selected indices, selected source windows, and monotonicity evidence are packet data, and the hsame and Cont rows transport and replay those same data without adding a second selection source.

The readback then passes through R and E. Since neither row has a coordinate for host sequential compactness, countable choice, quotient stream equality, an external subsequence, or ambient Real completeness, the local NameCert surface is exhausted by the displayed finite rows. □

Theorem 2372.3 (SequentialCompact obligation readiness)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the checked TasteGate carrier-alignment marker above makes the next obligation surface exactly the finite-window classifier exposure for $K, B, S, W, R, E, H, C, P, N$, subsequence-window monotonicity in W, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through R,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, and refusal of any host subsequence selector, quotient stream equality, countable choice, open-cover compactness theorem, or ambient Real completeness row.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier obligation readiness`

Proof. Start from Definition 2372.2 and the displayed TasteGate carrier-alignment marker attached to it. The checked alignment pins the TasteGate carrier to the same tuple $K, B, S, W, R, E, H, C, P, N$ used by the paper surface.

The finite-window classifier exposure is therefore not an additional carrier. It is the componentwise classifier read of the existing compact-metric source, Baire cylinder row, stream window,

subsequence window, regular readback, real seal, transport, continuation, provenance, and local naming rows.

The remaining rows are forced by dependency order. The subsequence-window monotonicity obligation is the monotonicity evidence inside W; the $\mathsf{RegSeqRat}^{\uparrow}$ handoff is R; and the terminal $\mathsf{Real}^{\uparrow}$ nonescape row is E.

Because none of the aligned carrier coordinates contains a host subsequence selector, quotient stream equality, countable choice, open-cover compactness theorem, or ambient real-completeness principle, those refusals are part of the exact obligation surface for the next closure step. □

Theorem 2372.4 (SequentialCompact finite-window cluster obligation)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the finite-window cluster obligation binds the $\mathsf{CompactMetric}^{\uparrow}$ *row* K*,* $\mathsf{BaireSpace}^{\uparrow}$ *row* B*,* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *to the selected finite-window route* W *inside the same packet. A cluster-facing consumer must read* $K, B, S, W, R, E, H, C, P, N$ *in the displayed surface and receives no host subsequence choice, quotient stream equality, open-cover compactness theorem, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactFormalTargetScope`

Proof. Start from the obligation readiness surface. It already identifies $K, B, S, W, R, E, H, C, P, N$ as the finite rows that can be consumed by the next closure step.

The selected cluster data are the finite row W. The compact metric source K, Baire cylinder discipline B, and stream-name schedule S are read before W, while R and E carry the regular rational and real-name endpoint.

The structural rows H, C, P, N preserve and name that same route. Since no coordinate of the packet names host subsequence choice, quotient stream equality, open-cover compactness, or ambient Real completeness, the cluster obligation stays finite-window local. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactFiniteWindowClusterObligation`

Theorem 2372.5 (SequentialCompact StreamName subsequence route)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier* $Q = (K, B, S, W, R, E, H, C, P, N)$*, every subsequence route read by a* $\mathsf{StreamName}^{\uparrow}$ *consumer factors through the source-window row* S *and the selected finite-window row* W *before it reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The route is a displayed finite-window cluster route, not a host subsequence selector, quotient stream equality, countable-choice witness, or open-cover compactness principle.*

Proof. Read S as the finite source-window schedule. The selected indices and selected windows are then displayed in W, so the route is already internal to the packet before any readback occurs.

Next pass through R and E. These rows expose regular rational readback and the terminal real seal, but they do not add stream quotienting or ambient completeness.

Finally use transport, replay, provenance, and local naming. The rows H, C, P, N keep the same S, W, R, E route visible to the consumer and do not create a separate selection principle. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactStreamNameSubsequenceRoute`

Theorem 2372.6 (SequentialCompact Real cluster nonescape)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier* $Q = (K, B, S, W, R, E, H, C, P, N)$*, any cluster-facing read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* E *must first expose the compact metric source* K*, the Baire cylinder row* B*, the stream-name row*

S, the selected finite-window row W, and the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. The seal exports only the displayed cluster route and no ambient Real completeness, hidden Real limit selector, quotient stream equality, host subsequence choice, or open-cover compactness.*

Proof. The carrier places E downstream of the finite route. A consumer reaches it only after the compact metric, Baire, stream-name, selected-window, and regular rational rows have been displayed.

Apply the readiness theorem to identify the exclusions. It refuses host subsequence selectors, quotient stream equality, countable choice, open-cover compactness, and ambient Real completeness as rows of the packet.

Thus the real seal is a terminal observation of the finite-window cluster route. It cannot be used as a separate completeness theorem or as a hidden limit-selection device. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier real cluster nonescape`

Theorem 2372.7 (SequentialCompact public cluster export)**.** *Every public cluster-facing consumer of an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *packet receives exactly the route*

$$K, B, S, W, R, E, H, C, P, N.$$

Here K is the $\mathsf{CompactMetric}^{\uparrow}$ *source row, B is the* $\mathsf{BaireSpace}^{\uparrow}$ *cylinder row, S and W are the* $\mathsf{StreamName}^{\uparrow}$ *source-window and selected-window rows, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The export is public only as this finite route: it refuses host subsequence choice, quotient stream equality, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactPublicClusterExport`

Proof. Start with the obligation readiness and finite-window cluster obligation. They expose the accepted carrier only through $K, B, S, W, R, E, H, C, P, N$ and keep the cluster obligation inside the displayed finite windows.

Next use the $\mathsf{StreamName}^{\uparrow}$ subsequence route. The rows S and W name the source and selected windows before any $\mathsf{RegSeqRat}^{\uparrow}$ readback can be consumed, so no host selector or quotient stream equality is introduced.

Finally apply the Real cluster nonescape theorem together with the public finite cluster route. The readback row R precedes the seal E, and H, C, P, N only transport, replay, source, and name the same finite packet. Thus the public consumer receives exactly the displayed route and none of the refused choice, compactness, quotient, or ambient-completeness principles. □

Theorem 2372.8 (SequentialCompact root obligation Baire window)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every root obligation that consumes selected finite windows must expose the $\mathsf{BaireSpace}^{\uparrow}$ *cylinder row B before the selected-window row W. The selected indices and selected source windows remain data of W inside the same* BHist *packet, transported by H, replayed by C, and named by N; they are not supplied by an external subsequence selector or by countable choice.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompact root obligation baire window`

Proof. Start from Definition 2372.3. It identifies the next obligation surface with the displayed rows $K, B, S, W, R, E, H, C, P, N$ and with the finite-window classifier exposure of those rows.

Apply Definition 2372.16. The handoff order places the compact-metric source K, the Baire cylinder row B, and the stream-window row S before the selected-window row W is consumed.

The structural rows then preserve that order. Transport H, replay C, provenance P, and local naming N keep the selected finite windows inside the displayed packet, so the root obligation cannot start from an external selector or a countable-choice schedule. □

Theorem 2372.9 (SequentialCompact root obligation Real seal)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every root obligation that reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal* E *must first consume* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*. The seal is therefore downstream of* K, B, S, W, R *and of the structural rows* H, C, P, N*, and it cannot be used as an ambient Real-completeness theorem, selected Real limit, quotient stream equality, or host subsequence principle.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier root obligation real seal`

Proof. Use Definition 2372.3 to read the root obligation surface. The readiness theorem names $\mathsf{RegSeqRat}^{\uparrow}$ handoff through R and $\mathsf{Real}^{\uparrow}$ seal nonescape through E as rows of the same finite carrier.

Apply Definition 2372.16. It routes selected finite windows through W before regular rational readback in R and before the terminal seal in E.

Finally use the existing nonescape route, including Definition 2372.20. The row E remains an endpoint of the displayed handoff, not a source of ambient completeness, selected limits, quotient equality, or host subsequence data. □

Theorem 2372.10 (SequentialCompact root obligation nonescape)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the root obligation surface consists only of the displayed rows $K, B, S, W, R, E, H, C, P, N$*. It has no row for quotient stream equality, externally selected subsequences, countable choice, open-cover compactness, selected Real limits, host sequential compactness, or ambient Real completeness.*

Proof. Project the carrier and apply Definition 2372.2. The local certificate surface is exactly the finite tuple $K, B, S, W, R, E, H, C, P, N$ with compact-metric source exposure, Baire-cylinder exposure, stream-window inspection, selected-window monotonicity, regular readback, Real seal nonescape, transport, replay, provenance, and local naming.

Use Definition 2372.3. It states that the aligned root surface refuses host subsequence selectors, quotient stream equality, countable choice, open-cover compactness, and ambient Real completeness as obligation rows.

The finite-subsequence handoff keeps the same refusal through the downstream route. Since H, C, P, N only preserve and name the displayed rows, the root obligation surface cannot export any of the excluded host or quotient principles. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRootObligationNonescape`

Theorem 2372.11 (SequentialCompact Baire cylinder exposure)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

any compact-metric completion consumer must read the $\mathsf{BaireSpace}^{\uparrow}$ *cylinder row* B *before it reads the selected finite-window row* W*. The row* B *is part of the same carrier surface as* $K, S, W, R, E, H, C, P, N$*, and the consumer may not replace it by a host choice-sequence branch, open-cover compactness theorem, countable-choice selector, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactBaireCylinderExposure`

Proof. Start from Definition 2372.2. The obligation surface includes Baire-cylinder exposure as a named row of the accepted packet, so B is visible before any downstream read can treat selected windows as evidence.

Apply Definition 2372.16. Its handoff order places $\mathsf{BaireSpace}^{\uparrow}$ before $\mathsf{StreamName}^{\uparrow}$ and before the finite subsequence-window row. Therefore a compact-metric completion consumer cannot inspect W without first passing through B.

Finally use Definition 2372.3. The readiness surface refuses host subsequence selection, quotient stream equality, countable choice, open-cover compactness, and ambient Real completeness, so the Baire exposure remains the displayed finite cylinder row. □

Theorem 2372.12 (SequentialCompact window transport)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the componentwise hsame *transport row* H *preserves the source stream row* S*, selected-window row* W*, regular readback row* R*, and terminal seal row* E *before any completion consumer reads the route. Transport cannot introduce a second selector, quotient stream equality, countable-choice witness, open-cover compactness theorem, or ambient real-completeness coordinate.*

Proof. Project the carrier in Definition 2372.1. The row H records componentwise transport exactly for the displayed analytic rows K, B, S, W, R, E.

Use Definition 2372.2 to identify the local certificate surface. Transport is one of its structural rows and acts on the existing carrier coordinates rather than on a hidden host sequence.

Apply Definition 2372.16. Since S, W, R, E are read in that order by completion consumers, the transported route preserves the same order and exports none of the excluded host principles. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier window transport`

Theorem 2372.13 (SequentialCompact selector refusal)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

there is no row naming a host subsequence selection function, countable-choice principle, quotient stream equality, or open-cover compactness theorem. Every selected-window read is the displayed finite row W *after the compact-metric source row* K*, Baire cylinder row* B*, and stream-window row* S *have been exposed.*

Proof. Begin with the carrier definition. The tuple contains W as finite selected-window data, but it contains no coordinate for a host selector, countable-choice object, quotient stream equality, or open-cover compactness theorem.

Apply Definition 2372.2. The local NameCert surface is exhausted by the displayed rows $K, B, S, W, R, E, H, C, P, N$, so no additional selector row can be supplied by the certificate.

Finally use Definition 2372.16. Any completion-facing consumer reaches W only through the finite handoff order, and the subsequent readback and seal rows preserve that refusal. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactSelectorRefusal`

Theorem 2372.14 (SequentialCompact public finite cluster route)**.** *Every public cluster read exported by an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *packet factors through the finite row route*

$$K, B, S, W, R, E, H, C, P, N.$$

The consumer reads $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{BaireSpace}^{\uparrow}$ *rows before the selected finite-window row, reads* $\mathsf{RegSeqRat}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and receives no host subsequence choice, countable choice, quotient stream equality, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with selector refusal, Definition 2372.13. It keeps every selected-window read inside the displayed row W after the compact-metric source K, Baire cylinder B, and stream-window row S have been exposed.

Next use the finite subsequence handoff, Definition 2372.16. The public cluster route therefore reads K, B, S, W in order before any regular-rational or Real-facing conclusion can be inspected.

Finally apply Definition 2372.6. The RegSeqRat readback row R precedes the terminal seal E, while H, C, P, N only transport, replay, source, and name the same finite packet. Since none of these rows contains host subsequence choice, countable choice, quotient stream equality, open-cover compactness, or ambient Real completeness, the public cluster read is exactly the stated finite route. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactPublicFiniteClusterRoute`

Theorem 2372.15 (SequentialCompact public NameCert route)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every public $\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}$ *consumer must read the same finite rows* $K, B, S, W, R, E, H, C, P, N$ *through the* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* $\mathsf{BaireSpace}^{\uparrow}$ *cylinder row,* $\mathsf{StreamName}^{\uparrow}$ *source-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before using the local NameCert row* N*. The public route is a finite* BHist *route over those displayed rows; it does not provide host subsequence choice, quotient stream equality, open-cover compactness, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactPublicNameCertCarrierRows`

Proof. Start with the finite public cluster surface of Definition 2372.14. It already forces public cluster reads through $K, B, S, W, R, E, H, C, P, N$ and refuses the host selector, quotient, choice, open-cover, and Real-completeness exits.

Next use the source and window boundaries. The $\mathsf{StreamName}^{\uparrow}$ subsequence route of Definition 2372.5, the Baire exposure of Definition 2372.11, and the root selected-window route of Definition 2372.30 place B, S, W before any public NameCert consumer can use selected-window data.

Now read the downstream seal route. Apply Definition 2372.6, Definition 2372.33, and Definition 2372.10. They force the RegSeqRat row R and terminal Real seal E to remain finite-window

observations, not hidden subsequence objects, quotient stream equalities, open-cover compactness arguments, countable-choice schedules, or ambient completeness principles.

Finally use H, C, P, N only as transport, replay, provenance, and local naming rows. Since the earlier rows have already exhausted the public carrier surface, the local NameCert names exactly the displayed finite route and exports no additional public principle. □

Theorem 2372.16 (SequentialCompact finite subsequence handoff)**.** *Every accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *packet consumed by a compact-metric or Baire-space completion route must expose the finite handoff*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{BaireSpace}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

in that order: compact source data and Baire cylinder data are read before stream windows, stream windows are read before the displayed subsequence-window row, and the selected windows are read before the regular rational handoff and Real seal. The handoff exports no host subsequence selector, quotient stream equality, open-cover compactness theorem, countable choice, or ambient Real completeness row.

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier finite subsequence handoff`

Proof. Project the carrier $Q = (K, B, S, W, R, E, H, C, P, N)$. The rows K and B are the only compact-metric and Baire-space sources available to the consumer.

Next read the stream and subsequence windows. The row S gives finite source-window access, and the row W gives the selected finite windows and monotonicity evidence over those source windows.

Finally apply the readback and seal rows. The row R consumes only the selected windows from W, and the row E seals only the accepted regular rational readback. The transport, continuation, provenance, and NameCert rows preserve this same handoff, so no host subsequence selector, quotient stream equality, open-cover compactness theorem, countable choice, or ambient Real completeness can be exported. □

Theorem 2372.17 (SequentialCompact RegSeqRat readback route)**.** *Any accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *packet that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal must first expose the selected finite windows in* W *and then the regular rational readback row* R*. No consumer may replace* R *by a host subsequence limit, quotient stream equality, countable-choice selector, open-cover compactness theorem, or ambient Real completeness.*

Proof. Start from the NameCert obligations, Definition 2372.2. They identify W and R as displayed carrier rows, not as hidden host selectors or quotient-stream data.

Apply the finite subsequence handoff, Definition 2372.16. It orders the completion-facing route so that selected windows are exposed before regular rational readback and before the terminal RealUp seal.

Use window transport and selector refusal, Definition 2372.12 and Definition 2372.13. Transport preserves the displayed rows, while the refusal theorem leaves no coordinate for a host subsequence limit, quotient stream equality, countable-choice selector, open-cover compactness theorem, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier regseqrat readback route`

Theorem 2372.18 (SequentialCompact selector monotonicity)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the selected finite windows exposed to any compact-metric or Baire-space completion consumer are monotone exactly because the row W displays the selected index list, the selected source windows, and the monotonicity evidence for that list. No consumer may replace W by an externally selected subsequence, countable-choice function, quotient stream selector, or host sequential compactness theorem.

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactSelectorMonotonicity`

Proof. Project the carrier from Definition 2372.1. The only coordinate that stores selected windows is W, and its displayed data include the selected indices, selected source windows, and monotonicity evidence.

Apply Definition 2372.16. Any completion consumer reads K, B, S before it reaches W, and the subsequent rows R, E, H, C, P, N preserve the same finite handoff.

Thus selector monotonicity is not imported from a host choice principle. It is the projection of the finite row W, transported by H and replayed by C without adding any second selector coordinate. □

Theorem 2372.19 (SequentialCompact RegSeqRat handoff exactness)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ *handoff available after the finite subsequence-window row W has been displayed. Every rational-tail budget, regular readback, or downstream completion request that depends on selected windows must pass through R before it can reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal E.*

Proof. Read the handoff order in Definition 2372.16. The route reaches $\mathsf{StreamName}^{\uparrow}$ through S, then the selected finite windows through W, and only then the regular rational readback through R.

The carrier has no alternate regular rational coordinate. The rows H and C can transport and replay R, while P and N record provenance and naming for the same displayed row.

Consequently exactness of the $\mathsf{RegSeqRat}^{\uparrow}$ handoff is a projection claim about R. A consumer that asks for rational-tail data after W receives that row and cannot bypass it through quotient stream equality, a selected limit, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRegSeqRatHandoffExactness`

Theorem 2372.20 (SequentialCompact Real seal nonescape)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the terminal $\mathsf{Real}^{\uparrow}$ *row E is reachable only after the compact metric source K, Baire cylinder row B, stream-window row S, subsequence-window row W, regular rational handoff R, and structural rows H, C, P, N have been displayed. The seal exports no ambient Real completeness, selected limit, quotient equality of streams, countable choice, or host sequential compactness theorem.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCarrier real seal nonescape`

Proof. Start with the carrier projection. The row E is listed after R and is described as the $\mathsf{Real}^{\uparrow}$ seal reached after the regular rational readback is accepted.

Use Definition 2372.18 to keep the selected finite windows inside W. Then use Definition 2372.19 to force every rational-tail read from those windows through R.

It remains only to inspect the structural rows. Transport, replay, provenance, and naming preserve the displayed route K, B, S, W, R, E; they do not add completeness, quotient, or choice coordinates. Hence the real seal is a nonescaping endpoint of the finite handoff, not an ambient Real-completeness principle. □

Theorem 2372.21 (SequentialCompact window extraction scope)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every finite extraction request must expose the compact metric source row K, the Baire cylinder row B, the stream-window row S, and the selected finite-window row W before any $\mathsf{RegSeqRat}^{\uparrow}$ *readback or terminal* $\mathsf{Real}^{\uparrow}$ *seal is available. The extraction scope exports no host subsequence selector, countable choice, quotient stream equality, open-cover compactness theorem, selected Real limit, or ambient Real completeness.*

Proof. Begin with Definition 2372.11. It places the Baire cylinder row B before selected-window data can be consumed, so an extraction request cannot start from a detached selector.

Next apply Definition 2372.16. The route reads K, B, S, W in finite order, and the selected source windows are packet rows rather than an infinite subsequence object.

Use Definition 2372.18. It keeps the selected indices and selected windows inside W, while H, C, P, N only transport, replay, source, and name the same displayed rows.

The later rows R and E are downstream of the window route. Hence the extraction scope is finite and does not export the excluded host selector, choice, quotient, compactness, selected-limit, or completeness principles. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactWindowExtractionScope`

Theorem 2372.22 (SequentialCompact Baire RegSeqRat exhaustion)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every regular rational readback requested after a Baire cylinder exposure must pass through the row R. The request first displays B, then the stream and selected-window rows S, W, and only then reads R before the seal E; no host subsequence selector, countable choice, quotient stream equality, open-cover compactness theorem, or ambient Real completeness is exported.

Proof. Read the Baire exposure through Definition 2372.11. It supplies the cylinder row B as displayed finite data before selected windows are available.

Apply Definition 2372.21. The request reaches the selected windows through K, B, S, W, so the regular rational readback is tied to the same finite route.

Now use Definition 2372.19. It identifies R as the only $\mathsf{RegSeqRat}^{\uparrow}$ handoff after W, and the structural rows do not add another readback coordinate.

Therefore the Baire-to-RegSeqRat route is exhausted by B, S, W, R and cannot be replaced by a host selector, a choice schedule, quotient stream equality, open-cover compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactBaireRegSeqRatExhaustion`

Theorem 2372.23 (SequentialCompact Real seal window nonescape)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is a window endpoint: it may be read only after the Baire cylinder row* B*, stream-window row* S*, selected-window row* W*, and regular rational readback row* R *have been displayed. The seal exports no host subsequence selector, countable choice, quotient stream equality, open-cover compactness theorem, selected Real limit, or ambient Real completeness.*

Proof. Start with Definition 2372.21. It forces every extraction request to expose B, S, W as finite packet rows before downstream readback can begin.

Then apply Definition 2372.22. Every regular rational request after that exposure passes through R, so the seal cannot be reached from a detached stream or selector.

Finally use Definition 2372.20. The row E is downstream of R and of the structural rows H, C, P, N, all of which preserve the displayed route.

Thus the Real seal remains a finite-window endpoint. It does not provide a host subsequence selector, countable choice, quotient stream equality, open-cover compactness, selected Real limit, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRealSealWindowNonescape`

Theorem 2372.24 (SequentialCompact cylinder monotone window)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every $\mathsf{BaireSpace}^{\uparrow}$ *cylinder exposure consumed by a compact-metric or Baire-space route is tied to the monotone selected-window row* W*. The consumer may inspect* B *and then* W*, transported by* H *and replayed by* C*, but it may not replace that route by a host choice-sequence branch, a nonmonotone selector, quotient stream equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Baire exposure theorem Definition 2372.11. It places the cylinder row B before any downstream read of selected windows, so the consumer reaches the window surface through the displayed carrier order.

Apply Definition 2372.16 and Definition 2372.18. The handoff places W after K, B, S, and the selector monotonicity theorem identifies the monotone selected indices and selected source windows as data stored inside W.

Finally use Definition 2372.20. The later readback and seal rows preserve the same finite route, so no consumer can bypass the Baire cylinder and monotone selected-window boundary through a host selector or an ambient compactness principle. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCylinderMonotoneWindow`

Theorem 2372.25 (SequentialCompact regular tail nonescape)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every tail request made after the selected finite-window row W *must pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before it can reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The request exports no quotient stream equality, selected limit, countable-choice schedule, host sequential compactness theorem, open-cover compactness theorem, or ambient Real completeness row.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRegularTailNonescape`

Proof. Read W through Definition 2372.18. The selected finite windows and their monotonicity evidence are packet data, not a host subsequence object.

Next apply Definition 2372.19. It identifies R as the only regular rational handoff available after W, so every rational-tail budget or regular readback request must use that row.

Now apply Definition 2372.20. The seal row E is reachable only after R and the structural rows have been displayed, hence the tail request cannot escape through quotient streams, selected limits, countable choice, host compactness, or ambient completeness. □

Theorem 2372.26 (SequentialCompact Real seal consumer boundary)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every compact-metric, Baire-space, regular-rational, stream-window, or Real-facing consumer of the terminal seal can inspect only the rows $K, B, S, W, R, E, H, C, P, N$*. In particular, the consumer sees no row for external subsequence selection, quotient stream equality, open-cover compactness, countable choice, selected Real limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier from Definition 2372.1. Its visible coordinates are exactly $K, B, S, W, R, E, H, C, P, N$, and the local NameCert obligation theorem identifies those rows as the certificate surface.

Use Definition 2372.16 for the consumer order. Compact-metric and Baire reads pass through K and B, stream-window reads pass through S and W, regular rational reads pass through R, and the Real-facing endpoint is E.

Finally combine Definition 2372.19 with Definition 2372.20. They force the regular tail through R and the Real seal through E, while the structural rows preserve the displayed route and do not add excluded host or quotient data. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRealSealConsumerBoundary`

Theorem 2372.27 (SequentialCompact finite subsequence obligation)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every finite subsequence obligation read from Q *is a* BHist *obligation over the displayed rows* $K, B, S, W, R, E, H, C, P, N$*. The selected-window row* W *must be transported by the componentwise* hsame *row* H*, replayed through the displayed* Cont *row* C*, and named by the local* $\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}$ *row* N *before any compact-metric, stream-window, regular-rational, or Real-facing consumer can use it. The obligation refuses host subsequence selectors, countable choice, quotient stream equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactFiniteSubsequenceObligation`

Proof. Project the carrier from Definition 2372.1. The only row that stores selected subsequence information is W, and the carrier records it as finite selected indices, selected source windows, and monotonicity evidence.

Use Definition 2372.16. The handoff forces the consumer to reach W only after the compact-metric, Baire-cylinder, and stream-window rows have been displayed.

Now read the structural rows. The hsame row H transports the selected-window data componentwise, the Cont row C replays the same finite route, and the local $\mathsf{NameCert}$ row N names that displayed packet. None of these rows contains a coordinate for a host selector, countable-choice schedule, quotient stream equality, or ambient Real completeness. □

Theorem 2372.28 (SequentialCompact cluster carrier stability)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

any cluster-window read exposed by Q *is stable only along the same* BHist *carrier tuple. If a consumer changes presentation through* hsame*, the cluster read remains the transported* W, R, E *route replayed by* Cont *and named by* $\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}$*; it does not become a host subsequence selector, a countable-choice witness, a quotient stream equality, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactClusterCarrierStability`

Proof. Start with Definition 2372.12. The row H preserves the stream-window, selected-window, regular-readback, and terminal-seal rows before any completion consumer reads the route.

The cluster read is therefore carrier-local. It can use W for selected finite windows, R for regular rational readback, and E for the terminal seal, but each of these rows remains inside the same tuple Q.

Finally apply Definition 2372.26. A Real-facing or compact-metric consumer can inspect only $K, B, S, W, R, E, H, C, P, N$, so no presentation change can export the excluded host selector, choice, quotient, or ambient completeness data. □

Theorem 2372.29 (SequentialCompact compactmetric consumer scope)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every $\mathsf{CompactMetric}^{\uparrow}$ *consumer that uses the sequential-compactness packet has scope exactly the finite* BHist *rows* $K, B, S, W, R, E, H, C, P, N$*. It may read compact-metric source data, Baire cylinders, stream windows, finite subsequence windows, regular rational readback, the Real seal,* hsame *transport,* Cont *replay, package provenance, and the local* NameCert *row, but it may not request host subsequence selectors, countable choice, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCompactMetricConsumerScope`

Proof. Read the compact-metric source through K. The carrier definition gives no other compactness coordinate, and Definition 2372.11 places the Baire row B before selected windows are consumed.

Next use Definition 2372.27. It binds the finite subsequence obligation to W, H, C, N, so the compact-metric consumer receives displayed packet data rather than an external selector.

The downstream rows are R and E. By Definition 2372.19 and Definition 2372.20, those rows provide regular readback and the terminal seal without exporting quotient stream equality, countable choice, host subsequence selection, or ambient Real completeness. □

Theorem 2372.30 (SequentialCompact root selected-window route)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every root consumer that requests a finite selected subsequence window must expose the Baire-cylinder row B*, the StreamName source-window row* S*, and the selected-window row* W *before any compact-metric or Real-facing conclusion is read. The request is a finite* BHist *route through* K, B, S, W, H, C, P, N*, not a host subsequence selector, countable-choice schedule, quotient stream equality, or open-cover compactness argument.*

Proof. Project the carrier from Definition 2372.1. The rows that can supply selected-window data are B, S, W together with the compact-metric source K and the structural rows H, C, P, N.

Apply Definition 2372.16. It forces every subsequence handoff to pass through the finite selected-window row W after the compact-metric, Baire-cylinder, and stream-window data have been displayed.

Finally use Definition 2372.29. A root compact-metric consumer sees only $K, B, S, W, R, E, H, C, P, N$, so the selected-window route cannot be replaced by a host selector, countable choice, quotient stream equality, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRootSelectedWindowRoute`

Theorem 2372.31 (SequentialCompact root RegSeqRat exposure)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

any root consumer that has read a selected finite window through W must read the resulting regular-rational tail data through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ *row R before it can inspect the terminal seal E. The exposure route is $K, B, S, W, R, H, C, P, N$ and exports no quotient stream equality, selected limit, countable-choice subsequence, host sequential compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the selected-window route of Definition 2372.30. It places every root window request inside the displayed rows K, B, S, W, H, C, P, N.

Apply Definition 2372.19. The regular rational readback available after a selected window is exactly the row R, so a consumer cannot bypass R by treating the selected observations as quotient stream data or as a chosen limit.

The structural rows then replay the same finite route. The rows H, C, P, N transport, replay, source, and name R together with the selected-window data, and none of them contains countable choice, host sequential compactness, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRootRegSeqRatExposure`

Theorem 2372.32 (SequentialCompact root Real seal refusal)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

no root consumer may inspect the terminal $\mathsf{Real}^{\uparrow}$ *seal row E until the compact-metric source, Baire-cylinder row, StreamName source-window row, selected-window row, RegSeqRat readback row, componentwise transport, displayed replay, provenance, and local naming rows have been displayed. Thus the Real seal cannot serve as a shortcut for host sequential compactness, selected limits, countable choice, quotient stream equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRootRealSealRefusal`

Proof. First apply Definition 2372.31. It forces every root selected-window read to pass through R before the terminal seal can be considered.

Now use Definition 2372.20. The seal row E is only the terminal row of the displayed finite route; it does not introduce host sequential compactness, selected limits, countable choice, quotient stream equality, open-cover compactness, or ambient Real completeness.

Finally apply Definition 2372.26. A Real-facing consumer can inspect only $K, B, S, W, R, E, H, C, P, N$, so no root consumer obtains a seal shortcut outside the finite NameCert carrier. □

Theorem 2372.33 (SequentialCompact Baire real-window admission)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every Baire-window admission consumed by a Real-facing root reader must expose the Baire cylinder row B*, the StreamName source-window row* S*, the selected finite-window row* W*, the RegSeqRat readback row* R*, and the terminal Real seal row* E *in that order. The admitted window is a displayed* BHist *route through* $K, B, S, W, R, E, H, C, P, N$*, not a host subsequence selector, countable-choice branch, quotient stream equality, open-cover compactness proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier of Definition 2372.1. The only rows available for a Baire-window request are the compact-metric source K, the Baire cylinder row B, the stream source row S, and the selected finite-window row W.

Apply Definition 2372.30. It requires every root selected-window request to display B, S, W before any compact-metric or Real-facing conclusion is read.

Now use Definition 2372.31 and Definition 2372.32. These force the regular rational readback R and terminal seal E to remain downstream of the finite Baire and stream windows.

The rows H, C, P, N only transport, replay, source, and name that route. Since no row stores a host selector, choice branch, quotient equality, open-cover proof, or ambient completeness witness, the admission is exactly the displayed BHist window route. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactBaireRealWindowAdmission`

Theorem 2372.34 (SequentialCompact RegSeqRat cluster handoff)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every cluster read exported to a completion or Real-facing consumer must pass through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *after the finite selected-window row* W *and before the terminal seal* E*. The cluster handoff is therefore the finite route* $K, B, S, W, R, E, H, C, P, N$*; it is not a selected subsequence object, a quotient stream class, a countable-choice schedule, or a host compactness conclusion.*

Proof. Start with Definition 2372.28. A cluster-window read remains the transported W, R, E route inside the same carrier tuple, even after presentation transport through hsame.

Apply Definition 2372.33. The row W is available only after the Baire and stream windows have been displayed, and the terminal seal E is available only after the regular rational readback route has appeared.

The handoff to a completion consumer therefore goes through R. By Definition 2372.19, R is the only regular-rational row exported by the packet, so a selected subsequence object or quotient stream class has no carrier coordinate from which to replace it.

Finally, H, C, P, N preserve the same route under transport, replay, provenance, and naming. This exhausts the cluster handoff surface seen by downstream consumers. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRegSeqRatClusterHandoff`

Theorem 2372.35 (SequentialCompact compactmetric root surface)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the root CompactMetric$^{\uparrow}$ *consumer receives only the finite compact-metric carrier row* K*, Baire and stream window rows* B, S, W*, RegSeqRat and Real seal rows* R, E*, and the structural rows* H, C, P, N*. In particular, compact-metric consumers may use the finite cluster-carrier and seal rows recorded by* Q*, but they may not import sequential compactness as a primitive, choose subsequences externally, identify quotient streams, invoke countable choice, or replace the route by an open-cover compactness theorem.*

Proof. Read the compact-metric consumer scope from Definition 2372.29. It restricts every such consumer to the rows $K, B, S, W, R, E, H, C, P, N$.

Use Definition 2372.34. Any cluster read that leaves the selected-window surface must pass through R before reaching the terminal seal E, so the compact-metric consumer receives finite cluster-carrier data rather than a selected subsequence object.

Apply Definition 2372.33. The Baire and stream windows remain displayed before Real-facing use, and the seal row cannot shortcut the window route.

The remaining structural rows are transport, replay, provenance, and local naming rows only. They carry no primitive sequential compactness, external selection, quotient stream equality, countable-choice schedule, or open-cover compactness proof, so the root surface is exactly the finite carrier-and-seal interface stated above. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCompactMetricRootSurface`

Theorem 2372.36 (SequentialCompact root obligation surface)**.** *For an accepted* SequentialCompact$^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

every root obligation read for the L10 compactness corridor must expose the CompactMetric$^{\uparrow}$ *source row* K*, the* BaireSpace$^{\uparrow}$ *cylinder row* B*, the* StreamName$^{\uparrow}$ *source-window row* S*, the finite selected-window row* W*, the* RegSeqRat$^{\uparrow}$ *readback row* R*, and the terminal* Real$^{\uparrow}$ *seal row* E *before transport, replay, provenance, and local naming are consulted. The obligation is a finite* BHist *surface over* $K, B, S, W, R, E, H, C, P, N$*, not countable choice, quotient stream equality, external subsequence selection, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRootObligationSurface`

Proof. Project the carrier of Definition 2372.1. The root reader sees only the compact-metric, Baire, stream, finite-window, regular-rational, Real-seal, transport, replay, provenance, and local naming rows.

Apply Definition 2372.30 and Definition 2372.31. These force the selected-window read through B, S, W and then through the regular-rational row R before any Real-facing conclusion is available.

Apply Definition 2372.20. The seal row E cannot supply host sequential compactness, a selected subsequence object, quotient stream equality, countable choice, or ambient Real completeness. The remaining rows H, C, P, N preserve the same finite route. □

Theorem 2372.37 (SequentialCompact compactmetric handoff)**.** *Every* CompactMetric$^{\uparrow}$ *consumer that receives an accepted* SequentialCompact$^{\uparrow}$ *packet receives the compact-metric row* K *together with the Baire, StreamName, selected-window, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows* $B, S, W, R, E, H, C, P, N$*. The handoff permits downstream compact and completion chapters to consume finite carrier-and-window obligations, but it does not export a primitive sequential compactness theorem, an externally selected subsequence, quotient stream equality, countable choice, open-cover compactness, or ambient Real completeness.*

Proof. Use Definition 2372.29. It already restricts compact-metric consumers to the rows $K, B, S, W, R, E, H, C, P,$

Apply Definition 2372.36. The new root surface records the same rows as an obligation boundary, so the compact-metric handoff is a finite packet read rather than a hidden theorem about all sequences.

Finally use Definition 2372.34 and Definition 2372.26. They route cluster and Real-facing reads through R and E without introducing selected representatives, host stream equality, choice schedules, or ambient completion. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactCompactMetricHandoff`

Theorem 2372.38 (SequentialCompact RegSeqRat stream scope)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exported by an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *packet is scoped by the displayed* $\mathsf{StreamName}^{\uparrow}$ *source row* S *and finite selected-window row* W*. A downstream completion or Real-facing consumer may read* R *only as a regular-rational readback of the finite stream window* S, W*; it may not replace the route by quotient stream equality, an externally chosen subsequence, countable choice, host real equality, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRegSeqRatStreamScope`

Proof. Read the source-window scope from Definition 2372.30. The stream source S and selected finite window W are displayed before the RegSeqRat row can be used.

Apply Definition 2372.31. It makes R the exposed regular-rational readback row for root consumers, not a selector or quotient-class object.

Use Definition 2372.33 to keep the Baire and Real-facing route attached to B, S, W, R, E. Since the carrier has no row for quotient stream equality, external subsequence selection, choice, host real equality, or ambient completeness, the RegSeqRat stream scope is exactly the displayed finite-window route. □

Theorem 2372.39 (SequentialCompact obligation closure)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the compact-metric row K*, Baire row* B*, StreamName row* S*, finite selected-window row* W*, RegSeqRat row* R*, terminal Real seal row* E*, and structural rows* H, C, P, N *together supply the full* $\mathsf{obligation}$ *surface for the* $\mathsf{SequentialCompact}^{\uparrow}$ *packet. Every compact-metric, Baire-space, RegSeqRat, or Real-facing consumer reads a finite* BHist *obligation over exactly these rows, with no host sequential compactness, countable choice, quotient stream equality, open-cover compactness, external subsequence selector, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactObligationClosure`

Proof. Start with Definition 2372.3. It identifies the next obligation surface with the displayed rows $K, B, S, W, R, E, H, C, P, N$ and refuses host subsequence selectors, quotient stream equality, countable choice, open-cover compactness, and ambient Real completeness.

The finite-window obligations are then exhausted by the local root and selector theorems. Apply Definition 2372.4, Definition 2372.10, and Definition 2372.13. These keep the selected-window data inside W and rule out any second selector or quotient-stream coordinate.

Next read the downstream handoffs. Use Definition 2372.19, Definition 2372.20, Definition 2372.36, and Definition 2372.38. They force every RegSeqRat read through R and every terminal Real-facing read through E after the displayed finite windows have appeared.

Finally use the compact-metric and structural consumer boundaries, Definition 2372.35 and Definition 2372.37. The rows H, C, P, N transport, replay, source, and name the same finite packet, so the obligation surface is closed exactly over $K, B, S, W, R, E, H, C, P, N$. □

Theorem 2372.40 (SequentialCompact public export no-choice boundary)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *carrier*

$$Q = (K, B, S, W, R, E, H, C, P, N),$$

the public SequentialCompact consumer receives only the finite cluster window W*, the* $\mathsf{CompactMetric}^{\uparrow}$ *handoff row* K*, the* $\mathsf{BaireSpace}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *window rows* B, S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the transport, replay, provenance, and local* NameCert *rows* H, C, P, N*. This public export is the already displayed finite route; it does not add a choice-selected subsequence, quotient stream, open-cover compactness theorem, host sequential compactness principle, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactPublicExport`

Proof. Start with Definition 2372.39. It closes the obligation surface over exactly the rows $K, B, S, W, R, E, H, C, P$, and excludes host compactness, countable choice, quotient stream equality, external subsequence selection, and ambient Real completeness.

Use Definition 2372.4 and Definition 2372.14. The public cluster read is the finite selected-window route through W, not an externally selected subsequence object.

Apply Definition 2372.15 and Definition 2372.37. These route public naming and compact-metric consumers through the same $K, B, S, W, R, E, H, C, P, N$ packet.

Finally use Definition 2372.38. It keeps every regular-rational readback scoped by the displayed stream and selected-window rows before the Real seal is consumed. Since no additional row is present in the carrier, the public export boundary is exactly the no-choice finite route stated above. □

Theorem 2372.41 (SequentialCompact formal target scope)**.** *The formal target for* $\mathsf{SequentialCompact}^{\uparrow}$ *is exactly the finite cluster route*

$$K, B, S, W, R, E, H, C, P, N$$

exported by Definition 2372.40: the $\mathsf{CompactMetric}^{\uparrow}$ *root surface* K*, the* $\mathsf{BaireSpace}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *window rows* B, S*, the selected finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the structural* hsame*,* Cont*,* Pkg*, and local* NameCert *rows* H, C, P, N*. It excludes selected subsequence objects outside* W*, open-cover compactness, countable-choice schedules, quotient-stream equality, and ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactFormalTargetRouteCertificate`

Proof. Start with the public export boundary of Definition 2372.40. It states the visible consumer surface as exactly the finite cluster window, compact-metric handoff, Baire and StreamName rows, RegSeqRat readback, Real seal, and structural rows.

The RegSeqRat handoff and stream scope are already fixed by Definition 2372.19 and Definition 2372.38. These keep the readback row R downstream of B, S, W and upstream of the Real seal E.

The compact-metric root surface and Real seal boundary are supplied by Definition 2372.35, Definition 2372.37, and Definition 2372.20. Together they prevent the formal target from becoming an open-cover compactness claim or an ambient completeness claim.

Finally, Definition 2372.13 and Definition 2372.4 keep subsequence information inside the displayed finite-window row W. Thus the formalization queue receives the same finite Baire/StreamName/RegSeqRat/ cluster route and none of the excluded choice or completeness principles. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactFormalTargetStructuralRowsCertificate`

Theorem 2372.42 (SequentialCompact Real subsequence Cauchy handoff)**.** *For an accepted* $\mathsf{SequentialCompact}^{\uparrow}$ *packet, any Real-facing cluster consumer that reads the selected finite-window row must factor through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the* $\mathsf{Real}^{\uparrow}$ *seal as a Cauchy readback handoff. The consumer receives the displayed rows* S, W, R, E *from the finite-window route, not a host subsequence object, countable-choice schedule, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the public export of Definition 2372.40. It makes the selected finite-window row W, stream row S, regular-rational readback row R, and terminal Real seal E part of the same public packet.

Use the handoff exactness of Definition 2372.19 together with the stream scope of Definition 2372.38. These rows force every regular-rational readback to pass through the displayed $\mathsf{StreamName}^{\uparrow}$ source and selected finite window before it can be consumed downstream.

Finally apply Definition 2372.20. The Real-facing boundary reads E only after the S, W, R route is visible, so the handoff is a Cauchy readback route through finite data and not an additional subsequence, choice, quotient, selected-limit, or completeness object. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactRealSubsequenceCauchyHandoff`

Theorem 2372.43 (SequentialCompact standard bridge scope)**.** *Any standard-facing bridge for* $\mathsf{SequentialCompact}^{\uparrow}$ *may read only the displayed compact-metric row* K, *the* $\mathsf{BaireSpace}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *window rows* B, S, *the selected finite-window row* W, *the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R, *the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E, *and the structural* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows* H, C, P, N *of the public packet. The bridge may not export host sequential compactness, a choice-selected subsequence, quotient stream equality, open-cover compactness, countable-choice schedules, selected limits outside* W, *or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 2372.40. It identifies the public consumer surface as exactly the finite route through $K, B, S, W, R, E, H, C, P, N$.

Use Definition 2372.19. The regular-rational readback row stays downstream of the displayed stream and selected finite-window rows, so a bridge cannot replace it by quotient stream equality or a host-selected subsequence.

Finally apply Definition 2372.20. The Real-facing seal is consumed only after the finite StreamName and RegSeqRat route is present. Hence the standard-facing bridge is scoped to the displayed finite Baire/StreamName/RegSeqRat/Real boundary and exports none of the excluded classical compactness or completeness principles. □

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactStandardBridgeScope`

Theorem 2372.44 (SequentialCompact mature public bridge package)**.** *The mature public package for* $\mathsf{SequentialCompact}^{\uparrow}$ *is exactly the finite route*

$$K, B, S, W, R, E, H, C, P, N$$

assembled by Definition 2372.40, Definition 2372.41, Definition 2372.42, and Definition 2372.43. It exports the compact-metric source row, Baire and StreamName window rows, selected finite-window row, RegSeqRat readback, terminal Real seal, componentwise transport, replay, provenance, and local naming, with the same exclusions: no host sequential compactness, choice-selected subsequence outside W, quotient stream equality, open-cover compactness, countable-choice schedule, selected limit outside the displayed route, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean credential, or bridge checking.*

Lean4 ✓ `BEDC.Derived.SequentialCompactUp.SequentialCompactMaturePublicBridgePackage`

Proof. Start with Definition 2372.40. It gives the public consumer exactly the finite cluster route through $K, B, S, W, R, E, H, C, P, N$.

Use Definition 2372.41 and Definition 2372.42. They keep the formal target and Real-facing Cauchy handoff on the same StreamName, selected-window, RegSeqRat, and Real-seal rows.

Finally apply Definition 2372.43. The standard-facing bridge may read only the displayed public packet and inherits the same exclusions, so the mature paper package is exactly the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 2372.1, Definition 2372.2, Definition 2372.15, Definition 2372.39, Definition 2372.40, Definition 2372.43, and Definition 2372.44 close the public finite subsequence-window route and its standard-facing bridge scope for compact-metric, Baire-space, RegSeqRat, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequential compactness, countable choice, quotient stream equality, open-cover compactness, external subsequence selection, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Mature closure requires Lean verification and bridge checking for the same public finite-window route; those remain separate verification-axis work.

Constructive story: A $\mathsf{SequentialCompact}^{\uparrow}$ packet is generated from CompactMetric source data, BaireSpace cylinder data, StreamName source windows, displayed finite subsequence windows, RegSeqRat readback, Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Chapter 2373

A Concrete Naming Certificate for $\mathsf{SeparatedMetricCompletion}^{\uparrow}$

Following Bishop–Bridges and Kelley, the $\mathsf{SeparatedMetricCompletion}^{\uparrow}$ packet names the finite completion boundary obtained after zero-distance identifications are made visible rather than quotient-hidden. It sits between the metric completion source of chapter 1506, the separated metric classifier of chapter 1411, the Cauchy-filter route of chapter 333, the Cauchy-net route of chapter 589, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes a separated completion handoff for L10 Real and Completion consumers; it is not a quotient completion, selected representative principle, host equality theorem, countable-choice selector, or ambient completeness assertion.

Definition 2373.1 (SeparatedMetricCompletion carrier)**.** *A* $\mathsf{SeparatedMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, B, Q, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row naming the completion request and its metric evidence.*
2. *B is the selected Cauchy branch row, either the* $\mathsf{CauchyFilter}^{\uparrow}$ *route or the* $\mathsf{CauchyNet}^{\uparrow}$ *route, together with its displayed observation schedule.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback handoff extracted from the same finite Cauchy branch.*
4. *R records the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier used to identify when two completion reads name the same separated point.*
5. *Z is the local zero-distance comparison ledger tying R to the source metric row M and the branch row B.*
6. *H records componentwise* hsame *transport for the metric-completion source, Cauchy branch, readback, zero-distance classifier, comparison ledger, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through the selected branch, regular readback, Real seal, zero-distance classifier, and separated handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{SeparatedMetricCompletion}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient completion classes, selected representatives, host equality, countable choice, ambient completeness, or an unrecorded completion object.

Lean4 ✓ `BEDC.Derived.SeparatedMetricCompletionUp.SeparatedMetricCompletionTasteGate single carrier alignment`

Theorem 2373.2 (SeparatedMetricCompletion NameCert obligations)**.** *For every accepted* SeparatedMetricComple *carrier $S = (M, B, Q, R, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedMetricCompletion}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *source, selected Cauchy branch, regular readback, Real seal, zero-distance classifier, comparison ledger, transport, continuation, provenance, and local naming rows;*
2. *source-first exposure, requiring every separated completion read to consume M before it reads the branch row B or the readback row Q;*
3. *branch exactness, requiring B to be one displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *route and requiring Q to be read from that same route;*
4. *separation exactness, requiring the zero-distance classifier R and comparison ledger Z to mediate all same-point reads before a consumer treats the handoff as separated;*
5. *ledger refusal, excluding quotient completion classes, selected representatives, host equality, countable-choice selectors, ambient completeness, and detached completion objects.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 2373.1. Its public rows are exactly $M, B, Q, R, Z, H, C, P, N$, so carrier admission exposes a metric-completion source, one Cauchy branch, the readback handoff, the zero-distance classifier, and the structural rows.

The source and branch obligations follow by replaying C. A separated completion read first consumes M, then chooses the displayed branch row B, and only then reads the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff in Q.

The separation obligation is carried by R and Z. These rows are the only coordinates that compare completion reads as zero-distance data, while H, P, and N transport, package, and name the same displayed route.

Every excluded object is absent from the carrier. Quotient classes, selected representatives, host equality, countable choice, ambient completeness, and detached completion objects therefore cannot supply an additional local obligation. □

Theorem 2373.3 (SeparatedMetricCompletion MetricCompletion handoff)**.** *Let $S = (M, B, Q, R, Z, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetricCompletion}^{\uparrow}$ *packet. Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer that reads the separated handoff factors through the finite route*

$$M \longmapsto B \longmapsto Q \longmapsto R, Z \longmapsto H, C, P, N.$$

Thus the completion source is read before the Cauchy-filter or Cauchy-net branch, the Real-facing readback is read from that same branch, and the $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier mediates separated equality before the packet exits to downstream L10 consumers.*

Proof. Start with an accepted separated completion read. By carrier admission, the only completion source available to the consumer is the displayed row M.

Replay the selected branch. The row B records whether the finite Cauchy evidence is filter-presented or net-presented, and the readback row Q is attached to that same branch through the continuation row C.

Now apply the separated classifier rows. The row R supplies the $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance classifier, and Z records its compatibility with the source metric and the selected branch. Hence same-point use is mediated by displayed zero-distance data rather than by host equality.

Finally pass through the structural rows H, C, P, N. They preserve and name the route already displayed, so the handoff cannot introduce quotient completion classes, selected representatives, countable choice, ambient completeness, or a detached completion object. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedMetricCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2373.1, Definition 2373.2, and Definition 2373.3 seed the finite separated completion boundary between metric completion evidence, Cauchy-filter or Cauchy-net presentation, regular readback, Real sealing, and zero-distance classification.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion classes, selected representatives, host equality, countable-choice selectors, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, branch exactness, separation exactness, MetricCompletion handoff, and ledger refusal proofs for the same packet.

Constructive story: A $\mathsf{SeparatedMetricCompletion}^{\uparrow}$ packet is generated from a MetricCompletionUp source row, a displayed CauchyFilterUp or CauchyNetUp branch, RegSeqRatUp readback, a RealUp seal, a SeparatedMetricUp zero-distance classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2374

A Concrete Naming Certificate for $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$

Following Riesz–Fischer/Hilbert-space projection theorem treatments, the $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$ packet records the finite theorem-facing surface of orthogonal projection data without importing the full classical projection theorem as a host principle. It sits over the Hilbert carrier of chapter 91, the inner-product rows of chapter 86, the norm surface of $\mathsf{Norm}^{\uparrow}$, the Bessel-bound route of chapter 2207, and the vector-space operations of chapter 47. The singleton projection row of Definition 91.25 is the checked sibling surface: this chapter names the general finite packet that a theorem-facing projection consumer must read before any closed-subspace or minimizer claim can be exported.

Definition 2374.1 (Orthogonal projection theorem carrier)**.** *An* $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(H, V, I, Nm, B, A, Q, R, O, T, C, P, N)$$

whose visible rows are:

1. *H is the displayed* $\mathsf{Hilbert}^{\uparrow}$ *source carrier, read through its finite* $\mathsf{NameCert}_{\mathsf{Hilbert}^{\uparrow}}$ *rows;*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *reduct carrying addition, subtraction, scalar action, and the displayed affine subspace operations used by the projection row;*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the Hilbert source, and Nm is the associated* $\mathsf{Norm}^{\uparrow}$ *row used to state the distance-minimizing comparison;*
4. *B is the* $\mathsf{BesselInequality}^{\uparrow}$ *dependency row that bounds the finite orthogonal comparison ledger;*
5. *A is the displayed closed-affine constraint row for the target subspace surface visible to the packet;*
6. *Q is the candidate projection endpoint row;*
7. *R is the residual row $x - Q$ formed through the* $\mathsf{VecSpace}^{\uparrow}$ *operations;*
8. *O is the orthogonality classifier asserting that the residual row is orthogonal to the displayed subspace directions through I;*
9. *T is the minimality comparison row stating that scheduled norm comparisons through Nm factor through the same residual and orthogonality ledger;*

10. *C, P, N are the consumer replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{OrthogonalProjectionTheorem}^{\uparrow}}$ *rows. The carrier has no coordinate for a host closed-subspace type, no choice-selected minimizer, no quotient Hilbert equality, no global Riesz representation theorem, and no ambient completeness argument beyond the displayed* $\mathsf{Hilbert}^{\uparrow}$ *rows.*

Lean4 ✓ `BEDC.Derived.OrthogonalProjectionTheoremUp.OrthogonalProjectionTheoremTasteGate single carrier alignment`

Theorem 2374.2 (Orthogonal projection theorem NameCert obligations)**.** *For an accepted* OrthogonalProjectionTh *carrier* $(H, V, I, Nm, B, A, Q, R, O, T, C, P, N)$*, the local NameCert obligation surface consists of the following finite rows:*

1. *carrier admission for the Hilbert source H, vector-space reduct V, inner-product row I, norm row Nm, Bessel-bound row B, displayed constraint row A, candidate projection Q, residual R, orthogonality classifier O, minimality comparison T, replay C, provenance P, and naming row N;*
2. *dependency admission through* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{BesselInequality}^{\uparrow}$, *and* $\mathsf{VecSpace}^{\uparrow}$*;*
3. *residual formation, stating that R is built from the displayed vector-space operations and the candidate endpoint Q;*
4. *orthogonality classification, stating that O reads only the inner-product rows visible through I and the finite directions named by A;*
5. *Bessel-controlled comparison, stating that B bounds the finite orthogonal ledger before T records the norm-minimality comparison;*
6. *singleton compatibility, stating that the Hilbert singleton projection row of Definition 91.25 is an admitted special case of the same residual, orthogonality, and norm-readback pattern;*
7. *nonescape, stating that the packet exports no host projection operator, no selected minimizer outside the displayed rows, no closed-subspace completeness theorem, and no quotient Hilbert equality.*

Proof. Project the carrier of Definition 2374.1. Its coordinates list exactly the Hilbert source, vector-space reduct, inner product, norm, Bessel ledger, constraint row, candidate endpoint, residual, orthogonality classifier, norm comparison, replay, provenance, and local name.

The dependency rows are finite because each is read from a named sibling surface. The $\mathsf{Hilbert}^{\uparrow}$ row supplies the source carrier, $\mathsf{InnerProduct}^{\uparrow}$ supplies the orthogonality observations, $\mathsf{Norm}^{\uparrow}$ supplies the distance comparison, $\mathsf{BesselInequality}^{\uparrow}$ supplies the finite bound ledger, and $\mathsf{VecSpace}^{\uparrow}$ supplies the algebraic residual operations.

Residual formation and orthogonality are then local rows. The residual R is formed by the displayed vector operations, while O can inspect only inner-product entries named by I and directions named by A. The minimality row T reads the same norm row Nm after the Bessel ledger has fixed the finite orthogonal comparison surface.

For the sibling check, specialize to the Hilbert singleton projection row of Definition 91.25. There the candidate endpoint, residual, norm readback, and inner-product readback are all the displayed singleton zero rows, so the general packet pattern collapses to the existing finite certificate surface.

Since every row is one of these displayed coordinates, no host projection operator, chosen minimizer, quotient equality, or external closed-subspace theorem can be read from the packet. □

Theorem 2374.3 (Orthogonal projection theorem Hilbert handoff)**.** *Every Hilbert-facing consumer of an* $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$ *packet must read the displayed Hilbert source* H*, vector-space reduct* V*, inner-product row* I*, norm row* Nm*, Bessel-bound row* B*, constraint row* A*, candidate projection* Q*, residual row* R*, orthogonality classifier* O*, and norm-minimality comparison* T *before exporting a projection-theorem conclusion. The handoff is therefore a finite NameCert route through* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{BesselInequality}^{\uparrow}$*, and* $\mathsf{VecSpace}^{\uparrow}$*, not a claim of the full host projection theorem.*

Proof. Start with a consumer asking for projection-theorem data over a displayed Hilbert source. By Definition 2374.1, the only available Hilbert data are the rows H, V, I, Nm and the finite theorem-facing rows $B, A, Q, R, O, T, C, P, N$.

Apply the obligation surface of Definition 2374.2. It forces residual formation through V, orthogonality through I, bounded comparison through B, and norm-minimality readback through Nm before the consumer can reach the local name.

The checked singleton sibling in Definition 91.25 shows that this route has a concrete Hilbert projection instance, but it does not promote the packet to a global closed-subspace projection theorem. The handoff exports only the displayed finite rows and excludes host choice, quotient Hilbert equality, and non-displayed completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{OrthogonalProjectionTheorem}^{\uparrow}}$.

Constructive story: An orthogonal-projection-theorem packet is generated from a displayed Hilbert source, vector-space reduct, inner-product and norm rows, a Bessel-bound ledger, a displayed constraint row, a candidate projection endpoint, residual formation, orthogonality classification, norm-minimality comparison, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrthogonalProjectionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2374.1, Definition 2374.2, and Definition 2374.3 declare the finite theorem-facing carrier and Hilbert handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrthogonalProjectionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host closed-subspace projection operator, choice-selected minimizers, quotient Hilbert equality, or the full classical projection theorem.

Upgrade path: Obligation closure requires checked carrier admission, dependency admission, residual formation, orthogonality classification, Bessel-controlled comparison, singleton compatibility, and consumer nonescape for the same finite packet.

Chapter 2375

A Concrete Naming Certificate for $\mathsf{VietorisTopology}^{\uparrow}$

Following Vietoris and Kelley, the $\mathsf{VietorisTopology}^{\uparrow}$ packet records the finite subbasic-hit and subbasic-miss topology read on compact-subset names. It sits over the compact-subset surface of chapter 1660, the finite-net distance route of chapter 2086, the compact metric source of chapter 129, and the ambient topology carrier of chapter 88. The packet names the lower-hit and upper-miss generators as BEDC rows; it is not a host powerset topology, not subset equality, not a choice-selected point, and not open-cover compactness.

Definition 2375.1 (Vietoris topology carrier)**.** *A* $\mathsf{VietorisTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (H, K, L, U, M, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hyperspace}^{\uparrow}$ *source row, recording the compact-subset naming surface and the finite Hausdorff-distance ledger through which compact-subset requests are read.*
2. *K is the compact-subset row over the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source, including the finite subset-net schedules and nonempty compact-subset admission data that the hyperspace route exposes.*
3. *L is the lower-hit row. It records subbasic generators of the form "the compact-subset name hits a displayed open row" through finite witness windows routed by H and K.*
4. *U is the upper-miss row. It records subbasic generators of the form "the compact-subset name is covered by a displayed open row" through finite miss certificates and compact-metric net checks.*
5. *M is the metric and finite-net compatibility row, comparing the lower-hit and upper-miss requests with the* $\mathsf{HausdorffMetric}^{\uparrow}$ *finite-net distance route and the* $\mathsf{CompactMetric}^{\uparrow}$ *source schedules.*
6. *T is the topology transport row from the displayed subbasic hit and miss generators into the ambient* $\mathsf{Topology}^{\uparrow}$ *carrier.*
7. *C records displayed* Cont *replay of the route*

$$H, K, L, U, M \longmapsto T.$$

8. *P is the* Pkg *provenance over* VietorisTopology$^{\uparrow}$, Hyperspace$^{\uparrow}$, HausdorffMetric$^{\uparrow}$, CompactMetric$^{\uparrow}$, Topology$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{VietorisTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, K, L, U, M, T, C, P, N$. It has no coordinate for host subset equality, choice-selected points, open-cover compactness, quotient compacta, or ambient powerset topology.

Lean4 ✓ `BEDC.Derived.VietorisTopologyUp.VietorisTopologyTasteGate single carrier alignment`

Theorem 2375.2 (VietorisTopologyUp NameCert obligations)**.** *For every accepted* VietorisTopology$^{\uparrow}$ *carrier*

$$V = (H, K, L, U, M, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VietorisTopology}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the hyperspace source, compact-subset row, lower-hit row, upper-miss row, finite-net compatibility row, topology transport row, replay row, provenance row, and local naming row;*

2. *lower-hit exactness, requiring every hit generator in L to be read through the displayed hyperspace and compact-subset rows before a witness window is exposed;*

3. *upper-miss exactness, requiring every miss generator in U to be read through the same compact-metric net schedules before a cover read is exposed;*

4. *finite-net compatibility, requiring M to preserve the HausdorffMetric and CompactMetric tolerance ledgers attached to the hit and miss rows;*

5. hsame *and* Cont *transport, requiring T and C to carry the subbasic rows into* Topology$^{\uparrow}$ *without adding a hidden classifier surface;*

6. *ledger nonescape through P and N, excluding host subset equality, choice-selected points, open-cover compactness, quotient compacta, and ambient powerset topology.*

No Vietoris topology obligation is stored outside these rows.

Closure status for $\mathsf{NameCert}_{\mathsf{VietorisTopology}^{\uparrow}}$**.**

Constructive story: A VietorisTopology$^{\uparrow}$ packet is generated from a HyperspaceUp source, compact-subset rows, lower-hit generators, upper-miss generators, HausdorffMetric and CompactMetric finite-net compatibility, topology transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{VietorisTopology}^{\uparrow}}$, seed)

Scope closed: Definition 2375.1 and Definition 2375.2 seed the finite lower-hit and upper-miss topology surface over hyperspace, HausdorffMetric, CompactMetric, and Topology rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{VietorisTopology}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host subset equality, choice-selected points, open-cover compactness, quotient compacta, ambient powerset topology, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-hit exactness, upper-miss exactness, finite-net compatibility, topology transport, replay, provenance, local naming, and ledger nonescape for BEDC.Derived.VietorisTopologyUp.

Chapter 2376

A Concrete Naming Certificate for $\mathsf{LocatedRegSeqRat}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRegSeqRat}^{\uparrow}$ packet records a located regular sequence of rational approximants as finite BEDC NameCert data. It sits after the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback surface of chapter 301, the located real boundary of **??**, and the terminal real-name seal of chapter 38. The packet supplies Real and Completion consumers with a nonquotient route from displayed regular sequence data to located real-name handoff, without importing selected limits, quotient stream equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2376.1 (LocatedRegSeqRat carrier)**.** *A* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, Q, W, H, K, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, exposing finite dyadic scales and comparison rows used by later location requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule, naming the finite windows at which rational approximants may be read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence source row, carrying rational readback and regularity evidence for the scheduled windows.*
4. *Q is the located comparison row, recording for each displayed dyadic tolerance the finite branch that locates the regular sequence relative to the requested rational cut.*
5. *W is the tail-window row, binding the location read to a finite suffix of the scheduled regular sequence.*
6. *H records componentwise* hsame *transport for D, S, R, Q, W, K, P, N.*
7. *K records displayed* Cont *replay from a location request through the dyadic, stream, regular-sequence, comparison, tail-window, transport, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRegSeqRat}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $D, S, R, Q, W, H, K, P, N$. It has no coordinate for quotient stream equality, a selected limit representative, countable choice, trichotomy, host rational order, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRegSeqRatUp.LocatedRegSeqRatTasteGate single carrier alignment`

Theorem 2376.2 (LocatedRegSeqRat NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier $L = (D, S, R, Q, W, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedRegSeqRat}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite stream-window exposure, regular rational readback, located comparison classification, tail-window binding, componentwise* hsame *transport, displayed* Cont *replay, package provenance, local naming, and ledger refusal for quotient streams, selected limit representatives, countable choice, trichotomy, host rational order, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 2376.1. The packet exposes the dyadic ledger D, the observation schedule S, the regular rational row R, the located comparison row Q, and the tail-window row W before the transport, replay, provenance, and local naming rows can be consumed.

The NameCert obligations are precisely these projections. The dyadic and stream rows determine which finite tolerance and observation windows are available; the regular rational row supplies the readback; the located comparison and tail-window rows state where the location request is decided.

Transport and replay are exhausted by H and K. Since the classifier has no additional coordinate beyond $D, S, R, Q, W, H, K, P, N$, the local naming row cannot import quotient stream equality, selected limit representatives, countable choice, trichotomy, host rational order, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2376.3 (LocatedRegSeqRat tail-window stability)**.** *Every transported* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *location read preserves the same finite tail-window route. If a consumer requests a dyadic tolerance through D, the transported packet must still read the scheduled stream windows S, the regular rational source R, the located comparison row Q, and the tail-window row W before it can inspect the local naming row N.*

Proof. Project the transport row H from the carrier. It acts componentwise on the dyadic ledger, stream schedule, regular rational source, located comparison row, tail-window row, replay, provenance, and local naming rows.

The replay row K then repeats the same finite route after transport. A tolerance request first reads D, then the scheduled windows S, then the regular rational source R, and then the located comparison row Q bound to the suffix named by W.

No transported read can bypass this suffix because the local naming row is not exposed until the displayed route has been replayed. Thus tail-window stability is internal to the carrier surface. □

Lean4 ✓ `BEDC.Derived.LocatedRegSeqRatUp.LocatedRegSeqRatCarrier tail window stability`

Theorem 2376.4 (LocatedRegSeqRat RealUp handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *packet factors through the located regular-sequence carrier before the terminal real-name seal is read. The handoff exposes only $D, S, R, Q, W, H, K, P, N$ and the sibling* $\mathsf{LocatedReal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *certificate surfaces, so it cannot supply a quotient completion, selected limit, countable-choice schedule, trichotomy decision, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Proof. Begin with a Real-facing read. The carrier forces the read through the dyadic tolerance ledger, finite stream schedule, regular rational source, located comparison classifier, and tail-window row before it reaches provenance or local naming.

The sibling $\mathsf{LocatedReal}^{\uparrow}$ boundary consumes the displayed location row and not a host cut predicate. The $\mathsf{Real}^{\uparrow}$ seal is therefore terminal for the displayed route rather than a source of further completeness data.

Since no classifier coordinate stores quotient completion, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the handoff exports only the finite located regular-sequence certificate surface. □

Theorem 2376.5 (LocatedRegSeqRat modulus consumer route)**.** *Every accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *packet used by a Real or Completion consumer factors through its displayed locatedness row, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{Real}^{\uparrow}$ *seal before any consumer-visible located read is exported. The locatedness row is downstream of finite windows and cannot be replaced by quotient stream equality, a selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier as $L = (D, S, R, Q, W, H, K, P, N)$. The carrier exposes the dyadic tolerance ledger D, the finite window schedule S, the regular rational readback row R, the located comparison row Q, and the tail-window row W before provenance or local naming can be consumed.

Apply Definition 2376.2 to identify the displayed location surface and Definition 2376.4 to route Real-facing reads through the terminal $\mathsf{Real}^{\uparrow}$ seal. The existing handoff makes the consumer pass through the same finite rows rather than through an external completion principle.

The locatedness row is therefore downstream of finite windows, regular rational readback, and dyadic tolerance data. Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, no consumer-visible located read can bypass this modulus route. □

Theorem 2376.6 (LocatedRegSeqRat Bishop located-completion handoff)**.** *Every* $\mathsf{BishopLocatedCompletion}^{\uparrow}$ *read sourced from an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *packet must pass through the displayed DyadicRatCore tolerance ledger, StreamName window schedule, RegSeqRat readback row, located comparison row, finite tail-window row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *before a completion-facing located seal is exposed. The completion consumer therefore reads the route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{LocatedReal}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BishopLocatedCompletion}^{\uparrow}$$

only through the finite rows $D, S, R, Q, W, H, K, P, N$ *of Definition 2376.1.*

Proof. Project the accepted carrier as $L = (D, S, R, Q, W, H, K, P, N)$. By Definition 2376.2, the local NameCert surface exposes the dyadic tolerance ledger, stream windows, regular rational readback, located comparison row, tail-window row, transport, replay, provenance, and local naming as the complete set of readable rows.

Apply Definition 2376.3 to keep the same finite suffix after transport. The completion-facing consumer cannot move the located comparison away from the displayed tail-window route, because every transported location request must replay D, S, R, Q, W before it can inspect local naming.

Apply Definition 2376.4 and Definition 2376.5. These results force Real-facing and Completion-facing reads through the located row, the finite StreamName window, the RegSeqRat readback, the

DyadicRatCore tolerance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any consumer-visible located read is exported.

The $\mathsf{BishopLocatedCompletion}^{\uparrow}$ consumer therefore receives a located completion seal only after the same finite rows have been displayed. Since the $\mathsf{LocatedRegSeqRat}^{\uparrow}$ carrier contains no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, none of those objects can be inserted into the handoff. □

Theorem 2376.7 (LocatedRegSeqRat explicit-modulus handoff)**.** *Every explicit-modulus consumer of an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier* $L = (D, S, R, Q, W, H, K, P, N)$ *must read the dyadic tolerance ledger* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, located comparison row* Q*, and tail-window row* W *before any Real-facing or completion-facing located seal is exported. The handoff therefore exposes an explicit finite route from tolerance and window data to the located seal, not quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $L = (D, S, R, Q, W, H, K, P, N)$. The explicit-modulus consumer can inspect only the displayed dyadic ledger, stream schedule, regular rational source, located comparison, and tail-window rows before the structural rows are replayed.

Apply Definition 2376.3. It keeps every transported location request on the same finite suffix route through D, S, R, Q, W.

Apply Definition 2376.5 and Definition 2376.6. These handoffs require the Real-facing or completion-facing located seal to be exported only after the finite tolerance ledger, finite window schedule, regular sequence readback, located comparison, and tail-window row have been displayed.

Since no carrier coordinate stores quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, an explicit-modulus consumer cannot bypass this finite route. □

Theorem 2376.8 (LocatedRegSeqRat finite location decision)**.** *Every located comparison row* Q *of an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier is decided only after the dyadic tolerance ledger* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and tail-window row* W *have been displayed. Thus a location decision is a finite BEDC route through* D, S, R, W, Q*, not a host trichotomy decision, selected limit comparison, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *order test.*

Proof. Project the accepted carrier $L = (D, S, R, Q, W, H, K, P, N)$. The carrier lists the dyadic tolerance ledger, stream schedule, regular rational row, located comparison row, and tail-window row as displayed data before transport, replay, provenance, or local naming can be read.

The comparison row Q is downstream of D, S, R, W. The tolerance to be decided is supplied by D, the finite observation windows by S, the rational readback by R, and the finite suffix binding by W.

The structural rows H, K, P, N only preserve and replay this displayed route. Since no coordinate stores trichotomy, selected limits, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ order, the located decision remains a finite comparison over the displayed rows. □

Theorem 2376.9 (LocatedRegSeqRat tail-modulus transport)**.** *Componentwise* hsame *transport of an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier preserves the same dyadic tolerance and finite* $\mathsf{StreamName}^{\uparrow}$ *schedule for every transported tail-window read. In particular, a transported comparison cannot replace the displayed tolerance ledger* D *or schedule* S *with a new modulus source outside the carrier.*

Proof. Start with the transport row H of $L = (D, S, R, Q, W, H, K, P, N)$. By carrier projection, H acts componentwise on the dyadic ledger, stream schedule, regular rational readback, located comparison, tail-window, replay, provenance, and local naming rows.

Apply Definition 2376.3. It already forces every transported location request to replay D, S, R, Q, W before the local naming row is inspected.

The same route preserves the tolerance and schedule used by the original tail-window read. If a transported packet changed the dyadic tolerance source or finite StreamName schedule, it would leave the componentwise transport row and therefore would not be the accepted transported $\mathsf{LocatedRegSeqRat}^{\uparrow}$ packet. □

Theorem 2376.10 (LocatedRegSeqRat window-modulus fusion)**.** *For every accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier* $L = (D, S, R, Q, W, H, K, P, N)$*, finite location decisions and tail-modulus transport share one displayed route through the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any Real-facing consumer reads locatedness. The fused route exports no detached location test and no detached modulus source.*

Proof. Apply Definition 2376.8. A location decision reads the dyadic tolerance ledger D, finite StreamName schedule S, regular rational row R, tail-window row W, and comparison row Q as one finite BEDC route.

Apply Definition 2376.9. The transported tail-window read preserves the same tolerance ledger and finite schedule, so the modulus side cannot replace D or S by a source outside the carrier.

Finally apply Definition 2376.11. The $\mathsf{Real}^{\uparrow}$ seal is terminal for the displayed route $D, S, R, Q, W, H, K, P, N$. Therefore the location decision and transported modulus read fuse before the Real seal is consumed, and neither can export a separate host order test, selected limit, quotient stream equality, or ambient completeness principle. □

Theorem 2376.11 (LocatedRegSeqRat Real seal nonescape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *carrier is terminal for the displayed finite route. It cannot export quotient stream equality, selected limits, trichotomy, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness to a Real-facing or Completion-facing consumer.*

Proof. Use Definition 2376.4. Every Real-facing consumer first factors through the dyadic ledger, finite stream schedule, regular rational source, located comparison, tail-window row, transport, replay, provenance, and local naming.

Use Definition 2376.5 and Definition 2376.6. These handoffs keep Real-facing and Completion-facing reads downstream of the finite rows $D, S, R, Q, W, H, K, P, N$.

The terminal seal is therefore a boundary row, not a source of additional host principles. Since the carrier has no coordinate for quotient stream equality, selected limits, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported by the seal. □

Theorem 2376.12 (LocatedRegSeqRat RealEquality handoff)**.** *Every equality-facing consumer of an accepted* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *packet must read the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, located comparison row, tail-window row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before it can invoke the* $\mathsf{RealEquality}^{\uparrow}$ *classifier boundary. The handoff exports no quotient stream equality, selected limit, trichotomy, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 2376.10. The located decision and tail-modulus read share the same finite route through the dyadic ledger, StreamName schedule, RegSeqRat readback, located comparison row, and tail-window row.

Apply Definition 2376.11. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of those displayed rows and cannot export a quotient, selected limit, trichotomy row, countable-choice schedule, host equality, or ambient completeness principle.

Finally use the classifier and NameCert boundary of Definition 1636.2 and Definition 1636.3. A $\mathsf{RealEquality}^{\uparrow}$ read can inspect equality only after the same finite windows, regular readbacks, dyadic tolerance ledger, and Real-seal boundary are visible, so the accepted $\mathsf{LocatedRegSeqRat}^{\uparrow}$ packet reaches RealEquality through the displayed L10 rows and no hidden equality source. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRegSeqRat}\uparrow}$.

Constructive story: A $\mathsf{LocatedRegSeqRat}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName observation windows, RegSeqRat readbacks, a located comparison row, a finite tail-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRegSeqRat}\uparrow}, \mathsf{seed})$

Scope closed: Definition 2376.1, Definition 2376.2, Definition 2376.3, and Definition 2376.4 seed the finite route from displayed regular rational sequence data to located Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRegSeqRat}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, location classification, tail-window stability, RealUp handoff, and ledger refusal for BEDC.Derived.LocatedRegSeqRatUp.

Chapter 2377

A Concrete Naming Certificate for $\mathsf{FiniteRealCover}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{FiniteRealCover}^{\uparrow}$ packet records the finite ball-cover data used by metric and compact-metric arguments without importing arbitrary open-cover compactness or a choice-selected subcover. It sits over the $\mathsf{Met}^{\uparrow}$ surface of chapter 57, the $\mathsf{Real}^{\uparrow}$ distance seal of chapter 38, the dyadic radius arithmetic of chapter 291, the total-bounded witness interface of chapter 127, and the compact-metric consumer route of chapter 129. The packet names only finite ball rows, dyadic radii, coverage witnesses, refinement ledgers, componentwise transport, replay, provenance, and local naming evidence.

Definition 2377.1 (Finite real cover carrier)**.** *A* $\mathsf{FiniteRealCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, R, D, B, W, E, H, C, P, N)$$

with the following displayed coordinates:

1. *M is the accepted* $\mathsf{Met}^{\uparrow}$ *row whose distance observations are sealed through* $\mathsf{Real}^{\uparrow}$*;*
2. *R is a finite row of* $\mathsf{Real}^{\uparrow}$ *or metric source probes to be covered;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, with each radius recorded as a positive dyadic tolerance;*
4. *B is the finite ball row assigning each listed center and dyadic radius to its displayed metric-distance witness;*
5. *W is the coverage witness row, pairing each inspected source probe in R with an admitted ball in B and its distance bound;*
6. *E is the refinement ledger, recording how a finer finite ball row reuses or refines the displayed centers, dyadic radii, and coverage witnesses;*
7. *H is the componentwise* hsame *transport row for the metric, probe, radius, ball, coverage, refinement, provenance, and local naming coordinates;*
8. *C is the displayed* Cont *replay route for metric distance reads, radius reads, coverage reads, and refinement reads;*
9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRealCover}^{\uparrow}}$ *evidence.*

The carrier has no coordinate for an arbitrary open cover, a host finite-subcover selection function, a powerset compactness theorem, a quotient real equality, or an ambient completeness object.

Definition 2377.2 (Finite real cover classifier)**.** *Two accepted* $\mathsf{FiniteRealCover}^{\uparrow}$ *packets*

$$F = (M, R, D, B, W, E, H, C, P, N)$$

and

$$F' = (M', R', D', B', W', E', H', C', P', N')$$

are classified together exactly when the stored hsame *rows transport* M *to* M'*,* R *to* R'*,* D *to* D'*,* B *to* B'*,* W *to* W'*,* E *to* E'*,* P *to* P'*, and* N *to* N'*, and the displayed* Cont *rows replay the same metric-distance, dyadic-radius, coverage, and refinement route on both packets. The classifier does not compare host subsets, arbitrary cover families, selected subcovers, completed metric spaces, or quotient real representatives.*

Theorem 2377.3 (Finite real cover NameCert obligations)**.** *For the carrier of Definition 2377.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteRealCover}^{\uparrow}}$ *surface consists exactly of carrier admission for* $F = (M, R, D, B, W, E, H, C, P, N)$ *classifier stability by Definition 2377.2, metric-distance witness admission through* M*, dyadic radius admission through* D*, finite ball admission through* B*, coverage witness admission through* W*, refinement-ledger admission through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.FiniteRealCoverUp.FiniteRealCoverCarrier namecert obligations`

Proof. Project the carrier. Its rows display the metric source, inspected probes, dyadic radii, ball witnesses, coverage witnesses, refinement ledger, transport, replay, provenance, and local name as one finite packet.

Use the classifier definition for stability. It compares only the displayed rows and transports them componentwise through hsame, then replays the same route through C.

The omitted open-cover, subcover-choice, quotient, and completeness objects are not coordinates of F. Coordinate exhaustion therefore leaves exactly the listed NameCert obligations. □

Theorem 2377.4 (Finite real cover refinement stability)**.** *Any accepted refinement read of a* $\mathsf{FiniteRealCover}^{\uparrow}$ *packet must pass through the displayed refinement ledger* E*. If a finer packet refines* F*, the read transports the metric row* M*, dyadic radius ledger* D*, ball row* B*, and coverage row* W *through the stored* hsame *entries and replays the same* Cont *route before the finer coverage witnesses are exposed. It cannot replace the ledger by a host cover refinement, arbitrary finite-subcover choice, completed metric compactness result, or quotient real equality.*

Proof. Start with a refinement-facing consumer. Carrier projection gives access only to the rows $M, R, D, B, W, E, H, C, P, N$.

The refinement ledger E is the only row whose role is to relate the displayed balls, dyadic radii, and coverage witnesses to a finer finite ball row. Transport through H preserves those coordinates componentwise, and replay through C preserves the metric and dyadic reads.

Since no host refinement operation or subcover selector is stored in the packet, the accepted refinement remains the finite ledger route described above. □

Theorem 2377.5 (Finite real cover total-bounded handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer citing an accepted* $\mathsf{FiniteRealCover}^{\uparrow}$ *packet receives a finite handoff through*

$$M \longmapsto D \longmapsto B \longmapsto W \longmapsto E.$$

The handoff supplies the metric-distance witness, dyadic tolerance, finite ball row, coverage witness, and refinement ledger needed by total-bounded and compact-metric reads. It supplies no general open-cover compactness theorem, no choice-selected subcover, no ambient powerset cover object, no independent complete-metric carrier, and no quotient real representative.

Proof. Read the consumer through the carrier. The metric row M gives the distance source, D gives the dyadic tolerance budget, B gives the finite ball witnesses, and W gives the coverage witnesses.

For refinement-sensitive consumers, apply refinement stability. The ledger E keeps finer covers inside the same finite ball and dyadic-radius route before any total-bounded or compact-metric handoff is exported.

The listed excluded objects are not stored in the carrier, classifier, transport, replay, provenance, or local NameCert rows. Therefore the total-bounded and compact-metric handoff is exhausted by the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealCover}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRealCover}^{\uparrow}$ packet is generated from a metric source row, Real-valued distance probes, dyadic radius rows, finite ball rows, coverage witnesses, a refinement ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRealCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope records the finite carrier, classifier, NameCert obligations, refinement stability, and total-bounded handoff for explicit metric ball covers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRealCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, choice-selected subcovers, hyperspace compactness, quotient real equality, or ambient metric completion.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, coverage-witness nonescape, refinement-ledger stability, and total-bounded handoff for BEDC.Derived.FiniteRealCoverUp.

Chapter 2378

A Concrete Naming Certificate for $\mathsf{RealNullSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealNullSequence}^{\uparrow}$ packet records a displayed real-valued sequence whose finite convergence surface is tied to the zero $\mathsf{Real}^{\uparrow}$ row. It sits after the real-name seal of chapter 38, the finite-window discipline of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the displayed sequence-limit interface of chapter 1413. The packet gives later sequence-algebra and Cauchy-criterion consumers a finite zero-limit route without importing host sequence equality, quotient limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2378.1 (RealNullSequence carrier)**.** *A* $\mathsf{RealNullSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, 0, W, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *S is a displayed sequence of* $\mathsf{Real}^{\uparrow}$ *names, each read only through the finite packet rows made visible to this carrier.*
2. *0 is the displayed zero* $\mathsf{Real}^{\uparrow}$ *row, supplied as the candidate limit and not as a host-level constant outside the packet.*
3. *W stores the* $\mathsf{StreamName}^{\uparrow}$ *finite windows used to inspect sequence entries and the zero row at the requested tolerances.*
4. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
5. *D stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, slack rows, and comparison budgets used by every scheduled read.*
6. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *convergence classifier row, specialized to the displayed sequence S and the zero row 0.*
7. *H records componentwise* hsame *transport for sequence rows, zero row, windows, readbacks, tolerances, convergence classifier, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from sequence windows through regular rational readback, dyadic tolerance comparison, and the zero-limit classifier.*
9. *P is the* Pkg *provenance over* $\mathsf{RealNullSequence}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealNullSequence}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, 0, W, R, D, L, H, C, P, N$. It has no coordinate for host sequence equality, quotient limits, countable-choice schedules, trichotomy decisions, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 2378.2 (RealNullSequence NameCert obligations)**.** *For every accepted* $\mathsf{RealNullSequence}^\uparrow$ *carrier $Z = (S, 0, W, R, D, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealNullSequence}^\uparrow}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed* $\mathsf{Real}^\uparrow$ *sequence row, zero* $\mathsf{Real}^\uparrow$ *row, finite* $\mathsf{StreamName}^\uparrow$ *windows,* $\mathsf{RegSeqRat}^\uparrow$ *readbacks,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerances,* $\mathsf{RealSequenceLimit}^\uparrow$ *classifier, transport, replay, provenance, and local naming rows;*
2. *zero-row exposure, requiring every accepted limit read to expose the displayed zero* $\mathsf{Real}^\uparrow$ *row before the sequence-limit classifier is consumed;*
3. *finite-window convergence, requiring all convergence evidence to pass through the scheduled W, R, D, L rows;*
4. *transport and replay stability, requiring* hsame *transport and* Cont *replay to preserve the same sequence, zero, window, readback, tolerance, and classifier rows;*
5. *refusal of host sequence equality, quotient limits, countable choice, trichotomy, and ambient completeness as packet coordinates.*

No zero-limit obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 2378.1. The accepted packet displays exactly the sequence row, zero row, finite windows, regular readbacks, dyadic tolerances, convergence classifier, transport, replay, provenance, and local name.

The analytic read is then forced by the row order. The sequence row S and zero row 0 are inspected only through the scheduled windows W, readbacks R, and tolerance ledger D, and the convergence classifier L is the only row that can certify approach to the displayed zero.

Transport and replay stability follow from the structural rows H and C. They preserve the same displayed rows componentwise and replay the same finite route before the local name is consumed.

Finally inspect the carrier inventory. Since host sequence equality, quotient limits, countable choice, trichotomy, and ambient $\mathsf{Real}^\uparrow$ completeness are not coordinates of Z, none can become a local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.RealNullSequenceUp.RealNullSequenceCarrier namecert obligations`

Closure status for $\mathsf{NameCert}_{\mathsf{RealNullSequence}^\uparrow}$.

Constructive story: A $\mathsf{RealNullSequence}^\uparrow$ packet is generated from a displayed RealUp sequence, a zero RealUp row, finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, a RealSequenceLimit convergence classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealNullSequence}^\uparrow}$, seed)

Scope closed: Definition 2378.1 and Definition 2378.2 seed the finite zero-limit route for displayed real sequences.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealNullSequence}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close sequence algebra, Cauchy criteria, quotient limits, host sequence equality, countable choice, trichotomy, ambient $\mathsf{Real}^\uparrow$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-row exposure, finite-window convergence, transport stability, replay stability, and refusal rows for BEDC.Derived.RealNullSequenceUp.

Chapter 2379

A Concrete Naming Certificate for $\mathsf{FanModulusBoundary}^{\uparrow}$

Following Brouwer's fan theorem and Bishop–Bridges constructive analysis, the $\mathsf{FanModulusBoundary}^{\uparrow}$ packet records the boundary at which a finite fan-bar depth becomes a compact-uniform-continuity modulus handoff. It sits over the finite bar packet of chapter 400, the bar-to-window schedule of chapter 1707, the compact-uniform-continuity consumer of chapter 388, and the uniform-modulus surface of chapter 369. The packet uses ProbeBundle routes for finite branch windows and finite compact-source probes; it is not open-cover compactness, not countable choice, not a selected branch, and not $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2379.1 (Fan modulus boundary carrier)**.** *A* $\mathsf{FanModulusBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, M, W, Q, U, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *row, recording the binary fan, decidable bar classifier, finite depth ledger, and finite branch-prefix witness window.*
2. *M is the* $\mathsf{BishopFanModulus}^{\uparrow}$ *row, exposing the bar-depth-to-window-modulus schedule through StreamName, RegSeqRat, DyadicRatCore, and Real readback rows.*
3. *W is the boundary-window row. It records the finite branch-prefix window that may be handed to compact-uniform-continuity consumers without selecting an infinite branch.*
4. *Q is the* ProbeBundle *route row, aligning finite fan-prefix probes with the compact finite-net probes used by the compact-uniform-continuity source.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row, recording the tolerance-only modulus schedule exported from the finite fan-bar boundary.*
6. *R is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *readback row, recording that the exported modulus is consumed only as a compact finite-net and pointwise-modulus handoff.*
7. *H records componentwise* hsame *transport for the fan row, Bishop fan modulus row, boundary window, ProbeBundle route, UniformModulus row, compact-uniform readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$F, M, W, Q \longmapsto U \longmapsto R.$$

9. *P is the* Pkg *provenance over* FanModulusBoundary$^{\uparrow}$, FanTheorem$^{\uparrow}$, BishopFanModulus$^{\uparrow}$, CompactUniformContinu UniformModulus$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{FanModulusBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, M, W, Q, U, R, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected branches, selected limits, quotient stream equality, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FanModulusBoundaryUp.FanModulusBoundaryTasteGate single carrier alignment`

Theorem 2379.2 (FanModulusBoundaryUp NameCert obligations)**.** *For every accepted* FanModulusBoundary$^{\uparrow}$ *carrier*

$$B = (F, M, W, Q, U, R, H, C, P, N),$$

the local NameCert$_{\text{FanModulusBoundary}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite fan row, Bishop fan modulus row, boundary window, ProbeBundle route, UniformModulus consumer, compact-uniform readback, transport, replay, provenance, and local naming rows;*

2. *fan-bar depth exactness, requiring every finite depth used by W to be read through the displayed* FanTheorem$^{\uparrow}$ *bar classifier and witness window;*

3. *Bishop modulus boundary exactness, requiring the window schedule in M to be the only Real and Completion-facing modulus source exposed to U;*

4. *ProbeBundle compatibility, requiring Q to align finite fan-prefix probes with compact finite-net probes before the compact-uniform-continuity readback R is public;*

5. hsame *and* Cont *transport through H and C, preserving the same fan-bar, modulus, ProbeBundle, UniformModulus, and compact-uniform rows under replay;*

6. *ledger nonescape through P and N, excluding open-cover compactness, countable choice, selected branches, selected limits, quotient stream equality, host real equality, and ambient* Real$^{\uparrow}$ *completeness.*

No fan modulus boundary obligation is stored outside these rows.

Closure status for NameCert$_{\text{FanModulusBoundary}^{\uparrow}}$.

Constructive story: A FanModulusBoundary$^{\uparrow}$ packet is generated from a FanTheoremUp finite bar row, BishopFanModulusUp bar-to-window schedule, finite boundary windows, ProbeBundle compatibility, UniformModulus handoff, CompactUniformContinuity readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FanModulusBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 2379.1 and Definition 2379.2 seed the finite fan-bar modulus boundary consumed by compact-uniform-continuity and UniformModulus rows.

Formal verification: FormalStatus(NameCert$_{\text{FanModulusBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, selected branches, selected limits, quotient stream equality, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-bar depth exactness, Bishop modulus boundary exactness, ProbeBundle compatibility, UniformModulus handoff, compact-uniform readback, transport, replay, provenance, local naming, and ledger nonescape for BEDC.Derived.FanModulusBoundaryUp.

Chapter 2380

A Concrete Naming Certificate for $\mathsf{PhysicalInduction}^{\uparrow}$

The $\mathsf{PhysicalInduction}^{\uparrow}$ packet realizes the open-continuation discipline of section 9414.25 as a finite audit-ledger induction carrier. It sits beside the physical model audit of chapter 1129, the ontic source surface of chapter 1125, the state-space model carrier of chapter 329, and the observer-budget support packet of chapter 1121. Those sibling rows supply audit comparison, reality-facing source, model-state presentation, and observer-bounded access; this packet binds an observation row to a hypothesis row, falsifier ledger, step transport row, and local naming row before any induction read is accepted.

Definition 2380.1 (PhysicalInduction carrier)**.** *A* $\mathsf{PhysicalInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (O, H, A, S, B, F, T, R, P, N)$$

with the following displayed rows:

1. *O is the observation row, read through the* $\mathsf{OnticState}^{\uparrow}$ *source and the* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *support boundary.*
2. *H is the hypothesis row, read through the* $\mathsf{StateSpaceModel}^{\uparrow}$ *model-state presentation and the displayed comparison bundle.*
3. *A is the* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row recording the accepted audit comparison between observation and hypothesis data.*
4. *S is the step row naming the finite transition from the current observed prefix to the next licensed prediction read.*
5. *B is the observer-budget row specifying which bounded observation support may inspect the step.*
6. *F is the falsifier ledger, naming finite observations, signature mismatches, or budget failures that defeat the proposed step.*
7. *T records componentwise* hsame *transport for observation, hypothesis, audit, step, budget, falsifier, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from observation and hypothesis rows through the audit row and into the finite step boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{PhysicalInduction}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{OnticState}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalInduction}^{\uparrow}}$ *row.*

The carrier has no coordinate for a final induction oracle, total future fit, host physical truth, unbounded observation, detached model equality, or an induction step outside the displayed audit and falsifier ledger.

Lean4 ✓ `BEDC.Derived.PhysicalInductionUp.PhysicalInductionTasteGate single carrier alignment`

Theorem 2380.2 (PhysicalInduction NameCert obligations)**.** *For every accepted* $\mathsf{PhysicalInduction}^{\uparrow}$ *carrier* $I = (O, H, A, S, B, F, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PhysicalInduction}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the observation row, hypothesis row, physical-model audit row, finite step row, observer-budget row, falsifier ledger, transport, replay, provenance, and local naming row;*
2. *observation exposure, requiring O to be read through* $\mathsf{OnticState}^{\uparrow}$ *and* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *before a hypothesis step is consumed;*
3. *hypothesis and audit exposure, requiring H and A to display the state-space model row and audit comparison used by the proposed step;*
4. *falsifier-ledger exposure, requiring F to name the finite observations, signature mismatches, or support failures that defeat the step;*
5. *step transport stability, requiring T, R, P, N to preserve the same observation, hypothesis, audit, budget, and falsifier rows under accepted replay.*

No accepted physical-induction read may bypass any one of these rows.

Proof. Carrier admission is projection from Definition 2380.1. The accepted packet displays the observation, hypothesis, audit, step, observer-budget, falsifier, transport, replay, provenance, and local naming rows as its complete surface.

The observation and hypothesis rows are read before the step row. The observation row is bounded by the ontic-source and observer-budget siblings, while the hypothesis row is bounded by the displayed state-space model presentation.

The audit and falsifier rows are the decisive middle boundary. The audit row states which comparison licenses the step, and the falsifier ledger states which finite observations or support failures defeat it.

Finally the structural rows T, R, P, N transport, replay, source, and name the same packet. Since no further coordinate exists, an accepted induction read cannot detach the step from its observation, hypothesis, audit, budget, or falsifier ledger. □

Falsifiable prediction: Every accepted $\mathsf{PhysicalInduction}^{\uparrow}$ read must expose an observation row, hypothesis row, falsifier ledger, step transport row, and local NameCert row; a read omitting any one of these rows is outside the carrier.

Independence witness: physical-model-audit, ontic-state, state-space-model, observer-budget-support: none is bijective because $\mathsf{PhysicalInduction}^{\uparrow}$ binds observation, hypothesis, audit, observer budget, falsifier ledger, step transport, replay, provenance, and local NameCert rows in one packet. PhysicalModelAuditUp audits a comparison without isolating the induction step; OnticStateUp exposes the source without the hypothesis row; StateSpaceModelUp exposes model state without the falsifier ledger; ObserverBudgetSupportUp bounds access without licensing a hypothesis step.

The Lean follow-up must provide `Nontrivial PhysicalInductionUp` and `FieldFaithful PhysicalInductionUp` instances in `lean4/BEDC/Derived/PhysicalInductionUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalInduction}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicalInduction}^{\uparrow}$ packet is generated from observation, hypothesis, physical-model audit, finite step, observer-budget, falsifier-ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicalInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2380.1 and Definition 2380.2 seed physical induction as a finite observation-step NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicalInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not assert a final induction oracle, total future fit, host physical truth, unbounded observation, Lean verification, or bridge checking for $\mathsf{PhysicalInduction}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, observation exposure, hypothesis and audit exposure, falsifier-ledger exposure, step transport stability, nontriviality, and field faithfulness for BEDC.Derived.PhysicalInductionUp.

Chapter 2381

A Concrete Naming Certificate for $\mathsf{CompletionIdempotence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompletionIdempotence}^{\uparrow}$ packet records the finite reflector surface by which a displayed completion request over an already completed name is read back through the same completion boundary. It sits over the Cauchy completion functor of chapter 423, the metric completion surface of chapter 1506, the separated completion seal of chapter 1612, and the uniform completion route of chapter 1473. The packet is a reuse certificate for completed names; it does not construct a second quotient object, select representatives, assert host equality, invoke choice, or claim an ambient completeness theorem.

Definition 2381.1 (Completion idempotence carrier)**.** *A* $\mathsf{CompletionIdempotence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, R, Q, W, D, G, A, C, P, N)$$

with the following displayed rows:

1. *F is the first completion seal, naming the completed boundary already available to downstream consumers.*
2. *R is the second completion request row, recording that a consumer asks to complete the already sealed boundary.*
3. *Q is the Cauchy readback row, requiring every second request to read the same finite Cauchy evidence used by F.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing the finite windows through which the repeated completion request is observed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger tying the first seal and the second request to the same dyadic comparison budget.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, keeping regular rational readback attached to the displayed Cauchy data.*
7. *A is the classifier transport row, recording componentwise* hsame *movement for the first seal, second request, Cauchy readback, window, tolerance, and handoff rows.*
8. *C is the displayed* Cont *replay row from the second completion request through R, Q, W, D, G, A back to the first completion seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionIdempotence}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a second completion object, quotient class, selected representative, host equality, choice principle, detached Cauchy witness, or unrecorded completeness assertion.

Lean4 ✓ `BEDC.Derived.CompletionIdempotenceUp.CompletionIdempotenceTasteGate single carrier alignment`

Theorem 2381.2 (CompletionIdempotence NameCert obligations)**.** *For every accepted* $\mathsf{CompletionIdempotence}^{\uparrow}$ *carrier* $I = (F, R, Q, W, D, G, A, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionIdempotence}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the first completion seal, second completion request, Cauchy readback, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat handoff, classifier transport, continuation replay, provenance, and local naming row;*
2. *first-seal visibility, requiring F to be read before the second request is admitted;*
3. *repeated-request exactness, requiring R and Q to reuse the Cauchy data already attached to the first seal;*
4. *window and tolerance stability, requiring W, D, G to keep finite observation windows, dyadic tolerances, and regular rational handoff on the same displayed route;*
5. *classifier and replay closure, requiring A, C, P, N to transport, replay, source, and name only the displayed rows;*
6. *nonescape, excluding a second completion object, quotient class, selected representative, host equality, choice principle, detached Cauchy witness, and unrecorded completeness assertion.*

No completion idempotence obligation is stored outside these rows.

Proof. Project the carrier of Definition 2381.1. The only rows available to the local certificate are $F, R, Q, W, D, G, A, C, P, N$.

The first-seal and repeated-request obligations follow by reading F before R. The Cauchy readback row Q attaches the second request to the same displayed evidence rather than to a fresh completion object.

The window, tolerance, and handoff obligations are carried by W, D, G. They keep the observed StreamName windows, DyadicRatCore tolerances, and RegSeqRat readback on the route already named by the first seal.

The structural rows A, C, P, N transport, replay, source, and name the displayed packet. Since every excluded object is absent from the tuple, the certificate cannot export a second completion object, quotient class, selected representative, host equality, choice principle, detached Cauchy witness, or unrecorded completeness assertion. □

Theorem 2381.3 (Completion idempotence stable reflection)**.** *Let* $I = (F, R, Q, W, D, G, A, C, P, N)$ *be an accepted* $\mathsf{CompletionIdempotence}^{\uparrow}$ *carrier. Every downstream completion consumer that reads the second request factors through the finite route*

$$F \longmapsto R, Q \longmapsto W, D, G \longmapsto A, C, P, N.$$

Thus a completed name can be reused through its first completion seal, Cauchy readback, finite StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat handoff, classifier transport, continuation replay, provenance, and local NameCert row, without constructing or naming a second completion object.

Proof. Start from an accepted repeated-completion read. Carrier admission exposes the first seal F and the second request R as rows of the same finite packet.

The Cauchy readback row Q ties the second request to the evidence already carried by F. The rows W, D, G then preserve finite observation windows, dyadic tolerances, and regular rational handoff along that same route.

Finally the classifier transport A, continuation replay C, provenance P, and local naming row N package the route for downstream consumers. None of these rows adds a second completion object, so the reflection is stable by exhaustion of the displayed carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionIdempotence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionIdempotence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2381.1, Definition 2381.2, and Definition 2381.3 seed the finite completion-idempotence reflector over first completion seals, repeated requests, Cauchy readback, StreamName windows, DyadicRatCore tolerances, RegSeqRat handoff, classifier transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionIdempotence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, quotient completion classes, selected representatives, host equality, choice principles, detached Cauchy witnesses, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, repeated-request exactness, window and tolerance stability, classifier transport, replay closure, and nonescape for BEDC.Derived.CompletionIdempotenceUp.

Constructive story: A $\mathsf{CompletionIdempotence}^{\uparrow}$ packet is generated from a first completion seal, a second completion request, Cauchy readback, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat handoff, classifier transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2382

A Concrete Naming Certificate for $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$

The $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$ packet realizes the confluence audit-map boundary of chapter 9378 as finite frontier critical-pair data. It reads the critical-pair boundary of chapter 2212, the frontier dependency matrix of chapter 2307, the closed-normal fragment of chapter 737, the bounded normal-equality checker of chapter 752, and the subject-reduction route classifier of chapter 785. The packet names local frontier joins for audit consumers; it does not assert global confluence, arbitrary closed-term Church–Rosser, residual-substitution compatibility, or unchecked subject-reduction discharge.

Falsifiable prediction: Every accepted $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$ packet routes confluence audit reads through redex-frontier, finite critical-pair, local-join, bounded-checker, substitution-boundary, transport, replay, provenance, and local naming rows.

Independence witness: metacic-confluence-critical-pair-boundary, metacic-frontier-dependency-matrix, metacicconfluencenormalfragment, bounded-normal-equality-checker, and subject-reduction-route-classifier: these siblings respectively expose common-reduct boundary rows, frontier dependency accounting, closed-normal fragments, bounded normal-form comparison, and typing-route separation; none is bijective with the packet that jointly records redex-frontier critical pairs, local joins, substitution-boundary refusal, transport, replay, provenance, and local naming.

Definition 2382.1 (MetaCIC frontier critical-pair carrier)**.** *A* $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, F, J, E, U, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the redex-frontier row read from the finite MetaCIC frontier cases.*
2. *F is the finite critical-pair table row, listing the frontier overlaps accepted by the packet.*
3. *J is the local-join row, recording displayed join candidates for each accepted frontier critical pair.*
4. *E is the* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *row used when a local join is checked by bounded normal equality.*
5. *U is the substitution-boundary row, recording that residual-substitution compatibility and arbitrary closed substitution are not supplied by the packet.*

6. *S is the subject-reduction route-classifier row, keeping typing discharge separate from confluence audit reads.*
7. *H records componentwise* hsame *transport for frontier, critical-pair, local-join, bounded-checker, substitution-boundary, route-classifier, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an audit-map request through the frontier table, local join, bounded checker, substitution boundary, and route classifier.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$, $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$, $\mathsf{MetaCICFrontierDependencyMatrix}^{\uparrow}$, $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}}$ *row.*

The carrier contains no coordinate for global confluence, arbitrary closed-term Church–Rosser, full parallel diamond, residual-substitution compatibility, unchecked subject-reduction discharge, or an audit-map consumer that bypasses the displayed frontier table.

Lean4 ✓ `BEDC.Derived.MetaCICFrontierCriticalPairUp.MetaCICFrontierCriticalPairTasteGate single carrier alignment`

Theorem 2382.2 (MetaCIC frontier critical-pair NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$ *carrier* $K = (R, F, J, E, U, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the redex-frontier row, finite critical-pair table, local-join row, bounded-checker row, substitution-boundary row, route-classifier row, transport, replay, provenance, and local naming row;*
2. *frontier enumeration, requiring every accepted critical pair to be read from R and F before a local join is consulted;*
3. *local-join exactness, requiring J to display the join candidate before the bounded checker E is used;*
4. *substitution-boundary visibility, requiring U to remain visible whenever the audit-map boundary is cited;*
5. *route separation, requiring S to keep subject-reduction discharge outside the confluence critical-pair route;*
6. *nonescape, excluding global confluence, arbitrary closed-term Church–Rosser, full parallel diamond, residual-substitution compatibility, unchecked subject-reduction discharge, and audit-map reads outside $R, F, J, E, U, S, H, C, P, N$.*

No frontier critical-pair obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 2382.1. The projection exposes exactly $R, F, J, E, U, S, H, C, P, N$.

Frontier enumeration reads R and F first. Therefore the packet can inspect only finite frontier overlaps that appear in the displayed critical-pair table.

The local-join obligation reads J before the bounded checker E. This keeps bounded normal-equality checking downstream of a displayed join candidate rather than turning the checker into a global confluence proof.

The boundary and route-separation obligations are carried by U and S. They keep substitution compatibility and subject-reduction discharge outside the packet's confluence route.

The structural rows H, C, P, N transport, replay, source, and name only the displayed route. Since the excluded confluence and typing claims are absent from the carrier, the local NameCert surface is exhausted by the stated rows. □

Theorem 2382.3 (MetaCIC frontier critical-pair route)**.** *Every confluence audit-map read from an accepted* $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$ *packet factors through the finite route*

$$R \longmapsto F \longmapsto J \longmapsto E \longmapsto U, S \longmapsto H, C, P, N.$$

Thus the packet supplies a redex-frontier, finite critical-pair, local-join, bounded-checker, substitution-boundary, transport, replay, provenance, and local naming handle for the audit map, without claiming global confluence or discharging the substitution boundary.

Proof. An audit-map read begins at the redex-frontier row R and the finite critical-pair table F, because no unfrontiered confluence coordinate appears in the carrier.

For an accepted pair, the local-join row J is read before the bounded checker E. The checker is therefore attached to displayed local joins, not to arbitrary closed terms.

The substitution-boundary row U and route-classifier row S remain visible before the structural rows package the read. The rows H, C, P, N preserve and name the same finite route, so the packet remains a critical-pair frontier handle rather than a global confluence theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2382.1, Definition 2382.2, and Definition 2382.3 seed the finite MetaCIC frontier critical-pair route over redex-frontier rows, critical-pair tables, local joins, bounded checking, substitution-boundary refusal, route separation, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global confluence, arbitrary closed-term Church–Rosser, full parallel diamond, residual-substitution compatibility, unchecked subject-reduction discharge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, frontier enumeration, local-join exactness, substitution-boundary visibility, route separation, and nonescape for BEDC.Derived.MetaCICFrontierCriticalPairUp.

Constructive story: A $\mathsf{MetaCICFrontierCriticalPair}^{\uparrow}$ packet is generated from redex-frontier rows, finite critical-pair rows, local-join rows, a bounded-checker row, a substitution-boundary row, a subject-reduction route-classifier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2383

A Concrete Naming Certificate for $\mathsf{FixedPointIteration}^{\uparrow}$

Following Banach's fixed-point iteration and Bishop–Bridges constructive analysis, the $\mathsf{FixedPointIteration}^{\uparrow}$ packet records the finite orbit ledger read between the contraction-map surface of chapter 1418, the one-step Picard route of chapter 395, the complete-metric handoff of chapter 128, the metric source of chapter 57, and the endpoint fixed-point certificate of chapter 396. The packet names displayed iterate rows, residual budgets, transport, continuation, provenance, and local naming before any completed endpoint row is consumed.

Definition 2383.1 (FixedPointIteration carrier)**.** *A* $\mathsf{FixedPointIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, d, T, x_0, I, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the admitted point classifier for the iteration domain.*
2. *d is the distance row used to read finite adjacent-iterate distances inside X.*
3. *T is the self-map graph row supplied by the* $\mathsf{ContractionMapping}^{\uparrow}$ *surface and read one application at a time.*
4. *x_0 is the initial-point row from which the finite orbit is generated.*
5. *I is the finite iterate ledger, listing displayed rows $x_0, x_1, \ldots, x_n$ with application witnesses that each x_{k+1} is read from T at x_k.*
6. *R is the residual budget row, recording the finite distance and contraction-ratio estimates available for the displayed orbit window.*
7. *H records componentwise* hsame *transport for the metric source, distance row, self-map graph, initial point, iterate ledger, residual budget, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for extending a finite orbit window by one certified application row and for handing the finite residual rows to completion-facing consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{FixedPointIteration}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FixedPointIteration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected fixed point, a completed limit, host function equality, or ambient completeness outside the displayed completion handoff.

Lean4 ✓ `BEDC.Derived.FixedPointIterationUp.FixedPointIterationTasteGate single carrier alignment`

Theorem 2383.2 (FixedPointIteration NameCert obligations)**.** *For an accepted* $\mathsf{FixedPointIteration}^{\uparrow}$ *carrier* $Q = (X, d, T, x_0, I, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FixedPointIteration}^{\uparrow}}$ *surface consists exactly of carrier admission, initial-point admission, self-map graph readability, finite iterate-ledger formation, residual-budget exposure, componentwise transport, continuation replay, package provenance stability, and local naming for the carrier of Definition 2383.1. No obligation is stored outside those displayed rows.*

Proof. Carrier admission projects the rows $X, d, T, x_0, I, R, H, C, P, N$ from the finite packet. The initial-point and self-map obligations read x_0 and T against the metric-source classifier before any iterate is formed.

The iterate-ledger obligation then checks each displayed application row in I. The residual-budget obligation reads only the finite adjacent-distance and contraction-ratio rows in R, so it does not require a completed limit object.

Transport and replay are supplied by H and C, while P and N record provenance and local naming. Since the carrier has no other coordinate, the public NameCert surface is exactly the listed finite iteration-orbit surface. □

Theorem 2383.3 (FixedPointIteration residual budget)**.** *Every accepted* $\mathsf{FixedPointIteration}^{\uparrow}$ *carrier exposes a residual budget only for the displayed finite orbit window* I*. The row* R *may be consumed as finite evidence for adjacent-distance control, tail-radius comparison over the displayed window, and contraction-ratio bookkeeping, but it is not a completed Cauchy sequence, not a selected endpoint, and not a proof of host fixed-point equality.*

Proof. Project the carrier through Definition 2383.1. The only residual coordinate is R, and it is attached to the finite iterate ledger I rather than to an infinite sequence object.

Read the contraction source through chapter 1418 and the one-step route through chapter 395. These surfaces supply adjacent application and distance comparisons for displayed rows only.

Thus a consumer may use R as finite residual bookkeeping for the orbit window. Any completed endpoint, Cauchy-limit object, or fixed-point equality must be supplied by a separate completion or fixed-point packet. □

Theorem 2383.4 (FixedPointIteration complete-metric handoff)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{BanachFixedPoint}^{\uparrow}$ *consumer of a* $\mathsf{FixedPointIteration}^{\uparrow}$ *packet must pass through the finite route*

$$X, d, T, x_0, I, R \longmapsto H, C, P, N.$$

The iteration packet supplies the orbit and residual rows consumed by completion-facing certificates, but the limit witness, endpoint seal, and classifier-fixed endpoint row remain outside $\mathsf{FixedPointIteration}^{\uparrow}$ *until the complete-metric and Banach fixed-point packets provide them.*

Proof. Start with an accepted carrier. The metric source X, distance row d, self-map row T, and initial point x_0 generate only the displayed ledger I and residual row R.

The continuation row C replays this finite route for a completion-facing consumer, and the transport row H preserves the same componentwise readings under the packet classifier. The provenance and naming rows P, N record that this route is the one exported by the packet.

Completeness and endpoint fixedness are therefore not read from $\mathsf{FixedPointIteration}^{\uparrow}$. They enter only when a $\mathsf{CompleteMetric}^{\uparrow}$ or $\mathsf{BanachFixedPoint}^{\uparrow}$ packet consumes the displayed finite orbit and supplies its own limit or endpoint rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{FixedPointIteration}^{\uparrow}}$.

Constructive story: A $\mathsf{FixedPointIteration}^{\uparrow}$ packet is generated from a MetricUp source row, a distance row, a ContractionMapping self-map graph, an initial point, a finite iterate ledger, a residual budget, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FixedPointIteration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2383.1, Definition 2383.2, Definition 2383.3, and Definition 2383.4 seed the finite iteration-orbit packet over metric, contraction-map, Picard-step, complete-metric, fixed-point, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FixedPointIteration}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FixedPointIterationUp.FixedPointIterationTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close selected fixed points, completed limits, host fixed-point equality, ambient completeness outside the carried handoff, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, iterate-ledger formation, residual-budget exposure, completion handoff, transport stability, replay stability, provenance stability, and local naming for BEDC.Derived.FixedPointIterationUp.

Chapter 2384

A Concrete Naming Certificate for $\mathsf{RaikovCompletion}^{\uparrow}$

Following Raikov and the Bourbaki–Kelley treatment of two-sided uniform completion, the $\mathsf{RaikovCompletion}^{\uparrow}$ packet records the completion route for a separated uniform group as finite BEDC NameCert data. It sits after the entourage carrier of chapter 339, the separated comparison boundary of chapter 1876, the Cauchy-filter surface of chapter 333, and the completion handoff of chapter 1473. The packet names the two-sided Cauchy-filter route without quotient representatives, selected limits, host equality of completion points, trichotomy, countable choice, or ambient complete-group structure.

Definition 2384.1 (Raikov completion carrier)**.** *A* $\mathsf{RaikovCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, U, S, L, R, F, C, H, P, N)$$

with the following displayed rows:

1. *G is the source group row, read only through the finite multiplication, inverse, and unit observations needed by uniform consumers.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row on the source, carrying both left and right translate requests as displayed finite entourage data.*
3. *S is the* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *comparison row, recording that the diagonal boundary is separated before completion-facing reads are exported.*
4. *L is the left Cauchy-filter ledger and R is the right Cauchy-filter ledger, each read through the* $\mathsf{CauchyFilter}^{\uparrow}$ *surface.*
5. *F is the two-sided compatibility row asserting that the same displayed filter packet satisfies the left and right Cauchy requests after common finite refinement.*
6. *C is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row consumed by completion-facing readers only after U, S, L, R, F have been displayed.*
7. *H records componentwise* hsame *transport for the group, uniformity, separated comparison, two Cauchy-filter ledgers, compatibility, handoff, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{RaikovCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RaikovCompletion}^{\uparrow}}$ *row.*
The carrier predicate is exactly the assertion that these rows form one two-sided uniform completion packet. It has no coordinate for quotient representatives, selected limits, host equality, trichotomy, choice, or an ambient completed group.

Lean4 (definition) `BEDC.Derived.RaikovCompletionUp.RaikovCompletionUp`
Lean4 ✓ `BEDC.Derived.RaikovCompletionUp.RaikovCompletionTasteGate single carrier alignment`

Theorem 2384.2 (Raikov completion NameCert obligations)**.** *For every accepted* $\mathsf{RaikovCompletion}^{\uparrow}$ *carrier* $K = (G, U, S, L, R, F, C, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RaikovCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, left and right Cauchy-filter visibility, two-sided common-refinement compatibility, separated-boundary visibility, uniform-completion handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Every obligation is read through the finite rows

$$G, U, S, L, R, F, C, H, P, N.$$

No obligation is stored as a quotient completion, a chosen representative, a selected limit, host equality of completion points, trichotomy, countable choice, or an ambient complete-group principle.

Proof. Project the carrier of Definition 2384.1. The projection exposes the source group row, uniform entourage row, separated comparison row, left and right Cauchy-filter ledgers, two-sided compatibility row, completion handoff, transport row, provenance row, and local naming row.

The left and right Cauchy obligations are exactly the rows L and R. The compatibility row F is downstream of both, so a completion-facing consumer cannot read only one side of the uniform structure and call it a Raikov route.

The separated boundary is the row S, and the completion handoff is the row C. The replay data require the route through U, S, L, R, F before C is available, while H, P, N preserve transport, provenance, and local naming for the same finite packet.

Since the carrier has no quotient, representative-selection, host-equality, trichotomy, choice, or ambient complete-group coordinate, none of the listed obligations can export such data. □

Theorem 2384.3 (Raikov completion two-sided Cauchy-filter route)**.** *Every completion-facing read of an accepted* $\mathsf{RaikovCompletion}^{\uparrow}$ *packet factors through the finite two-sided route*

$$\mathsf{UniformSpace}^{\uparrow} \longrightarrow \mathsf{SeparatedUniformSpace}^{\uparrow} \longrightarrow (\mathsf{CauchyFilter}^{\uparrow}_{\mathrm{left}}, \mathsf{CauchyFilter}^{\uparrow}_{\mathrm{right}}) \longrightarrow \mathsf{UniformCompletion}^{\uparrow}.$$

Equivalently, a consumer first reads the displayed uniform entourage row U, then the separated comparison row S, then the paired left and right Cauchy-filter ledgers L, R together with their compatibility row F, and only then the completion handoff row C. The route exports no quotient representative, chosen limit, host equality of completion points, trichotomy, countable choice, or ambient complete-group object.

Proof. Start with an accepted carrier $K = (G, U, S, L, R, F, C, H, P, N)$. The only uniform data available to a completion-facing consumer is the displayed row U, and the only separated comparison data is the displayed row S.

The Cauchy-filter part of the route is two-sided. The left ledger L and right ledger R are both required before the compatibility row F can be read, so the packet does not expose a one-sided completion boundary.

The completion handoff is the row C. By Definition 2384.2, C is downstream of the uniform, separated, left-filter, right-filter, and compatibility rows, with the same hsame, Cont, Pkg, and local NameCert provenance.

Thus every completion-facing read factors through the displayed two-sided Cauchy-filter route. The exclusions follow from the carrier inventory in Definition 2384.1. □

Closure status for $\mathsf{NameCert}_{\mathsf{RaikovCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RaikovCompletion}^{\uparrow}$ packet is generated from a source group row, UniformSpaceUp entourage row, SeparatedUniformSpaceUp comparison row, left and right CauchyFilterUp ledgers, a two-sided compatibility row, UniformCompletionUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RaikovCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2384.1, Definition 2384.2, and Definition 2384.3 seed the two-sided uniform completion route over UniformSpace, SeparatedUniformSpace, CauchyFilter, and UniformCompletion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RaikovCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion construction, uniqueness of completion points, selected representatives, host equality, trichotomy, countable choice, ambient complete-group structure, or bridge checking.

Upgrade path: Formal verification remains the route from the paper carrier and two-sided handoff rows to checked theorem, axiom-clean, and bridge-checked status for BEDC.Derived.RaikovCompletionUp.

Chapter 2385

A Concrete Naming Certificate for $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$

Following Bishop and Bridges on compact intervals and located real-number approximation, the $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$ packet records the finite dyadic-net data available for a located closed interval. It sits over the real-name endpoint seal of chapter 38, the regular rational readback of chapter 301, the finite window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the closed bounded interval carrier of chapter 1591, and the compact-metric finite-net consumer of chapter 129. The packet names the constructive finite-net substitute for interval compactness; it does not assert unrestricted open-cover compactness or a general Heine–Borel theorem for arbitrary subsets of $\mathsf{Real}^{\uparrow}$.

Definition 2385.1 (Heine–Borel located interval carrier)**.** *A* $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, E, R, S, D, F, K, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing lower and upper endpoint names, interval membership, and boundedness witnesses.*
2. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row, read only through the finite endpoint windows attached to I.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row naming the requested positive approximation scale and its finite readback.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the inspected endpoint and mesh windows before any coverage handoff.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *subdivision ledger, recording the dyadic mesh, endpoint-radius comparisons, and inclusion checks for every displayed cell.*
6. *F is the finite-net row, consisting of finitely many dyadic centers, their radius budget, and the cell-coverage witnesses obtained from I, E, R, S, D.*
7. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *handoff row read after the finite-net row has been displayed.*
8. *H records componentwise* hsame *transport for the interval, endpoint seal, tolerance, window, dyadic, finite-net, compact-metric handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from interval endpoint inspection through dyadic subdivision, finite-net coverage, compact-metric handoff, and local naming.*

10. *P is the* Pkg *provenance over* HeineBorelLocatedInterval$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CompactMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HeineBorelLocatedInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, E, R, S, D, F, K, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcover functionals, quotient real equality, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HeineBorelLocatedIntervalUp.TasteGate.HeineBorelLocatedIntervalTasteGate`
`single carrier alignment`

Theorem 2385.2 (Heine–Borel located interval finite-net obligation)**.** *For every accepted* HeineBorelLocatedInterva *carrier $L = (I, E, R, S, D, F, K, H, C, P, N)$, the finite-net obligation is exactly the route*

$$I, E, R, S, D \longmapsto F \longmapsto K, H, C, P, N.$$

Thus a compactness-facing consumer may read only the displayed closed bounded interval source, endpoint seals, regular rational tolerance, finite stream windows, dyadic subdivision ledger, finite dyadic centers, compact-metric handoff, transport, replay, provenance, and local NameCert rows. No read exports unrestricted open-cover compactness, a selected finite subcover outside F, quotient equality of real names, countable choice, or ambient completeness.

Proof. Project the carrier of Definition 2385.1. The interval source, endpoint seal, tolerance row, finite windows, and dyadic ledger are the only rows from which a net can be constructed.

The finite-net row F is read after those rows. Its centers and radius budget are displayed dyadic data, and each coverage witness is tied to the same endpoint, tolerance, stream-window, and dyadic comparison surface.

Finally K, H, C, P, N hand the displayed net to compact-metric consumers while preserving transport, replay, provenance, and local naming. Since no carrier coordinate stores arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient completeness, the local obligation surface exports none of those data. □

Theorem 2385.3 (Heine–Borel located interval compact-metric handoff)**.** *Every* CompactMetric$^{\uparrow}$ *consumer of an accepted* HeineBorelLocatedInterval$^{\uparrow}$ *packet must first display the finite dyadic-net row F together with its source rows I, E, R, S, D and structural rows H, C, P, N. The handoff is a finite located closed-interval coverage certificate over* ClosedBoundedInterval$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, *and* DyadicRatCore$^{\uparrow}$*; it is not an open-cover compactness theorem, a selected subcover principle, a quotient-completion statement, or an ambient completeness assertion.*

Proof. Start from the finite-net obligation of Definition 2385.2. It forces the compact-metric consumer to read the interval, endpoint, tolerance, window, dyadic, and finite-net rows before K is available.

Read the compact-metric handoff row K next. This row packages only the displayed centers, mesh radius, and cell-coverage witnesses already stored in F; it does not add a host compactness theorem or a cover selector.

The transport and replay rows H, C keep the same finite dyadic data stable under accepted componentwise reads, while P, N bind provenance and local naming. Hence the handoff remains a finite located interval certificate and cannot export open-cover compactness, selected subcovers, quotient completion, or ambient completeness. □

Falsifiable prediction: A compact-metric consumer that reads $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$ without displaying the closed bounded interval, Real endpoint seals, regular rational tolerance, stream windows, DyadicRatCore subdivision ledger, finite dyadic net, compact-metric handoff, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: closedboundedinterval, real, regseqrat, streamname, dyadicratcore, compactmetric: no listed sibling is bijective to $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$ because this packet binds located closed-interval endpoints, tolerance readback, finite windows, dyadic subdivision, finite-net coverage, compact-metric handoff, transport, replay, provenance, and local naming in one interval-coverage interface.

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelLocatedInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, RealUp endpoint seals, a RegSeqRatUp tolerance row, StreamNameUp finite windows, a DyadicRatCoreUp subdivision ledger, a finite dyadic-net row, a CompactMetricUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelLocatedInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2385.1, Definition 2385.2, and Definition 2385.3 seed the finite located closed-interval net interface for compact-metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelLocatedInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted open-cover compactness, general Heine–Borel compactness for subsets of $\mathsf{Real}^{\uparrow}$, selected subcovers, quotient real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint sealing, tolerance readback, finite-window replay, dyadic subdivision, finite-net coverage, compact-metric handoff, transport, provenance, and local naming for BEDC.Derived.HeineBorelLocatedIntervalUp.

Chapter 2386

A Concrete Naming Certificate for DyadicCauchyModulusLattice$^{\uparrow}$

Following Bishop and Bridges, the DyadicCauchyModulusLattice$^{\uparrow}$ packet records the finite lattice surface by which dyadic tolerance requests, Cauchy convergence moduli, finite stream windows, regular rational readback, and Real seal handoff are compared without quotient streams or selected limits. It sits over the dyadic comparison ledger of chapter 291, the convergence-modulus threshold route of chapter 1438, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal boundary of chapter 38. The packet is a directed Real and Completion input surface; it is not a quotient completion object, not a host modulus function, and not a choice principle.

Definition 2386.1 (Dyadic Cauchy modulus lattice carrier)**.** *A* DyadicCauchyModulusLattice$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, M, W, Q, R, J, H, C, P, N)$$

with the following visible rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row naming the dyadic precision requests and their comparison ledger.*
2. *M is the* CauchyConvergenceModulus$^{\uparrow}$ *threshold row assigning accepted tail windows to the dyadic requests.*
3. *W is the* StreamName$^{\uparrow}$ *finite-window row used by the modulus threshold.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row exposed through the window.*
5. *R is the* Real$^{\uparrow}$ *seal handoff row, available only after D, M, W, Q have been displayed.*
6. *J is the directed lattice row, recording finite meet and weak-later refinement comparisons between displayed dyadic-modulus requests.*
7. *H records componentwise* hsame *transport for tolerance, modulus, window, readback, seal, lattice, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a dyadic precision request through $D, M, W, Q, R, J, H, P, N$.*
9. *P is the* Pkg *provenance over* DyadicCauchyModulusLattice$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyConvergenceModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyModulusLattice}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, M, W, Q, R, J, H, C, P, N$. It has no coordinate for quotient stream equality, selected limit, host real equality, ambient Real completeness, countable choice, or a host-level modulus function.

Lean4 ✓ `BEDC.Derived.DyadicCauchyModulusLatticeUp.DyadicCauchyModulusLatticeTasteGate single carrier alignment`

Theorem 2386.2 (Dyadic Cauchy modulus lattice NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ *carrier $L = (D, M, W, Q, R, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyModulusLattice}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, convergence-modulus threshold exposure, finite-window readback, regular rational handoff, directed lattice comparison, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the displayed route*

$$D, M, J \longmapsto W, Q \longmapsto R \longmapsto H, C, P, N$$

before using the lattice as evidence for a dyadic Cauchy modulus comparison.

Proof. Project the carrier of Definition 2386.1. The rows D and M expose the dyadic request and the convergence-modulus threshold assigned to that request, while J records only finite directed comparisons between such displayed rows.

The finite observation stage is then forced through W and Q. The window row supplies the inspected $\mathsf{StreamName}^{\uparrow}$ segment, and the readback row supplies the $\mathsf{RegSeqRat}^{\uparrow}$ route consumed by later Real and Completion arguments.

Finally read R, H, C, P, N. The Real seal row is downstream of the displayed dyadic, modulus, lattice, window, and readback rows, while the structural rows transport, replay, source, and name the same finite route. Since no carrier coordinate supplies quotient streams, selected limits, countable choice, host real equality, ambient Real completeness, or a host modulus function, the listed obligations exhaust the local naming surface. □

Theorem 2386.3 (Dyadic Cauchy modulus lattice tail refinement)**.** *Let $L = (D, M, W, Q, R, J, H, C, P, N)$ be an accepted* $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ *packet. If two dyadic tolerance requests are related by the directed lattice row J, then the refined request is served by a weakly later* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *threshold, a weakly later* $\mathsf{StreamName}^{\uparrow}$ *finite window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route, and the same downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary. The refinement route is*

$$D, M, J \longmapsto W, Q \longmapsto R \longmapsto H, C, P, N.$$

It does not select a stream representative, choose a limit, or invoke ambient Real completeness.

Proof. Read the dyadic tolerance row D together with the directed lattice row J. A refinement in J can compare only displayed dyadic-modulus requests, so the refined request remains inside the finite carrier rows.

Use the threshold row M to pass from the refined dyadic request to a weakly later Cauchy convergence threshold. The finite-window row W and readback row Q then preserve the same $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route, changing only by moving to a weakly later accepted window.

The Real-facing endpoint is still the row R, followed by H, C, P, N. Because the route has no quotient stream coordinate, selected-limit coordinate, choice schedule, or ambient completeness coordinate, the tail refinement is exactly the displayed finite lattice refinement. □

Theorem 2386.4 (Dyadic Cauchy modulus lattice common-refinement exhaustion)**.** *Let* $L = (D, M, W, Q, R, J, H, C, P, N)$ *be an accepted* $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ *packet. If two dyadic tolerance requests are accepted by the same packet, then any common refinement visible to a Real or Completion consumer must be a displayed row of the directed lattice component* J*. After that refinement is chosen inside* J*, every consumer still factors through the same route*

$$D, M, J \longmapsto W, Q \longmapsto R \longmapsto H, C, P, N.$$

Thus common-refinement reads cannot pass through quotient streams, selected limits, host modulus functions, or ambient Real completeness.

Proof. Project the carrier of Definition 2386.1. The only component that compares dyadic tolerance requests is J, and it records finite meet and weak-later comparisons between requests already displayed by D and served by M.

Apply Definition 2386.3 to the first request and then to the second request. Both refinements remain on weakly later $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ thresholds, finite $\mathsf{StreamName}^{\uparrow}$ windows, the same $\mathsf{RegSeqRat}^{\uparrow}$ readback route, and the same downstream $\mathsf{Real}^{\uparrow}$ seal boundary.

Now use Definition 2386.5. The Real-facing handoff is available only after the dyadic tolerance, convergence-modulus, lattice, window, and readback rows have been displayed, and the structural rows H, C, P, N preserve that same finite route. Since the carrier has no quotient-stream, selected-limit, host-modulus, or ambient-completeness coordinate, the displayed common refinement in J exhausts the consumer-visible comparison. □

Theorem 2386.5 (Dyadic Cauchy modulus lattice Real seal handoff)**.** *Every accepted* $\mathsf{DyadicCauchyModulusLattice}$ *packet exposes its* $\mathsf{Real}^{\uparrow}$ *seal only after the dyadic tolerance row, convergence-modulus row, directed lattice row, finite* $\mathsf{StreamName}^{\uparrow}$ *window, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have all been displayed. Thus any Real or Completion consumer using the lattice must factor through*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{CauchyConvergenceModulus}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

as carrier rows of the same BHist *packet, with transport, replay, provenance, and local naming supplied by* H, C, P, N*.*

Proof. Start from the accepted carrier and read the obligation route of Definition 2386.2. The row R is not an independent Real datum; it is the seal handoff attached to the already displayed dyadic request, convergence threshold, lattice comparison, window, and regular readback.

Apply tail refinement when the consumer asks for a stronger tolerance. Theorem 2386.3 keeps the request on the same weak-later modulus, window, readback, and seal route, so the endpoint cannot fork into a selected limit or quotient stream.

The structural rows H, C, P, N then transport, replay, source, and name the same handoff. No host real equality, ambient Real completeness theorem, countable choice principle, or host-level modulus function is available from the carrier, so the displayed rows are the whole Real seal boundary. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ Real or Completion consumer factors through one displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ threshold row, one directed lattice row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ before it may use a dyadic modulus comparison.

Independence witness: dyadicratcore, cauchy-convergence-modulus, streamname, regseqrat, real: $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately supply tolerance comparison, convergence thresholds, finite windows, regular rational readback, and terminal Real sealing, while this packet uniquely binds them to a directed lattice row consumed by Real and Completion arguments.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyModulusLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, a CauchyConvergenceModulus threshold row, a directed lattice row, a StreamName finite-window row, a RegSeqRat readback row, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyModulusLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2386.1, Definition 2386.2, Definition 2386.3, and Definition 2386.5 seed the directed dyadic Cauchy modulus lattice over DyadicRatCore, CauchyConvergenceModulus, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyModulusLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient stream equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed lattice comparison, dyadic tolerance exposure, convergence-modulus threshold exposure, finite-window readback, RegSeqRat handoff, Real seal handoff, structural transport, and non-escape for BEDC.Derived.DyadicCauchyModulusLatticeUp.

Chapter 2387

A Concrete Naming Certificate for $\mathsf{BishopLocatedLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedLimit}^{\uparrow}$ packet records the located-limit surface of a displayed constructive real sequence as finite NameCert data. It sits after the finite window schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the located-limit interface of chapter 1420, the located-real enclosure route of **??**, and the terminal real-name seal of chapter 38. The packet gives the L10 Real and Completion route a traditional constructive limit certificate without quotient stream equality, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2387.1 (Bishop located-limit carrier)**.** *A* $\mathsf{BishopLocatedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, D, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the finite windows inspected for the limit request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same schedule and tolerance data.*
4. *L is the located-limit witness row, recording the displayed modulus and enclosure data for the requested tail.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, D, R, L have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, tolerance, readback, located-limit, and Real-seal rows.*
7. *C records displayed* Cont *replay from a precision request through the schedule, tolerance ledger, readback, located-limit witness, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedLimitUp.BishopLocatedLimitTasteGate single carrier alignment`

Theorem 2387.2 (Bishop located-limit NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedLimit}^{\uparrow}$ *carrier* $B = (S, D, R, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedLimit}^{\uparrow}}$ *surface consists exactly of StreamName schedule exposure, DyadicRatCore tolerance accounting, RegSeqRat readback, located-limit witness display, Real-seal ordering, componentwise transport, continuation replay, package provenance, and local naming. Every Real or Completion consumer must read the finite route*

$$S, D \longmapsto R \longmapsto L \longmapsto E$$

together with H, C, P, N *before treating the packet as a Bishop located limit.*

Proof. Project the carrier of Definition 2387.1. The tuple exposes exactly the schedule, tolerance, readback, located-limit, Real-seal, transport, replay, provenance, and local naming rows.

The constructive source is finite. The rows S and D name the inspected windows and tolerances, and R reads those same windows as regular rational data rather than as host sequence equality.

The limit side is then read through L and E. The row L supplies the located witness for the displayed request, and the row E is downstream from that witness, so a Real-facing consumer cannot bypass the located route.

Transport through H and replay through C preserve the same ordering, while P and N record provenance and local naming. Since the carrier contains no quotient stream equality, selected limit, countable-choice schedule, trichotomy decision, or ambient-completeness row, the listed projections exhaust the NameCert obligations. □

Theorem 2387.3 (Bishop located-limit regular-Cauchy readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{BishopLocatedLimit}^{\uparrow}$ *carrier* $B = (S, D, R, L, E, H, C, P, N)$ *must read, in order, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{LocatedLimit}^{\uparrow}$ *witness* L*, the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure route carried by the same displayed limit data, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, followed by the structural rows* H, C, P, N*. In particular, the consumer cannot bypass the regular-Cauchy boundary* R *by appealing directly to a host located limit, quotient stream equality, selected real, countable choice, trichotomy, or ambient Real completeness.*

Proof. Project the carrier of Definition 2387.1. The schedule and tolerance rows S, D precede the readback row R, and the located-limit and seal rows L, E are downstream of that readback.

Apply Definition 2387.2. The theorem states that every Real or Completion consumer must read the finite route $S, D \longmapsto R \longmapsto L \longmapsto E$ together with the structural rows before treating the packet as a Bishop located limit.

The $\mathsf{LocatedReal}^{\uparrow}$ enclosure is therefore read only as part of the same located-limit witness and Real-seal path. Since no carrier coordinate stores a direct host limit, quotient stream equality, selected real, choice schedule, trichotomy decision, or ambient completeness theorem, the regular-Cauchy readback R is the mandatory boundary. □

Theorem 2387.4 (Bishop located-limit tail-modulus induction)**.** *Let* $B = (S, D, R, L, E, H, C, P, N)$ *be an accepted* $\mathsf{BishopLocatedLimit}^{\uparrow}$ *carrier. Any later located-limit precision request is discharged by induction over the same finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, located-limit witness* L*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, with* H, C, P, N *preserving the route.*

Thus a later request may narrow the displayed tolerance window, but it cannot replace the route by quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient Real completeness.

Proof. Project the carrier rows of Definition 2387.1. The later request has access only to the schedule S, tolerance ledger D, readback row R, located-limit witness L, Real seal E, and the structural rows.

Use the displayed schedule and tolerance ordering. A later precision request is a later finite window inside the same $\mathsf{StreamName}^{\uparrow}$ schedule and is budgeted by the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before the $\mathsf{RegSeqRat}^{\uparrow}$ readback can be inspected.

Induct over the finite request schedule. The initial request is the regular-Cauchy readback route of Definition 2387.3; the step narrows the tolerance row and reuses the same readback, located witness, and seal rows.

Finally repack through H, C, P, N. Since every step stays inside the displayed finite route, no quotient stream equality, selected host limit, countable choice, trichotomy, or ambient Real completeness is exported. □

Theorem 2387.5 (Bishop located-limit window determinacy)**.** *For every accepted* $\mathsf{BishopLocatedLimit}^{\uparrow}$ *carrier* $B = (S, D, R, L, E, H, C, P, N)$*, any two Real or Completion consumer reads that classify the same precision request must factor through the same finite route*

$$S, D \longmapsto R \longmapsto L \longmapsto E$$

and the same structural rows H, C, P, N*. No such read may switch to quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient Real completeness.*

Proof. Project the carrier of Definition 2387.1. The only rows available to the classifier are the displayed schedule, tolerance ledger, regular rational readback, located-limit witness, terminal Real seal, transport, replay, provenance, and local naming data.

Apply Definition 2387.2. Any Real or Completion consumer must read the route $S, D \longmapsto R \longmapsto L \longmapsto E$ together with H, C, P, N before treating the packet as a Bishop located limit.

Apply Definition 2387.3. The readback row R is the mandatory $\mathsf{RegSeqRat}^{\uparrow}$ boundary, so two reads of the same precision request cannot replace it by host located-limit equality or by a selected Real value.

It remains only to compare the available coordinates. Since the carrier has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, or ambient Real completeness, there is no second route through which either read can classify the request. Both reads are therefore determined by the same finite window route and by the same structural rows. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedLimit}^{\uparrow}$ read used by a Real or Completion consumer displays one $\mathsf{StreamName}^{\uparrow}$ schedule, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one located-limit witness, one terminal $\mathsf{Real}^{\uparrow}$ seal row, and the structural rows H, C, P, N.

Independence witness: streamname, dyadicratcore, regseqrat, locatedlimit, locatedreal, real: $\mathsf{BishopLocatedLimit}^{\uparrow}$ is not bijective to any listed sibling because it binds the Bishop located-limit witness to the same finite schedule, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedLimit}^{\uparrow}$ packet is generated from a StreamName finite schedule, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a located-limit witness, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 2387.1 and Definition 2387.2 seed the finite Bishop located-limit route over StreamName, DyadicRatCore, RegSeqRat, LocatedLimit, LocatedReal, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopLocatedLimit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient stream equality, selected host limits, quotient real equality, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exposure, tolerance accounting, regular readback ordering, located-limit witness display, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedLimitUp.

Chapter 2388

A Concrete Naming Certificate for $\mathsf{MetricEmbedding}^{\uparrow}$

Following Bourbaki and Kelley on metric embeddings, the $\mathsf{MetricEmbedding}^{\uparrow}$ packet records finite control data for an injective metric-route interface without requiring equality of all distances. It sits between the metric source of chapter 57, the graph and replay surface of chapter 130, the separation consumer of chapter 1411, and the stricter distance-equality interface of chapter 439. The packet is weaker than $\mathsf{IsometricEmbedding}^{\uparrow}$: it exposes displayed graph-distance control and separated-completion handoff rows, but it does not certify distance preservation, quotient completion classes, selected representatives, or host function equality.

Definition 2388.1 (MetricEmbedding carrier)**.** *A* $\mathsf{MetricEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, F, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *carrier and classifier row;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *carrier and classifier row;*
3. *F is the finite graph row displaying the source-to-target relation used by consumers;*
4. *D is the graph-distance control row, recording source distance reads, target distance reads, and the permitted control comparison between them;*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance and distance-read seal attached to the comparisons in D;*
6. *S is the separated-metric handoff row for consumers that need point separation after reading the graph;*
7. *H stores componentwise* hsame *transports for X, Y, F, D, R, S and for the structural rows below;*
8. *C stores the displayed* Cont *replay from source metric reads to graph reads, target metric reads, distance-control reads, and separated-consumer reads;*
9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricEmbedding}^{\uparrow}}$ *row.*

The carrier contains no host function object, no quotient map, no selected completion representative, no ambient completion theorem, and no $\mathsf{IsometricEmbedding}^{\uparrow}$ *distance-equality certificate.*

Lean4 (definition) `BEDC.Derived.MetricEmbeddingUp.MetricEmbeddingCarrier`

Theorem 2388.2 (MetricEmbedding carrier and classifier obligations)**.** *For every accepted* $\mathsf{MetricEmbedding}^{\uparrow}$ *carrier* $E = (X, Y, F, D, R, S, H, C, P, N)$*, the local carrier and classifier surface consists exactly of the displayed ten-row packet. Carrier admission reads the source metric row, target metric row, graph row, graph-distance control row, real-distance seal, separated handoff, transport, replay, provenance, and local naming rows. Classifier transport compares accepted packets componentwise through the* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg*, and* $\mathsf{NameCert}$ *surfaces, and it has no coordinate for host function equality, quotient maps, selected representatives, or isometric distance equality.*

Lean4 ✓ `BEDC.Derived.MetricEmbeddingUp.TasteGate.MetricEmbeddingTasteGate single carrier alignment`

Proof. Project the carrier definition. The accepted packet exposes exactly $X, Y, F, D, R, S, H, C, P, N$, so carrier admission is the finite BHist row inventory and not an external embedding object.

Classifier transport is componentwise on the same rows. The source and target metric classifiers compare X and Y, the continuous-map graph surface compares F, the distance-control and real-seal rows compare D and R, and the separated handoff compares S only after the graph and metric rows have been displayed.

The structural rows do not add analytic coordinates. They transport, replay, package, and name the same packet, so host functions, quotient maps, selected completion representatives, and the stricter $\mathsf{IsometricEmbedding}^{\uparrow}$ equality surface cannot be read from this carrier. □

Theorem 2388.3 (MetricEmbedding graph-distance control)**.** *Let* $E = (X, Y, F, D, R, S, H, C, P, N)$ *be an accepted* $\mathsf{MetricEmbedding}^{\uparrow}$ *packet. Every distance-control request first reads a source metric observation in* X*, then the displayed graph row* F*, then the target metric observation in* Y*, and only then the comparison row* D *with its* $\mathsf{Real}^{\uparrow}$ *seal* R*. The request receives the named graph-distance control data, not an isometric equality of source and target distances and not a detached continuous map.*

Lean4 ✓ `BEDC.Derived.MetricEmbeddingUp.MetricEmbeddingCarrier graph distance control`
↪ variant `BEDC.Derived.MetricEmbeddingUp.GraphDistanceControl.MetricEmbeddingGraphDistance control`
↪ variant `BEDC.Derived.MetricEmbeddingUp.MetricEmbeddingGraphDistanceControl`

Proof. Start with a distance-control request. Carrier projection forces the request to pass through the source metric row X and the graph row F before it can identify the corresponding target metric row Y.

Read the comparison row D only after those observations have been displayed. The seal R records the finite real-distance and tolerance data attached to this comparison, while H and C keep the source, graph, target, and real rows aligned.

The packet has no coordinate asserting equality of all source and target distances. Therefore the exported datum is the displayed graph-distance control route, weaker than the $\mathsf{IsometricEmbedding}^{\uparrow}$ distance-equality surface and independent of any host-level continuous map object. □

Theorem 2388.4 (MetricEmbedding separated-completion handoff)**.** *Every* $\mathsf{SeparatedMetric}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{MetricEmbedding}^{\uparrow}$ *packet factors through*

$$X \longmapsto F \longmapsto Y \longmapsto D \longmapsto R \longmapsto S$$

with the stored transport, replay, provenance, and local naming rows. The handoff may use graph-distance control to supply separated metric data, but it does not export quotient completion classes, selected representatives, ambient completion existence, or isometric distance preservation.

Lean4 ✓ `BEDC.Derived.MetricEmbeddingUp.MetricEmbeddingCarrier separated completion handoff`

Proof. Project the separated handoff row S. It is downstream from the displayed source metric row, graph row, target metric row, graph-distance control row, and real seal, so a separated consumer cannot read it before those rows have been exhibited.

Apply the graph-distance control theorem. The route to S uses the finite comparison data D, R attached to graph observations, not a host function and not an isometric equality certificate.

Finally read the structural rows H, C, P, N. They record transport, continuation replay, provenance, and local naming for the same displayed packet. Since quotient completion classes, selected representatives, ambient completion theorems, and isometric preservation are absent from the carrier, separated-completion consumers receive only the finite handoff route above. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricEmbedding}^{\uparrow}$ packet is generated from displayed source and target metric rows, a graph row, a graph-distance control row, a RealUp seal, a separated-metric handoff row, componentwise transport, displayed replay, package provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricEmbedding}^{\uparrow}}, \mathsf{obligation})$

Scope closed: The obligation scope enumerates carrier admission, classifier transport, graph-distance control, separated-completion handoff, and nonescape obligations for metric embeddings weaker than isometric embeddings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient completion classes, selected representatives, ambient completion existence, isometric distance preservation, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checking the MetricSpace, SeparatedMetric, BHist, hsame, Cont, Pkg, and NameCert rows against the same finite packet.

Chapter 2389

A Concrete Naming Certificate for $\mathsf{AffineContraction}^{\uparrow}$

Following Banach and Bishop–Bridges constructive metric analysis, an $\mathsf{AffineContraction}^{\uparrow}$ packet names an affine self-map whose linear part carries a displayed contraction bound. It refines the map-level contraction surface of chapter 1418, reads its bounded-distance comparison through chapter 410, and hands Cauchy approximation data to chapter 1506 and chapter 1473. The packet records the affine decomposition and the contraction ledger without selecting a fixed point, assuming ambient completeness, or identifying host affine maps.

Definition 2389.1 (AffineContraction carrier)**.** *An* $\mathsf{AffineContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, d, V, +, 0, L, b, T, G, \lambda, M, H, C, P, N)$$

with the following displayed rows:

1. X, d *are the metric carrier and distance-read rows used by the contraction and completion consumers.*
2. $V, +, 0$ *are the affine-coordinate rows naming the carried additive chart in which the affine decomposition is read.*
3. L *is the linear-part graph row, with displayed application reads inside the same carried chart.*
4. b *is the translation row.*
5. T *is the affine self-map row, read only through the finite graph equation* $T(x) = L(x) + b$.
6. G *is the graph-exactness row tying each accepted read of* T *to the displayed reads of* L, b, *and* $+$.
7. λ *is the rational contraction-bound ledger, with nonnegative and strict unit-bound rows for the linear part.*
8. M *is the induced Lipschitz and contraction-modulus row consumed by metric-completion and uniform-completion readers.*
9. H *stores componentwise* hsame *transport for the metric, affine-coordinate, linear-part, translation, self-map, graph, bound, modulus, replay, provenance, and local naming rows.*
10. C *stores displayed* Cont *replay for affine application, graph exactness, contraction-bound readback, modulus extraction, and completion-facing handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{AffineContraction}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{AffineContraction}^{\uparrow}}$ *row.*

The carrier exposes an affine contraction surface. It contains no coordinate for a selected fixed point, a completed endpoint, quotient equality of maps, ambient completeness, choice, or bridge checking.

Lean4 ✓ `BEDC.Derived.AffineContractionUp.AffineContractionTasteGate single carrier alignment`

Theorem 2389.2 (AffineContraction NameCert obligations)**.** *For an accepted* $\mathsf{AffineContraction}^{\uparrow}$ *carrier* $A = (X, d, V, +, 0, L, b, T, G, \lambda, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AffineContraction}^{\uparrow}}$ *surface consists of carrier admission, affine-coordinate visibility, linear-part graph visibility, translation visibility, self-map graph exactness, rational contraction-bound stability, induced Lipschitz-modulus visibility, metric-completion and uniform-completion handoff visibility, componentwise classifier transport, continuation replay, provenance, and local naming for the finite packet of Definition 3340.1.*

Proof. Carrier admission is projection from the displayed tuple. The rows $X, d, V, +, 0, L, b, T, G, \lambda, M, H, C, P, N$ are exactly the rows available to the local certificate.

Affine-coordinate visibility reads the additive chart rows $V, +, 0$. Linear-part and translation visibility then read L and b before the self-map row T can be consumed.

Graph exactness is the row G. It forces each accepted self-map application to replay through $L(x)$, b, and the displayed addition row, so the affine map is not identified by host function equality.

The contraction-bound and modulus obligations are carried by λ and M. Since λ stores the strict unit-bound ledger for the linear part, the induced modulus is available to contraction and completion consumers without selecting a fixed point.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. These rows export no ambient completeness proof, choice principle, endpoint seal, quotient equality, or bridge-checked standardization. □

Theorem 2389.3 (AffineContraction metric-completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{AffineContraction}^{\uparrow}$ *carrier must pass through*

$$X,\ d,\ V,\ +,\ 0,\ L,\ b,\ T,\ G,\ \lambda,\ M,\ H,\ C,\ P,\ N.$$

The handoff supplies a displayed affine self-map, graph-exact affine decomposition, rational contraction ledger, and induced modulus. It does not supply a selected fixed point, completed endpoint, quotient equality of affine maps, ambient completeness theorem, choice principle, or bridge-checked standard object.

Proof. Read the carrier of Definition 3340.1. The only completion-facing rows are the metric rows X, d, the affine decomposition rows $V, +, 0, L, b, T, G$, the contraction ledger λ, and the induced modulus row M.

The graph row G orders the affine read before any completion consumer sees the self-map. The consumer therefore receives a finite route from x to $L(x) + b$, not a host affine function.

The strict unit-bound row in λ and the induced modulus row M are the only contraction data exported to chapter 1506 and chapter 1473. A completion route may consume those rows to build Cauchy approximation data, but the endpoint seal and completeness proof remain outside this packet.

Transport and replay are exhausted by H and C, while P and N only record provenance and local naming. Thus the handoff is precisely the finite affine-contraction surface and cannot provide the excluded endpoint, quotient, choice, completeness, or bridge data. □

Closure status for $\mathsf{NameCert}_{\mathsf{AffineContraction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AffineContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3340.1, Definition 3340.2, and Definition 3340.3 seed the affine contraction packet over affine decomposition, contraction ledger, and completion-facing modulus handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AffineContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected fixed points, completed endpoints, quotient equality of affine maps, ambient completeness, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, affine-coordinate visibility, linear-part graph visibility, translation visibility, self-map graph exactness, rational bound stability, modulus visibility, completion handoff visibility, transport, replay, provenance, and local naming for BEDC.Derived.AffineContractionUp.

Constructive story: An $\mathsf{AffineContraction}^{\uparrow}$ packet is generated from a metric carrier, affine-coordinate rows, linear-part graph, translation row, affine self-map graph, rational contraction-bound ledger, induced modulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 2390

A Concrete Naming Certificate for $\mathsf{MetricClosure}^{\uparrow}$

Following Kelley on metric topology and Bishop–Bridges constructive metric spaces, the $\mathsf{MetricClosure}^{\uparrow}$ packet names the finite closure interface by which metric tests, neighbourhood tests, located-set rows, finite StreamName windows, RegSeqRat readbacks, and Real seals expose a candidate limit as closure evidence. It sits over the metric source of chapter 57, the topology surface of chapter 88, the located-set interface of chapter 1541, the sequence-limit handoff of chapter 1571, the finite windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a named BEDC surface for metric closure reads; it is not a host topological closure operator, not an arbitrary subsequence selector, not open-cover compactness, not quotient equality, and not $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2390.1 (MetricClosure carrier)**.** *A* $\mathsf{MetricClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, S, L, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row naming the finite metric comparison surface.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *row naming the neighbourhood tests compatible with M.*
3. *S is the subset or* $\mathsf{LocatedSet}^{\uparrow}$ *row whose admitted points are being closed.*
4. *L is the candidate limit row, read only through the same metric and topological tests.*
5. *U is the finite neighbourhood and metric-test ledger, pairing each displayed neighbourhood request with the matching metric tolerance request.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read the displayed approximating points and the candidate limit.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the same windows, tolerances, and metric-comparison requests.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, T, S, L, U, W, R have been displayed.*
9. *H records componentwise* hsame *transport for the metric, topology, subset or located-set, candidate limit, test ledger, window, readback, and Real seal rows.*

10. *C records displayed* Cont *replay from neighbourhood requests to metric tests, then through StreamName windows, RegSeqRat readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{MetricClosure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{SequentialClosure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricClosure}^{\uparrow}}$ *row.*

The classifier accepts only packets whose metric row, topology row, subset or located-set row, candidate limit, paired test ledger, finite windows, rational readbacks, Real seal, transport, replay, provenance, and local naming are all displayed. It has no coordinate for a host closure operator, arbitrary subsequence choice, open-cover compactness, quotient equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 2390.2 (MetricClosure NameCert obligations)**.** *For every accepted* $\mathsf{MetricClosure}^{\uparrow}$ *carrier* $K = (M, T, S, L, U, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for the ambient metric row, the compatible topology row, the subset or located-set row, the candidate limit row, the paired neighbourhood and metric-test ledger, StreamName windows, RegSeqRat readback, RealUp sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public closure read must pass through those rows before it can consume the candidate limit.*

Proof. Project the accepted carrier to the displayed rows $M, T, S, L, U, W, R, E, H, C, P, N$. The metric, topology, subset, and candidate rows give the only admissible source data for a closure read.

The ledger row U then binds each neighbourhood request to a finite metric-test request. The StreamName row W and RegSeqRat row R provide the visible windows and rational readbacks for that same request before the Real seal E is exposed.

Finally H, C, P, N transport, replay, source, and name the same displayed packet. Since no row stores a host closure operator, an arbitrary subsequence, an open-cover object, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the NameCert obligations are exhausted by the listed rows. □

Lean4 ✓ `BEDC.Derived.MetricClosureUp.MetricClosureCarrier namecert obligations`

Theorem 2390.3 (MetricClosure sequential-closure handoff)**.** *Every* $\mathsf{SequentialClosure}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricClosure}^{\uparrow}$ *packet reads the candidate limit through the finite route*

$$M, T, S, L, U, W, R, E, H, C, P, N.$$

The consumer receives a displayed metric row, a compatible topology row, a subset or located-set row, a candidate limit, paired neighbourhood and metric-test rows, finite StreamName windows, RegSeqRat readbacks, a RealUp seal, transport, replay, provenance, and local naming. It receives no ambient topological closure operator, arbitrary subsequence selector, open-cover compactness principle, quotient-equality row, or RealUp completeness theorem.

Proof. Start with a sequential-closure consumer. The carrier exposes the candidate limit L only together with the common metric row M, topology row T, and source row S, so the consumer cannot detach the limit from the displayed metric/topology interface.

Use the test ledger U to align the neighbourhood read with the metric tolerance read. The finite window row W, regular rational row R, and Real seal E then give the same handoff surface used by the $\mathsf{SequentialClosure}^{\uparrow}$ packet of chapter 1571.

The rows H, C, P, N preserve that route under transport, replay, provenance, and naming. Thus the handoff is the finite metric-closure surface itself, not a stronger host closure, subsequence-choice, compactness, quotient, or completeness principle. □

Falsifiable prediction: Every $\mathsf{MetricClosure}^{\uparrow}$ public read factors through a Metric row, a Topology row, a subset or LocatedSet row, a candidate-limit row, paired neighbourhood and metric-test ledgers, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed continuation, package provenance, and local naming.

Independence witness: metric, topology, locatedset, sequentialclosure, streamname, regseqrat, real: $\mathsf{MetricClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric/topology compatibility surface, a source subset or located-set row, a candidate limit, paired neighbourhood and metric tests, finite windows, rational readbacks, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricClosure}^{\uparrow}$ packet is generated from a Metric row, a compatible Topology row, a subset or LocatedSet row, a candidate limit, paired neighbourhood and metric-test rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3342.1, Definition 3342.2, and Definition 3342.3 seed the finite metric/topology closure interface for displayed candidate-limit reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host topological closure, arbitrary subsequence choice, open-cover compactness, quotient equality, $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric/topology compatibility, located-source exposure, paired test-ledger stability, StreamName and RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricClosureUp.

Chapter 2391

A Concrete Naming Certificate for $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$ packet records the finite equivalence between the Cauchy criterion read and an explicit convergence-modulus schedule before any completion or real-name consumer sees a terminal seal. It sits between the criterion surface of chapter 392, the convergence-modulus schedule of chapter 1438, the finite windows of chapter 126, the regular readback route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a finite-tail equivalence object for L10 Real and Completion consumers; it is not a quotient-stream equality, selected limit, countable-choice schedule, host convergence theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 2391.1 (CauchyCriterionEquivalence carrier)**.** *A* $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence and source-window row, exposing only the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows of the sequence under discussion.*
2. *Q is the criterion tail request row, naming the finite late-pair request consumed by the* $\mathsf{CauchyCriterion}^{\uparrow}$ *surface.*
3. *M is the convergence-modulus schedule row, naming the finite threshold data consumed by the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *surface.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the requested dyadic radius, split tolerances, slack cells, and comparison budget shared by Q and M.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed source windows and tolerance ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Q, M, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the source windows, criterion request, modulus schedule, dyadic tolerance ledger, regular readback, real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from source windows to criterion requests, from criterion requests to modulus schedules, from both finite surfaces to dyadic tolerance reads, and from the tolerance-readback route to the real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, M, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable-choice selection of thresholds, host real equality, detached convergence proofs, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2391.2 (CauchyCriterionEquivalence NameCert obligations)**.** *For every accepted* CauchyCriterionEquival *carrier*

$$K = (S, Q, M, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCriterionEquivalence}^{\uparrow}}$ *surface consists exactly of the bidirectional finite criterion/modulus obligations over the displayed packet. A criterion-facing read of Q may expose a convergence-modulus schedule only by reading the same source windows S, dyadic tolerance ledger D, regular readback R, real seal E, and structural rows H, C, P, N. Conversely, a modulus-facing read of M may expose the corresponding Cauchy-criterion tail request only through those same displayed rows. Neither direction exports quotient stream equality, a selected limit, countable choice over thresholds, host convergence, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or an ambient completion principle.*

Proof. Project the carrier of Definition 3343.1. The criterion request Q and the convergence-modulus schedule M are separate displayed rows, but they share the source-window row S, the dyadic tolerance row D, the regular readback R, the real seal E, and the structural rows.

For the criterion-to-modulus direction, read a finite late-pair request through Q. The continuation row C permits replay only along the displayed route from S through D and R before the schedule row M is exposed, so the modulus threshold is a packet-local finite row rather than an external selector.

For the modulus-to-criterion direction, read a displayed threshold in M. The same tolerance ledger D and readback R supply the late-pair comparison consumed by Q, and the transports in H preserve all rows componentwise under the local classifier.

Finally, the real seal E is downstream of both finite surfaces, while P and N only source and name the same packet. Since the carrier contains no quotient stream, selected limit, countable-choice schedule, host convergence theorem, detached real-completeness row, or ambient completion coordinate, the two finite directions exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CauchyCriterionEquivalenceUp.CauchyCriterionEquivalenceTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$ packet is generated from source sequence windows, a criterion tail request, a convergence-modulus schedule, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionEquivalence}^{\uparrow}}$, seed)

Scope closed: Definition 3343.1 and Definition 3343.2 seed the finite bidirectional criterion/modulus surface over $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionEquivalence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable-choice schedules, host convergence, detached $\mathsf{Real}^{\uparrow}$ completeness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-modulus projection, modulus-to-criterion projection, shared tolerance-readback exactness, Real seal nonescape, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.CauchyCriterionEquivalenceUp.

Chapter 2392

A Concrete Naming Certificate for $\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}$

Following Barendregt and Coquand-style metatheory, the $\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}$ packet records the finite BEDC witness surface by which MetaCIC closedness preservation is consumed before any subject-reduction theorem is claimed. It sits after the audit rows of chapter 786, the closure-trace packet of chapter 795, and the dependent-codomain transport packet of chapter 804. The packet gives downstream closed-normal and subject-reduction routes a single human-lineage certificate for closedness preservation without treating closedness as typing preservation.

Definition 2392.1 (MetaCIC closure-preservation witness carrier)**.** *A* $\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (A, T, D, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ClosurePreservationAuditWitness}^{\uparrow}$ *row that names the shift, substitution, beta-step, and finite beta-chain closedness-preservation audit chain;*
2. *T is the* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *row that records the accepted closure-preservation theorem rows and their finite replay surface;*
3. *D is the* $\mathsf{DependentCodomainClosurePreservation}^{\uparrow}$ *row that exposes codomain closedness transport without discharging dependent-codomain inversion;*
4. *L is the ledger row stating that the witness is a closedness-preservation route, not a typing-preservation or subject-reduction route;*
5. *H records componentwise* hsame *transport for A, T, D, L, P, N;*
6. *C records displayed* Cont *replay routes from the witness to the audit, trace, and dependent-codomain rows;*
7. *P is the* Pkg *provenance over MetaCIC closure preservation, the three sibling packets,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}}$ *row.*

The carrier contains no typing context, no conversion equality, no subject-reduction inhabitant, no normalization theorem, no confluence theorem, and no route from closedness preservation to closed consistency.

Lean4 ✓ BEDC.Derived.MetaCICClosurePreservationWitnessUp.MetaCICClosurePreservationWitnessTasteGate
single carrier alignment

Theorem 2392.2 (MetaCIC closure-preservation witness audit chain)**.** *For the carrier of Definition 3344.1, every accepted witness read factors through the chain*

$$\mathsf{ClosurePreservationAuditWitness}^{\uparrow} \longrightarrow \mathsf{MetaCICClosureTrace}^{\uparrow} \longrightarrow \mathsf{DependentCodomainClosurePreservation}^{\uparrow}.$$

The first row supplies the closedness-preservation audit inventory, the second row supplies the finite accepted-declaration trace, and the third row supplies the dependent-codomain closedness transport boundary. The chain exports only closedness-preservation data and its displayed ledger.

Proof. Project the carrier W. The first three rows are A, T, D, so any consumer reaches the audit witness, closure trace, and dependent-codomain transport surface before it can read the ledger.

The audit row A fixes the shift, substitution, beta-step, and beta-star closedness rows. The trace row T records those rows as accepted MetaCIC closure-preservation declarations, while the dependent-codomain row D records the codomain closedness transport boundary.

Finally inspect L, H, C, P, N. The ledger marks the route as closedness-only, and the transport, replay, provenance, and local naming rows preserve only the displayed chain. No coordinate adds typing preservation or subject reduction, so the audit chain has exactly the stated scope. □

Theorem 2392.3 (MetaCIC closure-preservation witness non-escape)**.** *Every public read of an accepted* $\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}$ *carrier remains inside*

$$A, T, D, L, H, C, P, N.$$

A consumer may cite the $\mathsf{ClosurePreservationAuditWitness}^{\uparrow}$ *audit row, the* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *accepted trace row, the* $\mathsf{DependentCodomainClosurePreservation}^{\uparrow}$ *codomain-transport row, the closedness-only ledger, componentwise transports, displayed replay, provenance, and local naming. It cannot extract subject reduction, type preservation, conversion, confluence, normalization, closed consistency, or a hidden MetaCIC kernel soundness premise.*

Proof. Carrier projection leaves exactly the finite tuple A, T, D, L, H, C, P, N. The three witness rows are already named as closedness-preservation surfaces, and the ledger row records that no typing-preservation route is being exported.

Replay through C and transport through H keep the same rows visible to downstream consumers. Provenance P identifies the sibling packets and the MetaCIC closure-preservation route, while N names the local certificate.

For any stronger request, inspect the carrier inventory. There is no coordinate for typing contexts, conversion equality, confluence, normalization, closed consistency, or kernel soundness. Thus every public read remains confined to the displayed closedness-preservation witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}$ packet is generated from the closure-preservation audit witness, MetaCIC closure trace, dependent-codomain closure-preservation transport row, closedness-only ledger, componentwise transports, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3344.1, Definition 3344.2, and Definition 3344.3 bind the finite witness surface joining audit rows, accepted trace rows, and dependent-codomain closedness transport.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove subject reduction, typing preservation, dependent-codomain inversion, confluence, normalization, closed consistency, Lean verification of the witness packet, or a public schema bridge.

Upgrade path: Obligation closure requires checked carrier admission, audit-chain exactness, dependent-codomain boundary preservation, closedness-only ledger exactness, provenance, local naming, and non-escape for the same finite witness packet.

Chapter 2393

A Concrete Naming Certificate for $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$ packet names the finite tail-comparison route for positive decreasing $\mathsf{RealSeries}^{\uparrow}$ terms. It sits next to the real-series surface of chapter 1581, the displayed limit interface of chapter 1413, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, and the terminal real-name seal of chapter 38. It refines the dyadic-block test packet of chapter 1478 by making the $\mathsf{RealSeries}^{\uparrow}$ tail carrier itself visible to Real and Completion consumers before any infinite sum or completed endpoint is read.

Definition 2393.1 (CauchyCondensationRealSeries carrier)**.** *A* $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, M, B, G, W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the positive decreasing* $\mathsf{RealSeries}^{\uparrow}$ *source row. Its terms are admitted only through finite term windows, and its decreasing evidence is read as adjacent finite comparisons.*
2. *M is the monotone-tail ledger, recording positivity, decreasing transport, and the finite tail cut from which the comparison begins.*
3. *B is the dyadic block-window ledger. It lists the inspected powers of two, the associated block endpoints, and the finite intervals of original terms visible at each requested tolerance.*
4. *G is the condensed-term row, displaying the term $2^n a_{2^n}$ on the same dyadic indices as B and tying it to the original* $\mathsf{RealSeries}^{\uparrow}$ *term windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule used for the original terms, block endpoints, condensed terms, and partial-sum windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every displayed original term, condensed term, and block partial sum.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and block-comparison ledger. It records the finite inequalities that bound each inspected original tail block above and below by the matching condensed-term rows.*

8. *R is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *route for the partial-sum and condensed-partial-sum windows that the packet exposes to downstream limit consumers.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, M, B, G, W, Q, D, R have been displayed.*
10. *H records componentwise* hsame *transport for the source, monotone-tail ledger, dyadic blocks, condensed terms, schedules, readbacks, tolerance ledger, limit route, Real seal, continuation, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a tail request through the monotone ledger, dyadic blocks, condensed terms, stream schedules, regular readbacks, dyadic comparisons, limit route, and Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationRealSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, B, G, W, Q, D, R, E, H, C, P, N$. It has no coordinate for host infinite sums, quotient real equality, countable choice, trichotomy, selected endpoints, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationRealSeriesUp.CauchyCondensationRealSeriesTasteGate`
`single carrier alignment`

Theorem 2393.2 (CauchyCondensationRealSeries obligations)**.** *For every accepted* $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$ *carrier $K = (A, M, B, G, W, Q, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationRealSeries}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed thirteen-row packet; positive decreasing* $\mathsf{RealSeries}^{\uparrow}$ *source exposure through A and M; dyadic block-window coverage through B; condensed-term formation through G;* $\mathsf{StreamName}^{\uparrow}$ *scheduling through W;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q;* $\mathsf{DyadicRatCore}^{\uparrow}$ *block comparison through D;* $\mathsf{RealSequenceLimit}^{\uparrow}$ *partial-sum routing through R;* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 3345.1. The accepted packet exposes exactly the source, monotone-tail ledger, dyadic block windows, condensed terms, stream schedules, regular readbacks, dyadic comparison ledger, limit route, Real seal, and structural rows.

The source obligations are finite. Positivity and decreasing behavior are read from M only on the term windows selected by W, and the original term observations are read back through Q before any block comparison is formed.

The condensation obligations are carried by B, G, D. The dyadic ledger B supplies the finite block endpoints, G forms the corresponding condensed terms, and D records the block inequalities that compare the original tail with the condensed tail on those displayed windows.

The consumer route is then R followed by E. The limit-facing row R receives only the partial-sum and condensed-partial-sum windows already displayed, and the Real seal E is reached only after that route has passed through the regular and dyadic ledgers.

Finally H, C, P, N transport, replay, source, and name the same packet. Since host infinite sums, quotient real equality, countable choice, trichotomy, selected endpoints, and ambient completeness are not coordinates of K, they cannot appear as local NameCert obligations. □

Theorem 2393.3 (CauchyCondensationRealSeries Cauchy route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$ *packet factors its tail-comparison read through*

the finite route

$$A, M \longmapsto B, G \longmapsto W, Q, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the original positive decreasing $\mathsf{RealSeries}^{\uparrow}$ *tail and the condensed tail are compared only by displayed dyadic block windows, scheduled stream reads, regular rational readbacks, and the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *partial-sum route before any* $\mathsf{Real}^{\uparrow}$ *seal is visible.*

Proof. Start with the accepted carrier. The source row A and monotone ledger M are the only rows from which a consumer can inspect the positive decreasing real-series tail.

Read the dyadic block rows next. The ledger B names the finite block windows, while G names the condensed terms on the same dyadic indices. No consumer can read a condensed comparison without preserving both rows.

Now pass through W, Q, D. The schedule W fixes the finite term and partial-sum windows, Q gives the regular rational readback for those windows, and D records the dyadic inequalities that compare each displayed original block with its condensed row.

The partial-sum route R is therefore already a displayed $\mathsf{RealSequenceLimit}^{\uparrow}$ route before the seal E is reached. The remaining rows H, C, P, N preserve and name that same finite route, so the handoff supplies no host infinite sum, quotient real equality, countable-choice schedule, trichotomy split, selected endpoint, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationRealSeries}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationRealSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3345.1, Definition 3345.2, and Definition 3345.3 seed the finite tail-comparison carrier for positive decreasing $\mathsf{RealSeries}^{\uparrow}$ terms, dyadic block windows, condensed terms, finite schedules, regular readbacks, dyadic comparison ledgers, limit routing, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationRealSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, monotone-tail exposure, dyadic block-window coverage, condensed-term formation, schedule and readback stability, dyadic comparison, limit routing, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationRealSeriesUp.

Constructive story: A $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$ packet is generated from a positive decreasing RealSeries source row, a monotone-tail ledger, dyadic block windows, condensed terms, StreamName schedules, RegSeqRat readbacks, DyadicRatCore comparison rows, a RealSequenceLimit route, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2394

A Concrete Naming Certificate for VariationOfConstants$^{\uparrow}$

Following Coddington–Levinson and Hartman on ordinary differential equations, the VariationOfConstants$^{\uparrow}$ packet records the finite inhomogeneous linear-ODE handoff by which a homogeneous local flow, a forcing row, and a Gronwall control row determine the displayed solution update without importing a host solution operator.

The packet sits next to the ODE source surface of chapter 193, the Picard–Lindelof existence route of chapter 1888, the local-flow endpoint packet of chapter 1899, the Gronwall comparison surface of chapter 2034, and the real endpoint seal of chapter 38. It names the standard variation-of-constants route as a BEDC certificate over displayed rows rather than as an ambient formula in a function space.

Definition 2394.1 (Variation-of-constants carrier)**.** *A* VariationOfConstants$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (O, P, L, G, R, H, C, Q, N)$$

with the following visible rows:

1. *O is the* Ode$^{\uparrow}$ *inhomogeneous linear source row, displaying the time window, initial state row, coefficient row, forcing row, and endpoint request.*
2. *P is the* PicardLindelof$^{\uparrow}$ *existence-and-uniqueness route read on the same local window.*
3. *L is the* PicardLindelofLocalFlow$^{\uparrow}$ *homogeneous local-flow row, naming the propagator surface used before the forcing contribution is accumulated.*
4. *G is the* GronwallInequality$^{\uparrow}$ *comparison row that bounds the accumulated forcing and the difference between any two displayed variation-of-constants reads.*
5. *R is the* Real$^{\uparrow}$ *endpoint and error-seal row for the finite observation of the homogeneous part, forcing integral ledger, and output state.*
6. *H stores componentwise* hsame *transport for the ODE source, Picard route, local-flow row, Gronwall row, real endpoint seal, replay row, provenance row, and local name.*
7. *C stores the displayed* Cont *replay from the ODE source through the Picard route, homogeneous flow row, forcing ledger, Gronwall comparison, and real endpoint seal.*
8. *Q is the* Pkg *provenance over* VariationOfConstants$^{\uparrow}$, Ode$^{\uparrow}$, PicardLindelof$^{\uparrow}$, PicardLindelofLocalFlow$^{\uparrow}$, GronwallInequality$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{VariationOfConstants}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only by the displayed source, Picard route, homogeneous-flow row, forcing ledger as replayed by C, Gronwall comparison, real endpoint seal, transport, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.VariationOfConstantsUp.VariationOfConstantsTasteGate single carrier alignment`

Theorem 2394.2 (Variation-of-constants NameCert obligations)**.** *For the carrier of Definition 3346.1, the local* $\mathsf{NameCert}_{\mathsf{VariationOfConstants}^{\uparrow}}$ *surface consists exactly of carrier admission for $V = (O, P, L, G, R, H, C, Q, N)$ ODE source admission through O, Picard–Lindelof route visibility through P, homogeneous local-flow visibility through L, Gronwall comparison visibility through G, endpoint sealing through R, componentwise transport through H, displayed replay through C, provenance through Q, and local naming through N. The packet exports no host fundamental matrix, selected global solution curve, quotient path equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an accepted carrier. The fields $O, P, L, G, R, H, C, Q, N$ are the only available rows, so every local naming obligation must be read from those fields.

The source and existence rows come first. The ODE row O supplies the inhomogeneous linear problem, and P records the Picard–Lindelof route on the same displayed window. The homogeneous row L is therefore not a detached fundamental matrix; it is the local-flow packet already named by chapter 1899.

The forcing contribution is read only by replay. The continuation row C accumulates the forcing ledger after the homogeneous flow row has been displayed, and the comparison row G bounds the accumulated read through the Gronwall surface of chapter 2034.

Finally R, H, Q, N seal, transport, source, and name the same finite route. Since no carrier coordinate stores a host solution operator, selected global curve, quotient path equality, choice schedule, or ambient completeness theorem, none of those objects can become a NameCert obligation. □

Theorem 2394.3 (Variation-of-constants Picard–Gronwall handoff)**.** *Every accepted* $\mathsf{VariationOfConstants}^{\uparrow}$ *carrier factors each inhomogeneous local-ODE read through the finite route*

$$\mathsf{Ode}^{\uparrow} \longmapsto \mathsf{PicardLindelof}^{\uparrow} \longmapsto \mathsf{PicardLindelofLocalFlow}^{\uparrow} \longmapsto \mathsf{GronwallInequality}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The Picard–Lindelof rows supply the displayed local-flow surface, the variation-of-constants replay reads the forcing ledger on that same surface, and the Gronwall row bounds the endpoint and comparison error before the $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Proof. Begin with O and P. They fix the ODE source row and the local Picard–Lindelof existence route on one displayed time window.

Read the homogeneous local flow next. The row L is consumed on the same window and supplies the propagator surface used by the forcing replay; no separate host fundamental matrix is opened.

The forcing step is the continuation route C. It records how the forcing ledger is accumulated after L, and it sends the resulting comparison request to the Gronwall row G.

The endpoint is sealed only after that comparison. The row R gives the visible $\mathsf{Real}^{\uparrow}$ endpoint and error seal, while H, Q, N keep transport, provenance, and local naming tied to the same packet. Hence an inhomogeneous local-ODE consumer sees exactly the Picard–Gronwall route above and cannot bypass it through a selected global solution curve or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{VariationOfConstants}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationOfConstants}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3346.1, Definition 3346.2, and Definition 3346.3 seed the finite inhomogeneous ODE route over ODE source, Picard–Lindelof, local-flow, Gronwall, Real endpoint, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationOfConstants}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fundamental matrices, global ODE existence, quotient path equality, selected solution curves, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard–Lindelof route visibility, local-flow visibility, forcing replay exactness, Gronwall comparison visibility, endpoint sealing, transport, replay, provenance, and local naming for BEDC.Derived.VariationOfConstantsUp.

Constructive story: A $\mathsf{VariationOfConstants}^{\uparrow}$ packet is generated from one inhomogeneous Ode source row, one PicardLindelof route, one PicardLindelofLocalFlow homogeneous-flow row, one GronwallInequality comparison row, one Real endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2395

A Concrete Naming Certificate for CompletionUniformFunctorialEnvelope$^{\uparrow}$

Following Bishop–Bridges constructive completion and Mac Lane functorial language, the CompletionUniformFuncto packet records the finite envelope that lets a completion-facing consumer read the uniform-completion route of chapter 1473, the metric-completion carrier of chapter 1506, the functorial completed-map handoff of chapter 1937, and the extension-uniqueness surface of chapter 397 through one local NameCert boundary. Its real-facing side remains attached to the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38; it does not add a quotient completion, selected representative, countable-choice schedule, or ambient real-completeness coordinate.

Definition 2395.1 (CompletionUniformFunctorialEnvelope carrier)**.** *A* CompletionUniformFunctorialEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, M, F, L, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UniformCompletion$^{\uparrow}$ *row, exposing the entourage-facing completion presentation and the displayed Cauchy data that it consumes.*
2. *M is the* MetricCompletion$^{\uparrow}$ *row, exposing the metric completion carrier, its distance-readback boundary, and the finite tolerance handoff aligned with U.*
3. *F is the* CauchyCompletionFunctoriality$^{\uparrow}$ *row, recording the completed-map transport and functorial composition ledger over the same source and target completion rows.*
4. *L is the* CompletionUniversalProperty$^{\uparrow}$ *row, recording extension existence and uniqueness over the completion surface presented by U, M, F.*
5. *S is the* StreamName$^{\uparrow}$ *finite-window row for the source, target, and completed-map observations inspected by the packet.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the displayed stream windows, metric tolerances, and real-facing observations.*
7. *A is the terminal* Real$^{\uparrow}$ *seal row reached only after S, R, U, M, F, L have been displayed.*
8. *H records componentwise* hsame *transport for the uniform-completion, metric-completion, functoriality, universal-property, stream-window, regular-readback, Real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a completion request through the uniform and metric rows, through the functorial completed-map row, through the universal-property row, and finally through the stream, regular-readback, and Real-seal boundary.*

10. *P is the* Pkg *provenance over* $\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, M, F, L, S, R, A, H, C, P, N$. It has no coordinate for quotient completions, selected representatives, countable choice, host completed spaces, function extensionality outside the displayed hsame *rows, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompletionUniformFunctorialEnvelopeUp.TasteGate.CompletionUniformFunctorialEnvelop`
`single carrier alignment`

Theorem 2395.2 (CompletionUniformFunctorialEnvelope NameCert obligations)**.** *For every accepted* $\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}$ *carrier $E = (U, M, F, L, S, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; uniform-completion exposure through U; metric-completion exposure through M; completed-map functoriality through F; extension and uniqueness exposure through L; finite stream-window exposure through S; regular rational readback through R; terminal real-name sealing through A; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 3347.1. The accepted packet exposes exactly the uniform-completion row, metric-completion row, functoriality row, universal-property row, stream windows, regular readbacks, Real seal, and structural rows.

The completion obligations are read in the order U, M, F, L. The uniform row supplies the entourage-facing completion presentation, the metric row supplies the distance and tolerance boundary, the functoriality row supplies completed-map transport, and the universal-property row supplies extension and uniqueness over those same completion coordinates.

The real-facing obligations are downstream of the completion envelope. The stream row S and regular readback R expose only finite observations, and the Real seal A is available only after the completion and functorial rows have already been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since quotient completions, selected representatives, countable choice, host completed spaces, external function extensionality, and ambient real completeness are not coordinates of E, they cannot appear as local NameCert obligations. □

Theorem 2395.3 (CompletionUniformFunctorialEnvelope consumer handoff)**.** *Every completion-facing or real-facing consumer of an accepted* $\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}$ *packet factors its read through the finite route*

$$U, M \longmapsto F \longmapsto L \longmapsto S, R, A \longmapsto H, C, P, N.$$

Thus a consumer can use uniform completion, metric completion, functorial completed maps, and extension uniqueness only as rows of one displayed envelope, and it reaches $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data only through the same finite packet.*

Proof. Start with an accepted carrier. The completion-facing side exposes U and M first, so the uniform and metric presentations are read from the same displayed packet rather than from independent host completions.

The functoriality row F then transports completed-map reads over those completion coordinates. The universal-property row L can expose extension and uniqueness only after that functorial route has been named.

The handoff to real-facing consumers is S, R, A. These rows provide the finite stream observations, regular rational readback, and terminal Real seal visible to downstream clients, with no selected representative or quotient-completion coordinate inserted between them.

The structural rows H, C, P, N preserve this route under transport, replay it as a displayed continuation, record provenance, and name the local certificate. Consequently every exported read factors through the displayed envelope and supplies no countable-choice schedule, host completed space, external function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}$ packet is generated from UniformCompletion, MetricCompletion, CauchyCompletionFunctoriality, CompletionUniversalProperty, StreamName, RegSeqRat, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3347.1, Definition 3347.2, and Definition 3347.3 seed the finite envelope binding uniform completion, metric completion, functorial completed maps, universal extension, finite stream windows, regular readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionUniformFunctorialEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host completed spaces, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion exposure, functorial completed-map transport, universal-property exposure, stream-window and regular-readback stability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionUniformFunctorialEnvelopeUp.

Chapter 2396

A Concrete Naming Certificate for $\mathsf{DarbouxProperty}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxProperty}^{\uparrow}$ packet records the finite intermediate-value route for a displayed real-valued map whose interval image cannot jump over a visible value row. It sits after the real-name boundary of chapter 38, the pointwise graph and modulus rows of chapter 130, the bisection handoff of chapter 1422, the regular rational readback of chapter 301, and the dyadic tolerance core of chapter 291. The chapter names the Darboux property as finite BEDC carrier data, not as a host theorem about all real functions or a choice-selected intermediate point.

Definition 2396.1 (DarbouxProperty carrier)**.** *A* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, F, A, B, Y, S, M, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source interval row, exposing the inspected endpoint cells and orientation data used by the property request.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row carrying the graph window, pointwise modulus, and metric-distance witnesses for the displayed map.*
3. *A and B are the endpoint value rows, read as* $\mathsf{Real}^{\uparrow}$ *names attached to the two endpoint cells of I.*
4. *Y is the target value row whose placement between the displayed endpoint values is tested only through finite real-name windows.*
5. *S is the sign or bracket row for the residual comparison $F(-) - Y$, expressed through dyadic and regular rational windows rather than host real subtraction.*
6. *M is the finite modulus budget row selecting the precision at which endpoint, target, and midpoint reads are inspected.*
7. *R is the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *route that retains a branch whose residual signs still bracket the target value row.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained branch windows and requested tolerances.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal offered to a downstream intermediate-value consumer after the displayed route has been read.*

10. *H stores componentwise* hsame *transport for interval, map, endpoint value, target value, residual bracket, modulus, bisection, regular readback, seal, replay, provenance, and local naming rows.*
11. *C stores displayed* Cont *replay from a Darboux request through the same finite rows.*
12. *P is the* Pkg *provenance over* $\mathsf{DarbouxProperty}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxProperty}^{\uparrow}}$ *row.*

The carrier exposes a finite bracketing certificate for target-value passage. It has no coordinate for host real equality, quotient real equality, a selected intermediate point, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or open-cover compactness.*

Lean4 ✓ `BEDC.Derived.DarbouxPropertyUp.TasteGate.DarbouxPropertyTasteGate single carrier alignment`

Theorem 2396.2 (DarbouxProperty NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier $D = (I, F, A, B, Y, S, M, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxProperty}^{\uparrow}}$ *surface consists of carrier admission, endpoint and target value visibility, residual bracketing visibility, finite modulus control, intermediate-value bisection handoff, regular rational readback, terminal real seal exposure, componentwise transport, continuation replay, provenance, and local naming for the displayed packet of Definition 3348.1.*

Proof. Project the carrier of Definition 3348.1. The interval row I, continuous-map row F, endpoint rows A, B, and target row Y are the only rows from which a Darboux request may be read.

The residual bracket is the row S. It is inspected at the precision selected by M, so the endpoint and target comparison remains inside finite dyadic and regular rational windows.

The bisection row R is then the only route to a retained branch. Its output is read back through Q before the real-name seal E is exposed.

The structural rows H, C, P, N transport, replay, source, and name that same packet. Since no coordinate stores host equality, quotient equality, a selected point, trichotomy, ambient completeness, or open-cover compactness, none of those objects can appear in the local NameCert surface. □

Theorem 2396.3 (DarbouxProperty intermediate-value route)**.** *Every target-value consumer of an accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier factors through*

$\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, Nam

In particular, a request for a displayed value between the endpoint reads first reaches the continuous-map and residual-bracket rows, then the finite bisection route, then the regular rational readback, and only then the real-name seal.

Proof. Start from $D = (I, F, A, B, Y, S, M, R, Q, E, H, C, P, N)$. The continuation row C exposes the interval, map, endpoint, and target rows before any branch row is visible.

The residual bracket S is measured at the budget M, with dyadic tolerance data supplied by the $\mathsf{DyadicRatCore}^{\uparrow}$ component named in provenance. This gives a finite sign or comparison surface for $F(-) - Y$.

The branch handoff is exactly R. It is the $\mathsf{IntermediateValueBisection}^{\uparrow}$ route, so the retained branch is visible only through the same finite bisection ledger used by the constructive intermediate-value surface.

The retained branch is then read through Q and sealed by E. The remaining rows H, C, P, N keep the route attached to one BEDC packet, so the consumer cannot bypass the route by appealing to a host intermediate-value theorem or a selected point. □

Theorem 2396.4 (DarbouxProperty real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier is downstream of the endpoint value rows, the target value row, the residual bracket row, the modulus budget, the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *route, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. The export is a named finite real-seal handoff, not host real equality, quotient real equality, a selected intermediate point, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or open-cover compactness.*

Proof. Read the route to the seal. The real-facing row E appears after the endpoint and target rows A, B, Y, the residual bracket S, the budget M, the bisection route R, and the regular readback Q in the displayed carrier.

The transport and replay rows H and C preserve those dependencies componentwise. Provenance P and local naming N record that the exposed seal belongs to the $\mathsf{DarbouxProperty}^{\uparrow}$ packet.

Therefore every real-facing read is exhausted by the finite rows already listed. There is no carrier field through which host equality, quotient equality, a selected intermediate point, trichotomy, ambient completeness, or open-cover compactness could be exported. □

Theorem 2396.5 (DarbouxProperty bisection target carrier)**.** *Let* $D = (I, F, A, B, Y, S, M, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier. Every target-value bisection read of* D *is carried by the finite row family*

$$I, F, A, B, Y, S, M, R.$$

The row R *may be inspected only after the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* F*, the endpoint* $\mathsf{Real}^{\uparrow}$ *rows* A, B*, the target* $\mathsf{Real}^{\uparrow}$ *row* Y*, the residual-bracket row* S*, and the finite modulus budget* M *have been displayed. Thus the bisection target is a BEDC packet over displayed residual windows, not a host-selected intermediate point.*

Proof. Project the carrier of Definition 3348.1. The only rows preceding the bisection route are the interval row, continuous-map row, endpoint and target value rows, residual bracket, and modulus budget.

The continuation row C preserves this read order. A target-value request therefore reaches R only after the finite residual comparison has been formed from F, A, B, Y, S, M.

The structural rows H, P, N transport, source, and name the same route. Since no coordinate stores a selected point or a host intermediate-value theorem, the bisection target remains the displayed carrier route. □

Theorem 2396.6 (DarbouxProperty residual-bracket stability)**.** *For an accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier* $D = (I, F, A, B, Y, S, M, R, Q, E, H, C, P, N)$*, extending the inspected bisection window through the same modulus budget preserves the residual bracket read. The comparison row* S *is transported by* H*, replayed by* C*, and consumed by the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *route* R *through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance data. No branch extension may replace* S *by real trichotomy or by host real subtraction.*

Proof. Begin with the residual bracket S at the precision selected by M. Its endpoint and target reads are already attached to the displayed $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows.

When the bisection window is extended, the replay row C requires the next read to use the same modulus budget and dyadic tolerance route. Componentwise transport in H moves the endpoint, target, and residual rows together, so the sign or comparison data remains tied to the same packet.

The bisection row R consumes exactly that transported residual bracket. Because the carrier has no trichotomy coordinate and no host subtraction coordinate, stability is only the finite persistence of S along the displayed branch route. □

Theorem 2396.7 (DarbouxProperty RegSeqRat readback)**.** *Let $D = (I, F, A, B, Y, S, M, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *seal exposed by E is preceded by a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q of the branch retained by R. The readback uses the dyadic tolerance data named in* $\mathsf{DyadicRatCore}^{\uparrow}$ *and the regular rational schedule of* $\mathsf{RegSeqRat}^{\uparrow}$ *before the terminal real-name row is public.*

Proof. Read the rows following the bisection handoff. The route R retains the displayed branch, while Q is the only row that converts the retained branch windows into regular rational data.

The dyadic budget already used by S and M supplies the tolerance side of the readback. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q then presents the requested rational windows before the terminal row E is available.

Finally, H, C, P, N keep the readback attached to the same carrier and NameCert. The real seal is therefore a finite readback boundary over Q, not an assertion of host real equality, selected convergence, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DarbouxProperty}^{\uparrow}$ packet is generated from an interval row, a ContinuousMap row, endpoint Real rows, a target Real row, a finite residual-bracket row, a modulus budget, an IntermediateValueBisection route, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DarbouxProperty}^{\uparrow}}$, seed)

Scope closed: Definition 3348.1, Definition 3348.2, Definition 3348.3, Definition 3348.4, Definition 3348.5, Definition 3348.6, and Definition 3348.7 seed the finite Darboux target-value route and its real-seal boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DarbouxProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient real equality, a selected intermediate point, trichotomy, ambient RealUp completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-bracket stability, intermediate-value bisection handoff, regular rational readback, and real-seal nonescape for BEDC.Derived.DarbouxPropertyUp.

Chapter 2397

A Concrete Naming Certificate for $\mathsf{LocatedCompleteMetric}^{\uparrow}$

Following Bishop and Bridges on constructive metric completeness, the $\mathsf{LocatedCompleteMetric}^{\uparrow}$ packet records a complete metric object whose Cauchy-limit service is located at every finite precision request. It sits after the completion surface of chapter 1506, the zero-distance classifier boundary of chapter 1411, the terminal real-name seal of chapter 38, the regular rational readback route of chapter 301, and the finite observation schedule of chapter 126. The packet names a constructive complete-metric carrier with displayed location and limit witnesses; it is not a quotient completion class, a selected representative, countable choice, host equality of points, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 2397.1 (LocatedCompleteMetric carrier)**.** *A* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, R, Q, W, A, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, exposing the metric carrier, completion handoff, and finite tolerance surface.*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row, requiring zero-distance comparisons to pass through the displayed separated metric boundary.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-seal row, used only after finite distance observations have been routed through regular rational readback.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for Cauchy approximants, limit budgets, and distance witnesses.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite observation schedule for Cauchy data and locatedness requests.*
6. *A records componentwise* hsame *transport for the metric-completion source, separated classifier, real seal, regular rational readback, stream windows, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a finite Cauchy request through W, Q, R and then through the separated classifier S over the completion source M.*

8. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompleteMetric}^{\uparrow}}$ *row.*

The carrier exports a displayed complete-metric service only through these rows. It has no coordinate for quotient completion equality, selected limits, a countable-choice schedule, host equality of carried points, or an unrestricted completeness principle for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedCompleteMetricUp.LocatedCompleteMetricTasteGate single carrier alignment`

Theorem 2397.2 (LocatedCompleteMetric NameCert obligation surface)**.** *For every accepted* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *carrier* $L = (M, S, R, Q, W, A, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompleteMetric}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the metric-completion source, separated classifier, real distance seal, regular rational readback, stream-window schedule, componentwise transport, continuation replay, provenance, and local naming row;*

2. *located request admission, requiring every precision request to be read through the finite* $\mathsf{StreamName}^{\uparrow}$ *window W before any limit witness is exposed;*

3. *regular readback stability, requiring Cauchy approximants, limit budgets, and distance witnesses to pass through Q before the* $\mathsf{Real}^{\uparrow}$ *seal R is consumed;*

4. *separated classifier stability, requiring zero-distance uniqueness for displayed limits to be compared through S over the same completion source M;*

5. *ledger non-escape, excluding quotient completion classes, selected representatives, countable-choice schedules, host equality of carried points, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3349.1. The displayed tuple contains exactly the rows $M, S, R, Q, W, A, C, P, N$, so carrier admission and local naming are exhausted by those coordinates.

A located request must enter through W. That row supplies the finite observation schedule, and Q turns the scheduled Cauchy approximants and requested budgets into regular rational readback before any terminal real-distance seal is visible.

The separated comparison is then confined to S over the same metric-completion source M. Transport through A and replay through C preserve the displayed route, while P records that no excluded quotient, selector, choice, host-equality, or ambient-completeness coordinate is exported. □

Theorem 2397.3 (LocatedCompleteMetric Cauchy-limit witness)**.** *Let $L = (M, S, R, Q, W, A, C, P, N)$ be an accepted* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *carrier. Every Cauchy-limit witness served by L factors through the finite route*

$$W \longmapsto Q \longmapsto R \longmapsto M, S \longmapsto A, C, P, N.$$

Thus the witness is a located finite-readback service over the displayed metric-completion source and separated classifier, not a selected host limit, quotient representative, choice sequence, or ambient completeness assertion.

Proof. Begin with a Cauchy-limit request against L. The only observation schedule in the carrier is W, so the request first fixes a finite stream window.

The regular rational row Q supplies the finite readback for the Cauchy approximants and the requested limit budget. The real-distance seal R is read after that regular handoff, so a downstream consumer receives only displayed distance information.

The completion source M and separated classifier S package the witness as a complete-metric service and compare any two displayed limits through zero-distance classification. The structural rows A, C, P, N transport, replay, source, and name the same route, so the excluded host-limit and quotient data have no row from which to be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompleteMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompleteMetric}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 3349.1, Definition 3349.2, and Definition 3349.3 enumerate the carrier, NameCert obligation surface, and Cauchy-limit witness obligations over MetricCompletion, SeparatedMetric, Real, RegSeqRat, StreamName, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompleteMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion equality, selected representatives, countable choice, host equality of carried points, standard bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located request admission, regular readback stability, separated classifier stability, and ledger non-escape for BEDC.Derived.LocatedCompleteMetricUp.

Constructive story: A $\mathsf{LocatedCompleteMetric}^{\uparrow}$ packet is generated from a MetricCompletion source row, a SeparatedMetric classifier row, a RealUp distance seal, RegSeqRat readback, StreamName windows, componentwise transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2398

A Concrete Naming Certificate for $\mathsf{CauchyCompletionBoundary}^{\uparrow}$

Following Bishop and Bridges constructive completion and Kelley-style completion interfaces, the $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ packet records the finite handoff surface between metric-completion, uniform-completion, named-window, dyadic-tolerance, regular-readback, and Real-seal consumers. It sits over the metric completion route of chapter 1506, the uniform completion route of chapter 1473, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet names the completion boundary without importing quotient stream equality, selected limits, ambient completeness, countable choice, or host completion operators.

Definition 2398.1 (Cauchy completion boundary carrier)**.** *A* $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, U, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row naming the metric Cauchy completion request and its displayed finite source route.*
2. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row naming the uniform completion request and its entourage-facing handoff route.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the metric and uniform completion reads.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to budget Cauchy comparisons, entourage requests, and Real-facing seal reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same finite windows and dyadic tolerances.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after M, U, S, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the metric-completion, uniform-completion, window, dyadic, readback, Real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-facing read through $M, U, S, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionBoundary}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionBoundary}^{\uparrow}}$ *row.*

The classifier accepts only packets whose metric-completion row, uniform-completion row, shared finite windows, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming are displayed in this order. It has no coordinate for quotient streams, selected representatives, selected limits, ambient completeness, countable choice, or host completion operators.

Lean4 ✓ `BEDC.Derived.CauchyCompletionBoundaryUp.CauchyCompletionBoundaryTasteGate single carrier alignment`

Theorem 2398.2 (Cauchy completion boundary NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ *carrier* $B = (M, U, S, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric-completion row, uniform-completion row, shared finite-window row, dyadic tolerance ledger, regular rational readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-boundary read must consume the rows* $M, U, S, D, R, E, H, C, P, N$ *before it exports a Real-facing completion handoff, and no obligation is stored outside those rows.*

Proof. Project the accepted carrier. The projection exposes the metric-completion request, uniform-completion request, shared windows, dyadic tolerances, regular readback, Real seal, transport, replay, provenance, and local name as one finite packet.

Read stability from the row order. A consumer that asks for a completion-facing handoff must pass through the shared $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before R or E can be inspected, so the metric and uniform routes cannot escape into a host completion object.

Finally apply coordinate exhaustion. Quotient streams, selected representatives, selected limits, ambient completeness, countable choice, and host completion operators are not coordinates of B, and the hsame, Cont, Pkg, and NameCert rows preserve the displayed packet rather than adding new analytic data. □

Theorem 2398.3 (Cauchy completion boundary finite handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer citing an accepted* $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ *packet receives only the finite handoff*

$$M \longmapsto U \longmapsto S \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The handoff supplies the metric-completion route, uniform-completion route, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local naming. It supplies no quotient stream equality, selected representative, selected limit, countable-choice schedule, ambient completeness theorem, or host completion operator.

Proof. Begin with a consumer of the boundary packet. Carrier projection gives the rows $M, U, S, D, R, E, H, C, P, N$ and no other completion-facing coordinate.

The shared observation route is finite. The row S stores the inspected windows, D stores the dyadic budget, R stores the regular readback, and E is terminal with respect to the displayed Real-facing seal.

The structural rows then keep the same route under transport and replay. Since the excluded quotient, choice, limit, completeness, and host-completion objects are absent from the carrier, every exported handoff is exhausted by the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ packet is generated from MetricCompletion and UniformCompletion rows, shared StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCompletionBoundary}\uparrow}$, seed)

Scope closed: Definition 3350.1, Definition 3350.2, and Definition 3350.3 seed the finite completion-boundary handoff for MetricCompletion, UniformCompletion, and RealUp consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected limits, countable choice, ambient completion, host completion operators, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window discipline, dyadic tolerance routing, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionBoundary

Chapter 2399

A Concrete Naming Certificate for $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$

Following Kelley and Bourbaki on metric completion, the $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ packet records the standard dense embedding of a metric carrier into its completion as finite BEDC data. It reads the metric source of chapter 57, the completion row of chapter 1506, the separated comparison surface of chapter 1411, the uniform completion handoff of chapter 1473, and the regular rational readback of chapter 301. The packet gives completion-uniqueness and universal-property consumers a visible dense-image route without quotient representatives, selected limits, countable choice, host equality of completion classes, or an ambient completion object.

Definition 2399.1 (MetricCompletionDenseEmbedding carrier)**.** *A* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, C, E, S, U, R, H, K, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Metric}^{\uparrow}$ *source row, carrying the source carrier, distance classifier, and finite metric reads inherited from chapter 57.*
2. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row, carrying the completion-facing Cauchy surface of chapter 1506.*
3. *E is the dense-image row, recording the displayed embedding route from a source point row in X to its completion name in C and the finite witness rows saying that every inspected completion neighbourhood is reached by a source image.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row from chapter 1411, used only after the source and completion rows have been displayed.*
5. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row from chapter 1473, recording the uniform completion consumer route that reads the same dense image surface.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row from chapter 301, exposing the finite regular-rational observations attached to completion-neighbourhood and distance-budget reads.*
7. *H records componentwise* hsame *transport for $X, C, E, S, U, R, K, P, N$.*
8. *K records displayed* Cont *replay from source metric reads through completion names, dense-image witnesses, separated comparisons, uniform completion handoff, and regular rational readback.*

9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$*, the five sibling chapters named above,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for quotient representatives, selected Cauchy limits, countable choice, host equality of completion classes, or a detached completion uniqueness theorem.

Lean4 ✓ `BEDC.Derived.MetricCompletionDenseEmbeddingUp.TasteGate.MetricCompletionDenseEmbeddingTasteGate`
`single carrier alignment`

Theorem 2399.2 (MetricCompletionDenseEmbedding NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *carrier* $D = (X, C, E, S, U, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionDense}}$ *surface consists exactly of carrier admission for the source metric row, completion row, dense-image row, separated comparison row, uniform completion handoff, regular rational readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must consume* X, C, E *before it can read* S, U, R, H, K, P, N*.*

Proof. Project the carrier of Definition 3351.1. The rows X, C, E expose the source metric, completion carrier, and dense image surface as displayed finite packet data.

The comparison and handoff rows are downstream. The separated comparison S reads the same source and completion rows, the uniform completion handoff U follows the same dense-image route, and the regular rational readback R exposes only the finite observation data attached to those reads.

Finally H, K, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores quotient representatives, selected limits, countable choice, or host completion equality, the listed rows exhaust the local NameCert obligations. □

Theorem 2399.3 (MetricCompletionDenseEmbedding handoff)**.** *Every completion-uniqueness, separated-completion, or uniform-completion consumer of an accepted* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *packet factors through*

$$\mathsf{Metric}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{DenseImage}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}.$$

The exported handoff is the displayed dense embedding of the metric source into its completion; it is not a quotient-representative selector, an ambient completion theorem, a host equality comparison, or a choice principle.

Proof. Start with a completion-facing consumer. By Definition 3351.2, the consumer first reads the source metric row X, the completion row C, and the dense-image row E.

The sibling chapters then determine the downstream route. The separated metric comparison is read through chapter 1411, the uniform handoff through chapter 1473, and the regular rational windows through chapter 301.

The structural rows H, K, P, N preserve that same finite route under transport, replay, provenance, and naming. Because the carrier has no row for representatives, selected limits, countable choice, host equality, or an ambient completion theorem, every accepted handoff remains the displayed dense embedding surface. □

Theorem 2399.4 (MetricCompletionDenseEmbedding universal-property route)**.** *Every completion universal-property read using the dense image of an accepted* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$

packet factors through the source metric row, completion row, dense image row, separated comparison row, uniform handoff row, RegSeqRat readback row, componentwise transport, displayed replay, provenance, and local NameCert *row. The route exports the source-to-completion dense embedding needed by universal-property consumers, not a quotient-representative selector, a selected limit, countable choice, host equality of completion classes, or an ambient completion theorem.*

Proof. Use Definition 3351.2 to read the carrier surface. A universal-property consumer first receives the source metric row, completion row, and dense image row, so its dense-source request is tied to displayed packet data.

Then apply the handoff of Definition 3351.3. The separated comparison, uniform completion handoff, and RegSeqRat readback rows are the only downstream completion-facing rows available to the consumer.

Finally the transport, replay, provenance, and local naming rows preserve that same route. Since no excluded host-side principle is a carrier coordinate, the universal-property read factors through the dense embedding surface alone. □

Falsifiable prediction: Every accepted $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ consumer that reaches a completion-uniqueness or uniform-completion handoff while omitting the source metric row, completion row, dense-image row, separated comparison row, or regular rational readback refutes the packet.

Independence witness: metric, metriccompletion, separatedmetric, uniformcompletion, regseqrat: no listed sibling is bijective with $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ because the packet jointly carries source metric data, completion data, dense-image witnesses, separated comparison, uniform handoff, regular rational readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ packet is generated from a metric source row, metric-completion row, dense-image row, separated comparison row, uniform completion handoff, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3351.1, Definition 3351.2, and Definition 3351.3 seed the standard dense embedding route from a metric carrier into its completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, selected Cauchy limits, countable choice, host equality of completion classes, completion uniqueness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-image exactness, separated comparison handoff, uniform completion handoff, regular rational readback, and TasteGate field faithfulness for BEDC.Derived.MetricCompletionDenseEmb

Chapter 2400

A Concrete Naming Certificate for ClosedPiDomainSubjectReduction$^{\uparrow}$

The ClosedPiDomainSubjectReduction$^{\uparrow}$ packet realizes the Pi-domain branch of the closed MetaCIC subject-reduction frontier as a finite NameCert carrier. It sits beside the four-row discharge socket of chapter 719, the discharge ledger of chapter 720, the beta-substitution packet of chapter 716, the closed substitution boundary of chapter 538, and the typed beta congruence trigger of chapter 760. The packet names the Pi-domain obligation as displayed closed term data; it does not export an unconditional closed subject-reduction theorem.

Definition 2400.1 (ClosedPiDomainSubjectReduction carrier)**.** *A* ClosedPiDomainSubjectReduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, D, D', C, Y, Z, B, H, R, Q, N)$$

with the following displayed rows:

1. *T is the displayed closed Pi term row, naming the source term $\Pi D.\, C$ and its closed context boundary.*
2. *D is the original domain row, carrying the domain annotation inspected before the congruence step.*
3. *D' is the reduced domain row reached by the displayed beta step from D.*
4. *C is the codomain row, read under the binder induced by the displayed domain.*
5. *Y is the typing row, recording the source typing judgement for $\Pi D.\, C$ and the target typing judgement demanded for $\Pi D'.\, C$.*
6. *Z is the closedness row, requiring the Pi term, original domain, reduced domain, and codomain reads to remain inside the same closed MetaCIC boundary.*
7. *B is the beta-step and typed congruence row, consuming the displayed Pi-domain beta step and the trigger surface of chapter 760.*
8. *H records componentwise* hsame *transport for $T, D, D', C, Y, Z, B, R, Q, N$.*
9. *R records displayed* Cont *replay from the source Pi term through the domain step, typing row, closedness row, and subject-reduction handoff.*

10. *Q is the* Pkg *provenance over chapter 719, chapter 720, chapter 716, chapter 538, chapter 760,* BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying the closed Pi term, both domain rows, the codomain row, the typing row, the closedness row, the Pi-domain beta step, transport, replay, provenance, and local naming. It has no coordinate for a blanket closed subject-reduction theorem, a host conversion rule, erased derivation semantics, quotient syntax equality, or an untracked binder context.

Lean4 ✓ `BEDC.Derived.ClosedPiDomainSubjectReductionUp.ClosedPiDomainSubjectReductionTasteGate`
`single carrier alignment`

Theorem 2400.2 (ClosedPiDomainSubjectReduction obligations)**.** *For every accepted* ClosedPiDomainSubjectRed *carrier $P = (T, D, D', C, Y, Z, B, H, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed closed Pi term, original domain, reduced domain, codomain, typing row, closedness row, beta-step row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The Pi-domain preservation read is accepted only when B displays the domain beta step and Y, Z display the corresponding typing and closedness rows.*

Proof. Project the carrier of Definition 3352.1. The rows T, D, D', C display the Pi term and the two domain readings, while Y and Z display the typing and closedness boundaries attached to the same context.

The beta-step row B is then read as the Pi-domain congruence trigger. It is not interchangeable with the beta-substitution row, the application-argument row, or the lambda-domain row of the subject-reduction socket, because the target branch changes the displayed Pi domain while preserving the codomain under the induced binder.

The structural rows H, R, Q, N transport, replay, source, and name only that finite packet. Since no row stores a host conversion rule, erased derivation semantics, quotient syntax equality, or a closed subject-reduction theorem, the displayed rows exhaust the local NameCert obligations. □

Theorem 2400.3 (ClosedPiDomainSubjectReduction handoff)**.** *Every subject-reduction discharge ledger read that consumes the Pi-domain branch from an accepted* $\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}$ *packet factors through the displayed route*

$$\Pi D.\, C,\ D,\ D',\ C,\ Y,\ Z,\ B,\ H,\ R,\ Q,\ N.$$

The handoff supplies the Pi-domain obligation row to the subject-reduction discharge socket and ledger; it does not supply the beta-substitution row, application-argument row, lambda-domain row, or an unconditional closed subject-reduction theorem.

Proof. Start with a subject-reduction consumer of the Pi-domain branch. The socket and ledger chapters, chapter 719 and chapter 720, require a distinct Pi-domain row before the parameterised subject-reduction route can be read.

The present carrier supplies that row only through T, D, D', C, Y, Z, B. These rows display the source Pi term, the original and reduced domains, the codomain, the typing judgement, the closedness boundary, and the beta-step trigger.

Finally H, R, Q, N preserve and name the same finite handoff. The beta-substitution preservation packet, closed substitution boundary, and typed beta congruence trigger remain sibling inputs rather than hidden substitute proofs, so the handoff is exactly the Pi-domain row and nothing stronger. □

Falsifiable prediction: Any accepted $\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}$ consumer reaching a subject-reduction conclusion without the displayed Pi-domain beta step and typing row refutes the carrier.

Independence witness: metacic-subject-reduction-obligation, betasubstitutionpreservation, closed-substitutionboundary, typedbetacongruencetrigger: none is bijective with $\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}$ because this packet jointly carries the closed Pi term, original domain, reduced domain, codomain, typing row, closedness row, Pi-domain beta step, transport, replay, provenance, and local naming.

The Lean TasteGate file for $\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}$ must provide explicit Nontrivial ClosedPiDomainSu and $\mathsf{FieldFaithful}\ \mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}$ instances preserving $T, D, D', C, Y, Z, B, H, R, Q, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}$ packet is generated from a closed Pi term row, original domain row, reduced domain row, codomain row, typing row, closedness row, beta-step row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3352.1, Definition 3352.2, and Definition 3352.3 seed the finite Pi-domain subject-reduction obligation packet for the closed MetaCIC discharge route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedPiDomainSubjectReduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close beta-substitution preservation, application-argument stability, lambda-domain preservation, unconditional closed subject reduction, host conversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Pi-domain beta-step exactness, typing-row exposure, closedness-row exposure, subject-reduction ledger handoff, and TasteGate field faithfulness for BEDC.Derived.ClosedPiDomainSubjectRed

Chapter 2401

A Concrete Naming Certificate for $\mathsf{FiniteTraceInductionGap}^{\uparrow}$

Following the Bishop and Brouwer distinction between finite verification and an induction schema, the $\mathsf{FiniteTraceInductionGap}^{\uparrow}$ packet records the finite-observation side of Definition 9393.4 and the non-internal-induction boundary of Definition 9393.5. It sits beside the finite-trace GAP socket of chapter 504, the transcendental induction socket of chapter 498, and the closed-observation ledger of chapter 616. The packet names a finite verification trace together with the GAP socket exposed by any attempted universal closure; it does not install a substrate-internal universal quantifier, dependent induction schema, host recursor, or future-observation oracle.

Definition 2401.1 (Finite trace induction gap carrier)**.** *A* $\mathsf{FiniteTraceInductionGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, O, A, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite verification trace row, listing only the observed indices and their closed-generation witness records.*
2. *O is the observed predicate row, storing the finite family of predicate reads actually checked by the trace.*
3. *A is the attempted induction-closure row, naming the requested passage from the finite trace to a universal claim without admitting the passage as a carrier coordinate.*
4. *Q is the GAP socket row exposed when A asks for substrate-internal induction beyond the displayed trace.*
5. *H records componentwise* hsame *transport for the finite trace, observed predicate rows, attempted closure row, GAP socket, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from each observed predicate read through T, O, A, Q, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteTraceInductionGap}^{\uparrow}$, $\mathsf{FiniteTraceGapSocket}^{\uparrow}$, $\mathsf{TranscendentalInductionSocket}^{\uparrow}$, $\mathsf{ClosedObservationSystem}^{\uparrow}$, BHist, Gap, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceInductionGap}^{\uparrow}}$ *row.*

The classifier accepts only packets whose finite trace, observed predicate rows, attempted induction-closure row, GAP socket, transport, replay, provenance, and local naming are all displayed. It has

no coordinate for a universal quantifier over unobserved indices, a substrate-internal induction schema, a host dependent recursor, an infinite observation ledger, or a future-observation oracle.

Lean4 ✓ BEDC.Derived.FiniteTraceInductionGapUp.FiniteTraceInductionGapTasteGate single carrier alignment

Theorem 2401.2 (Finite trace induction gap NameCert obligations)**.** *For every accepted* $\mathsf{FiniteTraceInductionGap}^{\uparrow}$ *carrier* $G = (T, O, A, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceInductionGap}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite trace row, observed predicate rows, attempted induction-closure row, GAP socket row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer that asks for induction closure must expose* A *and then consume* Q *as a GAP socket; no substrate-internal universal statement is exported by the packet.*

Proof. Project the accepted carrier. The projection exposes the finite trace T, the observed predicate rows O, the attempted closure row A, the GAP socket Q, and the structural rows H, C, P, N.

Read the induction request through A. If the consumer stays within the finite trace, it can use only the displayed rows T and O. If it asks for all unobserved indices, the next displayed row is the GAP socket Q, not a universal witness.

The transport and replay rows preserve that boundary. Since no universal quantifier, dependent induction schema, host recursor, infinite ledger, or future-observation oracle is a coordinate of G, the local NameCert obligations are exhausted by the finite trace and GAP route. □

Theorem 2401.3 (Finite trace induction gap non-escape)**.** *Every induction-facing consumer of an accepted* $\mathsf{FiniteTraceInductionGap}^{\uparrow}$ *packet factors through*

$$T \longmapsto O \longmapsto A \longmapsto Q \longmapsto H, C, P, N.$$

Thus the consumer may read the observed finite trace and the displayed predicate witnesses, but any attempted export of a universal induction claim reaches only the GAP socket. The packet exports no substrate-internal universal quantifier, no closed dependent recursor, no infinite observation object, and no promise over future observations.

Proof. Start with the carrier rows of Definition 3353.1. The trace row T and observed predicate row O give exactly the finite witness records already present in the closed observational system.

The attempted closure row A names the requested induction passage. It is deliberately followed by the GAP socket row Q, so a consumer that asks for unobserved indices receives a visible boundary rather than a hidden induction rule.

Finally replay and transport the same route through C and H, then read provenance and local naming through P, N. The excluded universal, recursor, infinite-ledger, and future-observation objects are absent from the carrier, so the displayed GAP route is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTraceInductionGap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteTraceInductionGap}^{\uparrow}$ packet is generated from a finite verification trace, observed predicate rows, an attempted induction-closure row, a GAP socket, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteTraceInductionGap}^{\uparrow}}$, seed)

Scope closed: Definition 3353.1, Definition 3353.2, and Definition 3353.3 seed the finite verification trace and induction-GAP boundary for closed observational systems.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteTraceInductionGap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a substrate-internal universal quantifier, dependent induction schema, host recursor, infinite observation ledger, future-observation oracle, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-trace visibility, observed-predicate stability, induction-GAP routing, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteTraceInductionGapUp.

Chapter 2402

A Concrete Naming Certificate for $\mathsf{OvertReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OvertReal}^{\uparrow}$ packet records positive information about real data as finite witnessable contact, not as a host open-set membership predicate. It sits over the real-name boundary of chapter 38, the located source interval of chapter 1709, the finite interval-cover route of chapter 1885, and the one-sided observation rows of chapter 1446 and chapter 1447. The packet supplies an L10 positive-information interface for downstream real and interval consumers without claiming classical open-cover compactness, arbitrary open-set membership, trichotomy, selected points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2402.1 (OvertReal carrier)**.** *An* $\mathsf{OvertReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (R, I, C, L, U, W, A, H, T, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row naming the real datum that may be observed only through the displayed real-name route.*
2. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row, exposing endpoint names, radius data, locator reads, locatedness moduli, and metric-bracket rows around the inspected real datum.*
3. *C is the* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *row, recording a finite located cover request through rational intervals, dyadic mesh data, refinement rows, finite windows, and readback data.*
4. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *positive lower-observation row. It records finite inhabited lower rational information that may witness nonempty contact from below.*
5. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *positive upper-observation row. It records finite upper-bound information that keeps the contact request located rather than host-open.*
6. *W is the finite witness row naming the particular cover cell, interval bracket, lower read, and upper read used by the positive-information claim.*
7. *A is the anti-escape ledger saying that the packet exports only witnessable contact and finite cover handoff, not arbitrary open-set membership or open-cover compactness.*
8. *H records componentwise* hsame *transport for $R, I, C, L, U, W, A, P, N$.*
9. *T records displayed* Cont *replay from the real seal to the located interval, from the interval to the cover request, and from the cover request to the lower and upper contact rows.*

10. *P is the* Pkg *provenance over* $\mathsf{OvertReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OvertReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, I, C, L, U, W, A, H, T, P, N$. It has no coordinate for host open sets, detached membership predicates, arbitrary open covers, compactness extraction, trichotomy, selected representatives, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.OvertRealUp.OvertRealTasteGate single carrier alignment`

Theorem 2402.2 (OvertReal NameCert obligations)**.** *For every accepted* $\mathsf{OvertReal}^{\uparrow}$ *carrier*

$$O = (R, I, C, L, U, W, A, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OvertReal}^{\uparrow}}$ *surface consists exactly of the finite positive-information obligations over the displayed packet:*

1. *real-source admission, requiring every real-facing read to pass through the terminal* $\mathsf{Real}^{\uparrow}$ *row R;*
2. *located-interval admission, requiring endpoint, radius, locator, locatedness, and metric-bracket requests to pass through I;*
3. *finite-cover handoff, requiring every positive contact claim to cite the displayed* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *row C;*
4. *one-sided observation exactness, requiring the lower and upper contact reads to be exactly L and U;*
5. *witness-row exactness, requiring the contact witness to be the finite row W and not a selected host point;*
6. *transport, replay, provenance, and local naming stability through H, T, P, N;*
7. *non-escape through A, excluding host open-set membership, arbitrary open-cover compactness, trichotomy, selected representatives, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 3354.1. The real datum is visible only through R, and the only interval information attached to that datum is the located row I.

The positive-information route next passes through C. Because C is a $\mathsf{LocatedIntervalCover}^{\uparrow}$ row, the cover request is finite, located, and routed through displayed rational and dyadic refinement data before any contact claim is available.

The one-sided rows L and U provide the observable lower and upper information. The witness row W binds these reads to one displayed cover cell and interval bracket, so the packet never replaces positive contact by a selected point or by detached host membership.

Finally H, T, P, N transport, replay, source, and name the same rows, while A records the forbidden exits. Since no other coordinate occurs in the carrier, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.OvertRealUp.OvertRealCarrier semantic name certificate`

Theorem 2402.3 (OvertReal positive-cover handoff)**.** *Every* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *consumer that asks whether an accepted* $\mathsf{OvertReal}^{\uparrow}$ *packet has positive contact with a displayed located interval factors through*

$$R, I, C, L, U, W, A, H, T, P, N.$$

The handoff exposes the source $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *bracket, the finite* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *request, the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *one-sided contact rows, the finite witness row, and the structural transport, replay, provenance, and local naming rows. It exports no host open-set membership predicate, no open-cover compactness theorem, no selected point of contact, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the accepted carrier O. The target consumer is cover-facing, so its first available cover row is the displayed coordinate C.

Reading C forces the consumer to retain the source interval row I and the terminal real seal R, because the cover route is attached to the located interval around the real datum rather than to an external open-set predicate.

The contact claim is then witnessed by L, U, W. The lower and upper rows provide the one-sided positive information, and W records the finite cover cell and bracket in which that information is consumed.

The rows A, H, T, P, N add no extra carrier coordinate. They only block escape, transport the displayed packet, replay the displayed route, record provenance, and name the local certificate. Thus every positive-cover handoff factors through exactly the stated finite surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{OvertReal}^{\uparrow}}$.

Constructive story: An $\mathsf{OvertReal}^{\uparrow}$ packet is generated from a terminal RealUp seal, a LocatedRealIntervalUp source interval, a LocatedIntervalCoverUp finite cover request, LowerRealUp and UpperRealUp one-sided contact rows, a finite witness row, an anti-escape ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OvertReal}^{\uparrow}}$, seed)

Scope closed: Definition 3354.1, Definition 3354.2, and Definition 3354.3 seed the finite positive-information surface over $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OvertReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim classical open-set membership, arbitrary open-cover compactness, selected points of contact, trichotomy, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, real-source exactness, located-interval exactness, finite-cover handoff, one-sided contact exactness, witness-row exactness, transport stability, replay stability, and non-escape for BEDC.Derived.OvertRealUp.

Chapter 2403

A Concrete Naming Certificate for $\mathsf{CertificateMachine}^{\uparrow}$

The $\mathsf{CertificateMachine}^{\uparrow}$ packet realizes the certificate-machine branch of subsection 9462.28.23 as finite BEDC carrier data. It names the surface on which a machine-like object is admitted only through a finite kernel row, accepted-observation rows, branch-refusal rows, audit replay, provenance, and local NameCert evidence. The packet is not an ordinary Turing-machine identity claim, not a semantic truth oracle, not a host execution trace, and not a replacement for the kernel and NameCert obligations it records.

Definition 2403.1 (CertificateMachine carrier)**.** *A* $\mathsf{CertificateMachine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, O, B, A, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite certificate-kernel row. It lists the admitted constructors, candidate rows, acceptance stamps, and refusal slots visible to this machine surface.*
2. *O is the accepted-observation row, recording the finite observations the machine has admitted as certificate-bearing rows.*
3. *B is the branch-refusal row, recording rejected or unlicensed branches together with the local reason each branch cannot be read as accepted data.*
4. *A is the audit-replay row, recording the finite replay route from generated candidate through accepted observation or branch refusal.*
5. *R is the replay-result row, naming the public result that may be consumed after the audit replay finishes.*
6. *S is the soundness-boundary row saying that the machine exports certificate acceptance and refusal data, not a host truth predicate or an external operational semantics.*
7. *H records componentwise* hsame *transport for K, O, B, A, R, S, P, N.*
8. *C records displayed* Cont *replay from kernel row to observation or refusal row, from that row to audit replay, and from audit replay to the public result.*
9. *P is the* Pkg *provenance over* $\mathsf{CertificateMachine}^{\uparrow}$*, finite certificate kernels, accepted observations, branch refusals, audit replay,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CertificateMachine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, O, B, A, R, S, H, C, P, N$. It has no coordinate for host machine equality, ordinary Turing-machine identity, semantic truth, unbounded execution logs, unlicensed branch acceptance, or external proof authority.

Lean4 ✓ `BEDC.Derived.CertificateMachineUp.CertificateMachineTasteGate single carrier alignment`

Theorem 2403.2 (CertificateMachine NameCert obligations)**.** *For every accepted* $\mathsf{CertificateMachine}^{\uparrow}$ *carrier*

$$M = (K, O, B, A, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CertificateMachine}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *kernel admission, requiring every candidate, constructor, acceptance stamp, and refusal slot to pass through K;*
2. *accepted-observation exactness, requiring every admitted observation to be one of the rows displayed in O;*
3. *branch-refusal exactness, requiring every rejected branch read to pass through B with its local refusal reason;*
4. *audit-replay determinacy, requiring every public result to be replayed through A before R is consumed;*
5. *soundness-boundary non-escape, requiring S to exclude semantic truth, ordinary Turing-machine identity, host execution logs, and external proof authority;*
6. *transport, continuation, provenance, and local naming stability through H, C, P, N.*

Lean follow-up must provide $\mathsf{Nontrivial}(\mathsf{CertificateMachine}^{\uparrow})$ *and* $\mathsf{FieldFaithful}(\mathsf{CertificateMachine}^{\uparrow})$ *instances before the object may be consumed as a nondegenerate field-facing certificate machine.*

Proof. Project the carrier of Definition 3355.1. The only kernel coordinate is K, so every candidate and acceptance stamp begins from that finite certificate-kernel row.

Accepted observations and refusals then split through O and B. The accepted side records only admitted observation rows, while the refusal side records branch-local reasons for rejection.

The audit route passes through A before the public result R is available. Thus a consumer cannot bypass replay by citing a host execution log or an unbounded operational trace.

Finally S, H, C, P, N bind the boundary, transport the same rows, replay the displayed route, record provenance, and name the local certificate. Since no coordinate adds semantic truth, ordinary Turing-machine identity, unlicensed branch acceptance, or external proof authority, the listed obligations exhaust the NameCert surface. □

Theorem 2403.3 (CertificateMachine audit-replay non-escape)**.** *Every public read of an accepted* $\mathsf{CertificateMachine}^{\uparrow}$ *carrier factors through*

$$K, O, B, A, R, S, H, C, P, N.$$

An accepted observation reaches the public result only by the route K, O, A, R, and a rejected branch reaches the public refusal surface only by the route K, B, A, R. Both routes keep the soundness boundary S visible and preserve the same transport, continuation, provenance, and local naming rows. No read exports host machine equality, semantic truth, unbounded execution, unlicensed branch acceptance, or an external proof oracle.

Proof. Start from the displayed carrier M. There are exactly two observation-facing routes after the kernel row: the accepted-observation row O and the branch-refusal row B.

In the accepted case, continuation replay through C sends K and O into the audit row A before the public result R can be read. In the refusal case, the same replay discipline sends K and B into A before the refusal result is visible.

The soundness boundary S is carried with both routes. It excludes the stronger readings that would identify the packet with an ordinary Turing machine, a semantic truth oracle, a host execution log, or an external proof source.

The remaining rows H, P, N only transport, source, and name the packet. Hence every public read remains inside the displayed finite surface. □

Theorem 2403.4 (CertificateMachine branch-refusal determinacy)**.** *Let $M = (K, O, B, A, R, S, H, C, P, N)$ be an accepted* $\mathsf{CertificateMachine}^{\uparrow}$ *packet. Every refused branch of M is determined by the finite kernel row K, the branch-refusal row B, the audit-replay row A, and the soundness-boundary row S. Before the refused branch can be consumed as a MetaCIC audit row, its read must pass through the accepted-kernel surface of chapter 549, the axiom-query ledger of chapter 654, and the closed-generator audit surface of chapter 709.*

Proof. Project the carrier of Definition 3355.1. The refusal side has only the kernel row K, the branch-refusal row B, the audit replay row A, and the soundness boundary S before the public result row can be read.

Apply audit-replay non-escape, Definition 3355.3. A rejected branch reaches the public refusal surface only by the route K, B, A, R, with S still visible as the boundary against host truth, unbounded execution, and external proof authority.

The MetaCIC sibling lattice supplies the concrete audit route for those rows. Kernel admission is read through chapter 549, proof-supply cleanliness through chapter 654, and closed-generator replay through chapter 709.

Thus the refused branch is determined by the displayed finite rows of the same packet and by the named sibling ledgers. No separate kernel-only or host-execution route can consume it as a MetaCIC audit row. □

Falsifiable prediction: Every $\mathsf{CertificateMachine}^{\uparrow}$ read factors through one finite certificate-kernel row, one accepted-observation row or one branch-refusal row, one audit-replay row, one replay-result row, one soundness-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: kernelacceptancewitness, axiomqueryledger, inscriptionevent, observerfilter, closedgeneratoraudit: $\mathsf{CertificateMachine}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries kernel admission, accepted observations, branch refusals, audit replay, result exposure, and soundness-boundary refusal as one finite machine packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CertificateMachine}^{\uparrow}}$.

Constructive story: A $\mathsf{CertificateMachine}^{\uparrow}$ packet is generated from a finite certificate-kernel row, accepted-observation rows, branch-refusal rows, audit replay, replay result exposure, a soundness-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertificateMachine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3355.1, Definition 3355.2, and Definition 3355.3 seed the finite machine surface over certificate kernels, accepted observations, branch refusals, audit replay, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertificateMachine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ordinary Turing-machine identity, semantic truth, host execution semantics, unbounded trace replay, unlicensed branch acceptance, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, kernel exactness, accepted-observation exactness, branch-refusal exactness, audit-replay determinacy, soundness-boundary non-escape, transport stability, replay stability, and the Nontrivial(CertificateMachine$^{\uparrow}$) and FieldFaithful(CertificateMachine$^{\uparrow}$) Lean instances for BEDC.Derived.CertificateMachineUp.

Chapter 2404

A Concrete Naming Certificate for GeneratingFunction$^{\uparrow}$

Following Wilf and Stanley, a GeneratingFunction$^{\uparrow}$ packet records a sequence by its coefficient stream and the finite algebraic windows through which coefficient extraction is read. It sits after the unary index discipline of chapter 28, the finite spine discipline of chapter 36, the stream-window interface of chapter 126, the real-series carrier of chapter 1581, and the coefficient-and-radius surface of chapter 1583. The packet is a traditional finite-combinatorics object in BEDC form: it exports coefficient readback and Cauchy-product handoff, not host analytic convergence or equality of functions.

Definition 2404.1 (GeneratingFunction carrier)**.** *A* GeneratingFunction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, W, Q, L, Pd, M, H, C, P, N)$$

with the following displayed rows:

1. *A is the coefficient source row, indexed through* Nat$^{\uparrow}$ *and exposed only by finite* StreamName$^{\uparrow}$ *windows.*
2. *W is the coefficient-window ledger, listing the finite prefixes and requested coefficient indices visible to the packet.*
3. *Q is the coefficient readback row, turning each displayed window into a* RegSeqRat$^{\uparrow}$ *or finite combinatorial count row before any series consumer reads it.*
4. *L is the finite* List$^{\uparrow}$ *polynomial-prefix row, carrying the inspected initial polynomial truncations and their coefficient positions.*
5. *Pd is the coefficientwise classifier row for equality-facing reads of displayed prefixes.*
6. *M is the product handoff row, exposing the Cauchy convolution window used by* CauchySeriesProduct$^{\uparrow}$ *and* RealPowerSeries$^{\uparrow}$ *consumers.*
7. *H stores componentwise* hsame *transport for coefficient source, windows, readbacks, finite prefixes, classifier rows, product handoff, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from a coefficient request through the stream window, readback, polynomial prefix, classifier, and product-handoff rows.*
9. *P is the* Pkg *provenance over* GeneratingFunction$^{\uparrow}$*,* Nat$^{\uparrow}$*,* List$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* RealSeries$^{\uparrow}$*,* CauchySeriesProduct$^{\uparrow}$*,* RealPowerSeries$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{GeneratingFunction}^\uparrow}$ *row.*
The carrier contains no coordinate for a host analytic function, quotient series equality, selected convergence radius, countable-choice coefficient family, or ambient $\mathsf{Real}^\uparrow$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.GeneratingFunctionUp.GeneratingFunctionTasteGate single carrier alignment`

Theorem 2404.2 (GeneratingFunction NameCert obligations)**.** *For every accepted* $\mathsf{GeneratingFunction}^\uparrow$ *carrier* $K = (A, W, Q, L, Pd, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GeneratingFunction}^\uparrow}$ *surface consists exactly of five finite rows: carrier admission for the displayed coefficient packet; coefficient-window readback through* A, W, Q, L*; coefficientwise classifier stability through* Pd, H, C*; Cauchy and product handoff through* M*; and ledger refusal for host functions, quotient series equality, analytic convergence, selected radii, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 3356.1. The accepted packet exposes only coefficient source, finite windows, readback rows, list-polynomial prefixes, classifier data, product handoff, transport, replay, provenance, and naming rows.

The coefficient-window readback is finite. A consumer first reads a $\mathsf{Nat}^\uparrow$ index request, then uses W to select a finite $\mathsf{StreamName}^\uparrow$ window, Q to read the coefficient data, and L to place the result in the displayed polynomial prefix.

Classifier stability is componentwise. The row Pd compares displayed prefixes only after the same windows and readbacks have been transported by H and replayed by C.

The Cauchy/product handoff is the row M. It exports exactly the finite convolution window needed by product and power-series consumers, so no host function equality, quotient series equality, analytic convergence theorem, selected radius, countable-choice family, or ambient completeness row enters the certificate. □

Theorem 2404.3 (GeneratingFunction coefficient readback)**.** *Every coefficient-facing consumer of an accepted* $\mathsf{GeneratingFunction}^\uparrow$ *packet factors through*

$$\mathsf{Nat}^\uparrow,\ A \longmapsto W \longmapsto Q, L \longmapsto Pd, H, C, P, N.$$

If the consumer asks for a product coefficient, the route additionally passes through the finite convolution ledger M *before any* $\mathsf{CauchySeriesProduct}^\uparrow$ *or* $\mathsf{RealPowerSeries}^\uparrow$ *handoff is visible. Thus the public readback is a finite coefficient-window certificate, not a host function evaluation, quotient equality of formal series, analytic convergence claim, selected infinite sum, or ambient* $\mathsf{Real}^\uparrow$ *completeness route.*

Proof. Begin with a displayed coefficient request. The only available index route is the $\mathsf{Nat}^\uparrow$ row named in the provenance, and the only available coefficient source is A.

The request then opens the selected finite window W. The readback row Q supplies the coefficient data, and the list-polynomial row L places the coefficient in a finite prefix rather than in an infinite host series.

For product-facing reads, use M after the same window and readback rows. The convolution comparison is therefore a displayed finite ledger handed to $\mathsf{CauchySeriesProduct}^\uparrow$ or $\mathsf{RealPowerSeries}^\uparrow$, not an equality of analytic functions.

The remaining rows Pd, H, C, P, N preserve and name this route. Since the carrier has no coordinate for host function evaluation, quotient series equality, analytic convergence, selected infinite sums, countable choice, or ambient completeness, every coefficient read is exhausted by the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GeneratingFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{GeneratingFunction}^{\uparrow}$ packet is generated from a Nat-indexed coefficient source, finite StreamName coefficient windows, RegSeqRat or finite-count readbacks, List polynomial prefixes, a coefficientwise classifier, a Cauchy-product handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GeneratingFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3356.1, Definition 3356.2, and Definition 3356.3 seed the finite coefficient-window certificate for generating functions and their product-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GeneratingFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host analytic functions, quotient series equality, analytic convergence, selected radii, selected infinite sums, countable choice, Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-window readback, coefficientwise classifier stability, Cauchy/product handoff, and ledger refusal for BEDC.Derived.GeneratingFunctionUp.

Chapter 2405

A Concrete Naming Certificate for $\mathsf{MetricIdentification}^{\uparrow}$

Following Bourbaki and Kelley on the identification of zero-distance points in a pseudometric space, the $\mathsf{MetricIdentification}^{\uparrow}$ packet records the finite BEDC route from displayed pseudometric distance rows to a separated metric-facing classifier. It sits between the pseudometric and metric rows of chapter 57, the zero-distance classifier boundary of chapter 1411, the completion consumer of chapter 1506, and the terminal real-distance seal of chapter 38. The packet names the identification surface without forming quotient primitives, host equality classes, selected representatives, or ambient completion points.

Definition 2405.1 (MetricIdentification carrier)**.** *A* $\mathsf{MetricIdentification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (P, M, Z, S, C, T, R, H, K, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Pseudometric}^{\uparrow}$ *source row, exposing point histories, distance histories, and pseudometric comparison ledgers.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *target row whose distance reads are allowed only after the identification classifier has accepted the source comparison.*
3. *Z is the* $\mathsf{Real}^{\uparrow}$ *zero-distance row, recording the displayed real-distance seal used to compare source points at distance zero.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier handoff, requiring every equality-facing read to pass through the separated metric boundary.*
5. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer boundary, available only after P, M, Z, S have displayed the finite identification route.*
6. *T records componentwise* hsame *transport for source points, distance rows, zero-distance witnesses, separated classifier rows, completion handoff rows, provenance rows, and local naming.*
7. *R records displayed* Cont *replay from a finite pseudometric comparison request through the zero-distance row and separated classifier to the metric and completion consumers.*
8. *H records the zero-distance history ledger: every accepted comparison supplies the same* BHist *source pair, the displayed real-distance row Z, and the classifier row by which the pair becomes identified for S.*

9. *K is the* Pkg *provenance over* $\mathsf{MetricIdentification}^{\uparrow}$, $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *Q is the quotient-refusal ledger, stating that no primitive quotient object, host equality class, selected representative, or uninspected completion point is a carrier coordinate.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricIdentification}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose source pseudometric, target metric, zero-distance Real row, separated classifier handoff, completion boundary, transport, replay, zero-distance history ledger, provenance, refusal ledger, and local naming are displayed. It compares accepted packets through those rows and through no host quotient relation.

Lean4 ✓ `BEDC.Derived.MetricIdentificationUp.MetricIdentificationTasteGate single carrier alignment`

Theorem 2405.2 (MetricIdentification NameCert obligations)**.** *For every accepted* $\mathsf{MetricIdentification}^{\uparrow}$ *carrier $I = (P, M, Z, S, C, T, R, H, K, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricIdentification}^{\uparrow}}$ *surface consists exactly of carrier admission for the pseudometric source, metric target, Real zero-distance row, separated metric classifier handoff, metric-completion consumer boundary, componentwise* hsame *transport, displayed* Cont *replay, zero-distance history ledger, package provenance, quotient-refusal ledger, and local naming. Every public identification read must pass through the zero-distance history row H and the separated classifier row S before any metric or completion consumer can read it.*

Proof. Project the accepted carrier of Definition 3357.1. The displayed analytic rows are exactly P, M, Z, S, C, H, and the structural rows are exactly T, R, K, Q, N.

The zero-distance comparison is therefore not a host equality assertion. It is the row H, read over the source pseudometric row P and the Real seal Z, then transported through T and replayed through R.

The separated metric row S is the first equality-facing consumer of that history. The metric row M and completion boundary C can only consume the result after S has displayed the classifier handoff. Since Q records the absence of quotient primitives, representatives, host equality classes, and uninspected completion points, the listed rows exhaust the local NameCert obligations. □

Theorem 2405.3 (MetricIdentification completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricIdentification}^{\uparrow}$ *packet reads zero-distance identification through*

$$\mathsf{Pseudometric}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{SeparatedMetric}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{MetricCompletion}^{\uparrow}.$$

The handoff is a finite classifier route from source pseudometric distance rows to a separated metric boundary. It is not a quotient completion, not a selected representative scheme, and not host equality of carried points.

Proof. Begin with a completion-facing read. The carrier exposes the completion boundary only as the row C, so the request must first inspect the pseudometric source P, the Real zero-distance row Z, and the zero-distance history ledger H.

The separated classifier S then supplies the equality-facing boundary. Only after that boundary is displayed can the metric row M and completion boundary C be consumed by the downstream route.

The structural rows T, R, K, N preserve the same displayed packet under transport, continuation replay, provenance, and naming. The refusal row Q excludes quotient primitives and selected representatives, so the completion handoff is exactly the finite route shown above. □

Falsifiable prediction: Every accepted $\mathsf{MetricIdentification}^{\uparrow}$ completion-facing read must expose a $\mathsf{Pseudometric}^{\uparrow}$ source row, a $\mathsf{Real}^{\uparrow}$ zero-distance row, a $\mathsf{SeparatedMetric}^{\uparrow}$ classifier handoff, a $\mathsf{Met}^{\uparrow}$ target row, a $\mathsf{MetricCompletion}^{\uparrow}$ consumer boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, quotient-refusal data, and local naming.

Independence witness: pseudometric, metric, real, separatedmetric, metriccompletion: $\mathsf{MetricIdentification}^{\uparrow}$ is not bijective to any listed sibling because it binds the zero-distance Real row and separated classifier handoff before the metric and completion consumers may read an identified source comparison.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricIdentification}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricIdentification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3357.1, Definition 3357.2, and Definition 3357.3 seed the zero-distance identification route from pseudometric rows to separated metric and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricIdentification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient construction, selected representatives, host equality of points, completion existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance ledger exactness, separated classifier handoff, completion consumer nonescape, transport and replay stability, provenance exhaustion, quotient-refusal faithfulness, and TasteGate field faithfulness for BEDC.Derived.MetricIdentificationUp.

Constructive story: A $\mathsf{MetricIdentification}^{\uparrow}$ packet is generated from a Pseudometric source row, a Metric target row, a Real zero-distance row, a SeparatedMetric classifier handoff, a MetricCompletion consumer boundary, componentwise hsame transport, displayed Cont replay, zero-distance history ledgers, Pkg provenance, quotient-refusal data, and a local NameCert row.

Chapter 2406

A Concrete Naming Certificate for EquicontinuityFiniteNetSelector$^{\uparrow}$

Following the Arzela–Ascoli finite-net reading in Bishop constructive analysis, the EquicontinuityFiniteNetSelector$^{\uparrow}$ packet records the finite selector surface that turns an equicontinuous family over a compact metric carrier into a displayed net-indexed modulus handoff. It sits over the family ledger of chapter 413, the compact source of chapter 129, the pointwise graph rows of chapter 130, the finite net surface of chapter 1767, and the uniform-modulus consumer of chapter 369. The packet selects from finite displayed rows only; it is not an open-cover compactness principle, not a host function-space topology, not a choice operator, and not a selector over external points.

Definition 2406.1 (Equicontinuity finite-net selector carrier)**.** *An* EquicontinuityFiniteNetSelector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, K, G, N, R, L, U, H, C, P, A)$$

with the following displayed rows:

1. *F is the* EquicontinuityFamily$^{\uparrow}$ *source row, exposing the shared family ledger and its pointwise tolerance-radius data.*
2. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing compact finite-net and located coverage data for the same source metric.*
3. *G is the* ContinuousMap$^{\uparrow}$ *graph row family whose pointwise modulus rows are inspected by the selector.*
4. *N is the* FiniteEpsilonNet$^{\uparrow}$ *row, carrying the displayed* ProbeBundle *of centers and the finite coverage ledger for the requested tolerance scale.*
5. *R is the positive rational radius ledger attached to the selected centers and family members.*
6. *L is the finite lower-bound row that compares the selected radii and exports the precision candidate to the modulus consumer.*
7. *U is the* UniformModulus$^{\uparrow}$ *handoff row, available only after F, K, G, N, R, L have displayed the finite selector route.*
8. *H records componentwise* hsame *transport for the family, compact metric, continuous-map, finite-net, radius, lower-bound, uniform-modulus, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact finite-net request through the family modulus rows and the lower-bound selector to the uniform-modulus consumer.*

10. *P is the* Pkg *provenance over* $\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *A is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose family, compact metric, continuous graph, finite net, radius ledger, lower-bound row, uniform-modulus handoff, transport, replay, provenance, and local naming are displayed in these coordinates. It has no coordinate for a host open cover, a global choice function, a function-space topology, an external finite subset, or a selected point outside the ProbeBundle *row.*

Lean4 ✓ `BEDC.Derived.EquicontinuityFiniteNetSelectorUp.EquicontinuityFiniteNetSelectorTasteGate`
`single carrier alignment`

Theorem 2406.2 (Equicontinuity finite-net selector NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}$ *carrier* $E = (F, K, G, N, R, L, U, H, C, P, A)$*, the local* $\mathsf{NameCert}_{\mathsf{EquicontinuityFiniteNetS}}$ *surface consists exactly of carrier admission for the equicontinuity-family row, compact metric row, continuous-map graph family, finite epsilon-net row, radius ledger, finite lower-bound row, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The selector is valid only when the finite-net centers and the family modulus rows share the same compact source metric before the uniform-modulus row is consumed.*

Proof. Project the accepted carrier of Definition 3358.1. The displayed source rows are F, K, G, N, the selector rows are R, L, U, and the structural rows are H, C, P, A.

The finite centers are read only from N. The family modulus information is read only from F and G, with K supplying the compact metric source used by the coverage ledger.

The lower-bound row L then compares the displayed radius rows R and exports a precision candidate to U. Transport through H and replay through C preserve the same row alignment, while P and A record provenance and local naming. No remaining coordinate can supply a host cover, a choice function, a function-space topology, or an external finite subset. □

Theorem 2406.3 (Equicontinuity finite-net selector uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}$ *packet reads the selector through*

$$\mathsf{EquicontinuityFamily}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{ContinuousMap}^{\uparrow},\quad \mathsf{FiniteEpsilonNet}^{\uparrow},\quad \mathsf{UniformModulus}^{\uparrow}.$$

The exported precision is the finite lower-bound row over the displayed net centers and family radius ledger; it is not an externally chosen modulus and not an open-cover compactness theorem.

Proof. Start with the uniform-modulus request. The carrier exposes the consumer boundary only as U, so the request must first inspect the equicontinuity family F, the compact metric source K, the continuous graph family G, and the finite epsilon-net row N.

The radius ledger R is then read at the displayed net centers and family members. The lower-bound selector L is a finite row over those displayed radii, so the precision candidate handed to U remains inside the packet.

The transport, replay, provenance, and naming rows H, C, P, A preserve this finite route. Thus every consumer sees the selector as a compact finite-net and equicontinuity-family handoff, not as a host-level selector. □

Falsifiable prediction: Every accepted EquicontinuityFiniteNetSelector$^{\uparrow}$ uniform-modulus read must expose an EquicontinuityFamily$^{\uparrow}$ source row, a CompactMetric$^{\uparrow}$ compact source row, ContinuousMap$^{\uparrow}$ graph rows, a FiniteEpsilonNet$^{\uparrow}$ ProbeBundle coverage row, finite radius and lower-bound rows, a UniformModulus$^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: equicontinuityfamily, compactmetric, continuousmap, finite-epsilon-net, uniformmodulus: EquicontinuityFiniteNetSelector$^{\uparrow}$ is not bijective to any listed sibling because it binds the family modulus rows to a compact finite-net lower-bound selector before a UniformModulus consumer can read a tolerance-only precision row.

Closure status for NameCert$_{\text{EquicontinuityFiniteNetSelector}^{\uparrow}}$ **.**

Theory closure: TheoryGate(NameCert$_{\text{EquicontinuityFiniteNetSelector}^{\uparrow}}$, seed)

Scope closed: Definition 3358.1, Definition 3358.2, and Definition 3358.3 seed the finite selector route from equicontinuity-family and compact-net rows to a uniform-modulus consumer.

Formal verification: FormalStatus(NameCert$_{\text{EquicontinuityFiniteNetSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Arzela–Ascoli compactness, function-space topology, host finite subsets, choice of representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source lock, finite-net center visibility, family radius exactness, lower-bound selector stability, uniform-modulus handoff, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.EquicontinuityFiniteNetSelectorUp.

Constructive story: An EquicontinuityFiniteNetSelector$^{\uparrow}$ packet is generated from an EquicontinuityFamily source row, a CompactMetric source row, ContinuousMap graph rows, a FiniteEpsilonNet ProbeBundle row, finite radius and lower-bound rows, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2407

A Concrete Naming Certificate for $\mathsf{RealBolzano}^{\uparrow}$

Following Bolzano and Bishop–Bridges constructive analysis, the $\mathsf{RealBolzano}^{\uparrow}$ packet records sign-change bracketing as finite Real-and-Completion route data. It sits over the real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the interval comparison surfaces of chapter 1591, chapter 411, and chapter 1786. The packet supplies a displayed bracket for later intermediate-value and root-isolation consumers without importing real trichotomy, unrestricted intermediate value, quotient real equality, selected roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2407.1 (RealBolzano carrier)**.** *A* $\mathsf{RealBolzano}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (a, b, L, U, S, D, J, R, E, H, C, P, N)$$

with the following displayed rows:

1. *a and b are endpoint real-name rows, each read through the* $\mathsf{Real}^{\uparrow}$ *seal route and exposed only as finite regular windows.*
2. *L and U are the left and right located sign witnesses, recording displayed apartness-from-zero evidence at the inspected endpoint windows.*
3. *S is the sign-change ledger, requiring the two endpoint sign witnesses to be opposed at the requested dyadic precision.*
4. *D is the dyadic bracket ledger, storing the interval endpoints, midpoint requests, tolerance radii, and width comparisons used by the finite bisection route.*
5. *J is the comparison row, carrying the ordered interval and nonescape checks that keep every retained bracket inside the displayed endpoint interval.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row assembled from the retained bracket windows and dyadic tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the endpoint rows, located sign witnesses, bracket ledger, comparison row, and regular handoff have been displayed.*
8. *H records componentwise* hsame *transport for the endpoint, sign, bracket, comparison, regular handoff, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite sign-change request through $a, b, L, U, S, D, J, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealBolzano}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *the closed bounded interval route, the regular Cauchy comparison route,* $\mathsf{RealRootBracket}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealBolzano}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $a, b, L, U, S, D, J, R, E, H, C, P, N$. It has no coordinate for real trichotomy, unrestricted intermediate value, a selected zero, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2407.2 (RealBolzano NameCert obligations)**.** *For every accepted* $\mathsf{RealBolzano}^{\uparrow}$ *carrier*

$$B = (a, b, L, U, S, D, J, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealBolzano}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for endpoint real rows, located sign witnesses, dyadic bracket ledger, comparison row, regular handoff, real seal boundary, transport, replay, provenance, and local naming;*
2. *endpoint sign exposure, requiring L and U to be read after the endpoint real-name rows a, b and to expose only located apartness data at displayed precision;*
3. *bracket-refinement stability, requiring each retained interval in D to preserve the displayed sign-change ledger S and to decrease the bracket width by dyadic comparison;*
4. *comparison nonescape, requiring J to keep every retained bracket inside the original displayed closed bounded interval;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff routing, requiring R to be assembled from the retained bracket windows and dyadic tolerance ledger rather than from a selected root;*
6. $\mathsf{Real}^{\uparrow}$ *seal routing, requiring E to remain downstream of a, b, L, U, S, D, J, R;*
7. *componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N for the same rows;*
8. *refusal of real trichotomy, unrestricted intermediate value, selected roots, quotient real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as certificate data.*

No RealBolzano obligation is stored outside these rows.

Proof. Project the carrier of Definition 3359.1. The endpoint rows a, b are the only real-name sources, and the located sign rows L, U expose sign information only at displayed precision.

The bracket route is finite. The ledger S records the sign-change request, while D stores the dyadic interval, midpoint, tolerance, and width-comparison data used by each retained bracket. The comparison row J keeps each retained interval inside the original closed bounded interval.

The completion-facing rows are downstream of that bracket route. The row R assembles the regular rational handoff from the retained bracket windows, and the seal E is read only after a, b, L, U, S, D, J, R have been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet rows. Since no excluded order, selection, quotient, or completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RealBolzanoUp.RealBolzanoTasteGate single carrier alignment`

Theorem 2407.3 (RealBolzano bracket seal route)**.** *Every accepted* $\mathsf{RealBolzano}^{\uparrow}$ *sign-change read passes through endpoint real rows, located sign witnesses, the sign-change ledger, dyadic bracket ledger, comparison row, regular handoff, and terminal Real seal along the finite route*

$$a, b, L, U, S, D, J, R, E, H, C, P, N.$$

The route records bracket-to-seal data for later root-bracketing consumers, but it does not provide unrestricted intermediate value, a selected root, real trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3359.1. The endpoint rows a, b are the only real sources, and the located sign witnesses L, U are read from those endpoint windows at displayed precision.

Use Definition 3359.2. Its obligation rows place the sign-change ledger S before the dyadic bracket ledger D, keep each retained bracket inside the displayed interval through J, and assemble the regular handoff R from retained bracket windows rather than from a selected root.

The same obligation surface requires the Real seal E to remain downstream of a, b, L, U, S, D, J, R, with H, C, P, N transporting and naming only that finite packet. Since no excluded endpoint principle occurs in the carrier, the bracket-to-seal route exports only displayed sign-change and bracketing data. □

Theorem 2407.4 (RealBolzano bracket-refinement stability)**.** *Let*

$$B = (a, b, L, U, S, D, J, R, E, H, C, P, N)$$

be an accepted $\mathsf{RealBolzano}^{\uparrow}$ *carrier. Replacing one retained dyadic bracket row in* D *by a displayed midpoint refinement that preserves the opposed located sign witnesses and passes the comparison row* J *yields another accepted* $\mathsf{RealBolzano}^{\uparrow}$ *packet with the same downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal route.*

Proof. Project the carrier of Definition 3359.1. The changed coordinate is a single retained bracket row inside D; the endpoint rows a, b, the located sign witnesses L, U, the sign-change ledger S, and the comparison row J remain displayed packet data.

Use Definition 3359.2. Its dependency order keeps S before D and J before R, so the midpoint replacement is admitted only when the opposed located sign witnesses are still present and the refined bracket still passes the displayed comparison row.

Transport the changed bracket row componentwise through H and replay the same finite request through C. The provenance row P and local naming row N continue to name the packet with the refined bracket ledger.

Finally apply Definition 3359.3. The regular handoff R is still assembled from the retained bracket windows, and the terminal Real seal E remains downstream of a, b, L, U, S, D, J, R. No selected root, real trichotomy, quotient equality, unrestricted intermediate value, or ambient completeness coordinate is introduced by the refinement. □

Theorem 2407.5 (RealBolzano regular-Cauchy bracket readback)**.** *Every accepted* $\mathsf{RealBolzano}^{\uparrow}$ *bracket-refinement read reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *only through the endpoint* $\mathsf{Real}^{\uparrow}$ *rows, located sign witnesses, the sign-change ledger, dyadic bracket ledger, comparison nonescape row, and displayed bracket windows. The terminal* $\mathsf{Real}^{\uparrow}$ *seal remains downstream of that regular-Cauchy readback, and the packet exports no unrestricted intermediate value theorem, selected root, trichotomy, quotient equality, or ambient Real completeness.*

Proof. Start with the NameCert obligations of Definition 3359.2. They force endpoint sign exposure through a, b, L, U, record the sign-change ledger in S, and keep every retained bracket inside the displayed interval through the comparison row J.

Apply the bracket seal route of Definition 3359.3. It orders every sign-change read through $a, b, L, U, S, D, J, R, E, H, C, P, N$, so the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R is assembled before the terminal Real seal E can be consumed.

Now use bracket-refinement stability from Definition 3359.4. Replacing a retained bracket row changes only the displayed dyadic bracket data inside D while preserving the same sign witnesses, comparison nonescape row, regular handoff, and downstream seal route.

Thus the regular-Cauchy bracket readback reaches $\mathsf{RegSeqRat}^{\uparrow}$ through the finite endpoint, sign, ledger, comparison, and window rows, with E, H, C, P, N only sealing, transporting, replaying, sourcing, and naming the route. None of the excluded host principles occurs as a carrier coordinate. □

Theorem 2407.6 (RealBolzano sign-change bisection)**.** *Let*

$$B = (a, b, L, U, S, D, J, R, E, H, C, P, N)$$

be an accepted $\mathsf{RealBolzano}^{\uparrow}$ *carrier. Any displayed midpoint refinement that keeps one opposed located sign pair and satisfies the comparison row J yields a retained bracket row whose* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff remains assembled from D and whose* $\mathsf{Real}^{\uparrow}$ *seal remains downstream of R. The bisection step does not export unrestricted intermediate value, a selected root, trichotomy, quotient real equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 3359.1. The midpoint refinement changes only the retained bracket data inside D, while the endpoint rows, located sign witnesses, sign-change ledger, comparison row, regular handoff, and Real seal remain displayed coordinates of the same packet.

Apply Definition 3359.2. The obligations admit the refined bracket only when one opposed located sign pair is still displayed and the comparison row J keeps the retained interval inside the original bracket surface.

Use Definition 3359.4. It transports the refined bracket through H, C, P, N and preserves the downstream handoff and seal route. Then apply Definition 3359.5: the $\mathsf{RegSeqRat}^{\uparrow}$ row R is still assembled from the dyadic bracket ledger D, and the terminal $\mathsf{Real}^{\uparrow}$ seal E remains downstream of R.

Since the carrier has no unrestricted intermediate-value row, selected-root coordinate, trichotomy principle, quotient real equality, or ambient completeness theorem, the theorem records only the constructive finite bisection step visible to later root-bracketing consumers. □

Theorem 2407.7 (RealBolzano located-bracket nonescape)**.** *Every located sign-change bracket exported by an accepted* $\mathsf{RealBolzano}^{\uparrow}$ *carrier*

$$B = (a, b, L, U, S, D, J, R, E, H, C, P, N)$$

remains inside the endpoint rows a, b, located sign witnesses L, U, sign-change ledger S, dyadic bracket ledger D, comparison row J, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N. The packet exports no unrestricted intermediate value theorem, selected root, trichotomy, quotient real equality, or ambient Real completeness.*

Proof. Use the NameCert obligations of Definition 3359.2. Endpoint sign exposure must pass through a, b, L, U, and comparison nonescape is recorded by the row J for every retained dyadic bracket in D.

Apply the bracket seal route of Definition 3359.3. It orders every sign-change read through $a, b, L, U, S, D, J, R, E, H, C, P, N$, so the regular readback and terminal Real seal remain downstream of the located bracket data.

Now use the sign-change bisection theorem Definition 3359.6. A retained midpoint bracket may be exported only when it preserves an opposed located sign pair and satisfies the comparison row J.

Thus each exported located bracket stays inside the displayed endpoint, sign, ledger, comparison, readback, seal, and structural rows. Since the carrier has no unrestricted intermediate-value, selected-root, trichotomy, quotient-equality, or ambient-completeness coordinate, none is exported. □

Falsifiable prediction: Every accepted $\mathsf{RealBolzano}^{\uparrow}$ read factors through two endpoint Real rows, two located sign witnesses, one sign-change ledger, one dyadic bracket ledger, one comparison row, one RegSeqRat handoff, one terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any intermediate-value or root-bracketing consumer may inspect it.

Independence witness: real, regseqrat, dyadicratcore, closedboundedinterval, regular-cauchy-comparison, real-root-bracket: $\mathsf{RealBolzano}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint real rows, located sign witnesses, a sign-change ledger, dyadic bracket refinement, comparison nonescape, regular handoff, real seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealBolzano}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealBolzano}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3359.1 and Definition 3359.2 seed the constructive sign-change bracketing packet over endpoint Real rows, located sign witnesses, dyadic bracket ledgers, comparison nonescape, RegSeqRat handoff, Real seal routing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealBolzano}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim real trichotomy, unrestricted intermediate value, selected roots, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint sign exposure, bracket-refinement stability, comparison nonescape, RegSeqRat handoff routing, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RealBolzanoUp.

Constructive story: A $\mathsf{RealBolzano}^{\uparrow}$ packet is generated from endpoint Real rows, located sign witnesses, a sign-change ledger, dyadic bracket refinement, comparison rows, a RegSeqRat handoff, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2408

A Concrete Naming Certificate for $\mathsf{CofinalFilterBase}^{\uparrow}$

Following Kelley and Bourbaki on cofinal filter bases, the $\mathsf{CofinalFilterBase}^{\uparrow}$ packet records the finite comparison interface by which one displayed filter base may replace another in Cauchy and completion consumers. It sits between the displayed base surface of chapter 1601, the Cauchy-filter route of chapter 333, the uniform completion route of chapter 1473, the metric completion route of chapter 1506, and the Cauchy-filter completion route of chapter 1569. The packet names cofinal replacement without quotient filters, selected representatives, selected limits, ultrafilters, Zorn arguments, or ambient completeness.

Definition 2408.1 (CofinalFilterBase carrier)**.** *A* $\mathsf{CofinalFilterBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, T, \rho, R, F, U, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{FilterBase}^{\uparrow}$ *row whose displayed packets may be used after replacement.*
2. *T is the target* $\mathsf{FilterBase}^{\uparrow}$ *row whose requests are issued by a downstream consumer.*
3. *ρ is the cofinal map row. For every target request it names a source base packet lying inside the requested target packet.*
4. *R is the containment and refinement witness ledger, recording the source-to-target containment reads, common-refinement reads, and replay edges used by ρ.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row, recording that the Cauchy-filter consumer reads the same cofinal replacement route.*
6. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer row, exposing the entourage-facing completion route after cofinal replacement.*
7. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row, exposing the metric-completion route after cofinal replacement.*
8. *H records componentwise* hsame *transport for $S, T, \rho, R, F, U, M, C, P, N$.*
9. *C records displayed* Cont *replay from a target base request through ρ, through the source base packet, and through the refinement ledger exposed to downstream consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{CofinalFilterBase}^{\uparrow}$*, the five sibling chapters named above,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalFilterBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient filters, ultrafilters, Zorn arguments, selected representatives, selected limits, countable choice, host filter equality, or ambient completion.

Lean4 ✓ `BEDC.Derived.CofinalFilterBaseUp.CofinalFilterBaseTasteGate single carrier alignment`

Theorem 2408.2 (CofinalFilterBase NameCert obligations)**.** *For every accepted* $\mathsf{CofinalFilterBase}^{\uparrow}$ *carrier* $B = (S, T, \rho, R, F, U, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalFilterBase}^{\uparrow}}$ *surface consists exactly of carrier admission for the source and target* $\mathsf{FilterBase}^{\uparrow}$ *rows, cofinal map row, containment and refinement ledger, CauchyFilter handoff, UniformCompletion consumer row, MetricCompletion consumer row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted target request must be witnessed by a displayed source packet through* ρ *and* R *before any Cauchy or completion consumer can read the replacement.*

Proof. Project the carrier of Definition 3360.1. The rows S and T expose the two displayed filter bases, while ρ and R store the only containment and refinement data connecting them.

The consumer rows are downstream of that comparison. The CauchyFilter row F, UniformCompletion row U, and MetricCompletion row M may read the replacement only after the target request has been replayed through ρ and the ledger R.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since quotient filters, ultrafilters, Zorn arguments, selected representatives, selected limits, countable choice, host filter equality, and ambient completion are absent from the carrier, no additional NameCert obligation is available. □

Theorem 2408.3 (CofinalFilterBase CauchyFilter handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer of an accepted* $\mathsf{CofinalFilterBase}^{\uparrow}$ *packet factors through*

$$T \longmapsto \rho \longmapsto S \longmapsto R \longmapsto F, H, C, P, N.$$

Thus a Cauchy-filter request against the target base is answered by a displayed source base packet and its containment ledger before the Cauchy row is read. The handoff supplies no quotient filter, ultrafilter, selected representative, selected limit, or choice schedule.

Proof. Begin with a Cauchy-filter consumer. The request is a target-base read through T, so the carrier forces the request to pass first through the cofinal map row ρ.

Apply Definition 3360.2. The row ρ names a source packet in S, and R records the containment and common-refinement reads that justify the replacement.

The handoff row F is read only after those rows. Transport by H and replay by C preserve the same displayed route, while P and N expose the packet as finite provenance and local naming. No excluded quotient, ultrafilter, selected representative, selected limit, or choice coordinate remains. □

Theorem 2408.4 (CofinalFilterBase completion nonescape)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer citing an accepted* $\mathsf{CofinalFilterBase}^{\uparrow}$ *packet receives only the displayed cofinal replacement route from target requests to source base packets. The completion-facing read is exhausted by* $S, T, \rho, R, F, U, M, H, C, P, N$ *and cannot escape to quotient filters, selected limits, host filter equality, ultrafilters, Zorn arguments, countable choice, or ambient completeness.*

Proof. Start from a completion-facing request. By Definition 3360.1, the only completion rows are U and M, and the Cauchy-filter completion consumer must pass through the same Cauchy handoff row F.

Apply Definition 3360.3. The target request is first replayed through ρ into the source base row S, then through the containment and refinement ledger R.

The sibling completion chapters named in the opening paragraph therefore receive a displayed cofinal-base route, not a detached completion principle. The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming, so no quotient, selected limit, host equality, ultrafilter, Zorn argument, choice schedule, or ambient completeness object is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalFilterBase}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalFilterBase}^{\uparrow}$ packet is generated from source and target FilterBase rows, a cofinal map from target requests to source base packets, containment and refinement witnesses, CauchyFilter handoff, UniformCompletion and MetricCompletion consumer rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalFilterBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3360.1, Definition 3360.2, Definition 3360.3, and Definition 3360.4 seed the cofinal-base replacement interface between FilterBase, CauchyFilter, and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalFilterBase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, host filter equality, ultrafilters, Zorn arguments, countable choice, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, cofinal map exactness, containment replay, CauchyFilter handoff, UniformCompletion and MetricCompletion consumer nonescape, and ledger-refusal proofs for BEDC.Derived.CofinalFilterBaseUp.

Chapter 2409

A Concrete Naming Certificate for $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$

Following Bishop and Bridges and the constructive bounded-variation treatment, the $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ packet records absolute continuity on a displayed real interval as finite partition control, variation budget, derivative/integral ledger, and real-name handoff data rather than as a host function quotient or a measure-completed derivative theorem. It sits after the regulated-function carrier of chapter 1906, the bounded-variation ledger of chapter 398, the integral surface of chapter 123, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The function-level carrier consumes the epsilon-delta finite partition surface of chapter 6066 before derivative, integral, bounded-variation, or Real-seal ledgers are read. The packet gives Real and Completion consumers a finite route for interval variation requests before any ambient measure algebra, selected derivative, host function equality, or completed L^1 object is available.

Definition 2409.1 (AbsoluteContinuousFunction carrier)**.** *An* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, F, M, P, V, D, L, T, W, Q, R, H, C, S, N)$$

with the following displayed rows:

1. *I is the source interval row, exposing the endpoint real-name windows, orientation data, and compact subinterval request on which the function is inspected.*
2. *F is the displayed real-valued function row, read only through finite input windows and output* $\mathsf{Real}^{\uparrow}$ *seals.*
3. *M is the modulus row assigning, for each dyadic error budget, a finite interval-length budget used by the absolute-continuity test.*
4. *P is the finite disjoint-partition ledger. It lists the inspected interval family, total displayed length, endpoint windows, and the corresponding value-jump windows.*
5. *V is the* $\mathsf{BoundedVariation}^{\uparrow}$ *budget row asserting that the finite sum of visible jumps along P is controlled by the error budget selected by M.*
6. *D is the derivative ledger row. It records only displayed derivative-window requests and their local variation accounting.*

7. *L is the* $\mathsf{Integral}^{\uparrow}$ *handoff row for the interval derivative or variation-density request consumed by integration-facing clients.*
8. *T is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *approximation row used to expose stepwise endpoint behavior before the gauge row is read.*
9. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting the interval, partition, derivative, integral, regulated approximation, and seal observations consumed by the packet.*
10. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for interval lengths, output jumps, regulated approximants, and integral estimates.*
11. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by downstream Real and Completion consumers after the partition, regulated, gauge, regular, and dyadic rows have been displayed.*
12. *H stores componentwise* hsame *transport for interval, function, modulus, partition, variation, derivative, integral, regulated, stream, regular readback, Real seal, replay, provenance, and local naming rows.*
13. *C stores displayed* Cont *replay from an absolute-continuity request through the same finite rows.*
14. *S is the* Pkg *provenance over* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{AbsolutelyContinuousFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host function equality, quotient real functions, measure completion, a selected derivative, countable additivity, ambient variation space completion, or a completed L^1 representative.

```
Lean4✓  BEDC.Derived.AbsolutelyContinuousFunctionUp.AbsolutelyContinuousFunctionTasteGate
single carrier alignment
```

Theorem 2409.2 (AbsoluteContinuousFunction NameCert obligations)**.** *For every accepted* AbsolutelyContinuousF *carrier $A = (I, F, M, P, V, D, L, T, W, Q, R, H, C, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbsolutelyContinuousFunction}^{\uparrow}}$ *surface consists exactly of carrier admission; partition-refinement stability through P and W; variation-budget exactness through V; derivative/integral ledger handoff through D, L; regulated approximation through T; StreamName and RegSeqRat readback through W, Q; Real seal nonescape through R; componentwise transport, displayed replay, provenance, and local naming through H, C, S, N.*

Proof. Project the accepted carrier of Definition 3361.1. The visible rows are exactly $I, F, M, P, V, D, L, T, W, Q, R,$ so every local naming obligation must be read from one of those rows.

The source and control obligations are I, F, M, P, V. The interval and function rows determine the inspected endpoint windows, while the modulus row chooses the finite length budget. The partition and variation ledgers then record the only admissible test that small total displayed length forces small total displayed jump.

The analytic handoff obligations are D, L, T, W, Q, R. The derivative ledger records the local window request, the integral row carries the integration-facing handoff, the regulated row exposes stepwise endpoint behavior, and the stream and regular rows provide the finite numerical readbacks before the terminal Real seal is visible.

Finally H, C, S, N transport, replay, source, and name the same packet. Since no carrier coordinate stores host function equality, quotient real functions, measure completion, a selected derivative, countable additivity, ambient variation space completion, or a completed L^1 representative, none of those objects can appear in the local NameCert surface. □

Theorem 2409.3 (AbsoluteContinuousFunction bounded-variation handoff)**.** *Every bounded-variation or fundamental-theorem consumer reads an accepted* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *packet only through the displayed* $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route*

$$I, F, M \longmapsto P, V \longmapsto D, L, T \longmapsto W, Q \longmapsto R, H, C, S, N.$$

Thus a consumer reaches the $\mathsf{Integral}^{\uparrow}$ *row only after the absolute-continuity partition budget and* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger have been displayed, and reaches the* $\mathsf{Real}^{\uparrow}$ *seal only after regulated approximation, StreamName windows, and regular rational readback have also been displayed.*

Proof. Start with the interval, function, and modulus rows. They fix the displayed real interval, the finite function windows, and the dyadic budget used by the absolute-continuity request.

The partition route is next. The row P lists the inspected disjoint intervals and their total displayed length, and V records the corresponding finite jump bound. No gauge-facing read is available before these rows have been consumed.

Only then does the route reach the derivative, integral, and regulated rows. The derivative ledger D records the local request, the $\mathsf{Integral}^{\uparrow}$ row L receives the integration-facing handoff, and the $\mathsf{RegulatedFunction}^{\uparrow}$ row T supplies the stepwise approximation boundary.

The sibling dependency is exact: the bounded-variation row is read through chapter 398, the regulated approximation through chapter 1906, the integral handoff through chapter 123, and the terminal numerical route through chapter 126, chapter 301, and chapter 38.

The terminal read is numerical and sealed. Rows W and Q provide finite observation windows and regular rational comparisons for the displayed estimates, while R, H, C, S, N seal, transport, replay, source, and name the packet. Hence the exported handoff is finite BEDC route data, not a host derivative theorem, measure-completed integral, quotient function equality, or selected L^1 representative. □

Theorem 2409.4 (AbsoluteContinuousFunction partition-modulus stability)**.** *Let* $A = (I, F, M, P, V, D, L, T, W, Q$ *and* $A' = (I', F', M, P', V', D', L', T', W', Q', R', H', C', S', N')$ *be accepted* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *packets sharing the same modulus row* M*. If their partition ledgers* P *and* P' *are related componentwise by* hsame *through the transport row* H*, then the variation-budget row* V *exports the same absolute-continuity jump bound before any derivative row, integral handoff, or Real seal is read.*

Proof. Project the two accepted carriers through Definition 3361.1. The shared row M fixes the dyadic length budget used by both absolute-continuity requests, while P and P' list the corresponding displayed disjoint interval families.

Use the componentwise hsame data in H to compare the partition ledgers. Since the comparison is rowwise over the displayed endpoint windows and total-length entries, the same partition budget is presented to the variation row on both sides.

Now read the variation-budget obligation from Definition 3361.2. The row V is upstream of D, L, T, W, Q, R, so the equality of jump bounds is obtained before derivative requests, integral handoffs, regulated approximations, numerical readbacks, or Real seals can contribute extra data. □

Theorem 2409.5 (AbsoluteContinuousFunction Real and Completion consumer boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *packet factors through the displayed rows*

$$M \longmapsto P \longmapsto V \longmapsto T \longmapsto W \longmapsto Q \longmapsto R$$

in that order before it exports an endpoint, variation, or integral-facing real read. Such a consumer cannot replace the route by host function equality, quotient real functions, measure completion, selected derivatives, countable additivity, or ambient L^1 completion.

Proof. Begin with the control rows. The modulus row M chooses the finite length budget, the partition ledger P displays the inspected intervals, and the variation row V records the corresponding finite jump bound.

Next compose with the bounded-variation handoff of Definition 3361.3. It places the regulated approximation row T before the StreamName and RegSeqRat reads, so a Real or Completion consumer must pass through the displayed approximation boundary before any terminal numerical seal is available.

Finally read W, Q, R. The finite observation windows, regular rational comparisons, and Real seal are the only consumer-facing numerical route, and the carrier has no coordinate for host function equality, quotient real functions, measure completion, selected derivatives, countable additivity, or ambient L^1 completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbsolutelyContinuousFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbsolutelyContinuousFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3361.1, Definition 3361.2, and Definition 3361.3 seed the finite absolute-continuity route over interval, function, modulus, partition, bounded-variation, derivative, integral, regulated, StreamName, regular, Real seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbsolutelyContinuousFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient real functions, measure completion, selected derivatives, countable additivity, ambient variation space completion, completed L^1 representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition coverage, variation-budget exactness, derivative and integral handoff, regulated approximation, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.AbsoluteContinuousFunctionUp.

Constructive story: An $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ packet is generated from an interval row, displayed real-valued function row, modulus budget, disjoint-partition ledger, bounded-variation budget, derivative ledger, Integral handoff, RegulatedFunction approximation, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2410

A Concrete Naming Certificate for $\mathsf{EberleinSmulian}^{\uparrow}$

Following Eberlein and Smulian, the $\mathsf{EberleinSmulian}^{\uparrow}$ packet records the weak-compactness-to-sequential-window route as finite NameCert data. It sits beside the sequential compactness carrier of chapter 2372, the compact metric surface of chapter 129, the metric row of chapter 57, and the Cauchy sequence space boundary of chapter 406. The packet is a traditional functional-analysis reconstruction in the BEDC carrier language: it stores finite weak-test ledgers, subsequence-selection rows, compactness handoffs, and terminal naming evidence without asserting unrestricted weak compactness, countable choice, Banach-space dual completeness, or host-level subsequence selection.

Definition 2410.1 (Eberlein–Smulian finite weak-window carrier)**.** *An* $\mathsf{EberleinSmulian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, H, K, M, Q, W, U, L, E, T, C, P, N)$$

with the following displayed rows:

1. *F is the functional-analysis source row naming the bounded linear-test context and the finite weak-test family inspected by the packet.*
2. *H is the Hilbert or Banach-facing source row that supplies the normed carrier, bounded sequence cells, and finite comparison windows.*
3. *K is the compactness handoff row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{SequentialCompact}^{\uparrow}$ *sibling surfaces when a finite compact window is displayed.*
4. *M is the metric row used to compare finite windows and to route Cauchy-style estimates through the sibling metric certificate.*
5. *Q is the Cauchy sequence equivalence boundary: two displayed subsequence windows are compared only through finite regular-window reads and not through quotient sequence equality.*
6. *W is the weak-test ledger listing the finitely many linear tests, tolerances, and observation windows requested by the consumer.*
7. *U is the subsequence-selection row recording the displayed indices retained at each finite weak-test window.*
8. *L is the compactness handoff ledger that repacks the retained subsequence windows as a compact or sequentially compact local packet.*

9. *E is the terminal weak-cluster or convergence seal offered to downstream consumers after the ledgers have been read.*
10. *T stores componentwise* hsame *transports for $F, H, K, M, Q, W, U, L, E$.*
11. *C stores the displayed* Cont *replay routes from weak tests to retained subsequence windows and from compactness handoff to the terminal seal.*
12. *P is the* Pkg *provenance over the source rows, weak-test ledger, subsequence rows, compactness handoff, transport, replay, and local naming.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{EberleinSmulian}^{\uparrow}}$ *row.*

The classifier compares two accepted packets only through these rows. It has no coordinate for a global weak topology, an unrestricted functional separator, a choice function selecting subsequences from arbitrary sequences, a quotient of sequence tails, or an ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.EberleinSmulianUp.EberleinSmulianTasteGate single carrier alignment`

Theorem 2410.2 (Eberlein–Smulian seed obligations)**.** *For every accepted* $\mathsf{EberleinSmulian}^{\uparrow}$ *carrier $S = (F, H, K, M, Q, W, U, L, E, T, C, P, N)$, the local NameCert surface consists of:*

1. *carrier admission for the finite weak-window packet of Definition 3362.1;*
2. *weak-test exposure through the finite ledger W over the displayed source rows F and H;*
3. *subsequence-window exposure through U, with retained indices visible before any cluster or convergence seal is exported;*
4. *compactness handoff through K and L, routed through the sibling compact and sequential compactness certificates rather than through open-cover compactness;*
5. *metric and Cauchy-window comparison through M and Q before any equality or convergence read is consumed;*
6. *componentwise transport, replay, provenance, and local naming through T, C, P, N.*

These obligations do not include Banach-space weak compactness in full generality, unrestricted linear-functional choice, countable choice, quotient sequence equality, or ambient completeness.

Proof. Project the carrier rows of Definition 3362.1. The rows $F, H, K, M, Q, W, U, L, E, T, C, P, N$ are the only data visible to the local classifier.

The weak-test side is finite. The ledger W lists the requested tests and tolerances, and the source rows F, H bind those tests to the displayed normed or Hilbert-facing carrier before a subsequence row is read.

The subsequence side is also finite. The row U records the retained indices for the inspected windows, while M and Q keep metric comparison and Cauchy-window comparison inside displayed rows.

The compactness handoff is downstream from those ledgers. The rows K and L repack the retained windows through the compact metric and sequential compactness sibling surfaces, and E is exposed only after T, C, P, N transport, replay, source, and name the same packet. Since the excluded principles are absent from the carrier, they cannot discharge a local NameCert obligation. □

Theorem 2410.3 (Eberlein–Smulian nonescape boundary)**.** *Every consumer of an accepted* $\mathsf{EberleinSmulian}^{\uparrow}$ *packet factors through the finite route*

$$W \longmapsto U \longmapsto (K, L) \longmapsto (M, Q) \longmapsto E$$

with componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{EberleinSmulian}^{\uparrow}}$ *evidence. Thus a weak-cluster or sequential-compactness read cannot bypass the weak-test ledger, the retained subsequence windows, the compactness handoff, or the metric and Cauchy-window comparison rows.*

The boundary exports no unrestricted weak topology, no selected subsequence for arbitrary input streams, no quotient equality of sequence tails, no open-cover compactness theorem, and no ambient completeness principle.

Proof. Start with an accepted packet S. A consumer reaches the terminal seal E only by following the continuation row C, so its first readable data are the weak-test ledger W and the displayed source rows F, H.

The retained windows are then read through U. The indices are visible finite rows, and the comparison rows M, Q keep the resulting tail and equality checks inside displayed metric and Cauchy-window data.

Next read the compactness handoff. The rows K, L connect the retained windows to the compact metric and sequential compactness sibling certificates before any weak-cluster or convergence seal can be consumed.

Finally, T, C, P, N bind the route to one NameCert packet. Since the carrier contains none of the excluded global objects, the consumer has no escape route around the displayed finite ledgers. □

Closure status for $\mathsf{NameCert}_{\mathsf{EberleinSmulian}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EberleinSmulian}^{\uparrow}$ packet is generated from displayed functional-analysis and Hilbert or Banach-facing source rows, finite weak-test ledgers, subsequence-selection windows, compactness handoff rows, metric and Cauchy-window comparisons, componentwise transport, continuation replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EberleinSmulian}^{\uparrow}}$, seed)

Scope closed: Definition 3362.1, Definition 3362.2, and Definition 3362.3 bind the seed finite weak-window carrier and its nonescape boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EberleinSmulian}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not claim full Eberlein–Smulian equivalence, unrestricted weak compactness, Banach-space dual completeness, countable choice, quotient sequence equality, host-level subsequence selection, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-test ledger exposure, subsequence-window exposure, compactness handoff, metric and Cauchy-window comparison, transport replay, provenance, and local naming for the same finite packet.

Chapter 2411

A Concrete Naming Certificate for $\mathsf{SorgenfreyLine}^{\uparrow}$

Following Sorgenfrey and Kelley, the $\mathsf{SorgenfreyLine}^{\uparrow}$ packet records the lower-limit line as a finite naming certificate over the already named real and topology surfaces. It is a one-sided neighbourhood interface adjacent to the $\mathsf{Real}^{\uparrow}$ carrier of chapter 38, the local open-neighbourhood discipline of chapter 88, and the stream readback route of chapter 126. The packet also reads lower-limit interval witnesses through the located interval surface of chapter 1709 and regular rational approximation rows, but it does not identify the BEDC carrier with a host topology on the classical real line.

Definition 2411.1 (SorgenfreyLine carrier)**.** *A* $\mathsf{SorgenfreyLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, I, W, A, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *source row for the point being observed.*
2. *I is a* $\mathsf{LocatedRealInterval}^{\uparrow}$ *lower-limit interval row displaying half-open windows $[a, b)$ around the source point through located endpoint, radius, and bracket data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that fixes the finite precision and finite list of lower-limit neighbourhood reads exposed to a consumer.*
4. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row repacking the rational endpoint observations of I and W.*
5. *L is the lower-limit topology ledger saying that neighbourhood access is by displayed half-open interval windows and not by an arbitrary host-open predicate.*
6. *H records componentwise* hsame *transports for R, I, W, A, L, C, P, N.*
7. *C records displayed* Cont *replay from the real source row to the located half-open interval row, from that row to the stream window, and from the window to the regular rational readback.*
8. *P is the* Pkg *provenance over* $\mathsf{SorgenfreyLine}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SorgenfreyLine}^{\uparrow}}$ *row.*

The carrier stores no host topological space, no quotient real presentation, no selected point of a neighbourhood basis, no choice functional, and no completeness coordinate for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SorgenfreyLineUp.SorgenfreyLineTasteGate single carrier alignment`

Theorem 2411.2 (SorgenfreyLine NameCert obligations)**.** *For every accepted* $\mathsf{SorgenfreyLine}^{\uparrow}$ *carrier*

$$S = (R, I, W, A, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SorgenfreyLine}^{\uparrow}}$ *obligations are exactly the finite lower-limit rows displayed by the carrier:*

1. *real-source admission, requiring every point read to pass through the* $\mathsf{Real}^{\uparrow}$ *row* R*;*
2. *half-open interval admission, requiring every neighbourhood read to expose the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row* I *as a lower-limit window* $[a, b)$*;*
3. *stream-window exactness, requiring the finite precision and finite neighbourhood inspection route to be the row* W*;*
4. *regular-rational readback, requiring endpoint and bracket observations to repack through* A *before any downstream real-facing consumer reads them;*
5. *topology-ledger exhaustion, requiring the topology-facing claim to use the ledger* L *rather than an ambient open-set predicate;*
6. *transport, replay, provenance, and local naming stability through* H, C, P, N*.*

These obligations do not assert host topology, quotient real equality, selected neighbourhood choices, countable choice, trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier. The only point row is R, the only lower-limit interval row is I, and the only finite observation schedule is the stream window W.

The endpoint and bracket reads of the half-open window are then repacked by the regular rational row A. The ledger L records that topology-facing access is by displayed lower-limit windows, so a consumer cannot replace the route by an arbitrary host-open predicate.

The rows H, C, P, N only transport, replay, source, and name the displayed route. Since the carrier has no coordinate for quotient reals, selected neighbourhood choices, countable choice, trichotomy, host topology, or real completeness, none of those principles can be part of the local NameCert obligations. □

Theorem 2411.3 (SorgenfreyLine lower-limit window nonescape)**.** *Every accepted lower-limit neighbourhood read of an accepted* $\mathsf{SorgenfreyLine}^{\uparrow}$ *carrier*

$$S = (R, I, W, A, L, H, C, P, N)$$

must pass through the $\mathsf{Real}^{\uparrow}$ *source row* R*, the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *half-open interval row* I*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* A*, the lower-limit topology ledger* L*,* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{SorgenfreyLine}^{\uparrow}}$ *row* N*. The read exports no host topology, quotient real equality, selected neighbourhood basis, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier of Definition 3363.1. Its only point source is R, its only lower-limit neighbourhood row is the half-open $\mathsf{LocatedRealInterval}^{\uparrow}$ row I, and its only finite inspection schedule is the $\mathsf{StreamName}^{\uparrow}$ row W.

The endpoint observations of the half-open window then repack through A, and the topology-facing claim is exhausted by the ledger L. Apply Theorem 3363.2 to identify the remaining transport, replay, provenance, and local naming rows as H, C, P, N.

Because no other row occurs in the carrier, a lower-limit neighbourhood read cannot escape into host topology, quotient real equality, selected neighbourhood bases, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2411.4 (SorgenfreyLine lower-limit topology handoff)**.** *Every* $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, *or product-topology consumer of an accepted* $\mathsf{SorgenfreyLine}^{\uparrow}$ *packet*

$$S = (R, I, W, A, L, H, C, P, N)$$

receives the lower-limit neighbourhood read only through $R, I, W, A, L, H, C, P, N$*. The row* I *provides the located half-open interval witness, and the row* L *provides the lower-limit topology ledger. The downstream* $\mathsf{SorgenfreyPlane}^{\uparrow}$ *product route may read this one-dimensional boundary, but it receives no host topology, quotient real equality, selected neighbourhood basis, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the accepted carrier of Definition 3363.1. The real source is R, the located half-open interval row is I, the finite window and rational readback rows are W and A, and the topology ledger is L.

Apply Definition 3363.2 and Definition 3363.3. Together they identify the structural rows H, C, P, N and force every lower-limit neighbourhood read to stay inside the displayed route.

The $\mathsf{SorgenfreyPlane}^{\uparrow}$ consumer therefore receives the line component only as this lower-limit topology handoff. Since no carrier row stores host topology, quotient real equality, selected neighbourhood bases, countable choice, trichotomy, or ambient real completeness, the product route cannot import those objects from the line certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{SorgenfreyLine}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SorgenfreyLine}^{\uparrow}$ packet is generated from a RealUp source row, a LocatedRealIntervalUp lower-limit half-open interval row, a StreamName finite window, a RegSeqRat readback row, a lower-limit topology ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SorgenfreyLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3363.1 and Definition 3363.2 seed the lower-limit neighbourhood surface over $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SorgenfreyLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host topology, quotient real equality, selected neighbourhood bases, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, half-open interval admission, stream-window exactness, regular-rational readback, topology-ledger exhaustion, transport stability, replay stability, and non-escape for BEDC.Derived.SorgenfreyLineUp.

Chapter 2412

A Concrete Naming Certificate for $\mathsf{CauchyTailDiagonal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyTailDiagonal}^{\uparrow}$ packet records the finite diagonal-tail handoff by which two regular rational tails are read through one selected diagonal window before a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer inspects a seal. It sits between the diagonal extraction route of chapter 1773, the interleaving surface of chapter 414, the finite tail seal of chapter 559, the finite windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet is a finite handoff surface for Real and completion routes; it does not select an ambient limit, quotient stream, countable-choice schedule, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness.

Definition 2412.1 (CauchyTailDiagonal carrier)**.** *A* $\mathsf{CauchyTailDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, \delta, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *tail rows whose late observations are to be compared.*
2. *δ is the finite diagonal selector row, read through* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *and synchronized with the* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *handoff.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family naming the inspected late indices for X, Y, and the diagonal row δ.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the paired tail requests, diagonal slack, and finite comparison budget.*
5. *E is the* $\mathsf{FiniteTailDiagonalSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after X, Y, δ, W, D have been displayed.*
6. *H records componentwise* hsame *transport for the two tail rows, diagonal selector, window family, dyadic ledger, seal row, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from paired tail requests through the selected diagonal window, dyadic tolerance ledger, finite tail seal, and terminal real handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyTailDiagonal}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}$ $\mathsf{FiniteTailDiagonalSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyTailDiagonal}^\uparrow}$ *row.*
The classifier compares accepted packets only through $X, Y, \delta, W, D, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable-choice selectors, host equality of real names, trichotomy, or ambient completion.

Lean4 ✓ `BEDC.Derived.CauchyTailDiagonalUp.CauchyTailDiagonalTasteGate single carrier alignment`

Theorem 2412.2 (CauchyTailDiagonal NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailDiagonal}^\uparrow$ *carrier $K = (X, Y, \delta, W, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailDiagonal}^\uparrow}$ *surface consists exactly of carrier admission for the ten displayed rows, paired* $\mathsf{RegSeqRat}^\uparrow$ *tail admission through X, Y, diagonal selector exactness through δ, finite* $\mathsf{StreamName}^\uparrow$ *window coverage through W,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance accounting through D, finite tail seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3364.1. The only tail sources are X and Y, and the only diagonal selector is the row δ displayed by the packet.

Read the finite windows and tolerance ledger next. The row W names exactly the late observations inspected by the two tails and the diagonal selector, while D records the dyadic tolerances and slack needed by that finite comparison.

The seal row E is downstream of those rows. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the local certificate has no remaining coordinate from which a quotient stream, selected limit, countable-choice selector, host real equality, trichotomy row, or ambient completion principle could be exported. □

Theorem 2412.3 (CauchyTailDiagonal Real handoff)**.** *Every* $\mathsf{Real}^\uparrow$ *or completion-facing consumer of an accepted* $\mathsf{CauchyTailDiagonal}^\uparrow$ *carrier must read the finite route*

$$X, Y, \delta, W, D, E, H, C, P, N$$

before any Cauchy-tail conclusion is exported. The handoff first displays the two $\mathsf{RegSeqRat}^\uparrow$ *tails, then the diagonal selector governed by* $\mathsf{RegularCauchyDiagonalExtraction}^\uparrow$ *and* $\mathsf{RegularCauchyInterleaving}^\uparrow$*, then the selected* $\mathsf{StreamName}^\uparrow$ *windows and* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance ledger, and only then the* $\mathsf{FiniteTailDiagonalSeal}^\uparrow$ *and* $\mathsf{Real}^\uparrow$ *seal row.*

Proof. Begin with an accepted carrier and apply Definition 3364.2. The consumer-facing data are exhausted by the displayed packet $X, Y, \delta, W, D, E, H, C, P, N$.

Use the diagonal and interleaving coordinates in order. The selector row δ names the diagonal observations, and the interleaving handoff ensures that both tail rows are read on the same finite window family before the dyadic budget is consumed.

Finally read the finite tail seal. Since E is downstream of the paired tail rows, selected windows, and tolerance ledger, a Real or completion-facing consumer receives a finite diagonal-tail handoff rather than a quotient stream, selected limit, countable-choice schedule, host equality proof, trichotomy decision, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailDiagonal}^\uparrow}$.

Constructive story: A $\mathsf{CauchyTailDiagonal}^\uparrow$ packet is generated from two RegSeqRat tail rows, one finite diagonal selector, StreamName windows, a DyadicRatCore tolerance ledger, a FiniteTailDiagonalSeal and RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailDiagonal}^\uparrow}$, seed)

Scope closed: Definition 3364.1, Definition 3364.2, and Definition 3364.3 seed the finite diagonal-tail handoff over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteTailDiagonalSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailDiagonal}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host equality of real names, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal selector exactness, paired tail window coverage, dyadic tolerance accounting, finite tail seal handoff, Real handoff, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.CauchyTailDiagonalUp.

Chapter 2413

A Concrete Naming Certificate for SeparatedLimitUniqueness$^{\uparrow}$

Following Bishop and Bridges constructive metric-space analysis, the SeparatedLimitUniqueness$^{\uparrow}$ packet records the familiar uniqueness of metric limits in a separated metric space as finite BEDC certificate data. It sits over the separated classifier of chapter 1411, the complete-metric limit service of chapter 128, the Cauchy-sequence comparison route of chapter 1412, the terminal real seal of chapter 38, the regular rational readback surface of chapter 301, and the finite observation schedule of chapter 126. The packet names only the displayed zero-distance handoff between two limit rows; it is not a quotient completion equality, a selected representative theorem, countable choice, host equality of sequences, or an ambient completeness principle for Real$^{\uparrow}$.

Definition 2413.1 (SeparatedLimitUniqueness carrier)**.** *A* SeparatedLimitUniqueness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L_0, L_1, Q, M, Z, S, H, C, P, N)$$

with the following displayed rows:

1. *L_0 and L_1 are* CompleteMetric$^{\uparrow}$ *limit rows for the same displayed Cauchy datum, each exposing only the finite limit-service surface available in the complete metric packet.*
2. *Q is the common* CauchySequenceEquivalence$^{\uparrow}$ *comparison route through which the two limit reads are compared before any endpoint classifier is inspected.*
3. *M is the* Met$^{\uparrow}$ *distance-witness row carrying the displayed distance comparison between the two candidate limits.*
4. *Z is the* Real$^{\uparrow}$ *zero-distance row, read only after the distance witness has passed through finite regular rational and stream-window readback.*
5. *S is the* SeparatedMetric$^{\uparrow}$ *classifier handoff saying that the zero-distance row is the only route by which the two displayed limit reads may be identified.*
6. *H records componentwise* hsame *transport for $L_0, L_1, Q, M, Z, S, C, P, N$.*
7. *C records displayed* Cont *replay from the two limit rows through the common Cauchy comparison, the metric distance witness, the zero-distance row, and the separated classifier.*
8. *P is the* Pkg *provenance over* CompleteMetric$^{\uparrow}$, CauchySequenceEquivalence$^{\uparrow}$, Met$^{\uparrow}$, Real$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{SeparatedLimitUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L_0, L_1, Q, M, Z, S, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2413.2 (SeparatedLimitUniqueness NameCert obligations)**.** *For every accepted* SeparatedLimitUniquenes *carrier*

$$U = (L_0, L_1, Q, M, Z, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparatedLimitUniqueness}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *two-limit admission, requiring both displayed limit reads to pass through the* $\mathsf{CompleteMetric}^{\uparrow}$ *rows L_0 and L_1;*
2. *common Cauchy comparison, requiring the two limit rows to be compared through the single* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route Q;*
3. *distance-witness exactness, requiring the metric comparison to be the displayed* $\mathsf{Met}^{\uparrow}$ *distance row M;*
4. *zero-distance sealing, requiring the zero comparison to be the* $\mathsf{Real}^{\uparrow}$ *row Z reached after the finite readback route;*
5. *separated classifier handoff, requiring identification of the two limit reads to pass through the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row S;*
6. *transport, replay, provenance, and local naming stability through H, C, P, N for the same rows;*
7. *refusal of quotient completion equality, selected representatives, host sequence equality, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as certificate data.*

No SeparatedLimitUniqueness obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.SeparatedLimitUniquenessUp.SeparatedLimitUniquenessTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3365.1. The two candidate limits are visible only as the displayed complete-metric limit rows L_0 and L_1, so the certificate has no separate host endpoint from which to read equality.

The common comparison route is Q. It aligns the two limit reads as Cauchy data before the distance witness is inspected, keeping the route inside the finite $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ surface.

The metric comparison then passes through M and reaches the zero-distance row Z. The row Z is a terminal $\mathsf{Real}^{\uparrow}$ seal over the finite readback route, not a detached assertion of equality in a host real line.

Finally the separated classifier row S is consumed. Transport through H, replay through C, provenance through P, and local naming through N preserve the same displayed path, so the listed rows exhaust the NameCert obligations. □

Theorem 2413.3 (SeparatedLimitUniqueness zero-distance handoff)**.** *Every consumer that identifies two accepted* $\mathsf{CompleteMetric}^{\uparrow}$ *limit reads through an accepted* $\mathsf{SeparatedLimitUniqueness}^{\uparrow}$ *packet must factor the identification through*

$$L_0, L_1, Q, M, Z, S, H, C, P, N.$$

The handoff reads the common Cauchy comparison Q, the $\mathsf{Met}^{\uparrow}$ *distance witness M, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row Z, and then the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier S before any named limit uniqueness claim is visible. It exports no quotient sequence equality, selected representative, host equality of metric points, countable-choice schedule, trichotomy split, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier U. A uniqueness-facing consumer first sees only the two complete-metric rows L_0 and L_1 and the shared comparison route Q.

The metric witness M is downstream of that route. Thus the consumer cannot compare the endpoints by host equality or by selecting representatives before the finite Cauchy comparison has been displayed.

The zero-distance row Z is then read as a $\mathsf{Real}^{\uparrow}$ seal, and S translates that displayed zero-distance evidence into the separated classifier handoff. The structural rows H, C, P, N transport, replay, source, and name the same route.

Therefore every limit-uniqueness read is the stated finite zero-distance handoff, with no additional quotient, choice, or ambient-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedLimitUniqueness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedLimitUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3365.1, Definition 3365.2, and Definition 3365.3 seed the finite separated-limit uniqueness packet over complete-metric limit rows, Cauchy-sequence comparison, metric distance witnesses, Real zero-distance rows, separated classifiers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedLimitUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient completion equality, selected representatives, host sequence equality, countable choice, trichotomy, standard bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, common Cauchy comparison, distance-witness exactness, zero-distance sealing, separated classifier handoff, transport stability, replay stability, and non-escape for BEDC.Derived.SeparatedLimitUniquenessUp.

Constructive story: A $\mathsf{SeparatedLimitUniqueness}^{\uparrow}$ packet is generated from two CompleteMetricUp limit rows, a common CauchySequenceEquivalenceUp comparison route, a MetricUp distance witness, a RealUp zero-distance row, a SeparatedMetricUp classifier handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2414

A Concrete Naming Certificate for $\mathsf{CertificateMachineBranch}^{\uparrow}$

The $\mathsf{CertificateMachineBranch}^{\uparrow}$ packet realizes the branch-separation side of subsection 9462.28.23 as finite BEDC certificate data. It sits downstream of the finite certificate machine surface in chapter 3355, but it records a narrower packet: a kernel spine, an admission gate, a derivation-strength record, a cannot-claim ledger boundary, and explicit branch-separation rows for allegory and biological bridge candidates. The packet is not a plain Turing-machine identity claim, not a biological semantics claim, not a semantic truth oracle, and not an unbounded execution trace.

Definition 2414.1 (CertificateMachineBranch carrier)**.** *A* $\mathsf{CertificateMachineBranch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, A, D, L, G, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite kernel-spine row, naming the constructors, candidate rows, acceptance stamps, and refusal slots inherited from the BEDC certificate kernel.*
2. *A is the admission-gate row. It records the finite evidence by which a branch candidate is accepted, refused, or kept outside the public certificate surface.*
3. *D is the derivation-strength record, naming the declared strength at which the accepted branch may be read.*
4. *L is the cannot-claim boundary ledger, excluding semantic truth, plain Turing-machine identity, unbounded execution, biological identity, and external proof authority.*
5. *G is the allegory-branch row, recording candidate symbolic patterns only as pre-admission branch material.*
6. *R is the biological bridge row, recording DNA-facing or external natural branches only as bridge candidates, not as kernel primitives.*
7. *S is the branch-separation row saying that allegory, DNA, and certificate-kernel reads remain distinct unless the admission gate names a finite accepted route.*
8. *H records componentwise* hsame *transport for $K, A, D, L, G, R, S, C, P, N$.*
9. *C records displayed* Cont *replay from kernel spine through admission gate, derivation-strength record, cannot-claim boundary, and branch-separation rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CertificateMachineBranch}^{\uparrow}$, $\mathsf{CertificateMachine}^{\uparrow}$, *finite certificate kernels, admission gates, derivation-strength records, cannot-claim ledgers, allegory branches, biological bridge branches,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CertificateMachineBranch}^{\uparrow}}$ *row.*

The classifier compares accepted branch packets only through $K, A, D, L, G, R, S, H, C, P, N$. It has no coordinate for host machine equality, semantic truth, biological identity, unbounded execution logs, unlicensed allegory admission, or external proof authority.

Lean4 ✓ `BEDC.Derived.CertificateMachineBranchUp.TasteGate.CertificateMachineBranchTasteGate single carrier alignment`

Theorem 2414.2 (CertificateMachineBranch NameCert obligations)**.** *For every accepted* CertificateMachineBranch *carrier*

$$B = (K, A, D, L, G, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CertificateMachineBranch}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *kernel-spine admission, requiring every branch candidate, constructor, acceptance stamp, and refusal slot to pass through K;*
2. *admission-gate exactness, requiring every accepted branch read to cite the finite row A;*
3. *derivation-strength exactness, requiring the public strength of the branch read to be the displayed row D;*
4. *cannot-claim boundary non-escape, requiring L to exclude semantic truth, plain Turing-machine identity, unbounded execution, biological identity, and external proof authority;*
5. *allegory and biological branch separation, requiring G, R, S to keep symbolic-pattern and DNA-facing candidates distinct from kernel primitives unless admitted by A;*
6. *transport, continuation, provenance, and local naming stability through H, C, P, N.*

Lean TasteGate formalization must include explicit $\mathsf{Nontrivial}(\mathsf{CertificateMachineBranch}^{\uparrow})$ *and* $\mathsf{FieldFaithful}(\mathsf{Certifica}$ *instances before the packet may be consumed as a nondegenerate field-facing branch certificate.*

Proof. Project the carrier of Definition 3366.1. The branch candidate first meets the kernel-spine row K and the admission-gate row A, so no public branch read can arise from an unlicensed symbolic or biological source.

The derivation-strength row D and cannot-claim ledger L then determine the public reading strength and the forbidden exits. These rows keep certificate acceptance separate from semantic truth, host machine equality, unbounded execution, and biological identity.

The rows G, R, S provide the branch inventory. They distinguish allegory candidates from DNA-facing bridge candidates and from kernel primitives, and they expose no equality between those sources unless the admission gate records the finite route.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no other coordinate occurs in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 2414.3 (CertificateMachineBranch separation non-escape)**.** *Every accepted public read of a* $\mathsf{CertificateMachineBranch}^{\uparrow}$ *packet factors through*

$$K, A, D, L, G, R, S, H, C, P, N.$$

The read first traverses the finite kernel spine K, the admission gate A, the derivation-strength record D, and the cannot-claim boundary L; only then may it inspect the allegory row G, biological bridge row R, and branch-separation row S. It exports no plain Turing-machine identity, biological semantics, host execution trace, unlicensed branch acceptance, or semantic truth predicate.

Proof. Begin with the accepted carrier B. The only kernel-facing row is K, and the only acceptance row is A, so a public read cannot skip directly to an allegory or DNA-facing branch.

The row D fixes the derivation strength carried by the accepted branch. The row L remains visible during the replay, so the consumer receives the stated boundary rather than a stronger semantic or biological claim.

The rows G, R, S are read after that boundary. They record branch inventory and separation, not an identification of allegory, biology, and kernel primitives.

The remaining rows H, C, P, N preserve the same finite route by transport, continuation replay, provenance, and local naming. Hence every accepted read stays inside the displayed packet. □

Falsifiable prediction: Every accepted $\mathsf{CertificateMachineBranch}^{\uparrow}$ branch read factors through a finite kernel spine, an admission gate, a derivation-strength record, a cannot-claim boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before any branch-separation row may be consumed.

Independence witness: finitewitnessroute, gapclosureboundary, finitetraceevaluator, kernelacceptancetrace: $\mathsf{CertificateMachineBranch}^{\uparrow}$ is not bijective to any listed sibling because none contains the joint admission-gate plus allegory/DNA branch-separation inventory together with derivation strength, cannot-claim boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CertificateMachineBranch}^{\uparrow}}$.

Constructive story: A $\mathsf{CertificateMachineBranch}^{\uparrow}$ packet is generated from a finite kernel spine, an admission gate, a derivation-strength record, a cannot-claim boundary, allegory and biological bridge branch rows, branch-separation evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertificateMachineBranch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3366.1, Definition 3366.2, and Definition 3366.3 seed the finite branch packet over certificate-machine kernels, admission gates, derivation-strength records, cannot-claim ledgers, allegory rows, biological bridge rows, branch separation, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertificateMachineBranch}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim plain Turing-machine identity, semantic truth, biological semantics, host execution traces, unlicensed branch acceptance, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked kernel-spine admission, admission-gate exactness, derivation-strength exactness, cannot-claim boundary non-escape, branch-separation exactness, transport stability, replay stability, and the $\mathsf{Nontrivial}(\mathsf{CertificateMachineBranch}^{\uparrow})$ and $\mathsf{FieldFaithful}(\mathsf{CertificateMachineBranch}^{\uparrow})$ Lean instances for BEDC.Derived.CertificateMac

Chapter 2415

A Concrete Naming Certificate for $\mathsf{SylvesterInertia}^{\uparrow}$

Following Sylvester's law of inertia and finite-dimensional quadratic-form theory, the $\mathsf{SylvesterInertia}^{\uparrow}$ packet records congruence-invariant positive, negative, and null sign-count rows. It reads the field source of chapter 45, the matrix presentation of chapter 49, the bilinear form row of chapter 146, and the inner-product substrate of chapter 86. The packet names finite inertia data as a displayed NameCert carrier; it does not assert analytic diagonalization, spectral theory, choice-selected bases, or completeness.

Definition 2415.1 (Sylvester inertia carrier)**.** *A* $\mathsf{SylvesterInertia}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, M, B, Q, D, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Field}^{\uparrow}$ *source row over which the scalar signs and matrix entries are read.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the finite square coordinate table used by the form.*
3. *B is the* $\mathsf{BilinForm}^{\uparrow}$ *row naming the symmetric bilinear form carried by the matrix presentation.*
4. *Q is the quadratic-form row obtained by reading the diagonal values of B on displayed coordinate vectors.*
5. *D is the finite diagonalization-witness row, recording the congruence table that exposes diagonal form entries without choosing an ambient basis outside the packet.*
6. *S is the sign-count ledger, listing the displayed positive, negative, and null diagonal entries as the inertia triple.*
7. *H records componentwise* hsame *transport for the field source, matrix presentation, bilinear form, quadratic form, diagonal witness, sign-count ledger, continuation replay, provenance, and local naming.*
8. *C records* Cont *replay from a finite congruence request through F, M, B, Q, D into the sign-count ledger S.*
9. *P is the* Pkg *provenance over* $\mathsf{SylvesterInertia}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{BilinForm}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SylvesterInertia}^{\uparrow}}$ *row naming the displayed inertia packet.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for a spectral theorem, analytic diagonalization process, choice-selected basis, quotient form equality, or completeness principle.

Lean4 ✓ `BEDC.Derived.SylvesterInertiaUp.SylvesterInertiaTasteGate single carrier alignment`

Theorem 2415.2 (Sylvester inertia NameCert obligations)**.** *For every accepted* $\mathsf{SylvesterInertia}^{\uparrow}$ *carrier* $K = (F, M, B, Q, D, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SylvesterInertia}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission for the field source, matrix presentation, bilinear form, quadratic form, diagonal witness, sign-count ledger, transport, continuation replay, provenance, and local naming row;*
2. *form coherence, requiring* M*,* B*, and* Q *to describe the same displayed finite quadratic-form packet over* F*;*
3. *diagonal witness exactness, requiring* D *to expose only congruence steps whose source and target rows are recorded in* M, B, Q*;*
4. *inertia ledger readback, requiring* S *to count exactly the displayed positive, negative, and null diagonal entries exposed by* D*;*
5. *non-escape, excluding spectral decomposition, analytic diagonalization, basis choice outside the packet, quotient form equality, and completeness arguments.*

No local NameCert obligation is stored outside those five rows.

Proof. Project the carrier of Definition 3367.1. Carrier admission exposes exactly $F, M, B, Q, D, S, H, C, P, N$.

The form-coherence row binds the matrix table M, bilinear row B, and quadratic row Q over the same field source F. The diagonal witness row D is then readable only as a finite congruence ledger for that displayed form data.

The sign-count ledger S reads the diagonal entries exposed by D and separates them into positive, negative, and null cells. Finally H, C, P, N transport, replay, source, and name only that finite packet, so the excluded analytic and choice-based coordinates have no NameCert row. □

Theorem 2415.3 (Sylvester inertia congruence invariance)**.** *If two accepted* $\mathsf{SylvesterInertia}^{\uparrow}$ *packets are related by a displayed congruence replay through their rows* $F, M, B, Q, D, H, C, P, N$*, then they preserve the displayed sign-count ledger* S*. In particular, congruent accepted packets export the same positive, negative, and null inertia counts through* $\mathsf{NameCert}_{\mathsf{SylvesterInertia}^{\uparrow}}$*.*

Proof. Begin with two accepted carriers and a displayed congruence replay between them. By Definition 3367.2, the replay must pass through the field source, matrix presentation, bilinear form, quadratic form, and diagonal witness rows before the sign-count ledger is read.

The diagonal witness exactness row forces the congruence table to expose the same diagonal-form cells on both sides of the accepted comparison. The inertia ledger readback row then counts those displayed cells as positive, negative, or null inside S.

Because the carrier has no row for an external basis selector, analytic diagonalizer, quotient equality, or spectral argument, the exported comparison is exactly the componentwise ledger comparison. Thus the positive, negative, and null counts are preserved. □

Closure status for $\mathsf{NameCert}_{\mathsf{SylvesterInertia}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SylvesterInertia}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3367.1, Definition 3367.2, and Definition 3367.3 seed the finite inertia carrier, five-row NameCert obligation surface, and congruence-invariant sign-count ledger.

Formal verification: FormalStatus(NameCert$_{\mathsf{SylvesterInertia}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the spectral theorem, analytic diagonalization, choice-selected bases, quotient form equality, completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, form coherence, diagonal witness exactness, inertia ledger readback, and non-escape for the same finite Sylvester inertia packet.

Constructive story: A SylvesterInertia$^{\uparrow}$ packet is generated from a field source, matrix presentation, bilinear form, quadratic-form row, diagonalization witness, positive-negative-null sign-count ledger, componentwise transport, continuation replay, provenance, and local NameCert row.

Chapter 2416

A Concrete Naming Certificate for $\mathsf{FundamentalGroup}^{\uparrow}$

Following Hatcher and Spanier on the fundamental group, the $\mathsf{FundamentalGroup}^{\uparrow}$ packet names the loop-composition group at a displayed basepoint by finite BEDC rows. It sits beside the homotopy surface of chapter 156, the algebraic group surface of chapter 41, and the path-lifting surface of chapter 2275. The certificate records based loops, loop homotopies, concatenation, inverse, identity, and covering-lift handoff ledgers; it does not import quotient classes of loops or a host topological theorem.

Definition 2416.1 ($\mathsf{FundamentalGroup}^{\uparrow}$ finite carrier)**.** *A* $\mathsf{FundamentalGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Pi = (X, x_0, L, Q, M, I, E, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient topological source row and x_0 is the displayed basepoint row.*
2. *L is the finite based-loop row family. Each loop starts and ends at x_0 and is read through the path-facing part of* $\mathsf{Homotopy}^{\uparrow}$*.*
3. *Q is the loop-homotopy row family. It compares based loops by endpoint-fixed* $\mathsf{Homotopy}^{\uparrow}$ *certificates, not by an ambient quotient of maps.*
4. *M is the concatenation ledger. It records finite composable loop pairs, their concatenated loop row, and the endpoint-gluing readback.*
5. *I is the inverse ledger. It records the reversed loop row and the homotopy rows witnessing the two cancellation routes back to the identity loop row.*
6. *E is the identity loop row at x_0 and its left and right unit ledgers for M.*
7. *U is the covering-lift handoff row. It exposes exactly the based-loop data consumable by chapter 2275: base path, initial lift point request, lifted segment route, sheet classifier, and endpoint seal.*
8. *H records componentwise* hsame *transport for $X, x_0, L, Q, M, I, E, U, C, P, N$.*
9. *C records displayed* Cont *replay for loop readback, loop-homotopy readback, concatenation, inverse, identity, and covering-lift handoff rows.*

10. *P is the* Pkg *provenance over* $\mathsf{FundamentalGroup}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{CoveringSpacePathLifting}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FundamentalGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. Thus the group object is carried as a finite based-loop and homotopy ledger over BHist, *not as a quotient set of host loops.*

Lean4 ✓ `BEDC.Derived.FundamentalGroupUp.FundamentalGroupTasteGate single carrier alignment`

Theorem 2416.2 ($\mathsf{FundamentalGroup}^{\uparrow}$ NameCert obligations)**.** *For every accepted* $\mathsf{FundamentalGroup}^{\uparrow}$ *carrier*

$$\Pi = (X, x_0, L, Q, M, I, E, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FundamentalGroup}^{\uparrow}}$ *surface consists exactly of carrier admission, basepoint admission, based-loop admission through* $\mathsf{Homotopy}^{\uparrow}$*, endpoint-fixed loop-homotopy comparison, concatenation ledger exactness, inverse ledger exactness, identity-loop exactness, covering-lift handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{Group}^{\uparrow}$ *consumer can inspect $L, Q, M, I, E, H, C, P, N$ as the finite algebraic surface, while every covering consumer can inspect U as the finite handoff route; neither consumer receives quotient classes of loops.*

Proof. Carrier admission is projection from Definition 3368.1. The rows $X, x_0, L, Q, M, I, E, U, H, C, P, N$ already list the base space, basepoint, loops, homotopies, operations, transport, replay, provenance, and local naming data.

The group obligation is read from M, I, E over the classifier Q. Concatenation uses the finite endpoint-gluing row of M, inverse uses the reversed-loop row and cancellation ledgers of I, and the unit laws use E. Each comparison is routed through endpoint-fixed $\mathsf{Homotopy}^{\uparrow}$ rows, so the algebraic equality surface is the finite loop-homotopy classifier.

The covering obligation is independent of any global universal cover. The handoff row U exposes a based loop as the base path required by chapter 2275, together with exactly the initial lift request, lifted segment route, sheet classifier, and endpoint seal that a path-lifting packet can read.

Since H, C, P, N only transport, replay, source, and name the displayed rows, there is no remaining coordinate through which a downstream consumer could demand a host loop quotient, a completed path space, or an uncarried fundamental-group representation. □

Theorem 2416.3 ($\mathsf{FundamentalGroup}^{\uparrow}$ covering path route)**.** *Let* $\Pi = (X, x_0, L, Q, M, I, E, U, H, C, P, N)$ *be an accepted* $\mathsf{FundamentalGroup}^{\uparrow}$ *carrier. Any* $\mathsf{CoveringSpacePathLifting}^{\uparrow}$ *consumer of a based loop from* Π *factors through the handoff row U, the original based-loop row in L, the endpoint-fixed loop-homotopy classifier Q, the componentwise transport H, the displayed replay C, the provenance P, and the local name N. The consumer may observe the lifted endpoint seal and sheet-classifier route supplied by the covering packet, but it cannot replace the loop row by a quotient class or a fundamental-group representation.*

Proof. Choose an accepted based loop row from L. Its initial and final endpoint rows are both the displayed basepoint x_0, and its admissibility is already read through the $\mathsf{Homotopy}^{\uparrow}$ path surface.

Project the handoff row U. By definition, U contains the base-path presentation, the initial lift request, and the finite route slots consumed by $\mathsf{CoveringSpacePathLifting}^{\uparrow}$. The path-lifting packet therefore receives the loop only as a carried base path with visible endpoint data.

Transport along H and replay along C. These rows preserve the same based-loop row, loop-homotopy comparison, provenance, and local name, so any covering endpoint seal remains tied to the finite packet Π.

The route ends at the covering packet's own sheet classifier and endpoint seal. No step introduces a quotient of loops, a universal-cover action, or a host representation theorem; all handoff information is finite BHist data with NameCert provenance. □

Closure status for $\mathsf{NameCert}_{\mathsf{FundamentalGroup}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FundamentalGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3368.1, Definition 3368.2, and Definition 3368.3 seed the finite basepoint, loop, loop-homotopy, concatenation, inverse, identity, covering-handoff, transport, replay, provenance, and local naming surface for the fundamental group.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FundamentalGroup}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FundamentalGroupUp.FundamentalGroupTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close van Kampen theorems, monodromy representations, universal covers, quotient path spaces, host loop equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, based-loop admission, loop-homotopy comparison, operation ledgers, covering handoff, transport, replay, provenance, and local naming for BEDC.Derived.FundamentalGroupUp.

Constructive story: A $\mathsf{FundamentalGroup}^{\uparrow}$ packet is generated from a displayed basepoint, finite based-loop rows, endpoint-fixed loop-homotopy rows, concatenation, inverse, identity, covering-lift handoff, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 2417

A Concrete Naming Certificate for $\mathsf{PartitionOfUnity}^{\uparrow}$

Following Kelley and Bourbaki on partitions of unity, the $\mathsf{PartitionOfUnity}^{\uparrow}$ packet records the finite BEDC surface by which a displayed locally finite open cover receives compatible bump rows and finite-support weight rows. It sits over the topological source of chapter 88, the support-window discipline of chapter 1726, the refinement ledger of chapter 1963, the chart-facing consumer surface of chapter 96, and the separation-function route of **??**. The packet names only displayed finite rows for local-to-global gluing; it does not select arbitrary host functions, assert compactness of open covers, or identify analytic functions extensionally.

Definition 2417.1 (Partition of unity carrier)**.** *A* $\mathsf{PartitionOfUnity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (T, L, Q, R, W, F, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the open-set operations and point-neighborhood reads on which all cover and support data are interpreted.*
2. *L is the* $\mathsf{LocallyCompact}^{\uparrow}$ *support-window row, recording the compactly supported local windows used by each bump row without exporting an open-cover compactness principle.*
3. *Q is the* $\mathsf{Paracompact}^{\uparrow}$ *locally finite cover ledger, including the displayed refinement cells, finite neighborhood witnesses, and assignment back to the original open-cover request.*
4. *R is the* $\mathsf{UrysohnLemma}^{\uparrow}$ *bump-row ledger, recording the separation-compatible construction of each nonnegative bump row inside the support window supplied by L and the locally finite cell supplied by Q.*
5. *W is the finite-support weight row, listing the finitely many bump rows visible at each displayed point-neighborhood read.*
6. *F is the displayed sum-to-one row, recording that the finitely supported weight rows add to the unit row on the covered region.*
7. *S is the manifold-facing handoff row, exposing exactly the partition rows consumable by* $\mathsf{Manifold}^{\uparrow}$ *chart gluing and by local-to-global analysis packets.*
8. *H records componentwise* hsame *transport for the topology source, support windows, locally finite cover ledger, bump rows, weight rows, sum row, manifold handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a partition request through $T, L, Q, R, W, F, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PartitionOfUnity}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{Paracompact}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PartitionOfUnity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host-selected function family, arbitrary subcover selection, open-cover compactness theorem, unlogged chart choice, or extensional equality of analytic functions.

Lean4 ✓ `BEDC.Derived.PartitionOfUnityUp.PartitionOfUnityTasteGate single carrier alignment`

Theorem 2417.2 (Partition of unity NameCert obligations)**.** *For every accepted* $\mathsf{PartitionOfUnity}^{\uparrow}$ *carrier*

$$U = (T, L, Q, R, W, F, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PartitionOfUnity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, support windows, locally finite cover ledger, bump-row ledger, finite-support weights, sum-to-one row, manifold handoff, transport, replay, provenance, and local naming;*
2. *support-window exactness, requiring every bump row to read its support through the displayed* $\mathsf{LocallyCompact}^{\uparrow}$ *row L and not through a host compactness claim;*
3. *locally finite cover exactness, requiring every weight row in W to be indexed only by the refinement cells and finite neighborhood witnesses displayed by Q;*
4. *Urysohn-compatible bump exactness, requiring every bump row in R to pass through the* $\mathsf{UrysohnLemma}^{\uparrow}$ *separation-function route before it can contribute to a weight row;*
5. *finite-support and sum exactness, requiring W and F to display the finite set of nonzero weights at each point-neighborhood read and the corresponding sum-to-one row;*
6. *manifold handoff exactness, requiring S to export only the rows $T, L, Q, R, W, F, H, C, P, N$ needed by* $\mathsf{Manifold}^{\uparrow}$ *chart gluing and local-to-global consumers;*
7. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve exactly the listed rows.*

No local partition-of-unity obligation is stored outside these seven rows.

Proof. Carrier admission is projection from Definition 3369.1. The accepted tuple displays exactly the topology source, local compact support windows, paracompact locally finite ledger, Urysohn-compatible bump rows, finite-support weights, sum row, manifold handoff, transport, replay, provenance, and local naming.

Support-window exactness is read from L, while locally finite cover exactness is read from Q. The row L supplies only the compactly supported local windows already displayed in the packet, and Q supplies only the refinement cells, assignments, and finite neighborhood witnesses of the paracompact ledger.

The bump-row gate is R. Each bump row is admitted through the $\mathsf{UrysohnLemma}^{\uparrow}$ separation-function route, so a weight row cannot be introduced by selecting an arbitrary host function.

The weight and sum gates are W and F. The row W lists the finite set of nonzero weights visible at each displayed neighborhood read, and F records the displayed sum-to-one row over that finite support.

Finally, S, H, C, P, N only hand off, transport, replay, source, and name the same finite packet. Thus a manifold or local-to-global consumer can read the partition surface without receiving a host-selected function family, arbitrary subcover, open-cover compactness theorem, unlogged chart choice, or extensional equality of analytic functions. □

Theorem 2417.3 (Partition of unity locally finite cover route)**.** *Let*

$$U = (T, L, Q, R, W, F, S, H, C, P, N)$$

be an accepted $\mathsf{PartitionOfUnity}^{\uparrow}$ *carrier. Every weight row in* W *and every sum-to-one row in* F *must first read the* $\mathsf{Paracompact}^{\uparrow}$ *locally finite cover ledger* Q *before reaching the* $\mathsf{UrysohnLemma}^{\uparrow}$ *bump rows* R*, the finite-support surface* W*, the sum row* F*, and the* $\mathsf{Manifold}^{\uparrow}$ *handoff* S*. The route does not select arbitrary subcovers or import open-cover compactness.*

Proof. Project the carrier of Definition 3369.1. The row Q is the only locally finite cover ledger in the packet, and it records the displayed refinement cells, finite neighbourhood witnesses, and assignment back to the original cover request.

Project the analytic rows R, W, F, S. The bump row R reads its separation and support data after the locally finite cell is known, the finite-support row W lists only the weights visible over that displayed locally finite neighbourhood, and the sum-to-one row F adds exactly those listed weights.

The handoff row S exports this same route to $\mathsf{Manifold}^{\uparrow}$ consumers. By Definition 3369.2, no local partition-of-unity obligation is stored outside the carrier rows, so neither arbitrary subcover selection nor open-cover compactness can replace Q. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartitionOfUnity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PartitionOfUnity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3369.1 and Definition 3369.2 seed the finite topology, local compactness, paracompact refinement, Urysohn bump, weight, sum-to-one, manifold handoff, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PartitionOfUnity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host-selected function families, arbitrary subcover selection, open-cover compactness, analytic function extensionality, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support-window exactness, locally finite cover exactness, Urysohn-compatible bump exactness, finite-support sum exactness, manifold handoff exactness, transport stability, replay stability, and non-escape proofs for BEDC.Derived.PartitionOfUnityUp.

Constructive story: A $\mathsf{PartitionOfUnity}^{\uparrow}$ packet is generated from a $\mathsf{Topology}^{\uparrow}$ source row, $\mathsf{LocallyCompact}^{\uparrow}$ support windows, a $\mathsf{Paracompact}^{\uparrow}$ locally finite cover ledger, $\mathsf{UrysohnLemma}^{\uparrow}$ bump rows, finite-support weights, a displayed sum-to-one row, a $\mathsf{Manifold}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2418

A Concrete Naming Certificate for $\mathsf{Bornology}^{\uparrow}$

Following Bourbaki and Kelley on bornologies, the $\mathsf{Bornology}^{\uparrow}$ packet records the finite bounded-family interface that sits between the bounded-subset certificate of chapter 1757, the directed base surface of chapter 1601, the uniform entourage surface of chapter 339, and the Cauchy-family specialization of chapter 1896. It names bounded families by displayed hereditary and finite-union rows before any completion, uniform, or Real-facing consumer can ask for a selected bound, a quotient family, countable choice, host suprema, or ambient completeness.

Definition 2418.1 (Bornology carrier)**.** *A* $\mathsf{Bornology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, S, U, E, D, H, C, P, N)$$

with the following displayed rows:

1. *F is the bounded-family source row. It lists the finite family requests that may be read as bounded data.*
2. *S is the subset-heredity ledger, recording that an accepted subfamily request is read only through a displayed parent family already named by F.*
3. *U is the finite-union ledger, recording binary and finite union requests as displayed rows over previously accepted bounded families.*
4. *E is the singleton and source-exposure row, naming the basic bounded packets available before hereditary or union closure is inspected.*
5. *D is the consumer handoff row for* $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{UniformSpace}^{\uparrow}$ *readers, and for the* $\mathsf{CauchyBornology}^{\uparrow}$ *specialization of the same bounded-family surface.*
6. *H records componentwise* hsame *transport for F, S, U, E, D, C, P, N.*
7. *C records displayed* Cont *replay from bounded-family admission through subset heredity, finite union, source exposure, consumer handoff, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{Bornology}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{Bornology}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for host suprema, selected bounds, quotient families, countable choice, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyTasteGate single carrier alignment`

Theorem 2418.2 (Bornology NameCert obligations)**.** *For every accepted* $\mathsf{Bornology}^{\uparrow}$ *carrier* $B = (F, S, U, E, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Bornology}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-family source exposure, subset-heredity ledger visibility, finite-union ledger visibility, singleton and source exposure,* $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{UniformSpace}^{\uparrow}$ *consumer handoff,* $\mathsf{CauchyBornology}^{\uparrow}$ *specialization handoff, componentwise transport, displayed continuation replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyNameCertObligations`

Proof. Carrier admission projects the displayed packet. The source row F and singleton/source row E expose the basic bounded-family entries before any closure rule is read.

Subset heredity is confined to S, and finite union is confined to U. These ledgers are rows of the same packet, so a consumer cannot replace them by a host powerset, a selected bound, or a quotient family.

The handoff row D then presents the same bounded-family surface to $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, and $\mathsf{CauchyBornology}^{\uparrow}$ consumers. The structural rows H, C, P, N transport, replay, source, and name only the displayed packet. □

Theorem 2418.3 (Bornology bounded-family union stability)**.** *Let* $B = (F, S, U, E, D, H, C, P, N)$ *be an accepted* $\mathsf{Bornology}^{\uparrow}$ *carrier. Every accepted finite union of displayed bounded-family reads is certified by the finite-union ledger* U *after the source row* F *and singleton/source row* E *have been exposed, and every accepted subfamily of such a union is routed back through the subset-heredity ledger* S*. The route exports no host supremum, selected bound, quotient family, countable-choice selector, open-cover compactness principle, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyBoundedFamilyUnionStability`

Proof. Read the carrier rows. Source and singleton exposure are the only entry points for basic bounded-family data, so a union request must first cite displayed rows from F and E.

The finite-union ledger U records the admitted union row. A later subfamily request cannot inspect that union through a host family predicate; it must pass through S, whose parent row is already displayed inside the packet.

Transport and replay through H and C preserve the same ledgers, while P and N package only the named dependencies and local certificate. Therefore the union-stability route remains finite and contains none of the excluded host principles. □

Theorem 2418.4 (Bornology CauchyBornology handoff)**.** *Every* $\mathsf{CauchyBornology}^{\uparrow}$ *consumer of an accepted* $\mathsf{Bornology}^{\uparrow}$ *carrier reads the general bounded-family surface through*

$$F, E \longmapsto S, U \longmapsto D \longmapsto H, C, P, N.$$

Thus the Cauchy specialization receives bounded-family source rows, singleton exposure, subset heredity, finite-union stability, consumer handoff, transport, replay, provenance, and local naming before it may open rate budgets, regular rational readback, Real seals, or completion-facing data.

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyCauchyBornologyHandoff`

Proof. Start with a $\mathsf{CauchyBornology}^{\uparrow}$ consumer. The only general bornology data available to it are the displayed source and singleton rows F, E.

The closure properties are read next. Subset heredity is supplied by S, and finite union is supplied by U, so the consumer receives the ordinary bornological closure rows before any Cauchy-specific budget or Real-facing row can be inspected.

The handoff is then the row D, preserved by H and replayed by C. Since P and N name only the general bounded-family packet and its Cauchy specialization, the route adds no selected bound, quotient family, countable-choice selector, host supremum, or ambient completeness premise. □

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyCarrier cauchy bornology handoff`

Theorem 2418.5 (Bornology obligation closure route)**.** *Every accepted* $\mathsf{Bornology}^{\uparrow}$ *obligation read exposes exactly the route*

$$F, S, U, E, D, H, C, P, N.$$

The rows are the bounded-family source, subset-heredity ledger, finite-union ledger, singleton and source exposure, $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{UniformSpace}^{\uparrow}$ *and* $\mathsf{CauchyBornology}^{\uparrow}$ *handoff, componentwise transport, displayed replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{Bornology}^{\uparrow}}$ *evidence. The route exports no host suprema, selected bounds, quotient families, countable choice, open-cover compactness, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyObligationClosureRoute`

Proof. The carrier of Definition 3370.1 supplies the visible rows $F, S, U, E, D, H, C, P, N$. The NameCert obligations of Definition 3370.2 identify those rows as carrier admission, bounded-family source exposure, heredity, finite union, source exposure, consumer handoff, transport, replay, provenance, and local naming.

The bounded-family union stability theorem Definition 3370.3 keeps union and subfamily reads inside U and S after the source rows F, E have been exposed. The CauchyBornology handoff of Definition 3370.4 routes every Cauchy consumer through the same displayed surface before any Cauchy-specific budget can be opened.

Together these results exhaust the finite obligation route. Since none of the carrier rows names host suprema, selected bounds, quotient families, countable choice, open-cover compactness, or ambient completeness, no accepted obligation read can export those omitted principles. □

Theorem 2418.6 (Bornology scoped bounded-family route)**.** *Every scoped bounded-family consumer of an accepted* $\mathsf{Bornology}^{\uparrow}$ *carrier*

$$B = (F, S, U, E, D, H, C, P, N)$$

must read the route

$$F, S, U, E, D, H, C, P, N$$

through the displayed $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before using the bounded-family surface. The route exports no host supremum, selected bound, quotient family, countable-choice selector, open-cover compactness principle, or ambient completeness premise.*

Proof. Start with the NameCert obligations of Definition 3370.2. They expose the bounded-family source row F, the subset-heredity ledger S, the finite-union ledger U, the singleton/source row E, the consumer handoff row D, and the structural rows H, C, P, N as the complete local surface.

Use bounded-family union stability, Definition 3370.3. It keeps every finite union and subfamily read inside U and S after F, E have been displayed, so the bounded-family consumer cannot replace the packet by a host family or selected bound.

Next apply the CauchyBornology handoff of Definition 3370.4. It forces completion-facing bounded-family reads through the same F, E, D, H, C, P, N surface before any Cauchy-specific budget is opened.

Finally compose with the obligation closure route Definition 3370.5. The scoped consumer therefore reads exactly the displayed carrier route through $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert, with no additional supremum, choice, quotient, compactness, or completeness coordinate. □

Theorem 2418.7 (Bornology scope kernel grounding)**.** *The bounded-family source, subset-heredity, finite-union, consumer handoff, transport, replay, provenance, and local NameCert rows of an accepted* $\mathsf{Bornology}^{\uparrow}$ *carrier are scoped exactly over* $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *Every scoped consumer must read the displayed route*

$$F, S, U, E, D, H, C, P, N$$

through those kernel and sibling rows, and the route adds no host supremum, selected bound, quotient family, countable-choice selector, compactness principle, or ambient completeness premise.

Lean4 ✓ `BEDC.Derived.BornologyUp.BornologyScopeKernelGrounding`

Proof. Start with the NameCert obligations of Definition 3370.2. They expose carrier admission, bounded-family source rows, subset heredity, finite union, singleton/source exposure, consumer handoff, componentwise transport, displayed replay, provenance, and local naming as the local $\mathsf{Bornology}^{\uparrow}$ surface.

Use bounded-family union stability, Definition 3370.3. It keeps heredity and finite-union reads inside the displayed S and U ledgers after F and E have been exposed, so a scoped consumer cannot replace the packet by host suprema, selected bounds, quotient families, or choice data.

Apply the CauchyBornology handoff of Definition 3370.4. The handoff row D presents the same bounded-family surface to $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, and $\mathsf{CauchyBornology}^{\uparrow}$ consumers before any Cauchy-specific or completion-facing data are opened.

Finally compose the obligation closure route Definition 3370.5 with the scoped bounded-family route Definition 3370.6. The resulting kernel grounding is exactly the route through $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert, with no extra compactness or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{Bornology}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Bornology}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 3370.1, Definition 3370.2, Definition 3370.3, Definition 3370.4, Definition 3370.5, Definition 3370.6, and Definition 3370.7 bind the finite bounded-family NameCert surface over bounded-set, filter-base, uniform-space, and Cauchy-bornology consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Bornology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host suprema, selected bounds, quotient families, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Public closure asks for a public bounded-family export theorem and later Lean verification for BEDC.Derived.BornologyUp.

Constructive story: A Bornology$^{\uparrow}$ packet is generated from bounded-family source rows, subset-heredity ledgers, finite-union ledgers, singleton and source exposure, FilterBaseUp or UniformSpaceUp handoff rows, CauchyBornologyUp specialization, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2419

A Concrete Naming Certificate for $\mathsf{MetricAnnulus}^{\uparrow}$

Following Kelley on metric neighbourhoods and Bishop–Bridges constructive metric spaces, the $\mathsf{MetricAnnulus}^{\uparrow}$ packet records the shell between an inner exclusion radius and an outer containment radius as finite BEDC certificate data. It sits over the metric source of chapter 57, the metric-ball surface of chapter 1450, the open-ball exclusion route of chapter 2191, the closed-ball containment route of chapter 1451, and the real-name radius seal of chapter 38. The packet is a metric shell neighbourhood certificate, not a host subset, not quotient point equality, not a selected-radius principle, not compactness, and not $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2419.1 (MetricAnnulus carrier)**.** *A* $\mathsf{MetricAnnulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, c, r_0, r_1, O, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row naming the finite distance-comparison surface.*
2. *c is the centre row, read only through the same metric source.*
3. *r_0 is the inner radius row, exposed as a positive or nonnegative* $\mathsf{Real}^{\uparrow}$ *radius seal according to the local metric-ball convention.*
4. *r_1 is the outer radius row, exposed through the same* $\mathsf{Real}^{\uparrow}$ *radius discipline.*
5. *O is the* $\mathsf{OpenBall}^{\uparrow}$ *exclusion row, recording that points in the shell are outside the displayed inner open ball around c with radius r_0.*
6. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *containment row, recording that points in the shell remain inside the displayed closed ball around c with radius r_1.*
7. *H records componentwise* hsame *transport for the metric source, centre, two radius rows, open-ball exclusion row, closed-ball containment row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a shell-membership request through the radius-order check, the open-ball exclusion test, and the closed-ball containment test.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricAnnulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{OpenBall}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricAnnulus}^{\uparrow}}$ *row.*

The carrier accepts only packets whose metric source, centre, inner radius, outer radius, exclusion row, containment row, transport, replay, provenance, and local name are all displayed in the same finite ledger.

Theorem 2419.2 (MetricAnnulus NameCert obligations)**.** *For every accepted* $\mathsf{MetricAnnulus}^{\uparrow}$ *carrier* $K = (M, c, r_0, r_1, O, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricAnnulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source and centre, visibility of the ordered inner and outer radius rows, inner-boundary exclusion through the* $\mathsf{OpenBall}^{\uparrow}$ *row, outer-boundary containment through the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row, classifier transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. Every shell-neighbourhood read is confined to those rows and cannot open a host subset, quotient point equality, selected-radius choice, compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted packet to the displayed rows $M, c, r_0, r_1, O, B, H, C, P, N$. The metric source and centre are the only source coordinates, and the two radius rows are the only numerical boundary coordinates available to a shell read.

The inner boundary is read through O: a point must avoid the displayed open ball around c at radius r_0. The outer boundary is read through B: the same point remains inside the displayed metric closed ball around c at radius r_1.

The transport row H and replay row C keep the classifier and continuation route componentwise on this packet. The provenance and local name rows P, N then certify that every later consumer reaches the shell only through the metric source, centre, radius rows, exclusion row, and containment row already displayed.

Since the carrier has no field for a host subset, quotient equality on points, a selected-radius operator, compactness data, or a completeness theorem for $\mathsf{Real}^{\uparrow}$, the ledger cannot escape to those principles. □

Lean4 ✓ `BEDC.Derived.MetricAnnulusUp.MetricAnnulusCarrier namecert obligations`

Closure status for $\mathsf{NameCert}_{\mathsf{MetricAnnulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricAnnulus}^{\uparrow}$ packet is generated from a Metric source row, a centre row, inner and outer Real radius rows, an OpenBall exclusion row, a MetricClosedBall containment row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricAnnulus}^{\uparrow}}$, seed)

Scope closed: Definition 3371.1 and Definition 3371.2 seed the finite metric shell certificate for displayed inner exclusion and outer containment reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricAnnulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host subsets, quotient point equality, selected radii, compactness, theorem-level Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, radius-order visibility, inner-boundary exclusion, outer-boundary containment, classifier transport, Cont replay, Pkg provenance, and ledger nonescape for BEDC.Derived.MetricAnnulusUp.

Chapter 2420

A Concrete Naming Certificate for RealArchimedeanProperty$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the RealArchimedeanProperty$^{\uparrow}$ packet records the finite BEDC surface by which a displayed Real$^{\uparrow}$ name receives a natural-number bound and the corresponding rational and dyadic comparison rows. It sits next to the RealArchimedeanBoundSchema$^{\uparrow}$ neighbour of chapter 2201, but it names the property-level handoff: every bound read starts from the Real$^{\uparrow}$ name of chapter 38, passes through Nat$^{\uparrow}$ of chapter 28, Rat$^{\uparrow}$ of chapter 37, DyadicRatCore$^{\uparrow}$ of chapter 291, StreamName$^{\uparrow}$ of chapter 126, and RegSeqRat$^{\uparrow}$ of chapter 301, and only then exposes an Archimedean bound ledger. The packet is a finite naming certificate for that route, not a host real-order axiom, trichotomy principle, quotient-real equality, or completeness theorem.

Definition 2420.1 (RealArchimedeanProperty carrier)**.** *A* RealArchimedeanProperty$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, n, q, d, S, G, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the* Real$^{\uparrow}$ *name whose finite real observations are being bounded.*
2. *n is the* Nat$^{\uparrow}$ *bound row, recording the natural-number index used by the bound.*
3. *q is the* Rat$^{\uparrow}$ *comparison row naming the rational face of the same bound.*
4. *d is the* DyadicRatCore$^{\uparrow}$ *comparison row naming the dyadic face of the same bound.*
5. *S is the* StreamName$^{\uparrow}$ *finite-window row inspected before the comparison is read.*
6. *G is the* RegSeqRat$^{\uparrow}$ *readback row that turns the inspected stream window into a regular rational Cauchy observation.*
7. *B is the Archimedean bound ledger, compatible with the* RealArchimedeanBoundSchema$^{\uparrow}$ *route of chapter 2201.*
8. *H records componentwise* hsame *transport for the real name, natural bound, rational row, dyadic row, stream window, readback row, bound ledger, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a bound request through S, G, q, d, and n.*
10. *P is the* Pkg *provenance over* RealArchimedeanProperty$^{\uparrow}$, Real$^{\uparrow}$, Nat$^{\uparrow}$, Rat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealArchimedeanBoundSchema$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanProperty}^{\uparrow}}$ *row.*
The carrier accepts only packets whose real observation, bound index, rational and dyadic comparisons, stream inspection, regular rational readback, bound ledger, transport, replay, provenance, and local name are all displayed in the same finite certificate.

Theorem 2420.2 (RealArchimedeanProperty NameCert obligations)**.** *For every accepted* RealArchimedeanPropert *carrier $A = (R, n, q, d, S, G, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanProperty}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{Real}^{\uparrow}$ *name,* $\mathsf{Nat}^{\uparrow}$ *bound row,* $\mathsf{Rat}^{\uparrow}$ *comparison row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, Archimedean bound ledger, componentwise transport through H, displayed continuation replay through C,* Pkg *provenance through P, and local naming through N. No obligation may read a host real-order axiom, trichotomy oracle, quotient-real equality, selected unbounded search, or ambient completeness theorem.*

Proof. Project the accepted carrier. The rows $R, n, q, d, S, G, B, H, C, P, N$ are the only coordinates available to the local certificate, so carrier admission and local naming are finite ledger facts.

The observation route begins with R and the inspected stream window S. The readback row G turns that finite window into the rational Cauchy surface already accepted by $\mathsf{RegSeqRat}^{\uparrow}$.

The bound route then reads q, d, and n as the rational, dyadic, and natural faces of the same displayed bound ledger B. The transport and replay rows preserve exactly these coordinates, and the provenance row names the sibling chapters from which they are read.

Since the carrier has no coordinate for host order, trichotomy, quotient equality, an unbounded search principle, or completeness, none of those principles can enter the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RealArchimedeanPropertyUp.RealArchimedeanPropertyTasteGate single carrier alignment`

Theorem 2420.3 (RealArchimedeanProperty natural-rational bound handoff)**.** *Every order-facing or approximation-facing consumer of an accepted* $\mathsf{RealArchimedeanProperty}^{\uparrow}$ *packet reaches the natural bound row only through the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Nat}^{\uparrow}.$$

The rational and dyadic comparison rows are read before the natural-number bound is exported, and the same handoff is compatible with the $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$ *ledger of chapter 2201.*

Proof. Begin with a consumer requesting a bound for the displayed real name. The continuation row C first routes the request through the finite $\mathsf{StreamName}^{\uparrow}$ window S and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row G.

The comparison rows q and d are then read as rational and dyadic witnesses for the same inspected real observation. Only after these rows are displayed does the natural-number row n become available as the bound face of the ledger B.

The natural bound row is consumed by finite unary induction over the displayed bound ledger. The base step reads the initial ledger face, and each successor step reuses the same $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, rational comparison, and $\mathsf{DyadicRatCore}^{\uparrow}$ comparison rows. The induction exports only the displayed Nat/Rat/Dyadic/Real route; it does not introduce unbounded search, trichotomy, host order, quotient equality, or completeness.

The compatibility with $\mathsf{RealArchimedeanBoundSchema}^{\uparrow}$ is structural: both packets expose the same real, stream, regular readback, rational, dyadic, and bound-ledger coordinates. The property packet adds the explicit $\mathsf{Nat}^{\uparrow}$ handoff without adding host order or completeness data. □

Theorem 2420.4 (RealArchimedeanProperty ledger nonescape)**.** *For an accepted* $\mathsf{RealArchimedeanProperty}^{\uparrow}$ *packet, every Archimedean-property read factors through the displayed rows* $R, n, q, d, S, G, B, H, C, P, N$*. In particular, the packet exports no hidden real supremum, no total order trichotomy, no quotient equality of real names, no unbounded search over naturals, no selected least bound, and no completeness principle for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Inspect the carrier inventory. The only real-facing row is R, the only finite observation rows are S and G, the only comparison rows are q and d, and the only natural bound row is n.

The replay row C can only traverse those displayed coordinates, while H transports them componentwise and P, N package the same route as provenance and local naming. Thus any Archimedean-property read must pass through the finite ledger described in the carrier.

Because no row stores a supremum, trichotomy decision, quotient equality test, unbounded natural search, selected least-bound operator, or completeness theorem, the packet cannot export any of those structures. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealArchimedeanProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealArchimedeanProperty}^{\uparrow}$ packet is generated from a RealUp name, NatUp bound row, RatUp comparison row, DyadicRatCoreUp comparison row, StreamNameUp finite-window row, RegSeqRatUp readback row, Archimedean bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealArchimedeanProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3372.1, Definition 3372.2, Definition 3372.3, and Definition 3372.4 seed the finite property-level bound route over Real, StreamName, RegSeqRat, Rat, DyadicRatCore, Nat, and RealArchimedeanBoundSchema rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealArchimedeanProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real order, trichotomy, quotient equality of real names, unbounded search, least-bound selection, Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, natural-rational-dyadic bound compatibility, finite-window readback, transport stability, replay stability, and ledger nonescape for BEDC.Derived.RealArchimedeanPropertyUp.

Chapter 2421

A Concrete Naming Certificate for $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ packet records the monotone-convergence route that is available when a bounded monotone real sequence is handed to a located supremum surface. It sits between the source sequence packet of chapter 1434, the located upper-bound and lower-approximation packet of chapter 1427, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the finite handoff from monotone sequence data to a located supremum read; it does not import arbitrary completeness of the real line.

Definition 2421.1 (Located monotone convergence carrier)**.** *A* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, B, U, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *source row, exposing the inspected sequence schedule, finite stream windows, regular readbacks, real seals, boundedness ledger, and monotonicity ledger.*
2. *B is the monotone bounded ledger read from M, recording the common upper-bound surface and the finite comparison rows that keep each inspected sequence value below it.*
3. *U is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row, displaying the upper-bound and lower-approximation ledgers supplied to the supremum packet.*
4. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *precision-window row through which the sequence observations, upper-bound ledger, and lower-approximation requests are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the windowed sequence observations and the located-supremum approximation ledger.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the requested dyadic precision, tail threshold, and comparison radii used to relate a late monotone term to the located supremum surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, B, U, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the monotone source, bounded ledger, located-supremum handoff, precision windows, regular readback, dyadic tolerance ledger, real seal, continuation route, provenance, and local naming row.*

9. *C records displayed* Cont *replay from a convergence request through $M, B, U, W, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* LocatedMonotoneConvergence$^{\uparrow}$, MonotoneRealSequence$^{\uparrow}$, LocatedSupremum$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{LocatedMonotoneConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through

$$M, B, U, W, R, D, E, H, C, P, N.$$

It has no coordinate for arbitrary real completeness, trichotomy, quotient stream equality, countable choice, open-cover compactness, or a selected ambient limit outside the displayed located-supremum handoff.

Lean4 ✓ `BEDC.Derived.LocatedMonotoneConvergenceUp.LocatedMonotoneConvergenceTasteGate single carrier alignment`

Theorem 2421.2 (Located monotone convergence NameCert obligations)**.** *For every accepted* LocatedMonotoneConvergence$^{\uparrow}$ *carrier*

$$L = (M, B, U, W, R, D, E, H, C, P, N),$$

the local NameCert$_{\text{LocatedMonotoneConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the monotone source, bounded ledger, located-supremum handoff, shared precision window, regular readback, dyadic tolerance ledger, real seal, transports, replay, provenance, and local naming;*
2. *monotone bounded ledger admission, requiring B to be read from the same* MonotoneRealSequence$^{\uparrow}$ *packet M that supplies the sequence schedule and monotonicity ledger;*
3. *located-supremum handoff, requiring U to expose upper-bound and lower-approximation rows through the* LocatedSupremum$^{\uparrow}$ *surface before any convergence read is exported;*
4. RegSeqRat$^{\uparrow}$ *readback, requiring R to repack the inspected stream windows and approximation witnesses rather than a hidden real representative;*
5. *dyadic tolerance replay, requiring D to bind each requested precision to a finite tail threshold and comparison radius;*
6. Real$^{\uparrow}$ *seal non-escape, requiring E to remain downstream of M, B, U, W, R, D together with H, C, P, N.*

No obligation may call on arbitrary Real$^{\uparrow}$ *completeness, trichotomy, quotient stream equality, countable choice, open-cover compactness, or an ambient selected limit.*

Proof. Project the carrier of Definition 3373.1. Carrier admission exposes exactly the rows $M, B, U, W, R, D, E, H, C$ so the only sequence source is the accepted MonotoneRealSequence$^{\uparrow}$ row M.

Read the order-facing rows next. The bounded ledger B is attached to the same inspected schedule and monotonicity ledger carried by M, while U is the only located-supremum handoff row and therefore the only place where upper-bound and lower-approximation information can be read.

The convergence-facing rows are downstream of these order rows. The shared window W, regular readback R, and dyadic tolerance ledger D supply the finite precision request, readback route, tail threshold, and comparison radius before the real seal E is exposed.

Finally the structural rows H, C, P, N transport, replay, source, and name the same packet. Since the excluded completeness, order, quotient, choice, compactness, and selected-limit coordinates do not occur in the carrier, they cannot occur among the local NameCert obligations. □

Theorem 2421.3 (Located monotone convergence supremum readback)**.** *Let $L = (M, B, U, W, R, D, E, H, C, P, N$ be an accepted* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing convergence read exported by L factors through the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row U and its displayed upper-bound and lower-approximation ledgers, then through the shared* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. Thus the read is a located-supremum factorization of the monotone source M, not an appeal to ambient completeness of arbitrary real subsets.*

Lean4 ✓ `BEDC.Derived.LocatedMonotoneConvergenceUp.LocatedMonotoneConvergenceCarrier supremum readback`

Proof. Start with a Real-facing convergence consumer. By Definition 3373.1, the only terminal real coordinate is E, and it is displayed after the monotone source, bounded ledger, located-supremum handoff, shared window, regular readback, and dyadic tolerance ledger.

Apply Definition 3373.2. Its located-supremum handoff row forces the upper-bound and lower-approximation reads through U, while its readback and tolerance rows force the same request through W, R, D before E can be read.

The packet M supplies only the bounded monotone source surface, and H, C, P, N can only transport, replay, source, and name the displayed route. Therefore every exported convergence read factors through $\mathsf{LocatedSupremum}^{\uparrow}$ and not through an ambient completeness principle. □

Theorem 2421.4 (Located monotone convergence bounded source route)**.** *Let $L = (M, B, U, W, R, D, E, H, C, P, N$ be an accepted* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *packet whose source row is supplied by an accepted* $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ *packet. Then every convergence read first consumes the source packet's monotonicity ledger, boundedness ledger, and* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *handoff before it may inspect the* $\mathsf{LocatedSupremum}^{\uparrow}$ *row U, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The readback is therefore a bounded-monotone-source route followed by a located-supremum route, not an ambient completeness shortcut.*

Proof. Project the carrier of Definition 3373.1. The rows M and B are the only source-facing rows available before the located-supremum handoff U and the readback rows W, R, D, E.

When M is supplied by $\mathsf{MonotoneBoundedSequence}^{\uparrow}$, apply Definition 3407.4. The source-side read must expose the monotonicity ledger, boundedness ledger, and $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ handoff through the same finite source surface before a located convergence consumer can inspect later rows.

Now apply Definition 3373.3. After the bounded source route is fixed, every $\mathsf{Real}^{\uparrow}$-facing convergence read factors through U, then through the shared window and readback rows W, R, D, and finally through the terminal seal E.

The structural rows H, C, P, N preserve this order under transport, replay, provenance, and naming. Since neither carrier has a coordinate for arbitrary real completeness or a selected ambient limit, the readback cannot bypass the bounded-source route. □

Theorem 2421.5 (Located monotone convergence source induction)**.** *Let*

$$L = (M, B, U, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing convergence read exported by* L *is generated by induction over the displayed finite rows* $M, B, U, W, R, D, E, H, C, P, N$*. The base rows are the monotone source* M *and boundedness ledger* B*. The step rows are the located-supremum handoff* U*,* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*,* Cont *replay* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{LocatedMonotoneConvergence}^{\uparrow}}$ *row* N*. The induction exposes no selected limit, quotient representative, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Begin with the finite carrier displayed in Definition 3373.1. Its only rows are $M, B, U, W, R, D, E, H, C, P, N$, so an induction on accepted convergence reads has base information only from the monotone source and boundedness ledger.

Apply Definition 3373.2. The NameCert obligations force carrier admission, bounded ledger admission, located-supremum handoff, readback, tolerance replay, and Real seal non-escape to occur through those same displayed rows.

The readback steps are fixed by Definition 3373.3. After the base rows are admitted, each Real-facing read must pass through U, W, R, D, E in order, with H, C, P, N only transporting, replaying, sourcing, and naming the route.

If the source is supplied by a bounded monotone packet, Definition 3373.4 identifies the same base rows as the monotonicity ledger, boundedness ledger, and finite source handoff before any later convergence row can be inspected.

Thus the induction covers every exported convergence read using exactly the displayed finite rows. Since the carrier and its NameCert obligations contain no coordinate for a selected limit, quotient representative, countable choice, trichotomy, or ambient Real completeness, none can appear in the generated read. □

Falsifiable prediction: Every accepted $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ convergence read factors through a MonotoneRealSequence source, a boundedness ledger, a LocatedSupremum handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Real-facing convergence consumer may inspect it.

Independence witness: monotone-real-sequence, locatedsupremum, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded monotone sequence source and a located-supremum handoff before the Real-facing convergence read is sealed.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMonotoneConvergence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMonotoneConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3373.1, Definition 3373.2, Definition 3373.3, Definition 3373.4, and Definition 3373.5 seed the finite handoff from bounded monotone real sequence data to a located-supremum Real-facing convergence read.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMonotoneConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient stream equality, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, monotone bounded ledger admission, located-supremum handoff, RegSeqRat readback, dyadic tolerance replay, and Real seal non-escape for BEDC.Derived.LocatedMonotoneConvergenceU

Constructive story: A $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ packet is generated from a MonotoneRealSequence source, a monotone bounded ledger, a LocatedSupremum handoff, a StreamName precision window, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2422

A Concrete Naming Certificate for $\mathsf{BaireSteinhaus}^{\uparrow}$

Following Baire, Steinhaus, and Banach–Steinhaus, the $\mathsf{BaireSteinhaus}^{\uparrow}$ packet records the finite BEDC handoff by which a Baire-category witness, a complete metric source, norm rows, functional-analysis probes, and a uniform-boundedness consumer are named in one certificate. The packet sits between the Baire-category surface of chapter 1542, the complete-metric surface of chapter 128, the norm surface of chapter 89, the functional-analysis source of chapter 94, and the uniform-boundedness boundary of chapter 1835. It is a traditional analysis reconstruction in the BEDC carrier language: the certificate names the finite pointwise-bounded handoff without asserting host Banach-space completeness, countable choice, quotient equality of function spaces, or an unrestricted uniform-boundedness theorem.

Definition 2422.1 (Baire–Steinhaus carrier)**.** *A* $\mathsf{BaireSteinhaus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, R, F, U, W, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open row read by the pointwise-bounded argument.*
2. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row supplying the complete metric carrier on which the Baire row is interpreted.*
3. *R is the* $\mathsf{Norm}^{\uparrow}$ *row used to read boundedness witnesses as finite norm estimates.*
4. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *source row naming the family of linear probes and the finite test windows visible to the packet.*
5. *U is the* $\mathsf{UniformBoundedness}^{\uparrow}$ *consumer row that may receive a uniform-bound request only after B, M, R, F have been displayed.*
6. *W is the pointwise-boundedness ledger, recording the inspected point, operator family window, norm bound, and finite comparison tolerance.*
7. *E is the Baire–Steinhaus handoff row from the pointwise ledger W to the uniform-boundedness consumer U.*
8. *H records componentwise* hsame *transport for B, M, R, F, U, W, E.*
9. *C records displayed* Cont *replay from a pointwise-bounded request through the Baire, complete-metric, norm, functional-analysis, and handoff rows.*

10. *P is the* Pkg *provenance over* BaireSteinhaus$^{\uparrow}$, BaireCategory$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Norm$^{\uparrow}$, FunctionalAnalysis$^{\uparrow}$, UniformBoundedness$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BaireSteinhaus}^{\uparrow}}$ *row.*

The carrier accepts only packets whose Baire, complete-metric, norm, functional-analysis, pointwise-boundedness, uniform-boundedness, transport, replay, provenance, and local naming rows are displayed in the same finite certificate.

Lean4 ✓ `BEDC.Derived.BaireSteinhausUp.BaireSteinhausTasteGate single carrier alignment`

Theorem 2422.2 (Baire–Steinhaus NameCert obligations)**.** *For every accepted* BaireSteinhaus$^{\uparrow}$ *carrier $S = (B, M, R, F, U, W, E, H, C, P, N)$, the local* NameCert$_{\text{BaireSteinhaus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* BaireCategory$^{\uparrow}$ *row,* CompleteMetric$^{\uparrow}$ *row,* Norm$^{\uparrow}$ *row,* FunctionalAnalysis$^{\uparrow}$ *row,* UniformBoundedness$^{\uparrow}$ *consumer row, pointwise-boundedness ledger, Baire–Steinhaus handoff, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. No obligation may read host Banach-space completeness, countable choice, quotient equality of function spaces, a selected dense point, or an unrestricted uniform-boundedness theorem.*

Proof. Project the carrier of Definition 3374.1. The rows $B, M, R, F, U, W, E, H, C, P, N$ are the only coordinates available to the local certificate, so every obligation is a finite row obligation.

The Baire-category side is read through B over the complete metric row M. The norm and functional-analysis rows R and F supply only the displayed finite observations used by the pointwise-boundedness ledger W.

The handoff row E is then the only route from W to the uniform-boundedness consumer U. Transport, replay, provenance, and local naming preserve that same route, and the carrier contains no coordinate for the excluded host-level principles. □

Theorem 2422.3 (Baire–Steinhaus pointwise-bounded handoff)**.** *Every pointwise-boundedness read accepted by a* BaireSteinhaus$^{\uparrow}$ *packet factors through the finite route*

$$\text{BaireCategory}^{\uparrow},\ \text{CompleteMetric}^{\uparrow},\ \text{Norm}^{\uparrow},\ \text{FunctionalAnalysis}^{\uparrow} \longmapsto \text{UniformBoundedness}^{\uparrow}.$$

The pointwise ledger W is exposed before the handoff row E can feed U, and the UniformBoundedness$^{\uparrow}$ *consumer receives only that displayed handoff. It receives no host Banach-space completeness theorem, no global operator-family supremum, no countable-choice selector, no quotient equality of function spaces, and no selected dense point.*

Proof. Begin with a pointwise-bounded request. The continuation row C first routes the request through the Baire row B and the complete-metric row M, so the category argument is anchored in the displayed metric source.

Next the request reads the norm row R and functional-analysis row F. These rows expose the finite operator-family windows and norm estimates stored in W, not a host family of all operators.

Finally the handoff row E repacks the displayed pointwise ledger for the uniform-boundedness consumer U. Since H, P, N only transport, source, and name the same finite rows, the consumer cannot recover any excluded completeness, choice, quotient, supremum, or selected-point principle. □

Closure status for NameCert$_{\text{BaireSteinhaus}^{\uparrow}}$**.**

Constructive story: A BaireSteinhaus$^{\uparrow}$ packet is generated from a BaireCategory row, CompleteMetric row, Norm row, FunctionalAnalysis source row, UniformBoundedness consumer row, pointwise-boundedness ledger, handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BaireSteinhaus}\uparrow}$, seed)

Scope closed: Definition 3374.1, Definition 3374.2, and Definition 3374.3 seed the finite pointwise-boundedness handoff over BaireCategory, CompleteMetric, Norm, FunctionalAnalysis, and UniformBoundedness rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BaireSteinhaus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Banach-space completeness, countable choice, quotient equality of function spaces, selected dense points, global operator-family suprema, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pointwise-boundedness ledger exposure, Baire-category routing, norm and functional-analysis compatibility, uniform-boundedness handoff, transport replay, provenance, and local naming for BEDC.Derived.BaireSteinhausUp.

Chapter 2423

A Concrete Naming Certificate for $\mathsf{BanachSteinhaus}^{\uparrow}$

Following Banach and Steinhaus, the $\mathsf{BanachSteinhaus}^{\uparrow}$ packet records the traditional theorem-level surface behind the uniform boundedness principle as finite NameCert data. It is the neighbour of the Baire handoff in chapter 3374 and the operator-family certificate in chapter 2302: the packet names the theorem route from Baire-category completeness data to a uniform boundedness read without importing a host Banach-space theorem, countable choice, quotient equality of function spaces, or an unrecorded operator-family supremum.

Definition 2423.1 (Banach–Steinhaus carrier)**.** *A* $\mathsf{BanachSteinhaus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, M, N, F, U, L, W, H, C, P, K)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *row that supplies the category witness used by the theorem-level route.*
2. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row over the displayed source, keeping the Baire read tied to a complete metric carrier.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row through which pointwise and uniform boundedness are read as norm estimates.*
4. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *row naming the linear-probe family and the finite observation windows visible to the packet.*
5. *U is the* $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ *row that receives the theorem-level uniform-bound read after the Baire, completeness, norm, and functional-analysis rows have been displayed.*
6. *L is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *family row over the same source and target surfaces.*
7. *W is the pointwise-boundedness-to-uniform-bound ledger, recording the inspected source windows, operator rows, norm bounds, and the single uniform operator-bound output row.*
8. *H records componentwise* hsame *transport for B, M, N, F, U, L, W.*
9. *C records displayed* Cont *replay from pointwise boundedness requests through the Baire-category, complete-metric, norm, functional-analysis, bounded-operator, and uniform-boundedness rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BanachSteinhaus}^{\uparrow}$, $\mathsf{BaireSteinhaus}^{\uparrow}$, $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *K is the local* $\mathsf{NameCert}_{\mathsf{BanachSteinhaus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host-level Banach-space completeness, countable choice, quotient equality of maps, an unrestricted operator-family selector, or a theorem object outside the finite route.

Lean4 ✓ `BEDC.Derived.BanachSteinhausUp.BanachSteinhausTasteGate single carrier alignment`

Theorem 2423.2 (Banach–Steinhaus NameCert obligations)**.** *For every accepted* $\mathsf{BanachSteinhaus}^{\uparrow}$ *carrier* $T = (B, M, N, F, U, L, W, H, C, P, K)$*, the local* $\mathsf{NameCert}_{\mathsf{BanachSteinhaus}^{\uparrow}}$ *surface consists exactly of carrier admission for the Baire-category row, complete-metric row, norm row, functional-analysis row, uniform-boundedness-principle row, bounded-linear-operator family row, pointwise-to-uniform ledger, componentwise transport, displayed replay, provenance, and local naming; Baire-source compatibility between B and M; operator-family compatibility between F and L; uniform-bound exactness through W and U; and non-escape from host completeness, countable choice, quotient equality of maps, unrestricted operator-family selectors, and theorem objects outside the displayed finite packet.*

Proof. Project the carrier of Definition 3375.1. The tuple $B, M, N, F, U, L, W, H, C, P, K$ is the whole accepted packet, so carrier admission and the named local rows are direct reads from the finite history.

The Baire-source compatibility is the shared route through B and M. The category row is interpreted only over the complete metric row displayed in the same packet, so a consumer cannot detach the Baire read from the carried source.

The operator-family compatibility is the shared route through F and L. The functional-analysis row names the finite probe windows, and the bounded-linear-operator row records the operator-family data over those same windows.

The uniform-bound exactness is the ledger W feeding the uniform-boundedness-principle row U. The transport, replay, provenance, and naming rows H, C, P, K certify that the same displayed route is preserved.

Since no coordinate names the excluded host-level objects, the local NameCert surface exports only the finite Banach–Steinhaus route. □

Theorem 2423.3 (Banach–Steinhaus Baire handoff)**.** *Every theorem-level read of an accepted* $\mathsf{BanachSteinhaus}^{\uparrow}$ *carrier factors through the ordered handoff*

$$\mathsf{BaireCategory}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Norm}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow},\ \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \mathsf{UniformBoundednessPr}$$

The $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$ *row receives the ledger W only after the Baire and complete-metric rows have been exposed through the same* BHist *packet. Thus the packet is a theorem-level neighbour of chapter 3374 and chapter 2302, not a replacement for either sibling and not a host Banach–Steinhaus theorem outside BEDC data.*

Proof. Read the pointwise-boundedness request through the continuation row C. The first part of the route exposes the Baire-category row B over the complete-metric row M, matching the Baire side of the handoff named in chapter 3374.

Next read the norm row N, the functional-analysis row F, and the bounded-linear-operator family row L. These rows provide the finite operator windows and norm estimates that can be assembled into the pointwise-to-uniform ledger W.

Finally feed W to the uniform-boundedness-principle row U, the same theorem-level consumer named in chapter 2302. The rows H, P, K transport, source, and name this route without adding an external theorem object.

The exported handoff is therefore exactly the displayed finite route, with no host completeness principle, countable-choice selector, quotient equality of function spaces, or unrestricted family supremum. □

Falsifiable prediction: Every accepted $\mathsf{BanachSteinhaus}^{\uparrow}$ packet must expose $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{UniformBoundednessPrinciple}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows before any theorem-level uniform-bound read is public.

Independence witness: baire-steinhaus, uniform-boundedness-principle, boundedlinearoperator, norm, complete-metric: $\mathsf{BanachSteinhaus}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the Baire-category source, complete-metric source, norm read, functional-analysis probe family, bounded-operator family, pointwise-to-uniform ledger, theorem-level uniform-boundedness consumer, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachSteinhaus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachSteinhaus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3375.1, Definition 3375.2, and Definition 3375.3 seed the finite theorem-level Banach–Steinhaus route over BaireCategory, CompleteMetric, Norm, FunctionalAnalysis, UniformBoundednessPrinciple, BoundedLinearOperator, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachSteinhaus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Banach-space completeness, countable choice, quotient equality of maps, unrestricted operator-family selection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Baire-source compatibility, operator-family compatibility, uniform-bound ledger exactness, Baire handoff stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.BanachSteinhausUp.

Constructive story: A $\mathsf{BanachSteinhaus}^{\uparrow}$ packet is generated from BaireCategory, CompleteMetric, Norm, FunctionalAnalysis, UniformBoundednessPrinciple, BoundedLinearOperator, pointwise-to-uniform ledger, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 2424

A Concrete Naming Certificate for $\mathsf{CauchyCompletionReflection}^{\uparrow}$

Following Bishop and Bridges constructive completion and Kelley reflection terminology, the $\mathsf{CauchyCompletionReflection}^{\uparrow}$ packet records the finite BEDC boundary where Cauchy completion data reflect through the displayed unit and counit routes before reaching the Real seal. It reads the dense unit route of chapter 1527, the completed-object return route of chapter 1539, the comparison surface of chapter 1954, the broader completion-reflection boundary of chapter 403, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a nonquotient reflection certificate for displayed completion routes; it does not identify quotient completions, choose stream representatives, assert host equality, invoke countable choice, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2424.1 (CauchyCompletionReflection carrier)**.** *A* $\mathsf{CauchyCompletionReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (U, V, Q, F, S, D, A, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row admitting source data into the completion-facing presentation.*
2. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *row returning completed data to a displayed completion consumer.*
3. *Q is the* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *row comparing the unit/universal-property presentation with the functorial metric-completion presentation.*
4. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *row tying the unit and counit routes to the same reflection boundary.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected before any terminal seal can be read.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the stream windows.*
7. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row shared by the unit, counit, comparison, and reflection routes.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, A have been displayed.*

9. *H records componentwise* hsame *transport for U, V, Q, F, S, D, A, E and the structural rows.*

10. *C records displayed* Cont *replay of the route*

$$U, V, Q, F \longmapsto S, D, A \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionReflection}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflection}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, host equality of completed objects, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectionUp.CauchyCompletionReflectionTasteGate single carrier alignment`

Theorem 2424.2 (CauchyCompletionReflection NameCert obligations)**.** *For every accepted* CauchyCompletionRefl *carrier*

$$R = (U, V, Q, F, S, D, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the unit route, counit route, comparison row, reflection row, stream windows, dyadic ledger, regular readback, Real seal, transport, replay, provenance, and local naming row;*

2. *unit exposure, requiring source admission to pass through U before a completion-facing read can inspect Q or F;*

3. *counit exposure, requiring completed-object return to pass through V before the same Q, F reflection boundary is read;*

4. *comparison agreement, requiring the unit route and counit route to use the shared* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *row Q before the finite analytic route is public;*

5. *reflection stability, requiring F to be the only reflection witness tying U, V, Q to the terminal seal;*

6. *finite seal routing, requiring all Real-facing reads to pass through S, D, A, E and then through H, C, P, N;*

7. *non-escape, requiring the packet to source and name no quotient completion equality, selected representative, host equality, countable-choice schedule, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Carrier admission is projection from Definition 3376.1. The accepted tuple exposes exactly the unit, counit, comparison, reflection, analytic readback, and structural rows listed there.

For the unit side, the source row is read through U before any completion-facing comparison is available. For the counit side, the completed-object return is read through V before the same comparison and reflection boundary can be inspected.

The comparison and reflection obligations use Q and F. The comparison row identifies the displayed completion presentations, while F records that both the unit and counit reads are attached to the same completion-reflection boundary.

Finally the finite seal route is forced through S, D, A, E. Induction on the finite $\mathsf{StreamName}^{\uparrow}$ windows in S shows that each inspected window carries only its dyadic tolerance row and regular rational readback before the terminal $\mathsf{Real}^{\uparrow}$ seal is reached. The transport, replay, provenance, and naming rows H, C, P, N preserve only these displayed coordinates, so no excluded completion or choice principle is exported. □

Theorem 2424.3 (CauchyCompletionReflection unit-counit triangle)**.** *Let*

$$R = (U, V, Q, F, S, D, A, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyCompletionReflection}^{\uparrow}$ *carrier. Every consumer that compares the unit route with the counit route factors through the finite triangle*

$$U, V \longmapsto Q, F \longmapsto S, D, A \longmapsto E.$$

The triangle is a displayed NameCert route over $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It is not quotient completion equality, not selected representative equality, not host equality of completed objects, not countable choice, and not ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier. A unit-facing read has access to U, and a counit-facing read has access to V; neither route contains a terminal seal on its own.

The two reads meet only at Q and F. The comparison row supplies the shared completion presentation, and the reflection row records the boundary that both the unit and counit routes must use.

The remaining analytic data are S, D, A, E. Induction on the finite stream-window family shows that every triangle consumer sees exactly the window row, attached dyadic tolerance, regular rational readback, and Real seal before the structural rows H, C, P, N replay and name the route. Since no other coordinate is present, the excluded quotient, representative, host-equality, choice, and completeness data cannot be read. □

Theorem 2424.4 (CauchyCompletionReflection Real-seal handoff)**.** *For an accepted* $\mathsf{CauchyCompletionReflection}^{\uparrow}$ *carrier* $R = (U, V, Q, F, S, D, A, E, H, C, P, N)$, *every Real-facing completion-reflection consumer receives the terminal seal* E *only through the route*

$$U, V, Q, F \longmapsto S, D, A \longmapsto E \longmapsto H, C, P, N.$$

Thus the handoff to $\mathsf{Real}^{\uparrow}$ *is mediated by the sibling* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows and by the displayed* $\mathsf{CompletionReflection}^{\uparrow}$ *boundary. It exports no quotient completion equality, selected representative, host equality, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean bridge, or detached seal.*

Proof. Start with a Real-facing consumer. Projection of the accepted carrier gives the only available completion-reflection rows: U, V, Q, F and the finite analytic route S, D, A, E.

The consumer cannot read E before the sibling route has been displayed. The stream windows in S determine the finite observations, D supplies their tolerances, and A supplies the regular rational readback.

After E is reached, H and C transport and replay the same route, while P and N source and name it. No carrier coordinate stores a quotient completion, selected representative, host equality, choice schedule, compactness argument, ambient real-completeness theorem, Lean bridge, or detached seal, so no Real-facing handoff can export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflection}^{\uparrow}$ packet is generated from CauchyCompletionUnit and CauchyCompletionCounit routes, a CauchyCompletionComparison row, a CompletionReflection witness, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3376.1, Definition 3376.2, Definition 3376.3, and Definition 3376.4 seed the finite nonquotient reflection boundary for L10 completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit exposure, counit exposure, comparison agreement, reflection stability, finite seal routing, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletion

Chapter 2425

A Concrete Naming Certificate for $\mathsf{CauchyRealArchimedean}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchyRealArchimedean}^{\uparrow}$ packet records the finite Archimedean witness consumed by L10 Cauchy-real readers before an order, located-comparison, or completion-facing consumer opens a real-name seal. It sits over the regular rational source rows of chapter 301, the dyadic scale rows of chapter 291, the terminal real-name surface of chapter 38, the Cauchy-real presentation route of chapter 1511, and the rational-bound witness surface of chapter 430. The packet names a displayed finite bound route; it is not a host least-bound principle, not quotient equality of real names, not a choice-selected integer part, and not ambient real completeness.

Definition 2425.1 (CauchyRealArchimedean carrier)**.** *A* $\mathsf{CauchyRealArchimedean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, D, E, W, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose finite regular-rational observations are the only Cauchy-real reads admitted by the packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row recording the dyadic tolerance, comparison budget, and rational arithmetic used to inspect G.*
3. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the displayed route through G and D.*
4. *W is the Archimedean bound witness row, read as the rational or dyadic bound surface supplied by chapter 430 for the sealed Cauchy-real name.*
5. *H records componentwise* hsame *transport for G, D, E, W, C, P, N.*
6. *C records displayed* Cont *replay from regular-rational windows through dyadic scale inspection, the terminal real seal, and the Archimedean witness row:*

$$G \longmapsto D \longmapsto E \longmapsto W.$$

7. *P is the* Pkg *provenance over* $\mathsf{CauchyRealArchimedean}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealPresentation}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealArchimedean}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through G, D, E, W, H, C, P, N. It has no coordinate for a host supremum, a selected least bound, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2425.2 (CauchyRealArchimedean NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealArchimedean}^{\uparrow}$ *carrier $A = (G, D, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealArchimedean}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed regular-rational source, dyadic scale, real seal, Archimedean witness, transport, replay, provenance, and local naming rows;*
2. *classifier transport, requiring comparisons of accepted packets to inspect matching G, D, E, W rows through the componentwise* hsame *data in H;*
3. *dyadic-scale exactness, requiring every bound or comparison request to pass through the displayed scale row D before the real seal E is consumed;*
4. *Archimedean witness exposure, requiring the bound witness W to be read after the same G, D, E route and before any order or located-comparison consumer uses it;*
5. *continuation, provenance, and naming stability through C, P, N.*

Proof. Project the carrier in Definition 3378.1. The regular-rational observations, dyadic scale data, real-name seal, bound witness, transport, replay, provenance, and local name are the only displayed coordinates.

The analytic route is supplied by the sibling Cauchy-real chapters. The $\mathsf{Real}^{\uparrow}$ seal is read through chapter 38, the regular rational source through chapter 301, the scale row through chapter 291, and the presentation face through chapter 1511.

The Archimedean part is then the displayed witness row. Apply the rational-bound surface of chapter 430: it supplies a finite bound route for the same real-name seal, while this carrier records that route as W downstream of G, D, E.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since no field stores a host supremum, selected least bound, quotient stream equality, countable-choice schedule, host equality row, or ambient completeness object, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyRealArchimedeanUp.CauchyRealArchimedeanCarrier namecert obligations`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealArchimedean}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRealArchimedean}^{\uparrow}$ packet is generated from displayed $\mathsf{RegSeqRat}^{\uparrow}$ source rows, $\mathsf{DyadicRatCore}^{\uparrow}$ scale rows, a terminal $\mathsf{Real}^{\uparrow}$ seal row, an Archimedean bound witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRealArchimedean}^{\uparrow}}$, seed)

Scope closed: Definition 3378.1 and Definition 3378.2 seed the finite Archimedean witness route for Cauchy-real names over RegSeqRat, DyadicRatCore, Real, CauchyRealPresentation, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRealArchimedean}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected least bounds, integer-part selection, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, dyadic-scale exactness, Archimedean witness exposure, replay stability, provenance stability, and local naming for the same displayed packet.

Chapter 2426

A Concrete Naming Certificate for $\mathsf{CauchyCompletionOperator}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyCompletionOperator}^{\uparrow}$ packet names the finite operator surface that turns displayed Cauchy data into a completion-facing handoff without selecting quotient representatives. It sits between the metric completion carrier of chapter 1506, the Cauchy carrier of chapter 3413, the StreamName finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the completion boundary of chapter 3350, the uniform completion route of chapter 1473, the separated limit surface of chapter 2355, and the terminal real-name seal of chapter 38. The operator is therefore a finite NameCert object over visible StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, completion-boundary rows, and Real-facing seals, not a host completion class or a choice of limits.

Definition 2426.1 (CauchyCompletionOperator carrier)**.** *A* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, exposing the metric Cauchy request and its displayed finite tolerance route;*
2. *B is the* $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ *row, recording the handoff from metric and uniform completion reads to finite-window and Real-facing consumers;*
3. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row, recording the entourage-facing completion presentation consumed by the same operator;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule of finite windows inspected by the completion request;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the scheduled windows;*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the Cauchy request, readback, and seal boundary;*
7. *Q is the* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *separated-limit row that receives the operator handoff only through the visible completion boundary;*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, B, U, S, R, D, Q have been displayed;*

9. *H records componentwise* hsame *transport for the source, boundary, uniform, window, readback, dyadic, separated-limit, Real-seal, replay, provenance, and local naming rows;*
10. *C records displayed* Cont *replay from an operator request through $M, B, U, S, R, D, Q, E, H, P, N$;*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionOperator}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionBoundary}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompleteSeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionOperator}^{\uparrow}}$ *row.*

The classifier accepts only packets whose operator handoff is exhausted by $M, B, U, S, R, D, Q, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorTasteGate single carrier alignment`

Theorem 2426.2 (CauchyCompletionOperator NameCert obligation surface)**.** *For every accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier $O = (M, B, U, S, R, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionOperat}}$ *surface consists exactly of carrier admission for the displayed twelve-row packet; metric-completion exposure through M; completion-boundary exposure through B; uniform-completion exposure through U; finite-window exposure through S; regular-rational readback through R; dyadic-tolerance exposure through D; separated-limit handoff through Q; terminal Real sealing through E; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperator namecert obligation surface`

↪ variant `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorCarrier namecert obligation surface`

Proof. Project the carrier of Definition 3379.1. The accepted packet exposes exactly the metric source row, completion-boundary row, uniform-completion row, finite windows, regular readback, dyadic ledger, separated-limit row, Real seal, and structural rows.

The operator obligations are read in the displayed order. The metric and uniform completion requests first pass through the boundary row B; the scheduled windows S, readback R, and dyadic ledger D then supply the finite evidence needed by both completion and Real-facing consumers.

The separated-limit and Real-seal rows are downstream of the same packet. The row Q is reached only through the visible boundary route, and the terminal seal E is reached only after the finite windows, readback, and tolerance ledger have already been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, and ambient real completeness are not coordinates of O, they cannot appear as local NameCert obligations. □

Theorem 2426.3 (CauchyCompletionOperator functorial handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *packet factors through the finite handoff*

$$M, U \longmapsto B \longmapsto S, R, D \longmapsto Q, E \longmapsto H, C, P, N.$$

Thus the operator may be replayed by later functorial completion surfaces only as a displayed route from metric and uniform completion requests through common finite windows, dyadic tolerances,

regular readback, separated-limit handoff, Real sealing, transport, replay, provenance, and local naming.

Proof. Start with an accepted carrier. The completion-facing rows M and U are not independent host completions; they are source rows of the same finite packet.

The boundary row B aligns those source rows before any consumer reaches the scheduled windows. The rows S, R, D then expose the common finite observations, regular rational readback, and dyadic tolerance ledger used by downstream completion requests.

The rows Q and E are terminal for the separated-limit and Real-facing sides of the handoff. They do not insert a quotient completion or a selected representative between the finite evidence and the terminal consumer.

The structural rows H, C, P, N preserve this route under transport, replay it as a displayed continuation, record provenance, and name the local certificate. Therefore any later functorial completion surface can consume only the displayed operator route. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorFunctorialHandoff`

Theorem 2426.4 (CauchyCompletionOperator triangle consumption route)**.** *Every accepted* CauchyCompletionOp *packet consumed by* CauchyCompletionFunctoriality$^{\uparrow}$ *or* ***??*** *for an identity or composition triangle read must route through*

$$M, U \longmapsto B \longmapsto S, R, D \longmapsto Q, E \longmapsto H, C, P, N.$$

The triangle read cannot bypass the completion-boundary row B, the finite StreamName$^{\uparrow}$ *windows S, the* RegSeqRat$^{\uparrow}$ *readback R, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, or the separated-limit handoff Q. It exports no quotient completion equality, selected representative, countable-choice schedule, host equality, selected limit, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorTriangleConsumptionRoute`

Proof. Project the carrier of Definition 3379.1. The only available rows are $M, B, U, S, R, D, Q, E, H, C, P, N$, so an identity or composition triangle consumer has no detached completion endpoint to inspect.

Apply Definition 3379.3. It places the metric and uniform source rows before B, then forces every completion-facing read through the finite windows, regular readback, dyadic tolerance ledger, separated-limit handoff, Real seal, transport, replay, provenance, and local naming.

The downstream consumers are the functorial completion surface of chapter 1937 and the separated completion functor of chapter 4094. Both may consume the operator packet only through the displayed route, so their triangle reads inherit the same completion-boundary and finite-window order.

The exclusion clause follows from the carrier inventory. None of quotient completion equality, selected representatives, selected limits, countable choice, host equality, or ambient Real completeness is a coordinate of the accepted packet. □

Theorem 2426.5 (CauchyCompletionOperator finite-window extraction)**.** *Every accepted* CauchyCompletionOpera *packet exposes its completion-facing request through a finite extraction window before any separated-limit or Real endpoint row is available. The extracted window consists exactly of the* StreamName$^{\uparrow}$ *schedule S, the* RegSeqRat$^{\uparrow}$ *readback R, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, the completion-boundary row B, and the structural rows H, C, P, N that transport, replay, source, and name the same finite packet.*

Consequently a consumer may reach Q or E only through the displayed route

$$B, S, R, D, H, C, P, N \longrightarrow Q, E.$$

No selected limit, quotient completion equality, host completion operator, host real equality, or countable-choice schedule is exposed by the extraction.

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorWindowExtraction`

Proof. Project the carrier of Definition 3379.1. The only rows between the metric and uniform source requests and the terminal consumers are the completion boundary, finite StreamName schedule, regular readback, dyadic ledger, separated-limit row, Real seal, and structural support.

Apply Definition 3379.2. Its obligation surface forces local naming to inspect B, S, R, D before Q or E can be consumed, while H, C, P, N only transport, replay, source, and name the displayed packet.

Use Definition 3379.3. The handoff order places the finite window and dyadic ledger between the completion source rows and the terminal rows, so the extraction is determined by the visible window data rather than by any host completion object.

The exclusion clause follows from the same carrier inventory. The packet has no coordinate for a selected limit, quotient completion equality, host completion operator, host real equality, or countable-choice schedule, so none can be read during extraction. □

Theorem 2426.6 (CauchyCompletionOperator ledger nonescape)**.** *No accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *packet exports quotient completion equality, selected representatives, selected limits, countable-choice schedules, host completion operators, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness data. Every consumer route to* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *must first read the packet rows* $M, B, U, S, R, D, Q, E, H, C, P, N$.

Proof. Inspect the carrier inventory in Definition 3379.1. Its analytic coordinates are the metric source, completion boundary, uniform source, finite windows, regular readback, dyadic ledger, separated-limit handoff, and Real seal.

The structural coordinates are only hsame, Cont, Pkg, and NameCert rows. They move, replay, source, and name the displayed packet; they do not add analytic data.

The excluded quotient, representative, limit, choice, host-operator, and ambient-completeness objects are absent from both inventories. Hence every separated-limit or Real-facing read is forced through the visible finite ledger and cannot escape the operator packet. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorLedgerNonescape`

Theorem 2426.7 (CauchyCompletionOperator Real-seal nonescape)**.** *Let T be any Real-facing consumer of an accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier* $O = (M, B, U, S, R, D, Q, E, H, C, P, N)$. *If T reads the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, then the read first factors through the completion-boundary row B, the finite* $\mathsf{StreamName}^{\uparrow}$ *window S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the displayed transport, replay, provenance, and local naming rows H, C, P, N.*

The terminal seal therefore exports only the displayed finite operator packet. It does not expose Real completeness, quotient limits, selected representatives, choice, host equality, or an ambient completion endpoint.

Proof. Begin with Definition 3379.5. It isolates the finite window and tolerance ledger that every terminal consumer must pass through before Q or E can be inspected.

Next apply Definition 3379.3. The Real-facing side of the handoff receives E only after B, S, R, D and the structural rows have already fixed the displayed route.

Finally use Definition 3379.6. Since the packet exports no quotient completion equality, selected representative, selected limit, choice schedule, host completion operator, or ambient Real-completeness coordinate, the terminal Real seal cannot escape the finite operator packet. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorRealSealNonescape`

Theorem 2426.8 (CauchyCompletionOperator obligation surface)**.** *Every accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N)$$

exposes exactly the following obligation surface: the $\mathsf{MetricCompletion}^{\uparrow}$ *row* M*, the* $\mathsf{CauchyCompletionBoundary}^{\uparrow}$ *row* B*, the* $\mathsf{UniformCompletion}^{\uparrow}$ *row* U*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *handoff* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionOperator}^{\uparrow}}$ *row* N*.*

The surface refuses quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission and local naming come from Definition 3379.2. That theorem projects exactly the twelve displayed rows $M, B, U, S, R, D, Q, E, H, C, P, N$ from the accepted carrier and assigns each row its local NameCert role.

The completion-facing order is supplied by Definition 3379.3. It places the metric and uniform source rows before the boundary row, then routes every later completion read through the finite window, regular readback, dyadic ledger, separated-limit handoff, Real seal, transport, replay, provenance, and local naming rows.

The finite inspection window is fixed by Definition 3379.5. It prevents Q or E from being consumed before B, S, R, D, H, C, P, N have been displayed.

Finally apply Definition 3379.6 and Definition 3379.7. These two nonescape clauses exclude quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, and ambient $\mathsf{Real}^{\uparrow}$ completeness from both the ledger and the terminal Real seal. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorPublicObligationSurface`

Theorem 2426.9 (CauchyCompletionOperator obligation triad)**.** *For every accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N),$$

the local NameCert obligations decompose exactly into the following three faces:

1. *finite-window extraction, reading the completion-boundary row* B*, StreamName window* S*, RegSeqRat readback* R*, DyadicRatCore ledger* D*, and structural rows* H, C, P, N *before any terminal read;*
2. *functorial handoff, routing the metric and uniform source rows* M, U *through* B*, then through* S, R, D*, and only then to* Q, E, H, C, P, N*;*
3. *ledger nonescape, requiring every separated-limit or Real-facing consumer to read only the displayed rows* $M, B, U, S, R, D, Q, E, H, C, P, N$ *and no quotient completion equality, selected representative, selected limit, countable-choice schedule, host completion operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorObligationTriad`

Proof. The finite-window face is exactly Definition 3379.5. It isolates B, S, R, D, H, C, P, N as the finite evidence a consumer must inspect before Q or E is available.

The handoff face is exactly Definition 3379.3. It places M, U on the source side, routes them through the boundary row B, and sends every completion-facing consumer through the common finite window before the separated-limit and Real-seal rows.

The nonescape face combines Definition 3379.6 with Definition 3379.7. The first theorem prevents any consumer from leaving the displayed ledger, and the second theorem applies the same refusal to terminal Real-seal reads. Together they exhaust the obligation surface recorded in Definition 3379.8. □

Theorem 2426.10 (CauchyCompletionOperator obligation window route)**.** *Every accepted* CauchyCompletionOper *carrier*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N)$$

satisfies the completion-operator obligation sequence

$$M, U \longrightarrow B \longrightarrow S, R, D \longrightarrow Q, E \longrightarrow H, C, P, N.$$

The metric and uniform source rows M, U are read first; the completion-boundary row B mediates the two source reads; the rows S, R, D expose the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *windows; the rows Q, E are terminal separated-limit and Real-seal consumers; and the rows H, C, P, N only transport, replay, source, and name the same packet.*

Proof. Start from the carrier inventory in Definition 3379.1. An accepted packet has exactly the displayed metric source, completion boundary, uniform source, finite window, regular readback, dyadic tolerance, separated-limit, Real-seal, transport, replay, provenance, and naming rows.

Apply Definition 3379.2. The local NameCert surface reads the metric and uniform source rows as obligations of the same carrier, and the boundary row B is the displayed mediator between those source reads and every later completion-facing consumer.

Use Definition 3379.5. Before either terminal row is available, the operator exposes the finite $\mathsf{StreamName}^{\uparrow}$ schedule S, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D, together with the structural rows that keep the extraction attached to the same packet.

Finally invoke Definition 3379.7. The terminal Real read can only occur after the boundary, finite window, readback, dyadic ledger, and structural rows have fixed the route. The separated-limit row Q is consumed on the same downstream side of the packet, while H, C, P, N merely transport, replay, source, and name what the carrier already displays. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorObligationWindowRoute`

Theorem 2426.11 (CauchyCompletionOperator universal factorization)**.** *Every completion-universal or functorial completion consumer of an accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N)$$

first reads the finite route

$$M, U \longmapsto B \longmapsto S, R, D \longmapsto Q, E \longmapsto H, C, P, N.$$

If the same consumer also cites a $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row or a* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row, that row is admitted only as a downstream read of the same boundary, finite-window, separated-limit, Real-seal, transport, replay, provenance, and local naming route. The consumer receives no host universal property, quotient completion, selected representative, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness shortcut around O.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorUniversalFactorization`

Proof. Start with a completion-universal or functorial completion consumer of O. By Definition 3379.3, the consumer already reads the metric and uniform source rows through the displayed boundary row before it can inspect finite windows, regular readback, dyadic tolerances, separated-limit handoff, Real seal, transport, replay, provenance, or local naming.

Next apply Definition 3379.10. It fixes the same order as an obligation sequence: M, U precede B; B precedes S, R, D; the terminal rows Q, E are downstream of those finite observations; and H, C, P, N only preserve and name the displayed packet.

Now consider an additional $\mathsf{CompletionUniversalProperty}^{\uparrow}$ or $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ citation. Such a citation can be read only after the rows needed by the operator route have been displayed, because the operator exports completion-facing data solely through the boundary and window route just identified. The cited universal or functorial row is therefore a later consumer of O, not an independent source of completion evidence.

Finally use Definition 3379.6 and Definition 3379.7. These exclude quotient completion equality, selected representatives, selected limits, countable-choice schedules, host completion operators, ambient Real completeness, and terminal-seal escapes from the packet. Hence no universal-property or functorial completion consumer can bypass the finite CauchyCompletionOperator route. □

Theorem 2426.12 (CauchyCompletionOperator separated-limit factorization)**.** *Every* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *consumer reading row Q from an accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N)$$

must first read the finite route

$$M, U \longmapsto B \longmapsto S, R, D \longmapsto H, C, P, N.$$

Thus Q is a downstream separated-limit handoff of the displayed finite-window route, not an independent completion witness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorSeparatedLimitFactorization`

Proof. Start with the obligation surface of Definition 3379.2. It exposes Q only as one row of the accepted carrier, after the metric source, completion-boundary, uniform source, StreamName window, RegSeqRat readback, and DyadicRatCore tolerance rows have already been displayed.

Apply finite-window extraction and the obligation-window route, Definition 3379.5 and Definition 3379.10. These two results force the separated-limit consumer through M, U, then B, then S, R, D, before the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same packet.

Finally use ledger nonescape, Definition 3379.6. Since quotient completion equality, selected limits, host completion operators, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, row Q cannot supply an independent completion object. It is only the separated-limit handoff downstream of the finite StreamName, RegSeqRat, and DyadicRatCore route. □

Theorem 2426.13 (CauchyCompletionOperator idempotent complete carrier)**.** *Let $O = (M, B, U, S, R, D, Q, E, H$ be an accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *packet whose source and target completion rows are already separated, and whose transport row is the identity replay over the displayed* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. Then any second application of the completion operator factors through the same finite observation windows, the same regular rational readback, the same dyadic tolerance ledger, and the same terminal Real seal.*

Thus the second application is read as an idempotent complete-carrier replay of O, not as a new quotient stream equality, selected limit, countable-choice schedule, host completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorIdempotentCompleteCarrier`

Proof. Start from the carrier of Definition 3379.1. The only rows available to either completion read are the metric and uniform source rows, the boundary row, the StreamName window, the RegSeqRat readback, the DyadicRatCore ledger, the separated-limit handoff, the Real seal, and the structural replay rows.

Apply the universal factorization theorem, Definition 3379.11. It forces every completion-universal or functorial consumer of the first application through $M, U, B, S, R, D, Q, E, H, C, P, N$ before any completion-facing handoff is available.

Next apply separated-limit factorization, Definition 3379.12. Since the source and target completion rows are already separated and the transport row is the identity replay over the displayed limit-seal, window, readback, dyadic, and Real rows, the second application has no additional separated-limit coordinate to inspect.

Finally use the scoped obligation closure of Definition 3379.14. The closed scope already exhausts carrier admission, finite-window routing, terminal Real sealing, transport, replay, provenance, and local naming. The repeated operator read therefore reuses the same finite observation windows and terminal seal without introducing quotient stream equality, a selected limit, countable choice, host completion data, or ambient Real completeness. □

Theorem 2426.14 (CauchyCompletionOperator scoped obligation closure)**.** *For every accepted* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *carrier*

$$O = (M, B, U, S, R, D, Q, E, H, C, P, N),$$

the metric and uniform source rows, completion-boundary row, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, separated-limit handoff,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local* NameCert *rows jointly discharge the* obligation *surface for the operator. Every scope is routed through the displayed BEDC primitives and sibling chapters, and no scope is supplied by quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorScopedObligationClosure`

Proof. Start with the obligation surface and functorial handoff, Definition 3379.2 and Definition 3379.3. These expose the metric source, uniform source, completion boundary, finite window, regular readback, dyadic ledger, separated-limit handoff, Real seal, and structural rows in the displayed carrier order.

Apply finite-window extraction, ledger nonescape, and Real-seal nonescape from Definition 3379.5, Definition 3379.6, and Definition 3379.7. They force terminal separated-limit and Real-facing reads through the same finite window and prevent escape to quotient, choice, host, or ambient-completeness data.

Finally use the obligation triad, obligation-window route, universal factorization, and separated-limit factorization, Definition 3379.9, Definition 3379.10, Definition 3379.11, and Definition 3379.12. These rows exhaust carrier admission, source routing, terminal handoff, transport, replay, provenance, and local naming, so the scoped obligation surface is closed exactly at obligation. □

Theorem 2426.15 (CauchyCompletionOperator composition uniqueness route)**.** *Let O_0 and O_1 be accepted* CauchyCompletionOperator$^\uparrow$ *packets with the same* MetricCompletion$^\uparrow$, CauchyCompletionBoundary$^\uparrow$, UniformCompletion$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, CompleteSeparatedMetric$^\uparrow$, Real$^\uparrow$, hsame, Cont, Pkg, *and* NameCert *rows. Then every completion-facing composition read induced by O_0 follows the same finite operator route as the read induced by O_1.*

Equivalently, agreement of the displayed rows forces agreement of the completion-facing handoff route

$$M, U \longmapsto B \longmapsto S, R, D \longmapsto Q, E \longmapsto H, C, P, N,$$

without asserting quotient completion equality, selected limits, host completion operators, countable choice, or ambient Real$^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorCompositionUniquenessRoute`

Proof. Start with the functorial handoff of Definition 3379.3. It forces any composition-facing read of either packet to pass through the same metric source, uniform source, completion boundary, finite window, regular readback, dyadic tolerance ledger, separated-limit handoff, Real seal, transport, replay, provenance, and local naming rows.

Next apply finite-window extraction and the obligation-window route, Definition 3379.5 and Definition 3379.10. Since O_0 and O_1 agree on the displayed StreamName, RegSeqRat, DyadicRatCore, boundary, and structural rows, both composition reads expose the same finite observation window before Q or E is available.

Use universal factorization and separated-limit factorization, Definition 3379.11 and Definition 3379.12. These theorems route the universal, functorial, and separated-limit consumers through the already displayed packet rows, so no second completion-facing route can be generated from data outside the common row family.

Finally invoke scoped obligation closure, Definition 3379.14. The closed scope exhausts the admissible carrier, handoff, window, seal, transport, replay, provenance, and naming obligations. Therefore two accepted packets with the same displayed rows induce the same completion-facing route, while quotient completion equality, selected limits, host completion operators, countable choice, and ambient Real$^\uparrow$ completeness remain outside the claim. □

Theorem 2426.16 (CauchyCompletionOperator public export)**.** *The public* CauchyCompletionOperator$^\uparrow$ *export is the finite route*

$$M, B, U, S, R, D, Q, E, H, C, P, N$$

from metric and uniform completion requests through StreamName$^\uparrow$ *windows,* RegSeqRat$^\uparrow$ *readback,* DyadicRatCore$^\uparrow$ *tolerances,* CompleteSeparatedMetric$^\uparrow$ *handoff, and the terminal* Real$^\uparrow$ *seal. Every downstream completion consumer must cite this displayed route before using the operator, rather than quotient completion equality, host completion equality, a selected representative, a selected limit, countable choice, or ambient* Real$^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorPublicExport`

Proof. Start with the obligation surface and functorial handoff, Definition 3379.2 and Definition 3379.3. They expose the source metric row, boundary row, uniform row, finite window, regular readback, dyadic ledger, separated-limit handoff, Real seal, and structural rows in the displayed carrier order.

Apply finite-window extraction and the obligation-window route, Definition 3379.5 and Definition 3379.10. These theorems force every completion-facing read through S, R, D before either the separated handoff Q or terminal seal E is available.

Use ledger nonescape, universal factorization, and separated-limit factorization, Definition 3379.6, Definition 3379.11, and Definition 3379.12. They keep the operator inside the finite dyadic and separated route, so no quotient, selected limit, host completion, countable-choice, or ambient-completeness coordinate can be read as a public export.

Finally invoke scoped obligation closure, Definition 3379.14. Since the scoped carrier surface already exhausts admission, finite-window routing, terminal Real sealing, transport, replay, provenance, and local naming, the public export is exactly the displayed finite route for downstream completion consumers. □

Theorem 2426.17 (Complete metric limit uniqueness outbound reference)**.** *Every public* CauchyCompletionOperat *export that later asserts uniqueness of a separated complete-metric limit must consume chapter 5983 after the public operator route of Definition 3379.16. The operator route exports the finite completion handoff only; it exports no selected limit, quotient representative, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the public export theorem. It binds every downstream completion consumer to the displayed route through $M, B, U, S, R, D, Q, E, H, C, P, N$ before the operator can be used.

A later uniqueness assertion is a separate separated complete-metric comparison. It therefore consumes the sibling route chapter 5983 after the operator export has supplied its completion-facing handoff.

Finally apply the operator nonescape clauses already used in the public export proof. They exclude selected limits, quotient representatives, countable-choice schedules, host completion objects, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the operator route, so uniqueness is imported only from the downstream sibling and not from an extra coordinate of $\mathsf{CauchyCompletionOperator}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorCompleteMetricLimitUniquenessOu`

Theorem 2426.18 (CauchyCompletionOperator bridge route)**.** *Every bridge-facing consumer of* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *must read the displayed operator through the functorial handoff, finite-window extraction, universal factorization, separated-limit factorization, and public export rows before treating it as a standard completion bridge. Concretely, the consumer first reads the metric and uniform source rows through* M, U *and the completion-boundary row* B*; then it reads the finite window, regular readback, and dyadic ledger rows* S, R, D*; then it reads the universal and separated-limit handoffs through* Q *and the terminal Real seal* E*; and only then may it replay transport, provenance, and local naming through* H, C, P, N*.*

This route is a bridge-readiness obligation on the paper surface. It does not assert bridgeChecked*, does not replace the existing public closure status, and does not add quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the functorial handoff, Definition 3379.3. It fixes the order in which metric and uniform source rows are routed through the displayed completion-boundary row before any terminal completion consumer is available.

Apply finite-window extraction, Definition 3379.5. This forces a bridge-facing consumer to inspect the $\mathsf{StreamName}^{\uparrow}$ window S, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D, and structural rows H, C, P, N before reading Q or E.

Use universal factorization and separated-limit factorization, Definition 3379.11 and Definition 3379.12. These theorems keep completion-universal, functorial, and separated-limit consumers inside the same displayed route.

Finally apply public export, Definition 3379.16. It binds downstream completion consumers to the finite public route. Since bridge checking is not claimed by that theorem or by the closurestatus block below, the two axes remain separate. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionOperatorUp.CauchyCompletionOperatorBridgeRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionOperator}^{\uparrow}$ packet is generated from MetricCompletion, CauchyCompletionBoundary, UniformCompletion, StreamName, RegSeqRat, DyadicRatCore, CompleteSeparatedMetric, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionOperator}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 3379.14 closes the scoped obligation surface over $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionBoundary}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompleteSeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows already exhibited by Definition 3379.1, Definition 3379.2, Definition 3379.5, Definition 3379.9, Definition 3379.10, Definition 3379.11, Definition 3379.12, and Definition 3379.16; the public export theorem binds downstream completion consumers to the same finite route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: No paper-side theory upgrade remains; bridge checking remains a separate formal-axis obligation unless a standard bridge theorem is supplied.

Chapter 2427

A Concrete Naming Certificate for $\mathsf{RealCauchyCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealCauchyCompleteness}^{\uparrow}$ packet records the classical regular-Cauchy completeness route as finite BEDC NameCert data. It sits over the dyadic radius ledger of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the Cauchy-limit seal of chapter 386, and the terminal real-name seal of chapter 38. The packet exposes a displayed completion handoff for regular Cauchy streams; it does not assert that $\mathsf{Real}^{\uparrow}$ already carries ambient completeness.

Definition 2427.1 (Real Cauchy completeness carrier)**.** *A* $\mathsf{RealCauchyCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, D, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule of finite windows used to inspect the Cauchy stream.*
2. *M is the explicit Cauchy-modulus row, exposing the threshold at which requested dyadic tolerances are met.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for positive radii, halving steps, comparison budgets, and tolerance addition.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback assembled from the retained windows and the modulus row.*
5. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *handoff row consuming the same S, M, D, R route before any real-facing read is exported.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the limit-seal handoff.*
7. *H records componentwise* hsame *transport for $S, M, D, R, L, E, C, P, N$.*
8. *C records displayed* Cont *replay of the diagonal route*

$$S, M, D \longmapsto R \longmapsto L \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealCauchyCompleteness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyCompleteness}^{\uparrow}}$ *row.*
The classifier accepts only packets that display the finite windows, explicit modulus, dyadic budgets, diagonal readback, limit-seal handoff, real seal, transport, replay, provenance, and local naming. It has no coordinate for quotient streams, selected limits, countable choice, open-cover compactness, host convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyCompletenessUp.RealCauchyCompletenessTasteGate single carrier alignment`

Theorem 2427.2 (Real Cauchy completeness NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyCompleteness}^{\uparrow}$ *carrier* $K = (S, M, D, R, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCauchyCompleteness}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite stream windows, explicit Cauchy modulus, dyadic tolerance ledger, diagonal regular readback, CauchyLimitSeal handoff, Real seal, componentwise transport, displayed replay, provenance, and local naming. The completion-facing read is accepted only when the modulus row M is exposed before the diagonal readback R, the handoff row L consumes the same S, M, D, R route, and every* $\mathsf{Real}^{\uparrow}$ *consumer reaches E through that displayed route.*

Proof. Carrier admission is projection from Definition 3380.1. The rows S, M, D display the finite stream windows, the explicit Cauchy modulus, and the dyadic tolerance ledger before any completion-facing read is available.

The diagonal limit handoff is then assembled in R. The row R reads the retained windows through the modulus thresholds and dyadic budgets, so the construction is a displayed regular rational readback rather than a quotient of streams or a selected host limit.

Classifier stability follows from H and C. Componentwise hsame transport preserves the same window, modulus, dyadic, readback, seal, provenance, and naming rows, while displayed Cont replay keeps the route ordered as $S, M, D \to R \to L \to E$.

The ledger rows P, N expose no extra coordinate. Since quotient streams, selected limits, countable choice, open-cover compactness, host convergence, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, every accepted completion read remains inside the displayed finite route. □

Theorem 2427.3 (Real Cauchy completeness seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{RealCauchyCompleteness}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyLimitSeal}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The read therefore supplies a finite Cauchy-completeness handoff to real-name consumers without adding quotient stream equality, a selected limit, countable choice, or the claim that $\mathsf{Real}^{\uparrow}$ *is already complete.*

Proof. Start with an accepted carrier $K = (S, M, D, R, L, E, H, C, P, N)$. By the carrier definition, the only real-facing endpoint is E, and E is downstream of the limit-seal row L.

The row L consumes the diagonal readback R. That readback is itself downstream of the finite stream schedule S, the explicit modulus M, and the dyadic ledger D.

Thus any $\mathsf{Real}^{\uparrow}$ consumer reaches the seal only through S, M, D, R, L, E and the structural rows H, C, P, N. The excluded host-side data have no carrier coordinate, so they cannot be introduced by the handoff. □

Theorem 2427.4 (Real Cauchy completeness uniform-tail seal)**.** *Let* $K = (S, M, D, R, L, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyCompleteness}^{\uparrow}$ *carrier. Suppose a consumer reads K through a* $\mathsf{UniformConvergence}^{\uparrow}$

shared threshold whose tail schedule dominates the explicit Cauchy-modulus row M and whose Cauchy-facing handoff is served by the $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$ *route of chapter 3876. Then every* $\mathsf{Real}^{\uparrow}$ *endpoint read factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, the* $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$ *handoff, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row L before the Real seal E is exposed.*

Proof. Project the carrier rows from Definition 3380.1. The only endpoint row is E, and Definition 3380.3 places E downstream of S, M, D, R, L.

The shared threshold is read through the $\mathsf{UniformConvergence}^{\uparrow}$ tail surface of chapter 3417. The dominance assumption says that this tail schedule cannot be consumed before it covers the explicit modulus row M already present in K.

The Cauchy-facing handoff is then the $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$ route. It binds the same uniform tail row to a finite Cauchy comparison before the regular readback R and the limit-seal row L are available to the endpoint consumer.

Thus the row order is S, M, D first, then the shared uniform tail and Cauchy-criterion handoff, then R, L, E. Since the carrier has no quotient coordinate, choice coordinate, or second endpoint row, every $\mathsf{Real}^{\uparrow}$ read follows this displayed route. □

Theorem 2427.5 (Real Cauchy completeness filtered minimality)**.** *Let $K = (S, M, D, R, L, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyCompleteness}^{\uparrow}$ *carrier. Every filtered or completion-service consumer that reads K through the* $\mathsf{BishopFilteredRegularCompletion}^{\uparrow}$ *route of chapter 8666 or the* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *service boundary of chapter 1606 must preserve exactly the displayed* $\mathsf{StreamName}^{\uparrow}$ *row S, explicit modulus row M,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row L,* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *row H, displayed* Cont *row C,* Pkg *row P, and local* $\mathsf{NameCert}_{\mathsf{RealCauchyCompleteness}^{\uparrow}}$ *row N before exporting a completion-facing Real read. Replacing this route by quotient streams, selected limits, countable choice, host convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness is outside the carrier.*

Proof. Project the inventory of rows from Definition 3380.1. It gives the consumer exactly $S, M, D, R, L, E, H, C, P,$ with no coordinate for quotient stream equality, a chosen limit, countable choice, host convergence, or an ambient completeness theorem.

The terminal Real read is constrained by Definition 3380.3. Any endpoint must pass through the displayed stream windows, dyadic tolerance ledger, regular readback, and limit-seal handoff before reaching E.

For filtered consumers, Definition 8666.3 supplies the finite synchronization principle. Its window induction reads the filter and regular Cauchy rows against the same dyadic tolerances and preserves the shared transport, replay, provenance, and local naming rows, so the filtered route cannot bypass $S, M, D, R, L, E, H, C, P, N$.

For completion-service consumers, the $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ chapter records the least displayed service boundary for completion reads, with Lean touchpoint

BEDC.Derived.CauchyCompletionMinimalityUp.CauchyCompletionMinimalityTasteGate_single_carrier_alignm

Reading K through that boundary therefore preserves the Real Cauchy route as the service-facing input rather than adding an external completion principle. □

Falsifiable prediction: Any accepted $\mathsf{RealCauchyCompleteness}^{\uparrow}$ consumer reaching a $\mathsf{Real}^{\uparrow}$ read without the displayed StreamName windows, explicit Cauchy modulus, DyadicRatCore ledger, RegSeqRat diagonal readback, and CauchyLimitSeal row refutes the carrier.

Independence witness: DyadicRatCore, StreamName, RegSeqRat, CauchyLimitSeal, and Real are not individually bijective with $\mathsf{RealCauchyCompleteness}^{\uparrow}$ because the packet carries the ordered completion route across all five surfaces together with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCauchyCompleteness}^{\uparrow}$ packet is generated from finite StreamName windows, an explicit Cauchy-modulus row, a DyadicRatCore tolerance ledger, a RegSeqRat diagonal readback, a CauchyLimitSeal handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3380.1, Definition 3380.2, Definition 3380.3, Definition 3380.4, and Definition 3380.5 seed the finite constructive Cauchy-completeness route through StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, UniformConvergence, UniformConvergenceCauchyCriterion, filtered completion, minimal completion service, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyCompleteness}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealCauchyCompletenessUp.RealCauchyCompletenessTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, open-cover compactness, host convergence, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, explicit Cauchy-modulus exposure, diagonal limit handoff, classifier stability, and ledger non-escape for BEDC.Derived.RealCauchyCompletenessUp.

Chapter 2428

A Concrete Naming Certificate for ClosedLamDomainSubjectReduction$^{\uparrow}$

The ClosedLamDomainSubjectReduction$^{\uparrow}$ packet realizes the lambda-domain branch of the closed MetaCIC subject-reduction frontier as a finite NameCert carrier. It sits beside the four-row discharge socket of chapter 719, the discharge ledger of chapter 720, the beta-substitution packet of chapter 716, the closed substitution boundary of chapter 538, the typed beta congruence trigger of chapter 760, and the Pi-domain sibling of chapter 3352. The packet names the lambda-domain obligation as displayed closed term data; it does not export an unconditional closed subject-reduction theorem.

Definition 2428.1 (ClosedLamDomainSubjectReduction carrier)**.** *A* ClosedLamDomainSubjectReduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, D, D', B, Y, Z, G, H, R, Q, N)$$

with the following displayed rows:

1. *T is the displayed closed lambda term row, naming the source term $\lambda D.\, B$ and its closed context boundary.*
2. *D is the original domain row inspected before the congruence step.*
3. *D' is the reduced domain row reached by the displayed beta step from D.*
4. *B is the body row, read under the binder induced by the displayed domain.*
5. *Y is the typing row, recording the source typing judgement for $\lambda D.\, B$ and the target typing judgement demanded for $\lambda D'.\, B$.*
6. *Z is the closedness row, requiring the lambda term, original domain, reduced domain, and body reads to remain inside the same closed MetaCIC boundary.*
7. *G is the beta-step and typed congruence row, consuming the displayed lambda-domain beta step and the trigger surface of chapter 760.*
8. *H records componentwise* hsame *transport for $T, D, D', B, Y, Z, G, R, Q, N$.*
9. *R records displayed* Cont *replay from the source lambda term through the domain step, typing row, closedness row, and subject-reduction handoff.*

10. *Q is the* Pkg *provenance over chapter 719, chapter 720, chapter 716, chapter 538, chapter 760, chapter 3352,* BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying the closed lambda term, both domain rows, the body row, the typing row, the closedness row, the lambda-domain beta step, transport, replay, provenance, and local naming. It has no coordinate for a blanket closed subject-reduction theorem, a host conversion rule, erased derivation semantics, quotient syntax equality, or an untracked binder context.

Theorem 2428.2 (ClosedLamDomainSubjectReduction obligations)**.** *For every accepted* ClosedLamDomainSubject *carrier $L = (T, D, D', B, Y, Z, G, H, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed closed lambda term, original domain, reduced domain, body row, typing row, closedness row, beta-step row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The lambda-domain preservation read is accepted only when G displays the domain beta step and Y, Z display the corresponding typing and closedness rows.*

Proof. Project the carrier of Definition 3381.1. The rows T, D, D', B display the lambda term, the two domain readings, and the body read, while Y and Z display the typing and closedness boundaries attached to the same context.

The beta-step row G is then read as the lambda-domain congruence trigger. It is not interchangeable with the beta-substitution row, the application-argument row, or the Pi-domain row of the subject-reduction socket, because the target branch changes the displayed lambda domain while preserving the body under the induced binder.

The structural rows H, R, Q, N transport, replay, source, and name only that finite packet. Since no row stores a host conversion rule, erased derivation semantics, quotient syntax equality, or a closed subject-reduction theorem, the displayed rows exhaust the local NameCert obligations. □

Theorem 2428.3 (ClosedLamDomainSubjectReduction handoff)**.** *Every subject-reduction discharge ledger read that consumes the lambda-domain branch from an accepted* $\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}$ *packet factors through the displayed route*

$$\lambda D.\, B,\ D,\ D',\ B,\ Y,\ Z,\ G,\ H,\ R,\ Q,\ N.$$

The handoff supplies the lambda-domain obligation row to the subject-reduction discharge socket and ledger; it does not supply the beta-substitution row, application-argument row, Pi-domain row, or an unconditional closed subject-reduction theorem.

Proof. Start with a subject-reduction consumer of the lambda-domain branch. The socket and ledger chapters, chapter 719 and chapter 720, require a distinct lambda-domain row before the parameterised subject-reduction route can be read.

The present carrier supplies that row only through T, D, D', B, Y, Z, G. These rows display the source lambda term, the original and reduced domains, the body, the typing judgement, the closedness boundary, and the beta-step trigger.

Finally H, R, Q, N preserve and name the same finite handoff. The beta-substitution preservation packet, closed substitution boundary, typed beta congruence trigger, and Pi-domain packet remain sibling inputs rather than hidden substitute proofs, so the handoff is exactly the lambda-domain row and nothing stronger. □

Falsifiable prediction: Any accepted $\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}$ consumer reaching a subject-reduction conclusion without the displayed lambda-domain beta step and typing rows refutes the carrier.

Independence witness: ClosedPiDomainSubjectReduction, BetaSubstitutionPreservation, ClosedSubstitutionBoundary, and TypedBetaCongruenceTrigger are not bijective with $\mathsf{ClosedLamDomainSubjectReduction}$ because this packet jointly carries the closed lambda term, original domain, reduced domain, body row, typing row, closedness row, lambda-domain beta step, transport, replay, provenance, and local naming.

The Lean TasteGate file for $\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ ClosedLamDom}$ and $\mathsf{FieldFaithful\ ClosedLamDomainSubjectReduction}^{\uparrow}$ instances preserving $T, D, D', B, Y, Z, G, H, R, Q, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}$ packet is generated from a closed lambda term row, original domain row, reduced domain row, body row, typing row, closedness row, beta-step row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3381.1, Definition 3381.2, and Definition 3381.3 seed the finite lambda-domain subject-reduction obligation packet for the closed MetaCIC discharge route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedLamDomainSubjectReduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close beta-substitution preservation, application-argument stability, Pi-domain preservation, unconditional closed subject reduction, host conversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lambda-domain beta-step exactness, typing-row exposure, closedness-row exposure, subject-reduction ledger handoff, and TasteGate field faithfulness for BEDC.Derived.ClosedLamDomainSub

Chapter 2429

A Concrete Naming Certificate for CauchyCompletenessCriterion$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyCompletenessCriterion$^{\uparrow}$ packet records the finite Cauchy-criterion route by which a metric source, an explicit Cauchy modulus, named stream windows, regular rational readback, dyadic tolerance accounting, and a terminal Real$^{\uparrow}$ seal are presented to completion-facing consumers. It sits over the metric completion surface of chapter 1506, the regular rational rows of chapter 301, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet gives later completion chapters a single criterion object to cite instead of restating the Cauchy-modulus handoff locally.

Definition 2429.1 (CauchyCompletenessCriterion carrier)**.** *A* CauchyCompletenessCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, \mu, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, carrying the named carrier, distance observations, and completion-facing request inherited by the metric completion route.*
2. *μ is the explicit Cauchy modulus row, displayed as finite threshold data for each inspected tolerance request.*
3. *S is the* StreamName$^{\uparrow}$ *window family naming the finite tail observations read from the source stream and the modulus thresholds.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row extracted from those windows.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger recording the rational budget, tail slack, and comparison bounds used by the readback.*
6. *E is the* Real$^{\uparrow}$ *seal row, visible only after M, μ, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the metric source, modulus, windows, readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-facing Cauchy request through $M, \mu, S, R, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* CauchyCompletenessCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletenessCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the ten displayed rows. It has no coordinate for quotient completions, selected limits, countable-choice schedules, trichotomy decisions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletenessCriterionUp.CauchyCompletenessCriterionTasteGate single carrier alignment`

Theorem 2429.2 (CauchyCompletenessCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletenessC}$ *carrier* $Q = (M, \mu, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, explicit Cauchy modulus, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must consume* M, μ, S, R, D *before it can inspect* E, H, C, P, N*.*

Proof. Project the carrier of Definition 3382.1. The rows M and μ expose the metric source and the Cauchy modulus as finite packet data.

Read the observation rows next. The row S stores exactly the inspected tail windows, R records the regular rational readback from those windows, and D stores the dyadic tolerance budget attached to the same finite observations.

Finally inspect the seal and structural rows. Since E, H, C, P, N transport, replay, source, and name the already displayed route, the certificate has no remaining coordinate from which a quotient completion, selected limit, countable-choice schedule, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem could be exported. □

Theorem 2429.3 (CauchyCompletenessCriterion Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or metric-completion consumer citing an accepted* $\mathsf{CauchyCompletenessCriterion}^{\uparrow}$ *packet receives only the finite route*

$$M, \mu, S, R, D, E, H, C, P, N.$$

The handoff first displays the metric source and Cauchy modulus, then the $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and only then the* $\mathsf{Real}^{\uparrow}$ *seal together with transport, replay, provenance, and local naming.*

Proof. Begin with an accepted carrier and apply Definition 3382.2. The consumer-facing data are exhausted by the displayed rows $M, \mu, S, R, D, E, H, C, P, N$.

The criterion route is ordered. A completion-facing read must first expose the metric source and explicit modulus, then read finite stream windows and regular rational observations, and then consume the dyadic tolerance ledger.

The Real seal is terminal with respect to this route. Because quotient completions, selected limits, countable-choice schedules, trichotomy decisions, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, every exported handoff is the displayed finite criterion packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletenessCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletenessCriterion}^{\uparrow}$ packet is generated from a metric source row, explicit Cauchy modulus, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletenessCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 3382.1, Definition 3382.2, and Definition 3382.3 seed the Bishop-style Cauchy criterion handoff for Real and completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletenessCriterion}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyCompletenessCriterionUp.CauchyCompletenessCriterionTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, trichotomy, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, finite window coverage, RegSeqRat readback, dyadic tolerance accounting, Real seal nonescape, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.CauchyCompletenessCriterionUp.

Chapter 2430

A Concrete Naming Certificate for $\mathsf{TailModulusLimitHandoff}^{\uparrow}$

Following the Bishop-style diagonal Cauchy proof route in section 9238.1, the $\mathsf{TailModulusLimitHandoff}^{\uparrow}$ packet records the finite tail-modulus handoff used by the diagonal regularity theorem of Definition 9238.4. It reads the finite windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet gives Real-completion proof targets a concrete landing for the shared tail threshold consumed by diagonal-limit consumers.

Definition 2430.1 (TailModulusLimitHandoff carrier)**.** *A* $\mathsf{TailModulusLimitHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\mu, \tau, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. μ *is the Cauchy modulus row for the regular rational sequence of regular rational sequences.*
2. τ *is the finite tail selector row naming the shared threshold used by the diagonal limit read.*
3. S *is the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected at the selected tail threshold.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the diagonal representative and the two tail observations compared by the proof.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the endpoint legs, middle modulus leg, and rational slack used by the diagonal estimate.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* μ, τ, S, R, D *have been displayed.*
7. H *records componentwise* hsame *transport for the modulus, tail selector, windows, readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a diagonal-limit request through* $\mu, \tau, S, R, D, E, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{TailModulusLimitHandoff}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{TailModulusLimitHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient streams, selected limits, countable-choice schedules, trichotomy decisions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TailModulusLimitHandoffUp.TailModulusLimitHandoffTasteGate single carrier alignment`

Theorem 2430.2 (TailModulusLimitHandoff NameCert obligations)**.** *For every accepted* TailModulusLimitHandoff *carrier* $T = (\mu, \tau, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TailModulusLimitHandoff}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy modulus, finite tail selector,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The diagonal-limit consumer must read* μ, τ, S, R, D *before it can export a Real-facing seal through* E, H, C, P, N*.*

Proof. Project the carrier of Definition 3383.1. The rows μ and τ display the modulus and the shared tail threshold used by the diagonal-limit proof.

Read the finite observations. The row S names the inspected windows, R records the regular rational readback, and D stores the dyadic tolerance ledger for the endpoint legs and the middle modulus leg.

The seal and structural rows add no analytic coordinate. The rows E, H, C, P, N seal, transport, replay, source, and name the displayed finite route, so quotient streams, selected limits, countable-choice schedules, trichotomy decisions, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the certificate. □

Theorem 2430.3 (TailModulusLimitHandoff diagonal handoff)**.** *Every Real-completion consumer of an accepted* $\mathsf{TailModulusLimitHandoff}^{\uparrow}$ *packet receives the finite diagonal route*

$$\mu, \tau, S, R, D, E, H, C, P, N.$$

The handoff supplies the Cauchy modulus, shared tail selector, selected $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming needed by the diagonal regularity route of Definition 9238.4.*

Proof. Start with a Real-completion consumer. By Definition 3383.2, the consumer first reads the modulus and tail selector, then the finite windows, readback row, and dyadic tolerance ledger.

The diagonal route is therefore finite before the Real seal is visible. The seal row E depends on the displayed rows μ, τ, S, R, D, and the structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming.

Since no carrier coordinate stores quotient streams, selected limits, countable-choice schedules, trichotomy decisions, or ambient completeness, every exported diagonal handoff is exhausted by the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{TailModulusLimitHandoff}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TailModulusLimitHandoff}^{\uparrow}$ packet is generated from a Cauchy modulus row, finite tail selector, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TailModulusLimitHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 3383.1, Definition 3383.2, and Definition 3383.3 seed the finite tail-modulus handoff used by the diagonal regularity proof route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TailModulusLimitHandoff}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.TailModulusLimitHandoffUp.TailModulusLimitHandoffTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail selector exactness, finite window coverage, RegSeqRat readback, dyadic tolerance accounting, Real seal nonescape, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.TailModulusLimitHandoffUp.

Chapter 2431

A Concrete Naming Certificate for $\mathsf{BorelSet}^{\uparrow}$

Following Bourbaki and Bishop–Bridges topology, the $\mathsf{BorelSet}^{\uparrow}$ packet names the finite boundary by which a topological or metric real-facing source exposes a generated set predicate without importing measure theory. It sits after the open-neighbourhood interface of chapter 88, the metric source of chapter 57, the terminal real-name seal of chapter 38, the finite observation route of chapter 126, and the regular rational readback surface of chapter 301. The packet records generator admission, finite constructor replay, and sibling provenance; it does not claim a measure, sigma-additivity, choice-selected codes, or classical completeness of the full Borel hierarchy.

Definition 2431.1 (Borel set carrier)**.** *A* $\mathsf{BorelSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, O, M, G, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-space row read either through the* $\mathsf{Topology}^{\uparrow}$ *interface of chapter 88 or through a metric presentation supplied by chapter 57.*
2. *O is the open-generator ledger naming basic open rows visible to the source topology.*
3. *M is the real-facing membership query surface, routed through* $\mathsf{Real}^{\uparrow}$ *names from chapter 38 when the source is a real or metric-real object.*
4. *G is the finite generator tree recording the displayed complements, finite unions, and finite intersections that the current consumer is allowed to replay.*
5. *R is the readback row tying finite membership observations to* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational names through chapter 126 and chapter 301.*
6. *H stores componentwise* hsame *transport for the source, generator, membership, readback, continuation, provenance, and local naming rows.*
7. *C stores the displayed* Cont *replay from a source query through open generators, finite constructor rows, and readback rows.*
8. *P is the* Pkg *provenance over* $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BorelSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, O, M, G, R, H, C, P, N$. It has no coordinate for measure values, countable additivity, a choice-selected code for an arbitrary hierarchy branch, or a completed classical Borel universe.

Lean4 ✓ `BEDC.Derived.BorelSetUp.BorelSetTasteGate single carrier alignment`

Theorem 2431.2 (Borel set NameCert obligations)**.** *For the carrier of Definition 3384.1, the local* $\mathsf{NameCert}_{\mathsf{BorelSet}^{\uparrow}}$ *surface consists exactly of source-space admission, open-generator admission, real-facing membership queries when the source is real or metric-real, finite generator-tree replay, StreamName and RegSeqRat readback, componentwise transport, displayed continuation replay, package provenance, and local naming. Every accepted Borel-set query must read the source topology or metric row before it reads O, G, R, H, C, P, N.*

Proof. Project the carrier $B = (X, O, M, G, R, H, C, P, N)$. The source row X and open-generator ledger O are the only rows that introduce topological information.

Read the finite constructor tree. Complements, finite unions, and finite intersections are replayed only through G, and the membership-facing observations are tied to M and R before a consumer can compare two packets.

The structural rows add no measure-theoretic content. The rows H, C, P, N transport, replay, source, and name the displayed route, so the listed rows exhaust the seed NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.BorelSetUp.BorelSetCarrier namecert obligations`

Theorem 2431.3 (Borel set generator stability)**.** *Let $B = (X, O, M, G, R, H, C, P, N)$ and*

$$B' = (X', O', M', G', R', H', C', P', N')$$

be accepted $\mathsf{BorelSet}^{\uparrow}$ *carriers. If the displayed source row, open-generator ledger, finite generator tree, membership surface, and readback row agree componentwise through the packet's* hsame *rows, then every topology-facing, metric-facing, or real-facing consumer sees the same generated set boundary from B and B'. The comparison uses only the rows $X, O, M, G, R, H, C, P, N$ and $X', O', M', G', R', H', C', P', N'$.*

Proof. Start with the NameCert obligations. Any consumer read first passes through the source-space row and open-generator ledger, then through the finite generator tree and readback rows.

Apply the displayed componentwise transports. The hypotheses identify the rows that determine the generator route, while H', C', P', N' preserve, replay, source, and name the same finite route for B'.

Thus the consumer-visible boundary is stable under the stated transport. No measure value, countable-additivity proof, hierarchy-completeness object, or choice-selected branch can refine the comparison, because none is a coordinate of either carrier. □

Falsifiable prediction: A $\mathsf{BorelSet}^{\uparrow}$ consumer that reaches a measure value, a countable-additivity row, or a choice-selected hierarchy code from the displayed packet refutes the carrier surface.

Independence witness: topology, metric, real, streamname, regseqrat: no listed sibling supplies the whole nine-row packet $B = (X, O, M, G, R, H, C, P, N)$, because each sibling contributes only source topology, metric control, real-name sealing, finite observation, or rational readback data while this chapter binds the generated-set boundary with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BorelSet}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelSet}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3384.1, Definition 3384.2, and Definition 3384.3 seed the finite generated-set boundary over topology, metric, real-name, StreamName, RegSeqRat, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelSet}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure theory, sigma-additivity, countable choice, choice-selected Borel codes, classical hierarchy completeness, open-cover compactness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, generator stability, readback preservation, transport, and ledger-refusal proofs for BEDC.Derived.BorelSetUp.

Constructive story: A $\mathsf{BorelSet}^{\uparrow}$ packet is generated from a topology or metric source row, an open-generator ledger, real-facing membership reads, a finite generator tree, StreamName and RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2432

A Concrete Naming Certificate for $\mathsf{OuterMeasure}^{\uparrow}$

Following Caratheodory and Bishop–Bridges constructive measure theory, the $\mathsf{OuterMeasure}^{\uparrow}$ packet records the finite cover-valued boundary from which measurable-event and measure rows can later be read. It sits between the generated-set surface of chapter 3384, the membership discipline of chapter 3668, the real-name endpoint seal of chapter 38, the finite observation windows of chapter 126, and the measure carrier of chapter 92. The packet names only displayed set rows, empty-set valuation, monotonicity comparisons, finite cover subadditivity, Caratheodory-measurability boundary tests, transport, replay, provenance, and local naming; it does not assert a completed measure space, a chosen sigma-algebra closure, countable choice of covers, quotient equality of subsets, or ambient measure completion.

Definition 2432.1 (OuterMeasure carrier)**.** *An* $\mathsf{OuterMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, S, Z, M, F, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the source object whose displayed subsets are read through* $\mathsf{SetLike}^{\uparrow}$ *and, when the source is real-facing, through the* $\mathsf{BorelSet}^{\uparrow}$ *generated-set boundary.*
2. *S is the displayed subset-family row naming the finite set requests visible to the packet.*
3. *Z is the empty-set value row, comparing the outer value of the displayed empty subset with the zero endpoint on the* $\mathsf{Real}^{\uparrow}$ *surface.*
4. *M is the monotonicity row, recording a finite inclusion witness $A \subseteq B$ together with the comparison $\mu^*(A) \leq \mu^*(B)$ on the displayed real endpoints.*
5. *F is the finite displayed cover subadditivity row, assigning a finite cover list $U_0, \ldots, U_k$ of a displayed subset A to the visible comparison*

$$\mu^*(A) \leq \mu^*(U_0) + \cdots + \mu^*(U_k).$$

6. *B is the Caratheodory-measurability boundary row: for each displayed test set T and candidate measurable set E, it records the two-sided split comparison between $\mu^*(T)$ and the displayed sum of the inside and outside rows $T \cap E$ and $T \setminus E$.*

7. *H stores componentwise* hsame *transport for the source row, subset-family row, value rows, inclusion and finite-cover ledgers, boundary row, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a subset request through empty-set value, monotonicity, finite cover subadditivity, boundary testing, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OuterMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, Z, M, F, B, H, C, P, N$. It has no coordinate for a completed measure, a host sigma-algebra, a selected cover family, quotient subset equality, or a hidden countable-additivity row.

Lean4 ✓ `BEDC.Derived.OuterMeasureUp.OuterMeasureTasteGate single carrier alignment`

Theorem 2432.2 (OuterMeasure NameCert obligations)**.** *For the carrier of Definition 3385.1, the local* $\mathsf{NameCert}_{\mathsf{OuterMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source and subset-family rows, empty-set zero readback, monotonicity under displayed inclusion, finite displayed cover subadditivity, Caratheodory-measurability boundary testing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every accepted outer-measure consumer must read the source subset through S, expose value comparisons through Z, M, F, B, and replay those rows through H, C, P, N before any* $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *sibling row is exposed.*

Proof. Project the carrier $O = (X, S, Z, M, F, B, H, C, P, N)$. The source row X and subset-family row S are the only admitted entry points for displayed set requests, so carrier admission is exhausted by those rows.

Read the value ledgers. The row Z supplies the empty-set zero comparison, M supplies monotonicity under a displayed inclusion witness, and F supplies the finite cover subadditivity comparison for a named finite cover list.

The boundary row B is the only place where a Caratheodory-measurability test is visible. It records the split comparison for displayed test sets and candidates, but it does not choose a completed sigma-algebra or assert ambient measure completion.

Finally replay the structural rows. Componentwise transport through H, continuation replay through C, provenance through P, and local naming through N preserve the same finite route. Since no further coordinate is present, the listed rows exhaust the local NameCert obligation surface. □

Theorem 2432.3 (OuterMeasure finite premeasure route)**.** *Every* $\mathsf{OuterMeasure}^{\uparrow}$ *packet exports a finite pre-measure route*

$$S \longmapsto Z, M, F, B \longmapsto H, C, P, N$$

that downstream $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, *and* $\mathsf{MeasurableFunction}^{\uparrow}$ *consumers may cite before reading measure-completion language. The route exposes empty-set zero, displayed inclusion monotonicity, finite cover subadditivity, and Caratheodory boundary rows, not a host measure space or a choice-selected completion.*

Proof. Start with an accepted subset request in S. The empty, inclusion, finite cover, and boundary rows are the only value-bearing rows available to the packet.

The finite cover row F keeps the route on a displayed list of cover sets, while the boundary row B tests only the named split of a displayed test set by a candidate measurable set. These two rows provide the pre-measure boundary consumed by later measure-facing chapters.

Replay through H, C, P, N. The provenance row records the allowed sibling surfaces, and the continuation row exposes them in the same order. Thus a downstream consumer can cite the finite pre-measure route without importing completed measure language or selected cover choices. □

Falsifiable prediction: An $\mathsf{OuterMeasure}^{\uparrow}$ consumer that obtains a completed measure, a chosen sigma-algebra closure, countable choice of covers, quotient equality of subsets, or a $\mathsf{Measure}^{\uparrow}$ countable-additivity row without first reading $S, Z, M, F, B, H, C, P, N$ refutes the carrier surface.

Independence witness: measure, borelset, setlike, real, streamname: no listed sibling supplies the whole ten-row packet $O = (X, S, Z, M, F, B, H, C, P, N)$, because each sibling contributes only measure values, generated-set membership, set-like membership, real endpoints, or finite observation windows while this chapter binds outer valuation, finite cover subadditivity, boundary testing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{OuterMeasure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OuterMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3385.1, Definition 3385.2, and Definition 3385.3 seed the finite outer-measure surface over displayed subsets, empty-set value, inclusion monotonicity, finite covers, Caratheodory boundary rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OuterMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed measure spaces, chosen sigma-algebra closures, countable choice of covers, quotient subset equality, MeasureUp countable additivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, empty-set zero, monotonicity, finite cover subadditivity, Caratheodory boundary testing, transport, provenance, and no-escape for BEDC.Derived.OuterMeasureUp.

Constructive story: An $\mathsf{OuterMeasure}^{\uparrow}$ packet is generated from a displayed source row, subset-family row, empty-set value row, inclusion monotonicity row, finite cover subadditivity row, Caratheodory boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

$\mathsf{LocallyConvexSpace}^{\uparrow}$ reads the vector-space, topological-vector, seminormed-space, and functional-analysis sibling rows through chapter 47, chapter 205, chapter 5868, and chapter 94 before the child files route the finite local-convexity carrier.

Chapter 2433

A Concrete Naming Certificate for $\mathsf{LocallyConvexSpace}^{\uparrow}$

Following Bourbaki and Treves on locally convex topological vector spaces, the $\mathsf{LocallyConvexSpace}^{\uparrow}$ packet records the finite BEDC surface where a vector-space carrier, a topological-vector-space carrier, a finite seminorm ledger, and a convex balanced neighbourhood ledger are read before any functional-analysis consumer can cite local convexity. It sits beside the vector-space source of chapter 47, the topological-vector-space source of chapter 205, the norm comparison surface of chapter 89, and the functional-analysis consumer frontier of chapter 94. The packet names the locally convex carrier only through displayed finite rows; it is not a Hahn–Banach principle, not a choice-selected dual, and not an ambient weak-star compactness theorem.

The seminorm and convex-balanced-neighbourhood ledgers consume the sibling rows in a fixed order: chapter 47 supplies the algebraic source, chapter 205 supplies the topological-vector continuity route, chapter 89 supplies the optional norm comparison row, and chapter 94 supplies the downstream consumer boundary. These links keep local convexity as a displayed finite dependency surface rather than an orphan analytic predicate.

Downstream $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumers use $\mathsf{LocallyConvexSpace}^{\uparrow}$ only through the finite seminorm ledger and the convex-balanced-neighbourhood ledger displayed here. The consumer chapter of chapter 94 may cite local convexity only after those two rows have been exposed with the vector-space, topological-vector-space, transport, replay, provenance, and local naming rows.

Definition 2433.1 (Locally convex space carrier)**.** *A* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (V, T, S, B, M, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *source row, including the additive carrier, scalar action, and vector-space laws used by downstream linear consumers.*
2. *T is the* $\mathsf{TopVecSpace}^{\uparrow}$ *source row, recording the topology and the displayed continuity of addition and scalar multiplication.*
3. *S is the finite seminorm-family ledger, listing the seminorm names, their vector-space source, triangle and scalar rows, and the generated neighbourhood probes accepted in the packet.*
4. *B is the convex balanced neighbourhood ledger, recording the finite neighbourhood rows certified as convex, balanced, and compatible with the topology read through T.*

5. *M is the* $\mathsf{Norm}^{\uparrow}$ *comparison row, used only when a named normed source is present and only as a comparison into the seminorm ledger rather than as a replacement for local convexity.*
6. *H records componentwise* hsame *transport for V, T, S, B, M and the local naming row.*
7. *C records displayed* Cont *replay through the vector source, topological-vector-space source, seminorm ledger, convex balanced neighbourhood ledger, norm comparison, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $V, T, S, B, M, H, C, P, N$. It contains no coordinate for an arbitrary dual selector, a host locally convex topology predicate, an unrestricted separation theorem, weak-star compactness, quotient completion, or a global choice principle.

Theorem 2433.2 (Locally convex space NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *carrier $L = (V, T, S, B, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$ *surface consists exactly of vector-space source exposure through V; topological-vector-space source exposure through T; finite seminorm-family evidence through S; convex balanced neighbourhood evidence through B; optional norm comparison through M; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.LocallyConvexSpaceUp.LocallyConvexSpaceCarrier namecert obligations`

Proof. Project the accepted carrier in Definition 3386.1. The rows $V, T, S, B, M, H, C, P, N$ are exactly the vector, topology, seminorm, neighbourhood, norm-comparison, transport, replay, provenance, and naming coordinates.

The vector and topological-vector rows are consumed first. They supply the additive carrier, scalar action, topology, and continuity obligations before any seminorm or neighbourhood evidence can be read.

The local-convexity evidence is then split across S and B. The seminorm ledger records finite probe families, while the neighbourhood ledger records the convex balanced neighbourhood rows generated from those probes.

Finally M, H, C, P, N compare, transport, replay, source, and name the same finite packet. Since no dual selector, separation theorem, weak-star compactness row, or host topology predicate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2433.3 (Locally convex space seminorm-filter stability)**.** *Let $L = (V, T, S, B, M, H, C, P, N)$ be an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *carrier. Any consumer that reads a finite seminorm probe from S and then passes to the neighbourhood filter generated by B must still factor through the same rows $V, T, S, B, M, H, C, P, N$. The handoff exports no candidate-free normed-space structure, no selected continuous dual, and no ambient weak topology beyond the displayed finite filter rows.*

Proof. Begin with a seminorm probe in S. Its vector-space source is the same V read by the carrier, and its topological compatibility is checked against the same T used to admit the packet.

Pass from the probe to the neighbourhood side through B. The rows in B record convexity, balancedness, and filter membership as displayed finite evidence, so the handoff remains inside the packet rather than introducing a host filter object.

The comparison row M may relate the probe to a norm row, but it is only a comparison coordinate. Transport and replay through H and C, with provenance and naming through P

and N, preserve the same route. Thus any accepted seminorm-filter read remains mediated by $V, T, S, B, M, H, C, P, N$ and cannot export a selected dual or ambient weak topology. □

Theorem 2433.4 (Locally convex space seminorm-family obligation)**.** *Let $L = (V, T, S, B, M, H, C, P, N)$ be an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *carrier. Any accepted consumer that reads the finite seminorm family S must expose the seminormed-space comparison row of chapter 5868 before using those probes. Any weak-star-facing consumer may pass through chapter 5192 only after the displayed seminorm, convex-balanced neighbourhood, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows S, B, H, C, P, N have been read together with the source rows V, T.*

Proof. Project the accepted carrier $L = (V, T, S, B, M, H, C, P, N)$. The row S is the finite seminorm-family ledger, while V and T are the vector-space and topological-vector-space sources that make each seminorm probe admissible.

Route S through the seminormed-space sibling named in chapter 5868. That sibling supplies the comparison surface for finite family indices, zero, triangle, scalar, and induced-neighbourhood reads before a local-convexity consumer may use the probes as neighbourhood data.

For weak-star-facing consumers, keep the route downstream of the local convexity packet. The weak-star topology chapter can be cited only after S, B, H, C, P, N and the sources V, T are displayed, so the weak-star use is a finite observation route over the local-convexity packet rather than a selected-dual principle. □

Theorem 2433.5 (Locally convex space topological-vector seminorm route)**.** *Every local-convex consumer of an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *carrier factors first through the topological-vector-space source of chapter 205, the vector-space source of chapter 47, and the norm-comparison surface of chapter 89. Only after those sibling rows have been displayed may a functional-analysis consumer read the finite seminorm ledger S and the convex balanced neighbourhood ledger B as local convexity evidence.*

Proof. Project the accepted carrier $L = (V, T, S, B, M, H, C, P, N)$. The rows T, V, and M are exactly the displayed topological-vector, vector, and norm-comparison coordinates named by the sibling chapters.

The seminorm and neighbourhood rows do not replace those siblings. They are read after V and T fix the algebraic and topological source, and after M records whether a norm comparison is present.

Thus a functional-analysis consumer reaches local convexity only through the ordered route $T, V, M, S, B, H, C, P, N$. No Hahn–Banach principle, selected dual, ambient weak topology, or host locally convex predicate is exported by this sibling handoff. □

Theorem 2433.6 (Locally convex space forward citation)**.** *Every* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer that cites an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet for seminorm or convex-balanced-neighbourhood data must first read the sibling rows named in the carrier route:* $\mathsf{VecSpace}^{\uparrow}$ *for algebraic source,* $\mathsf{TopVecSpace}^{\uparrow}$ *for topological-vector continuity,* $\mathsf{Norm}^{\uparrow}$ *for optional comparison, and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *for the downstream consumer boundary. The local convexity citation is therefore a horizontal dependency through those displayed rows, not an isolated analytic predicate.*

Proof. Read the carrier of Definition 3386.1. Its rows V, T, M are the vector-space, topological-vector-space, and norm-comparison coordinates, while S and B are the seminorm and convex-balanced-neighbourhood ledgers consumed downstream.

The functional-analysis endpoint is named by the provenance and consumer boundary already recorded in the chapter opening. A consumer cannot detach S or B from the source rows that make them meaningful.

Thus every forward citation travels through $V, T, M, S, B, H, C, P, N$. The route records a real sibling dependency and exports no stand-alone local-convexity predicate outside the finite NameCert packet. □

Theorem 2433.7 (Locally convex space functional-analysis anchor)**.** *Every* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet must read the same seminorm family S, topological-vector route T, convex-balanced filter-neighbourhood rows B, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$ *row N before any functional-analytic closure is exposed. The consumer boundary of chapter 94 may cite local convexity only through this finite route, not through a detached locally convex topology predicate, selected dual, Hahn–Banach principle, or weak-star compactness theorem.*

Proof. Project the carrier in Definition 3386.1. The rows S, T, B, H, C, P, N are explicit coordinates of the accepted packet, with S naming the seminorm family, T naming the topological-vector source, and B naming the finite filter-neighbourhood evidence.

Apply the forward-citation theorem Definition 3386.6. It already forces functional-analysis consumers to pass through the vector, topological-vector, norm-comparison, seminorm, neighbourhood, transport, replay, provenance, and local naming rows.

The present theorem records the same route at the functional-analysis boundary. Since the carrier has no coordinate for a detached topology predicate, selected dual, separation principle, or weak-star compactness theorem, no functional-analytic closure can be exposed before those displayed rows are read. □

Falsifiable prediction: No accepted $\mathsf{LocallyConvexSpace}^{\uparrow}$ consumer can cite local convexity unless it first exposes the vector-space source, topological-vector-space source, finite seminorm-family ledger, convex balanced neighbourhood ledger, transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: topvecspace, vecspace, norm, functionalanalysis: none is bijective with $\mathsf{LocallyConvexSpace}^{\uparrow}$ because this carrier alone binds finite seminorm probes to convex balanced neighbourhood rows while retaining the vector, topology, comparison, transport, replay, provenance, and local NameCert coordinates.

The Banach–Alaoglu and weak-star compactness packets read $\mathsf{LocallyConvexSpace}^{\uparrow}$ through its displayed seminorm and topological-vector rows before any dual-ball compactness surface is exposed. In particular, chapter 3420 and chapter 6401 consume the locally convex source only after the seminorm-family route of chapter 5868 has made neighborhoods, bounded dual probes, and transport rows visible; neither compactness packet may treat $\mathsf{LocallyConvexSpace}^{\uparrow}$ as a hidden kernel premise detached from those finite rows.

Theorem 2433.8 (Locally convex Banach-seminorm route)**.** *Every accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet that is consumed by a Banach-facing functional-analysis row must first expose the* $\mathsf{SeminormedSpace}^{\uparrow}$ *family route of chapter 5868 and the* $\mathsf{TopVecSpace}^{\uparrow}$ *linear-topology route of chapter 205. A* $\mathsf{Banach}^{\uparrow}$ *read from chapter 90 is then available only through displayed bounded completion, complete-metric limit, or bounded-linear consumer rows already carried by the downstream packet. It does not replace the locally convex carrier by a host Banach space, selected norm, selected dual, or ambient completeness principle.*

Proof. Project the accepted locally convex carrier through Definition 3386.1. The rows S and B provide the finite seminorm family and convex balanced neighbourhood ledger, while T provides the topological-vector operation-continuity surface.

Read the sibling sources next. The seminorm row is anchored by $\mathsf{SeminormedSpace}^{\uparrow}$, and the linear-topology row is anchored by $\mathsf{TopVecSpace}^{\uparrow}$; these rows are visible before any functional-analysis consumer may cite local convexity.

When a Banach-facing consumer is also present, the $\mathsf{Banach}^{\uparrow}$ row is downstream of those displayed routes. It contributes only the bounded completion or limit rows named by the consumer packet, so the locally convex read remains mediated by $V, T, S, B, M, H, C, P, N$ and cannot export a detached Banach carrier or selected norm. □

Theorem 2433.9 (Locally convex topological-vector dependency anchor)**.** *The* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *dependency surface ties every seminorm-family read to the* $\mathsf{TopVecSpace}^{\uparrow}$ *source before Banach completeness is consumed. Thus a downstream* $\mathsf{Banach}^{\uparrow}$ *or bounded-linear row may use locally convex data only after the topological-vector operations, seminorm family, convex balanced neighbourhood ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows have all been read from the same finite carrier.*

Proof. Start with the topological-vector coordinate T. It supplies the vector addition and scalar multiplication continuity route through chapter 205, so every seminorm probe in S is interpreted against a displayed linear topology.

The neighbourhood ledger B is then read from the same carrier. Its convex balanced rows are generated from the visible seminorm and topological-vector data, rather than from an ambient locally convex host predicate.

Finally the structural rows H, C, P, N transport, replay, source, and name the route. Any Banach-facing consumer of chapter 90 receives only that already displayed route plus its own bounded completion or limit rows; the locally convex packet supplies no separate completeness, selected dual, or host equality coordinate. □

Theorem 2433.10 (Locally convex compact-regular-function dependency route)**.** *Every compact-regular real-function or functional-analysis consumer that cites the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet must first read the topological-vector-space source of chapter 205, the seminorm ledger, and the convex-balanced neighbourhood ledger from the source certificate. The route lets compact regular real-function packets use* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *as a source for functional-analysis neighbourhood control, while the exported rows remain* $V, T, S, B, M, H, C, P, N$ *and do not become a selected dual, an open-cover compactness proof, or an ambient host locally convex predicate.*

Proof. Project the source carrier of Definition 3386.1. The topological-vector-space row T is the displayed route through chapter 205, while S and B are the only seminorm and convex-balanced neighbourhood rows exposed to downstream consumers.

A compact-regular real-function packet may therefore cite the locally convex source only after those rows are visible. Functional-analysis consumers receive the same route through transport, replay, provenance, and local naming in H, C, P, N.

Since no row stores a selected dual, open-cover compactness proof, or host locally convex predicate, the dependency is a finite cross-reference route rather than an additional compactness or duality principle. □

The $\mathsf{LocallyConvexSpace}^{\uparrow}$ packet supplies the finite seminorm and convex-neighbourhood rows consumed by the $\mathsf{FrechetSpace}^{\uparrow}$ carrier of chapter 3495 before that carrier reaches its Baire-category handoff through chapter 3570 and chapter 3535.

Thus a $\mathsf{LocallyConvexSpace}^{\uparrow}$ read exports local convexity to the Frechet/Baire downstream lattice only through displayed seminorm, neighbourhood, transport, replay, provenance, and local naming rows; it exports no Hahn–Banach separation, infinite seminorm family, selected metric, or ambient completion.

Frechet dependency route. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ packet supplies the finite seminorm-family rows and convex balanced neighbourhood-filter rows consumed by the $\mathsf{FrechetSpace}^{\uparrow}$ carrier of chapter 3495. The same read also consumes the $\mathsf{TopVecSpace}^{\uparrow}$ operation-continuity surface of chapter 205 and the $\mathsf{MetricCompletion}^{\uparrow}$ handoff of chapter 1506 before complete locally convex replay is available. Thus the dependency is horizontal: $\mathsf{LocallyConvexSpace}^{\uparrow}$ provides the local convexity evidence, while $\mathsf{FrechetSpace}^{\uparrow}$ repacks that evidence with topological-vector operations, metrizability, and completion-facing data without importing an ambient complete locally convex host, a selected metric, quotient completion equality, countable choice, or an infinite seminorm enumeration.

Frechet and topological-vector sibling lattice. The sibling lattice around $\mathsf{LocallyConvexSpace}^{\uparrow}$ has two mandatory dependency edges. A $\mathsf{FrechetSpace}^{\uparrow}$ read cites chapter 3495 for the metric-completion and metrizability rows, while a $\mathsf{TopVecSpace}^{\uparrow}$ read cites chapter 205 for the vector-space topology, addition-continuity, and scalar-continuity rows. A locally convex consumer may therefore export seminorm-family evidence only after those sibling rows have displayed the finite seminorm ledger, metric completion handoff, and vector-space topology surface; it does not bypass either sibling into an ambient locally convex host.

Frechet and topological-vector crosslink. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ carrier depends on the $\mathsf{TopVecSpace}^{\uparrow}$ source of chapter 205 for the compatibility between vector addition, scalar multiplication, and the displayed topology before its seminorm and convex-balanced neighbourhood rows can be read as local convexity. The same packet feeds the $\mathsf{FrechetSpace}^{\uparrow}$ carrier of chapter 3495 by adding countable seminorm-family, metrizable replay, and completion-facing constraints over that topological-vector surface. Thus the route from $\mathsf{TopVecSpace}^{\uparrow}$ through $\mathsf{LocallyConvexSpace}^{\uparrow}$ to $\mathsf{FrechetSpace}^{\uparrow}$ is a finite NameCert dependency chain, not a host-level assertion of an ambient locally convex complete vector space.

Theorem 2433.11 (Locally convex space forward lattice anchor)**.** *Every forward dependency read of an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet factors through the displayed lattice*

$$\mathsf{VecSpace}^{\uparrow},\ \mathsf{TopVecSpace}^{\uparrow},\ \mathsf{Norm}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow},\ S,\ B,\ H,\ C,\ P,\ N.$$

Here S is the finite seminorm ledger and B is the convex-balanced neighbourhood ledger. The sibling consumer of chapter 94 may cite local convexity only after these rows have been exposed, so the forward lattice records a finite NameCert dependency rather than an isolated analytic predicate.

Proof. Project the carrier of Definition 3386.1. Its source rows name $\mathsf{VecSpace}^{\uparrow}$ and $\mathsf{TopVecSpace}^{\uparrow}$, while the optional comparison row names $\mathsf{Norm}^{\uparrow}$ and the downstream boundary names $\mathsf{FunctionalAnalysis}^{\uparrow}$.

The local-convexity evidence is then read from S and B. The seminorm ledger supplies the finite probe family, and the neighbourhood ledger supplies the convex-balanced rows attached to the same topological-vector source.

Finally transport, replay, provenance, and naming are supplied by H, C, P, N. Repacking these rows gives the forward lattice above and leaves no coordinate for a detached locally convex predicate, selected dual, Hahn–Banach row, or weak-star compactness theorem. □

Every $\mathsf{LocallyConvexSpace}^{\uparrow}$ read that is consumed by $\mathsf{FunctionalAnalysis}^{\uparrow}$ or $\mathsf{FrechetSpace}^{\uparrow}$ must expose the convex-neighbourhood and seminorm-window surface before any downstream linear-topology or complete-metrizable row is read. The route passes from the local carrier of chapter 3386 through the $\mathsf{FrechetSpace}^{\uparrow}$ dependency of chapter 3495 and the functional-analysis consumers cited by chapter 94; it exports no host locally convex space, selected infinite seminorm family, quotient completion, or ambient completeness coordinate.

Theorem 2433.12 (Locally convex functional-analysis forward link)**.** *Every* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer that cites the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet must first read the vector-space source of chapter 47, the topological-vector-space source of chapter 205, the norm-comparison row of chapter 89, and the functional-analysis boundary of chapter 94 through the displayed seminorm ledger S and convex-balanced neighbourhood ledger B. The downstream Frechet route of chapter 3495 and weak-star route of chapter 5192 read* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *only through those same S and B rows, not through a selected dual or host locally convex predicate. The route exports finite local-convexity evidence only through $V, T, S, B, M, H, C, P, N$; it does not export a selected dual, a Hahn–Banach principle, weak-star compactness, or an ambient locally convex topology predicate.*

Proof. Project the carrier of Definition 3386.1. Its rows V, T, M are the displayed vector, topological-vector, and norm-comparison sources, while S and B are the only local-convexity ledgers.

The functional-analysis consumer can therefore reach local convexity only after those source rows have been read through the seminorm and convex-balanced neighbourhood data. The Frechet and weak-star consumers inherit the same restriction: they may inspect S and B, but they receive no selected dual, host locally convex predicate, or detached topology witness. Transport, replay, provenance, and naming through H, C, P, N preserve the same finite route, so no dual selector, Hahn–Banach row, weak-star compactness row, or host topology predicate is introduced. □

Theorem 2433.13 (Locally convex functional-analysis dependency route)**.** *Every* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet must first read the seminorm family row S, the* $\mathsf{TopVecSpace}^{\uparrow}$ *transport row T, the finite convex-balanced neighbourhood ledger B, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$ *row N. The consumer boundary of chapter 94 may then cite the packet only through those visible rows, never through a selected dual, a host locally convex topology predicate, a Hahn–Banach principle, quotient equality of functionals, or an ambient completeness theorem.*

Proof. Project the accepted carrier of Definition 3386.1. Its locally convex data are the seminorm row S and the convex-balanced neighbourhood ledger B, while the linear-topology compatibility is supplied by the $\mathsf{TopVecSpace}^{\uparrow}$ row T.

The downstream $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer can therefore replay local convexity only after S, T, B are visible, and only with the transport, replay, provenance, and naming rows H, C, P, N attached. The functional-analysis chapter of chapter 94 receives that finite route as a dependency surface, so no selected dual, host topology predicate, quotient equality, or completeness principle is introduced. □

The top-level $\mathsf{LocallyConvexSpace}^{\uparrow}$ hub exposes its sibling lattice through chapter 205, chapter 208, chapter 5868, and chapter 94. A locally convex read therefore enters the dossier through displayed topological-vector operations, convex-neighbourhood evidence, finite seminorm-family rows, and functional-analysis consumers before any downstream packet treats $V, T, S, B, M, H, C, P, N$ as a reusable source surface. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ dependency lattice is read through its displayed seminorm-family and topological-vector rows rather than through a detached host predicate.

A consumer reaches the packet by first reading $\mathsf{Seminorm}^{\uparrow}$ and $\mathsf{SeminormedSpace}^{\uparrow}$ of chapter 5868 for seminorm evidence, $\mathsf{TopVecSpace}^{\uparrow}$ of chapter 205 for addition and scalar-continuity transport, $\mathsf{ConvexSet}^{\uparrow}$ for convex balanced neighbourhood rows, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ for the downstream citation boundary. No route exports a selected dual, Hahn–Banach principle, weak-star compactness theorem, or ambient locally convex topology outside the finite NameCert packet.

Theorem 2433.14 (Locally convex neighbourhood sibling route)**.** *Every* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *neighbourhood read first consumes the* $\mathsf{TopVecSpace}^{\uparrow}$ *vector/topology rows of chapter 205 and the* $\mathsf{SeminormedSpace}^{\uparrow}$ *finite seminorm rows of chapter 5868. Only after those sibling rows are visible may the packet expose convex balanced neighbourhood data through the local rows* B, H, C, P, N*.*

Proof. Project the carrier of Definition 3386.1. The topological-vector row T records the linear topology and operation-continuity route, while the seminorm ledger S records the finite probes that generate the accepted neighbourhood reads.

Read those rows through their sibling chapters. The $\mathsf{TopVecSpace}^{\uparrow}$ route supplies the vector/topology source, and the $\mathsf{SeminormedSpace}^{\uparrow}$ route supplies the finite seminorm comparison surface before any convex balanced neighbourhood can be used.

The neighbourhood row B is therefore downstream of T and S. Transport, replay, provenance, and local naming through H, C, P, N preserve the same route and do not introduce a detached locally convex host predicate. □

The $\mathsf{LocallyConvexSpace}^{\uparrow}$ seminorm and convex-neighbourhood ledgers consume the sibling lattice directly: $\mathsf{VecSpace}^{\uparrow}$ supplies the linear operations through chapter 47, $\mathsf{TopVecSpace}^{\uparrow}$ supplies continuity of addition and scalar multiplication through chapter 205, $\mathsf{Norm}^{\uparrow}$ supplies scalar-bound readbacks through chapter 89, and $\mathsf{FunctionalAnalysis}^{\uparrow}$ supplies downstream replay through chapter 94. The $\mathsf{NormedSpace}^{\uparrow}$ row of chapter 1950 is the single-norm specialization whose scalar-bound readbacks are consumed before the finite seminorm-family route is generalized to $\mathsf{LocallyConvexSpace}^{\uparrow}$. The seminormed-space row of chapter 5868 and the topological-vector-space row are the finite routes through which the carrier reads convex-neighbourhood and seminorm-control data. A local-convexity consumer therefore reads those sibling rows as part of the finite ledger route before citing the packet. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ carrier consumes the finite seminorm-family ledger only after the topological-vector classifier surface of chapter 205 is visible. The same read is then available to the functional-analysis route of chapter 94: consumers inspect the S seminorm row and the B convex-balanced neighbourhood row as displayed NameCert data, not as a host locally convex predicate or an unbounded family of seminorms. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ carrier reads its separating seminorm family through the finite family-seminorm packet of chapter 5868 and reads topology compatibility through the $\mathsf{TopVecSpace}^{\uparrow}$ source of chapter 205 together with the complete-metrizable consumer route of chapter 3495. The seminorm rows generate the displayed locally convex neighbourhood basis before the B convex-balanced neighbourhood ledger can be used, so a downstream consumer reaches local convexity through S and B as BEDC NameCert rows rather than through an ambient locally convex predicate. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ dependency lattice reads the $\mathsf{Seminorm}^{\uparrow}$ family through the finite family route of chapter 5868 and the $\mathsf{TopVecSpace}^{\uparrow}$ carrier of chapter 205 before any convex-neighbourhood route is available. Thus the local-convexity packet exposes seminorm-control rows and topological-vector continuity rows as finite sibling data, then passes them to S, B, H, C, P, N for transport, replay, provenance, and local naming rather than treating local convexity as a kernel-only predicate. Every $\mathsf{LocallyConvexSpace}^{\uparrow}$ consumer reads seminorm-family rows through the finite seminormed-space carrier of chapter 5868 and reads topological-vector operations through chapter 205 before any convex-neighbourhood or continuous-linear functional route is used. Thus

the local-convexity handoff remains the displayed route through $V, T, S, B, M, H, C, P, N$, not a host locally convex predicate detached from its seminorm and topological-vector-space sources. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ packet reads its neighbourhood basis only after the finite seminorm-family row and the $\mathsf{TopVecSpace}^{\uparrow}$ linear-topology row have been displayed together. The seminorm ledger is anchored by chapter 5868, while the ambient additive-topological continuity source is anchored by chapter 205; downstream functional-analysis consumers therefore use the locally convex surface through $V, T, S, B, M, H, C, P, N$, not through a detached host predicate. The $\mathsf{LocallyConvexSpace}^{\uparrow}$ carrier reads its separating seminorm family through the finite family ledger of chapter 5868 and its ambient additive-topological structure through the $\mathsf{TopVecSpace}^{\uparrow}$ source of chapter 205. A local-convexity consumer therefore reaches the S seminorm row only after the topological-vector operations and continuity rows have been displayed, and the resulting packet remains the finite route $V, T, S, B, M, H, C, P, N$ rather than a host locally convex predicate.

Theorem 2433.15 (Locally convex space sibling dependency route)**.** *Every* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *consumer that exports a locally convex read must first expose the sibling route through the substantive dependency surfaces of chapter 205 for the* $\mathsf{TopVecSpace}^{\uparrow}$ *topology row, chapter 47 for the* $\mathsf{VecSpace}^{\uparrow}$ *or module algebra row, the finite local seminorm ledger carried by this packet, and chapter 89 for the optional* $\mathsf{Norm}^{\uparrow}$ *comparison row when present, together with the structural* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. The exported read is therefore a horizontal dependency over the displayed vector, topology, seminorm, norm-comparison, transport, replay, provenance, and naming surfaces; it is not a standalone host predicate for local convexity.*

Proof. Project the accepted carrier of Definition 3386.1. Its rows $V, T, S, B, M, H, C, P, N$ already order the vector, topology, seminorm, neighbourhood, comparison, transport, replay, provenance, and naming data.

The sibling route reads T and V before any locally convex probe is exported. The seminorm ledger S supplies finite local convexity probes, and the comparison row M supplies a norm route only when such a row is displayed by the packet.

The structural rows H, C, P, N then transport, replay, source, and name the same finite route. Since no independent host predicate occurs in the carrier, every locally convex read remains tied to the sibling dependency surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocallyConvexSpace}^{\uparrow}$ packet is generated from a vector-space source, a topological-vector-space source, a finite seminorm-family ledger, a convex balanced neighbourhood ledger, optional norm comparison rows, componentwise transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$, seed)

Scope closed: Definition 3386.1, Definition 3386.2, Definition 3386.3, and Definition 3386.15 seed the finite locally convex carrier over $V, T, S, B, M, H, C, P, N$ and its sibling dependency route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocallyConvexSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, choice-selected duals, ambient weak-star compactness, spectral theory, unrestricted barrelledness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked vector, topological-vector, seminorm, convex balanced neighbourhood, norm comparison, transport, replay, provenance, sibling dependency, and local naming rows for BEDC.Derived.LocallyConvexSpaceUp.

Theorem 2433.16 (Locally convex space sibling route)**.** *Every* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *consumer must read the* $\mathsf{Seminorm}^{\uparrow}$ *evidence carried by the finite seminorm-family route of chapter 5868, the* $\mathsf{TopVecSpace}^{\uparrow}$ *topology row of chapter 205, and the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer boundary of chapter 94 before treating the locally convex carrier as available. The local carrier is therefore a horizontal dependency through displayed seminorm, topological-vector, functional-analysis, transport, replay, provenance, and naming rows, not a detached host predicate.*

Proof. Project the accepted carrier of Definition 3386.1. The seminorm ledger, topological-vector source, convex-neighbourhood rows, and structural rows are all visible coordinates of the same finite packet.

The seminorm evidence is read first through the finite family route cited by the seminormed-space chapter, and the topology row is read through $\mathsf{TopVecSpace}^{\uparrow}$. Only after those sibling rows are displayed may a $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer use the packet as a locally convex source.

The remaining rows transport, replay, source, and name the same dependency surface. Since no coordinate stores a selected dual, Hahn–Banach principle, weak-star compactness theorem, or ambient locally convex topology predicate, the consumer receives only the displayed sibling route. □

Theorem 2433.17 (Locally convex TopVecSpace anchor)**.** *Every accepted* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *packet consumes the* $\mathsf{TopVecSpace}^{\uparrow}$ *carrier of chapter 205 and the* $\mathsf{ConvexSet}^{\uparrow}$ *neighbourhood rows of chapter 208 before any seminorm ledger, local-base read, or functional-analysis handoff is available. The local convexity read is therefore a sibling route through displayed vector-topology and convex-neighbourhood data, not an isolated host predicate.*

Proof. Project the carrier of Definition 3386.1. The row T is the topological-vector-space source, while B is the convex balanced neighbourhood ledger.

The row T must be read first because it supplies the topology, addition-continuity ledger, and scalar-continuity ledger used by every neighbourhood request. The row B is then read through $\mathsf{ConvexSet}^{\uparrow}$ as the displayed convex-neighbourhood evidence.

Only after T and B are visible may the finite seminorm ledger S or a local-base consumer inspect the packet. Transport, replay, provenance, and local naming keep the same route, so the chapter records a horizontal dependency through $\mathsf{TopVecSpace}^{\uparrow}$ and $\mathsf{ConvexSet}^{\uparrow}$ rather than a kernel-only local-convexity predicate. □

The $\mathsf{LocallyConvexSpace}^{\uparrow}$ carrier consumes the $\mathsf{TopVecSpace}^{\uparrow}$ carrier and operation-continuity transport route of chapter 205 together with the $\mathsf{Seminorm}^{\uparrow}$ family rows read through the finite seminormed-space surface of chapter 5868. Banach, Frechet, and weak-star consumers may inspect locally convex data only after those topological-vector and seminorm ledgers have displayed S, B, H, C, P, N as NameCert rows, so the route exports no detached locally convex host predicate, selected dual, Hahn–Banach principle, or ambient completeness theorem.

Theorem 2433.18 (Locally convex topological-vector-space dependency route)**.** *Every* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *consumer must read the* $\mathsf{TopVecSpace}^{\uparrow}$ *linear-topology row of chapter 205, the* $\mathsf{ConvexSet}^{\uparrow}$ *neighbourhood row of chapter 208, and the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *continuity-facing row of chapter 94 before treating the packet as locally convex. The route binds local convexity to displayed linear topology, convex neighbourhood, finite seminorm, continuity, transport, replay, provenance, and local naming rows; it is not a standalone host predicate for locally convex spaces.*

Proof. Project the carrier of Definition 3386.1. Its rows T, S, B already separate the topological-vector-space source, finite seminorm ledger, and convex balanced neighbourhood ledger.

The linear-topology row is read first through $\mathsf{TopVecSpace}^{\uparrow}$. The convex-neighbourhood row is then read through $\mathsf{ConvexSet}^{\uparrow}$ as the displayed source for the neighbourhood evidence in B.

Only after those rows are visible may the $\mathsf{FunctionalAnalysis}^{\uparrow}$ consumer inspect continuity-facing data. Transport, replay, provenance, and local naming preserve the same finite route, so no independent locally convex host predicate, selected dual, Hahn–Banach row, or weak-star compactness row is exported. □

Weak-star topology and weak-star compactness consumers read the $\mathsf{LocallyConvexSpace}^{\uparrow}$ source row before finite bounded-linear-functional windows: chapter 5192 uses the displayed weak-observation probes, and chapter 6401 consumes the same locally convex surface before the finite dual-ball compactness handoff. The route keeps weak-star reads tied to vector, topology, seminorm, convex-neighbourhood, transport, replay, provenance, and local naming rows rather than to a host locally convex predicate. The $\mathsf{ForwardSocketLedger}^{\uparrow}$ hub reads its forward request only after the supply ledger of chapter 528 and the far-end boundary of chapter 1061.

Chapter 2434

A Concrete Naming Certificate for $\mathsf{ForwardSocketLedger}^{\uparrow}$

The $\mathsf{ForwardSocketLedger}^{\uparrow}$ packet realizes the forward-socket family boundary of chapter 9401 as finite NameCert rows. It sits beside the supply-socket accounting of chapter 528, the apophatic socket classifier of chapter 536, the far-end boundary packet of chapter 1061, and the local inscription carrier of chapter 610. Its role is to make the forward read auditable before any consumer cites the apophatic far-end boundary.

The dependency route consumed before the forward socket export passes through the supply ledger of chapter 528 and the far-end boundary of chapter 1061; the forward packet only exports after those ledger and far-end rows are visible.

Definition 2434.1 (Forward socket ledger carrier)**.** *A* $\mathsf{ForwardSocketLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, R, A, G, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the socket-kind row, recording which forward socket is being read and how it is classified among the accepted socket forms.*
2. *R is the requested supply-shape row, recording the requested external shape without supplying it as a kernel object.*
3. *A is the non-internalization marker, recording that the requested far-end supply is a boundary and not a generated state, record, rule, or* BHist *constructor.*
4. *G is the* GAP *ledger row, binding the refusal of internal supply to the visible socket-use and supply-ledger routes.*
5. *T is the apophatic far-end boundary row, naming the far end only as the common boundary read by the forward socket family.*
6. *H records componentwise* hsame *transport for K, R, A, G, T and the local naming row.*
7. *C records displayed* Cont *replay through socket kind, requested supply shape, non-internalization,* GAP *ledger, far-end boundary, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ForwardSocketLedger}^{\uparrow}$*,* $\mathsf{SupplySocketLedger}^{\uparrow}$*,* $\mathsf{ApophaticSocket}^{\uparrow}$*,* $\mathsf{ApophaticFarEndSocket}^{\uparrow}$*,* $\mathsf{InscriptionPoint}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ForwardSocketLedger}^{\uparrow}}$ *row.*
The carrier contains no coordinate for T *as a kernel object, no hidden requested-supply witness, no socket selector outside K, no object-level equality between the far end and a local state, and no host fixed-point principle.*

Theorem 2434.2 (Forward socket ledger NameCert obligations)**.** *For every accepted* $\mathsf{ForwardSocketLedger}^{\uparrow}$ *carrier $F = (K, R, A, G, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ForwardSocketLedger}^{\uparrow}}$ *surface consists exactly of socket-kind exposure through K; requested supply-shape exposure through R; non-internalization evidence through A;* GAP *ledger exposure through G; apophatic far-end boundary exposure through T; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the accepted carrier of Definition 3387.1. The tuple lists socket kind, requested supply shape, non-internalization, gap ledger, far-end boundary, transport, replay, provenance, and local naming as explicit rows.

The socket can be read only after K and R expose its kind and requested shape. The rows A and G then mark the request as boundary supply rather than as an internal object.

The far-end boundary row T is downstream of those rows. Transport, replay, provenance, and naming through H, C, P, N preserve the same finite route. Since no hidden selector, requested-supply witness, internal far-end object, or host fixed-point principle occurs in the carrier, these rows exhaust the local NameCert surface. □

Theorem 2434.3 (Forward socket ledger apophatic non-escape)**.** *Every accepted read of the apophatic far-end boundary through* $\mathsf{ForwardSocketLedger}^{\uparrow}$ *must first expose $K, R, A, G, T, H, C, P, N$. It cannot cite the far end as an internal object, a generated state, a selected supply witness, a socket-family fixed point outside the ledger, or an equality between* T *and a local inscription point.*

Proof. Start with the rows K and R. They identify the forward socket and its requested supply shape before any far-end boundary is available.

The rows A and G are the non-internalization gate. They state that the requested supply remains a GAP-ledgered boundary rather than a kernel-side value.

Only then may T be read as the apophatic far-end boundary, and H, C, P, N only transport, replay, source, and name that same finite route. Thus any consumer that skips $K, R, A, G, T, H, C, P, N$ has no accepted route to the far end. □

Falsifiable prediction: Every accepted read through $\mathsf{ForwardSocketLedger}^{\uparrow}$ must expose socket kind, requested supply shape, non-internalization marker, GAP ledger, apophatic far-end boundary, transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ before any consumer can cite the far-end boundary.

Independence witness: supplysocketledger, apophaticsocket, apophaticfarendsocket, inscriptionpoint: none is bijective with $\mathsf{ForwardSocketLedger}^{\uparrow}$ because this carrier alone binds socket kind, requested supply shape, non-internalization, GAP ledger, far-end boundary, transport, replay, provenance, and local NameCert rows before a far-end read is accepted.

Closure status for $\mathsf{NameCert}_{\mathsf{ForwardSocketLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ForwardSocketLedger}^{\uparrow}$ packet is generated from socket-kind exposure, requested supply-shape exposure, non-internalization evidence, a GAP ledger row, an apophatic far-end boundary row, componentwise transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ForwardSocketLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3387.1, Definition 3387.2, and Definition 3387.3 seed the finite forward-socket ledger over $K, R, A, G, T, H, C, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ForwardSocketLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not internalize T, select a hidden supply witness, close a consciousness theorem, provide a host fixed-point theorem, claim object-level equality with a local inscription point, give Lean verification, or provide bridge checking.

Upgrade path: Obligation closure requires checked socket-kind, requested-supply, non-internalization, GAP-ledger, far-end boundary, transport, replay, provenance, and local naming rows for BEDC.Derived.ForwardSocketLedgerUp.

Theorem 2434.4 (Forward socket ledger MetaCIC candidate-discharge route)**.** *Let $F = (K, R, A, G, T, H, C, P, N)$ be an accepted* $\mathsf{ForwardSocketLedger}^{\uparrow}$ *carrier. Any forward socket export consumed by the MetaCIC candidate-discharge frontier of chapter 765 must expose the forward rows $K, R, A, G, T, H, C, P, N$ before the MetaCIC discharge socket D can be read. The forward rows are dependency data for the socket consumer; they are not a concealed subject-reduction discharge and do not fill D by themselves.*

Proof. Project the accepted carrier of Definition 3387.1. The rows $K, R, A, G, T, H, C, P, N$ expose the socket kind, requested shape, non-internalization marker, gap ledger, far-end boundary, transport, replay, provenance, and local naming before any export is available.

Now read the candidate-discharge frontier of chapter 765. Its packet keeps the discharge socket D visible while candidate-mediated strong-normalization, confluence-facing, bounded-conversion, and source-readiness rows are consumed.

A MetaCIC consumer that receives a forward socket export therefore receives dependency data already ordered by the forward carrier. Since the forward packet contains no subject-reduction certificate row and no coordinate that identifies the far-end boundary with a typing proof, the export can only feed the visible socket route.

Thus the MetaCIC discharge socket may read the forward rows as dependency surface, but D remains a separate socket row until an explicit subject-reduction certificate is displayed. □

Theorem 2434.5 (Forward socket ledger SocketUse dependency route)**.** *Let $F = (K, R, A, G, T, H, C, P, N)$ be an accepted* $\mathsf{ForwardSocketLedger}^{\uparrow}$ *carrier. Any accepted forward socket export that consumes the far-end boundary row T factors through the visible socket-use ledger of chapter 1044 before the local* $\mathsf{NameCert}_{\mathsf{ForwardSocketLedger}^{\uparrow}}$ *row is read. In particular, the export route must first expose the supply ledger of chapter 528, the far-end boundary of chapter 1061, the socket-use event rows $A, S, Q, V, R, H, C, P, N$ of* $\mathsf{SocketUseLedger}^{\uparrow}$*, and only then the forward rows $K, R, A, G, T, H, C, P, N$.*

Proof. Project the accepted carrier of Definition 3387.1. The forward packet presents the requested supply shape, non-internalization marker, GAP ledger, and far-end boundary as visible rows rather than as an internal object.

Use the supply-socket and far-end sibling routes cited in the carrier provenance. The supply ledger accounts for the requested shape and refusal route, while the apophatic far-end socket keeps the boundary row non-internalized.

The visible consumption of that boundary is the role of $\mathsf{SocketUseLedger}^{\uparrow}$. Its event rows expose the marked use and refusal ledger before an audit consumer reaches a local socket-use NameCert row. Therefore a forward export that cites T must pass through that event surface before N may name the forward packet. □

Chapter 2435

A Concrete Naming Certificate for $\mathsf{SuccessiveApproximation}^{\uparrow}$

Picard–Banach successive approximation reads an iterated approximation schedule through finite budgets before any completed limit claim is exposed. The $\mathsf{SuccessiveApproximation}^{\uparrow}$ packet sits on the L10 route from the convergence-modulus schedule of chapter 1438, the displayed limit handoff of chapter 1413, the regular rational readback of chapter 301, the finite observation windows of chapter 126, and the dyadic tolerance ledger of chapter 291. It gives contraction, Picard, and fixed-point consumers a finite iteration-budget surface rather than a host limit, countable-choice schedule, quotient sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 2435.1 (Successive approximation carrier)**.** *A* $\mathsf{SuccessiveApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, T, W, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite iteration row, listing the inspected Picard approximants and the displayed application of the step operator at each row;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error-budget ledger attached to the inspected rows;*
3. *T is the finite tail schedule that records which iteration indices are compared at each displayed budget;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to read each displayed approximant and its successor;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same windows and dyadic budgets;*
6. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff row, visible only after I, D, T, W, Q have been displayed;*
7. *H records componentwise* hsame *transport for iteration rows, budgets, tail schedules, windows, readbacks, and the limit handoff;*
8. *C records displayed* Cont *replay for consumers of the same finite schedule;*
9. *P is the* Pkg *provenance over* $\mathsf{SuccessiveApproximation}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SuccessiveApproximation}^{\uparrow}}$ *row.*

The packet contains no host sequence limit, no countable-choice selector for tails, no quotient stream equality, no trichotomy split, and no ambient completeness coordinate.

Theorem 2435.2 (Successive approximation NameCert obligations)**.** *For every accepted* $\mathsf{SuccessiveApproximation}^{\uparrow}$ *carrier* $K = (I, D, T, W, Q, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SuccessiveApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite iteration rows, budget-classifier stability through* D, T, W, Q*, convergence-modulus handoff through* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$*,* $\mathsf{RealSequenceLimit}^{\uparrow}$ *nonescape through* L*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, local naming through* N*, and refusal of host limits and countable choice. Every fixed-point, Picard, or contraction consumer receives only this displayed schedule before reading a terminal real-facing row.*

Proof. Project the carrier of Definition 3388.1. The iteration row I, dyadic budget ledger D, tail schedule T, finite windows W, and regular rational readbacks Q are the only approximation rows available to the packet.

Use the sibling convergence route. The convergence-modulus schedule of chapter 1438 consumes the same dyadic budgets and tail rows, while chapter 1413 accepts the resulting limit handoff only after $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks have been displayed.

Finally read the structural rows H, C, P, N. They transport, replay, source, and name the same finite schedule, so the packet cannot export a host limit, countable-choice tail selector, quotient sequence equality, trichotomy decision, or ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.SuccessiveApproximationUp.SuccessiveApproximationCarrier namecert obligations`

Falsifiable prediction: Every fixed-point consumer of a SuccessiveApproximationUp packet reads a finite iteration budget before any RealSequenceLimitUp handoff is visible.

Independence witness: cauchy-convergence-modulus, real-sequence-limit, regseqrat, streamname, dyadicratcore: SuccessiveApproximationUp is not bijective to any listed sibling because it jointly carries iteration rows, dyadic error budgets, tail schedules, finite windows, readback, limit handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SuccessiveApproximation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SuccessiveApproximation}^{\uparrow}$ packet is generated from finite Picard iteration rows, dyadic error budgets, tail schedules, StreamName windows, RegSeqRat readbacks, a RealSequenceLimit handoff, transport, replay, provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SuccessiveApproximation}^{\uparrow}}$, seed)

Scope closed: Definition 3388.1 and Definition 3388.2 declare the finite Picard-style iteration-budget surface for L10 Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SuccessiveApproximation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host limits, countable choice, quotient sequence equality, fixed-point existence, contraction uniqueness, trichotomy, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, budget classifier stability, convergence-modulus handoff, RealSequenceLimit nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SuccessiveApproximationUp.

Chapter 2436

A Concrete Naming Certificate for $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real names, the $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name is admitted into the $\mathsf{Real}^{\uparrow}$ seal. It sits after the regular-rational source of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the dense-embedding route of chapter 1453, and the terminal real-name seal of chapter 38. The packet exposes the source-to-seal admission route without importing quotient real equality, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2436.1 (RealCauchyDenseEmbedding carrier)**.** *A* $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, W, D, J, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, exposing the regular Cauchy rational name and its displayed modulus discipline;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect the finite source entries requested by a real-name consumer;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested precision, comparison budget, and slack rows used by the admission route;*
4. *J is the* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *route row that names the dense source-to-real embedding discipline;*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, W, D, J have been displayed;*
6. *H records componentwise* hsame *transport for the regular source, windows, dyadic ledger, dense-embedding route, Real seal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from a Real-admission request through R, W, D, J, S, H;*
8. *P is the* Pkg *provenance over* $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyDenseEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, a selected representative of a real name, countable choice over approximation stages, trichotomy, a host completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyDenseEmbeddingUp.RealCauchyDenseEmbeddingTasteGate single carrier alignment`

Theorem 2436.2 (RealCauchyDenseEmbedding NameCert obligations)**.** *For every accepted* RealCauchyDenseEmb *carrier* $E = (R, W, D, J, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCauchyDenseEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular-rational source* R*, finite window exposure through* W*, dyadic tolerance accounting through* D*, dense-embedding routing through* J*, Real-seal handoff through* S*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. A* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer must read* R, W, D, J *before the seal row* S *is available.*

Proof. Project the carrier of Definition 3389.1. The regular source, finite windows, dyadic tolerance ledger, dense-embedding route, Real seal, transport, replay, provenance, and local naming rows are exactly the displayed coordinates.

The source side is finite. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular Cauchy rational name, the $\mathsf{StreamName}^{\uparrow}$ row opens only the requested windows, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row records the tolerance ledger used by those windows.

The dense-embedding row J then mediates admission to the Real seal. The row S is downstream of R, W, D, J, and the structural rows H, C, P, N preserve and name the same route, so the certificate surface cannot expose quotient real equality, selected representatives, trichotomy, countable choice, or ambient completeness. □

Theorem 2436.3 (RealCauchyDenseEmbedding Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchyDenseEmbedding}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{Nam}$$

The terminal $\mathsf{Real}^{\uparrow}$ *row is only a seal for the displayed regular Cauchy rational source and its finite tolerance windows. It is not a source of quotient real equality, selected representatives, countable choice, trichotomy, host completion, or ambient real completeness.*

Proof. Start with the obligation surface of Definition 3389.2. A consumer cannot read the Real seal until the regular source, finite windows, dyadic tolerance ledger, and dense-embedding route have already been displayed.

The sibling rows enforce the direction of the read. $\mathsf{RegSeqRat}^{\uparrow}$ supplies the source name, $\mathsf{StreamName}^{\uparrow}$ supplies only finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the precision ledger, and $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ supplies the source-to-seal route.

Finally the rows H, C, P, N transport, replay, source, and name the same packet. Since no refused host-side principle is a coordinate of E, the Real row remains a seal and not an escape principle. □

Falsifiable prediction: Every accepted $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ consumer reads one $\mathsf{RegSeqRat}^{\uparrow}$ source row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and one $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ route before any $\mathsf{Real}^{\uparrow}$ seal is exposed.

Independence witness: regseqrat, streamname, dyadicratcore, regular-cauchy-dense-embedding, real: $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries

source regularity, finite windows, dyadic tolerance accounting, dense-embedding routing, Real seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyDenseEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ packet is generated from a RegSeqRat source row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegularCauchyDenseEmbedding route, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyDenseEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3389.1, Definition 3389.2, and Definition 3389.3 seed the finite regular-Cauchy rational source-to-Real seal admission packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyDenseEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected representatives, countable choice, trichotomy, host completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source regularity, finite window exposure, dyadic tolerance accounting, dense-embedding routing, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealCauchyDenseEmbeddingUp.

$\mathsf{RegularCauchyUniqueness}^{\uparrow}$ reads uniqueness through chapter 301, chapter 126, chapter 291, chapter 1412, and chapter 38 before any completion consumer cites the seal.

Chapter 2437

A Concrete Naming Certificate for $\mathsf{RegularCauchyUniqueness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ packet records the textbook uniqueness route for regular Cauchy names as finite BEDC data. It sits after the regular-rational name surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the comparison discipline of chapter 1412, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Real-completion consumers such as chapter 3579 use $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ to make the $\mathsf{Real}^{\uparrow}$ seal independent of the chosen $\mathsf{RegSeqRat}^{\uparrow}$ representative. The chapter only seeds the finite route from equality data for regular Cauchy names to the Real seal boundary.

Definition 2437.1 (Regular Cauchy uniqueness carrier)**.** *A* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, S, T, D, E, R, H, C, P, N)$$

with the following visible rows:

1. *X and Y are paired* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy name rows;*
2. *S and T are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which the two names are observed at the same requested tolerance;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the displayed radius, comparison budget, and rational-distance rows used by the uniqueness route;*
4. *E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row tying the paired windows to one finite equivalence decision;*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the paired names, windows, dyadic tolerance ledger, and comparison row have been displayed;*
6. *H stores componentwise* hsame *transport for X, Y, S, T, D, E, R and the structural rows;*
7. *C stores displayed* Cont *replay of the route*

$$X, Y \longmapsto S, T, D \longmapsto E \longmapsto R;$$

8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueness}^{\uparrow}}$ *row.*

The classifier compares two accepted carriers only by the displayed rows $X, Y, S, T, D, E, R, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, ambient Real completeness, or an unrecorded equality proof outside the packet.

Lean4 ✓ `BEDC.Derived.RegularCauchyUniquenessUp.RegularCauchyUniquenessTasteGate single carrier alignment`

Theorem 2437.2 (Regular Cauchy uniqueness NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *carrier*

$$U = (X, Y, S, T, D, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueness}^{\uparrow}}$ *surface consists exactly of carrier admission for the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *names, paired* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier stability under the same displayed rows; tolerance exactness through D; transport invariance through H; ledger visibility through C and P; and Real-seal nonescape through R.*

Proof. Carrier admission is projection from Definition 3390.1. The projection exposes exactly the two regular Cauchy names, their finite windows, the dyadic tolerance ledger, the comparison row, the seal row, and the structural rows.

Classifier stability follows because the classifier is componentwise on the same displayed rows. Tolerance exactness is the projection of D, and ledger visibility is the fact that every consumer route in C reads X, Y, S, T, D, E, R before the provenance and naming rows.

Transport invariance is supplied by H: each transported accepted carrier keeps the same row roles. The Real-seal boundary is downstream from E, so no consumer can read R without first passing through the finite comparison packet. □

Theorem 2437.3 (Regular Cauchy uniqueness Real-seal obligations)**.** *Every accepted* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *packet that exposes a* $\mathsf{Real}^{\uparrow}$ *seal must display the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *rows X, Y, the paired* $\mathsf{StreamName}^{\uparrow}$ *windows S, T, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and one* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row E before the seal row R is available. The seal obligation is therefore the ordered finite route*

$$X, Y \longmapsto S, T, D \longmapsto E \longmapsto R,$$

preserved by H, C, P, N and not by quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3390.1. The projection exposes exactly the paired regular Cauchy rows, paired stream windows, dyadic tolerance ledger, comparison row, and terminal seal row.

Use Definition 3390.4 to bind the comparison to the single row D. The windows S, T and names X, Y are opened at that same tolerance source before E is read.

Now use Definition 3390.7. It places every $\mathsf{Real}^{\uparrow}$-facing read downstream from E and excludes quotient stream equality, selected limits, host real equality, countable choice, and ambient completeness from the seal route. The structural rows H, C, P, N transport, replay, source, and name that same finite obligation surface. □

Theorem 2437.4 (Regular Cauchy uniqueness tolerance exactness)**.** *Every accepted comparison in a* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *packet reads its tolerance data through the single displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D. The paired* $\mathsf{StreamName}^{\uparrow}$ *windows S, T and paired* $\mathsf{RegSeqRat}^{\uparrow}$ *names*

X, Y are opened at that row's radius and comparison budget, and the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *row E consumes no tolerance source outside D.*

Consequently the uniqueness route exports no hidden metric estimate, quotient-stream equality, selected limit, or ambient Real-completeness argument.

Proof. Project the carrier and inspect the tolerance coordinate. The only dyadic radius and rational-distance data are stored in D.

The windows S, T are tied to that coordinate by the continuation route C. Thus the two regular Cauchy names are observed through the same finite tolerance request before the comparison row is read.

The comparison row E is downstream from S, T, D. Since no other tolerance coordinate is present in the carrier, an accepted comparison cannot be justified by an external estimate or by quotient equality of streams. □

Theorem 2437.5 (Regular Cauchy uniqueness transport invariance)**.** *Let $U = (X, Y, S, T, D, E, R, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *carrier. Componentwise* hsame *transport of the paired names, windows, tolerance ledger, comparison row, seal row, continuation route, provenance row, and local naming row produces another accepted carrier with the same uniqueness route. The transported classifier still reads only $X, Y, S, T, D, E, R, H, C, P, N$.*

Proof. Read the transport row H. Its components move the two $\mathsf{RegSeqRat}^{\uparrow}$ names, the two $\mathsf{StreamName}^{\uparrow}$ windows, the dyadic tolerance row, the comparison row, and the seal row together.

Replay the route through C after transport. The same ordered route from the paired names to the windows, tolerance, comparison row, and seal row remains visible.

Repack the transported rows with the same provenance and local naming data. Since the classifier has no coordinate outside the displayed rows, the transported packet is accepted by the same finite rule. □

Theorem 2437.6 (Regular Cauchy uniqueness tail-shift stability)**.** *Let $U = (X, Y, S, T, D, E, R, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *carrier whose paired* $\mathsf{RegSeqRat}^{\uparrow}$ *windows have the same* $\mathsf{Real}^{\uparrow}$ *seal row R and the same uniqueness tolerance ledger D. For any finite* $\mathsf{StreamName}^{\uparrow}$ *tail shift of the displayed windows S, T, the shifted windows preserve the uniqueness handoff through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row, and* $\mathsf{Real}^{\uparrow}$ *seal boundary, with H, C, P, N carrying the transported route.*

Proof. Project the carrier rows. The paired names X, Y, windows S, T, dyadic tolerance ledger D, comparison row E, and seal row R are all displayed before any Real-facing read is available.

Apply Definition 3390.4. The tail-shifted windows are still read at the same displayed tolerance source D, so the $\mathsf{RegSeqRat}^{\uparrow}$ readback and comparison row cannot import an external estimate.

Use Definition 3390.5 for the shifted windows and their transported structural rows. The same route through X, Y, S, T, D, E, R remains accepted after the finite reindexing.

Finally apply Definition 3390.7. Since the seal is downstream from the same comparison row and the carrier has no quotient stream equality, selected limit, countable-choice, ambient-completeness, or host-equality coordinate, the finite tail shift preserves the uniqueness handoff. □

Theorem 2437.7 (Regular Cauchy uniqueness Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *packet factors through the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *rows X, Y, the paired* $\mathsf{StreamName}^{\uparrow}$ *windows S, T, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row E, and only then the seal row R, with H, C, P, N preserving the same route.*

Thus the Real seal cannot escape to quotient stream equality, a selected limit, countable choice, ambient Real completeness, or any unrecorded host equality proof.

Proof. Start from a Real-facing read and project the continuation route C. The route lists the paired names, paired windows, dyadic tolerance row, and comparison row before the seal row R.

Use Definition 3390.4 to pin the comparison to D. Then use Definition 3390.5 to see that transport and replay preserve the same ordered finite rows.

The provenance and naming rows P, N attach the route to the local packet. Because the carrier contains no quotient stream, selected limit, countable-choice, ambient-completeness, or host-equality coordinate, no Real-facing consumer can read such data from the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ packet is generated from paired $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy names, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ comparison row, a terminal $\mathsf{Real}^{\uparrow}$ seal, transport data, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3390.1, Definition 3390.2, Definition 3390.3, Definition 3390.4, Definition 3390.5, and Definition 3390.7 name the L10 regular-Cauchy uniqueness route from finite RegSeqRat equality data through StreamName and DyadicRatCore tolerances to the Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, ambient Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier surface, classifier stability, Real-seal obligations, tolerance exactness, transport invariance, ledger visibility, and Real-seal nonescape rows for the displayed uniqueness packet.

The downstream $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ consumer of chapter 3579 reads $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ through the carrier of Definition 3390.1, the tolerance exactness row of Definition 3390.4, and the Real seal nonescape row of Definition 3390.7. This route keeps the $\mathsf{Real}^{\uparrow}$ seal independent of the chosen $\mathsf{RegSeqRat}^{\uparrow}$ representative: the completion witness consumes the displayed uniqueness comparison before the seal row is available, and it receives no quotient stream, selected limit, countable choice, or ambient completeness coordinate from the uniqueness packet.

Theorem 2437.8 (Regular Cauchy uniqueness classifier lock)**.** *Let*

$$U = (X, Y, S, T, D, E, R, H, C, P, N)$$

and

$$U' = (X', Y', S', T', D', E', R', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *carriers. If a consumer reads the two terminal* $\mathsf{Real}^{\uparrow}$ *seal rows R and R' as the same regular Cauchy limit, then that read must factor through the displayed Cauchy-equivalence classifier before either seal is consumed.*

Concretely, the read passes through the paired $\mathsf{RegSeqRat}^{\uparrow}$ *rows X, Y and X', Y', the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, T and S', T', the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers D, D', the comparison rows E, E', componentwise* hsame *transport H, H', displayed* Cont *replay C, C',* Pkg *provenance P, P', and the local* NameCert *rows N, N'. It receives no host quotient stream equality, no selected representatives, no countable choice, and no unrecorded equality proof outside the local packet rows.*

Proof. Project both accepted carriers through Definition 3390.1. The projection exposes the paired regular Cauchy names, finite stream windows, dyadic tolerance ledgers, comparison rows, terminal real seals, and structural rows on both sides.

Invoke the tolerance exactness row of Definition 3390.4. It binds each comparison read to the displayed dyadic ledger before the comparison row can be consumed, so the two seal reads cannot be compared without first exposing the same kind of finite tolerance source.

The sibling route then passes through chapter 1820 before chapter 38: the comparison rows E, E' are consumed as Cauchy-equivalence classifier data, and only after that classifier read are the terminal Real seal rows available.

Next use the completion-consumer route following the chapter closure block. That route says every $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ consumer reads $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ through the carrier, tolerance exactness, and Real seal nonescape rows before any $\mathsf{Real}^{\uparrow}$ seal is available.

Finally apply Definition 3390.7. Since the carriers contain no quotient stream, selected representative, countable-choice, or host-equality coordinate, the only available equality route is the displayed classifier route through E, E' together with $H, H', C, C', P, P', N, N'$. The read is therefore locked to the local Cauchy-equivalence classifier before either terminal seal is consumed. □

$\mathsf{RegularCauchyUniqueness}^{\uparrow}$ reads the completion-uniqueness boundary of chapter 1782 after the $\mathsf{RegSeqRat}^{\uparrow}$ comparison row and before any $\mathsf{Real}^{\uparrow}$-facing terminal seal. This dependency keeps the uniqueness route on displayed finite regular-Cauchy completion rows, and it rules out quotient stream equality, selected representatives, ambient real equality, or any choice of a preferred limit witness. The $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ route belongs to the Real classifier lattice: before any terminal uniqueness consumer compares two real-name seals, it reads the source $\mathsf{RegSeqRat}^{\uparrow}$ rows of chapter 301, inspects equality through the $\mathsf{RealNameClassifier}^{\uparrow}$ boundary of chapter 1517, and then consumes the $\mathsf{Real}^{\uparrow}$ seal rows already displayed by the carrier. This order keeps the terminal comparison attached to regular-rational source data and to the classifier inspection route rather than to quotient stream equality, selected representatives, host real equality, or ambient completeness.

Proof. Project the carrier rows and read the comparison from left to right. The regular Cauchy source rows provide the two names, the classifier boundary supplies the finite equality inspection, and the Real seal rows are consumed only after those entries have been displayed, so no uniqueness consumer receives an unrecorded terminal comparison. □

Chapter 2438

A Concrete Naming Certificate for $\mathsf{DyadicMeshComposition}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicMeshComposition}^{\uparrow}$ packet records the finite common-refinement route used when two displayed dyadic meshes are composed before a Real-and-Completion consumer reads a closed interval net. It sits between the dyadic mesh surface of chapter 358, the interval-net route of chapter 1250, the dyadic rational arithmetic surface of chapter 291, and the stream-window readbacks of chapter 126 and chapter 301. The packet is a finite naming certificate for mesh composition; it is not an open-cover compactness theorem, quotient stream equality, selected limit, host real equality, or ambient completeness primitive.

Definition 2438.1 (DyadicMeshComposition carrier)**.** *A* $\mathsf{DyadicMeshComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M_0, M_1, R, Q, H, C, P, N)$$

with the following displayed rows:

1. M_0 *is the source* $\mathsf{DyadicMesh}^{\uparrow}$ *row naming the first finite ordered dyadic mesh and its inspected cell ledger.*
2. M_1 *is the target* $\mathsf{DyadicMesh}^{\uparrow}$ *row naming the second finite ordered dyadic mesh and its inspected cell ledger.*
3. R *is the common-refinement relation row, listing for each displayed source cell the finite family of target cells that refines it and recording the reverse containment reads needed by downstream consumers.*
4. Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *cell-bound ledger storing the endpoint comparisons, radius splits, and dyadic slack witnesses used by the refinement relation.*
5. H *records componentwise* hsame *transport for* M_0, M_1, R, Q, C, P, N.
6. C *records displayed* Cont *replay from a mesh-composition request through the two mesh rows, the common-refinement relation, and the dyadic bound ledger.*
7. P *is the* Pkg *provenance over* $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshComposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for an infinite mesh, selected subcover, quotient equality of streams, host real equality, hidden point chooser, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2438.2 (DyadicMeshComposition NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMeshComposition}^{\uparrow}$ *carrier* $T = (M_0, M_1, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshComposition}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{DyadicMesh}^{\uparrow}$ *rows, common-refinement relation exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *cell-bound ledger admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance over the mesh, interval-net, stream, readback, history, transport, continuation, and naming rows, and local naming. Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *consumer of the packet must read* M_0, M_1, R, Q *before it can use the structural rows* H, C, P, N*.*

Proof. Project the carrier of Definition 3391.1. The rows M_0 and M_1 expose the two finite dyadic mesh ledgers, while R records the displayed common-refinement relation between their cells.

Read the cell-bound ledger next. The row Q supplies the dyadic endpoint comparisons and radius splits that witness each refinement edge in R, so the relation is checked through $\mathsf{DyadicRatCore}^{\uparrow}$ data rather than through a host-level order on real intervals.

The remaining rows add only structure. The transport row H preserves the displayed coordinates, C replays the finite route, P records provenance for the named dependencies, and N names the local certificate. These projections exhaust the NameCert surface. □

Lean4 ✓ `BEDC.Derived.DyadicMeshCompositionUp.DyadicMeshCompositionNameCertObligations`

Theorem 2438.3 (DyadicMeshComposition refinement transitivity)**.** *Let*

$$T = (M_0, M_1, R, Q, H, C, P, N)$$

be an accepted $\mathsf{DyadicMeshComposition}^{\uparrow}$ *carrier. If a displayed cell of* M_0 *refines through a finite* R*-row into displayed cells of* M_1*, and those target cells are later inspected by a second accepted dyadic mesh row, then the composite inspection is again represented by finite refinement rows over the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger. The composite exports no infinite refinement tree, quotient cell equality, hidden selector, or ambient completeness coordinate.*

Proof. Induct over the finite BHist rows displaying the refinement relation R. The empty row has no cell to export, so the composite route is the empty displayed refinement.

For the step row, project the current source cell and the finite family of target cells named by R. The ledger Q supplies the endpoint comparisons and radius splits for that row, while the induction hypothesis composes the remaining displayed rows.

Transport and replay preserve the constructed route. Componentwise hsame in H keeps the source mesh, target mesh, refinement row, and dyadic ledger aligned, and the Cont row C replays the same finite sequence of inspections. Thus the composite remains a finite mesh-refinement packet with no extra analytic coordinate. □

Theorem 2438.4 (DyadicMeshComposition closed-interval-net handoff)**.** *Every* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *consumer that uses a* $\mathsf{DyadicMeshComposition}^{\uparrow}$ *packet reads the interval net through the displayed mesh rows* M_0, M_1*, the common-refinement relation* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *cell-bound ledger* Q*, and the structural rows* H, C, P, N*. The handoff supplies the finite mesh-composition route needed by closed bounded interval nets without adding open-cover compactness, selected subcovers, quotient stream equality, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted closed-interval-net consumer. By chapter 1250, the consumer already reads interval coverage through finite dyadic mesh rows and their rational and dyadic cell ledgers.

Now insert the mesh-composition packet. The rows M_0, M_1, R, Q identify the finite common-refinement route, and Definition 3391.2 shows that this route is the complete local certificate surface before the structural rows are consumed.

Finally apply the refinement transitivity theorem. It keeps successive mesh inspections inside the displayed dyadic ledger and finite BHist induction. The closed-interval-net handoff is therefore exhausted by the stated rows and cannot expose any of the excluded compactness, quotient, selector, host-equality, or completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMeshComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMeshComposition}^{\uparrow}$ packet is generated from two DyadicMesh rows, a finite common-refinement relation, a DyadicRatCore cell-bound ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMeshComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3391.1, Definition 3391.2, Definition 3391.3, and Definition 3391.4 seed the finite common-refinement route consumed by closed bounded interval nets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMeshComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient stream equality, infinite refinement trees, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-refinement exactness, DyadicRatCore cell-bound accounting, transport stability, replay stability, closed-interval-net handoff, and provenance exhaustion for BEDC.Derived.DyadicMeshCompositionUp.

Chapter 2439

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimitOperator}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyLimitOperator}^{\uparrow}$ packet names the finite operator surface that turns a regular Cauchy family and its displayed modulus into a Real-facing limit seal. It sits after the tail-modulus handoff of chapter 3383 and beside the completion operator of chapter 3379; the originating proof route is the regular-Cauchy construction of section 9238.1. The packet gives Phase Real and Completion a single operator-level object over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not another handoff-only certificate.

Definition 2439.1 (RegularCauchyLimitOperator carrier)**.** *A* $\mathsf{RegularCauchyLimitOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (\mu, \tau, S, R, D, H_0, E, H, C, P, N)$$

with the following displayed rows:

1. μ *is the modulus-input row for the regular Cauchy family over* $\mathsf{RegSeqRat}^{\uparrow}$.
2. τ *is the finite tail selector row that turns a requested tolerance into the shared tail threshold used by the diagonal read.*
3. S *is the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected at the selected threshold and at the diagonal representative.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected family member, the diagonal representative, and the comparison witnesses read by the operator.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording endpoint tolerances, the middle modulus leg, slack accounting, and the final requested bound.*
6. H_0 *is the* $\mathsf{TailModulusLimitHandoff}^{\uparrow}$ *route imported from chapter 3383.*
7. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* μ, τ, S, R, D, H_0 *have been displayed.*
8. H *records componentwise* hsame *transport for the modulus input, tail selector, windows, regular readbacks, dyadic ledger, handoff route, Real seal, replay, provenance, and local naming rows.*
9. C *records displayed* Cont *replay from a limit-operator request through* $\mu, \tau, S, R, D, H_0, E, H, P, N$.

10. *P is the* Pkg *provenance over* RegularCauchyLimitOperator$^{\uparrow}$, TailModulusLimitHandoff$^{\uparrow}$, CauchyCompletionOperat StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{RegularCauchyLimitOperator}^{\uparrow}}$ *row.*

The classifier accepts only packets whose operator read is exhausted by these rows. It has no coordinate for quotient streams, selected host limits, countable-choice schedules, trichotomy decisions, host completion operators, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 2439.2 (RegularCauchyLimitOperator NameCert obligations)**.** *For every accepted* RegularCauchyLimitO *carrier $L = (\mu, \tau, S, R, D, H_0, E, H, C, P, N)$, the local* NameCert$_{\text{RegularCauchyLimitOperator}^{\uparrow}}$ *surface consists exactly of carrier admission for the modulus input, finite tail selector,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* TailModulusLimitHandoff$^{\uparrow}$ *route, terminal* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A completion-facing consumer must read μ, τ, S, R, D, H_0 before the Real seal row E is available.*

Proof. Project the carrier of Definition 3392.1. The rows μ and τ expose the constructive modulus request and the selected finite tail threshold.

Read the finite analytic rows. The window row S, readback row R, and tolerance ledger D supply the inspected StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ data used by the diagonal estimate.

The handoff route H_0 imports the already displayed tail-modulus route of chapter 3383. The Real seal E is downstream of that route, and H, C, P, N only transport, replay, source, and name the same finite packet.

Since quotient streams, selected host limits, countable-choice schedules, trichotomy decisions, host completion operators, and ambient completeness are absent from the carrier inventory, they cannot become local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitOperatorUp.RegularCauchyLimitOperatorNameCertObligations`

Theorem 2439.3 (RegularCauchyLimitOperator diagonal Real seal)**.** *Every Real-completion consumer of an accepted* RegularCauchyLimitOperator$^{\uparrow}$ *packet receives the finite operator route*

$$\mu, \tau, S, R, D, H_0 \longmapsto E \longmapsto H, C, P, N.$$

The route factors the diagonal regularity construction of section 9238.1 through the tail-modulus handoff of chapter 3383 and the completion-facing operator discipline of chapter 3379. It exports a Real$^{\uparrow}$ *seal only as a displayed consequence of the modulus input, selected tail, finite windows, regular readback, dyadic tolerance ledger, and handoff route.*

Proof. Start with an accepted limit-operator packet. By Definition 3392.2, the consumer first reads the modulus input, the tail selector, the finite windows, the regular-rational readback, and the dyadic tolerance ledger.

The tail-modulus row H_0 then packages those reads in the handoff form already isolated by Definition 3383.3. This is the finite route consumed by the diagonal regularity argument before any terminal real name can be sealed.

The Real row E therefore has no independent host-limit coordinate. The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming, so the exported diagonal seal is exhausted by the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimitOperator}^{\uparrow}$ packet is generated from a regular Cauchy modulus input, finite tail selector, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, TailModulusLimitHandoff route, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3392.1, Definition 3392.2, and Definition 3392.3 seed the finite operator surface from regular Cauchy modulus data to a Real-facing diagonal seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, trichotomy, host completion operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-input exactness, finite tail selector coverage, StreamName window coverage, RegSeqRat readback, DyadicRatCore tolerance accounting, TailModulusLimitHandoff compatibility, Real seal nonescape, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyLimitOperatorUp.

Chapter 2440

A Concrete Naming Certificate for DnaWindowSixBoundaryTile$^{\uparrow}$

The DnaWindowSixBoundaryTile$^{\uparrow}$ packet realizes the finite stop/Trp and Ile/Met $X_2 \sqcup \{11\}$ boundary-tile surface of Definition 9462.1154 and Definition 9462.1156 as BEDC NameCert data. It consumes the six-coordinate codon source window of chapter 2234, the standard-code transition rows of chapter 2245, the stop-suffix packet of chapter 1374, and the spectral stabilization route of chapter 2270. The packet records the two boundary tiles as finite classifier rows, not as a hidden biological table or an ambient stochastic model.

Definition 2440.1 (DnaWindowSixBoundaryTile carrier)**.** *A* DnaWindowSixBoundaryTile$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, M, B, I, S, L, H, C, P, N)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *source-window row exposing the six bit coordinates of the relevant codon windows;*
2. *M is the* CodonTransitionMatrix$^{\uparrow}$ *row exposing the standard-code bridge rows used to read stop, tryptophan, isoleucine, methionine, and initiation contexts;*
3. *B is the finite boundary-tile classifier row, recording the stop/Trp tile* $\mathrm{U} + \mathrm{RR} + X_2/11$ *and the Ile/Met tile* $\mathrm{AU} + X_2/11$*;*
4. *I is the Ile/Met initiation handoff row, distinguishing the Met amino-acid row from the canonical start bridge row when initiation context is present;*
5. *S is the* StopCodonZeckendorfSuffix$^{\uparrow}$ *stop-suffix handoff row for the stop-side tile;*
6. *L is the* SpectralStabilization$^{\uparrow}$ *sibling route row used by finite consumers that compare the same stop-face boundary with spectral support data;*
7. *H records componentwise* hsame *transport for source windows, transition rows, boundary tiles, initiation handoff, stop suffix, spectral route, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay from a boundary-tile request through W, M, B, I, S, L, H;*
9. *P is the* Pkg *provenance over* DnaWindowSixBoundaryTile$^{\uparrow}$, CodonSixBitWindow$^{\uparrow}$, CodonTransitionMatrix$^{\uparrow}$, StopCodonZeckendorfSuffix$^{\uparrow}$, SpectralStabilization$^{\uparrow}$, *the source vision of subsection 9462.28.21,* BHist, hsame, Cont, *and* NameCert*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}}$ *row.*
The classifier accepts only packets whose stop/Trp and Ile/Met boundary reads are exhausted by $W, M, B, I, S, L, H, C, P, N$. It has no coordinate for a hidden codon table, global biological semantics, probabilistic inference, quotient codon equality, or a selected stochastic process.

Lean4 (definition) `BEDC.Derived.DnaWindowSixBoundaryTileUp.DnaWindowSixBoundaryTileUp`

Theorem 2440.2 (DnaWindowSixBoundaryTile NameCert obligations)**.** *For every accepted* DnaWindowSixBound *carrier $T = (W, M, B, I, S, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}}$ *surface consists exactly of source-window admission through W, standard-code bridge-row admission through M, boundary-tile classifier exactness through B, initiation handoff through I, stop-suffix handoff through S, spectral-stabilization sibling routing through L, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 3393.1. The source window, transition bridge, boundary classifier, initiation handoff, stop suffix, spectral sibling route, transport, replay, provenance, and local naming rows are the only displayed coordinates.

The stop/Trp tile and the Ile/Met tile are finite classifier reads. The row W supplies the six coordinate positions, M supplies the standard-code bridge rows, and B records the two $X_2 \sqcup \{11\}$ partitions.

The rows I, S, L keep the initiation, stop-suffix, and spectral consumers attached to the same boundary-tile surface. Finally H, C, P, N transport, replay, source, and name that surface, so no hidden codon table, global biological semantics, probabilistic inference, quotient codon equality, or selected stochastic process is exported. □

Theorem 2440.3 (DnaWindowSixBoundaryTile consumer nonescape)**.** *Every accepted consumer of a* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *packet reads the route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto B, I, S, L \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Thus the six-coordinate codon window and standard-code bridge rows are read before any stop/Trp, Ile/Met, initiation, stop-suffix, or spectral-stabilization consumer can use the boundary-tile classifier. The route exports no hidden biological table, global semantics, probabilistic inference, quotient codon equality, or selected stochastic model.

Proof. Use Definition 3393.2. The boundary classifier row B is downstream of the source-window row W and standard-code bridge row M.

The initiation, stop-suffix, and spectral rows are also downstream. They may consume the displayed boundary-tile classifier, but they do not replace the six-coordinate source window or the standard-code bridge rows.

The structural rows H, C, P, N preserve and name the same finite route. Since the carrier contains no row for the refused external principles, every accepted consumer remains inside the displayed packet. □

Falsifiable prediction: Any accepted $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ consumer omitting the six-coordinate $\mathsf{CodonSixBitWindow}^{\uparrow}$ source window or the standard-code $\mathsf{CodonTransitionMatrix}^{\uparrow}$ bridge rows refutes the packet.

Independence witness: codon-six-bit-window, codon-transition-matrix, stopcodonzeckendorf-suffix, spectral-stabilization: $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two boundary-tile classifier rows, initiation handoff, stop-suffix routing, spectral sibling routing, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.DnaWindowSixBoundaryTileUp` must provide explicit Nontrivial DnaWindowSixBoundaryTile$^{\uparrow}$ and FieldFaithful DnaWindowSixBoundaryTile$^{\uparrow}$ instances preserving $W, M, B, I, S, L, H, C, P, N$ as separate displayed fields.

Closure status for NameCert$_{\text{DnaWindowSixBoundaryTile}^{\uparrow}}$ **.**

Constructive story: A DnaWindowSixBoundaryTile$^{\uparrow}$ packet is generated from codon six-bit windows, standard-code bridge rows, finite stop/Trp and Ile/Met boundary-tile classifiers, initiation handoff, stop-suffix handoff, spectral sibling routing, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DnaWindowSixBoundaryTile}^{\uparrow}}$, seed)

Scope closed: Definition 3393.1, Definition 3393.2, and Definition 3393.3 seed the finite boundary-tile packet over codon windows and standard-code bridge rows.

Formal verification: FormalStatus(NameCert$_{\text{DnaWindowSixBoundaryTile}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological table identity, global biological semantics, probabilistic inference, quotient codon equality, selected stochastic modeling, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-tile classifier exactness, initiation handoff, stop-suffix handoff, spectral sibling routing, transport, replay, provenance, local naming, Nontrivial DnaWindowSixBoundaryTileUp, and FieldFaithful DnaWindowSixBoundaryTileUp for BEDC.Derived.DnaWindowSixBoundaryTileUp.

Chapter 2441

A Concrete Naming Certificate for $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ packet records the finite route from located endpoint signs through dyadic bisection windows to the $\mathsf{Real}^{\uparrow}$ seal. It sits next to the sign-bracket certificate of chapter 1402 and the dyadic branch certificate of chapter 2203, but it keeps the located real output as a sealed finite read rather than a selected root or a quotient real.

The packet is an L10 Real and Completion neighbour. Its source cells are located interval endpoints, its branch rows are dyadic, and its consumer boundary is the same finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route used by the regular-real seal.

Definition 2441.1 (Located real intermediate-value carrier)**.** *A* $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, S, B, Q, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row, including the lower endpoint cell, upper endpoint cell, located interval comparison data, and the dyadic endpoint refinements consumed by the branch route;*
2. *S is the* $\mathsf{IntermediateValue}^{\uparrow}$ *sign ledger, recording the accepted negative-side and positive-side endpoint reads and the displayed midpoint sign rows carried along the route of Definition 1402.11;*
3. *B is the* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *branch data, retaining the finite sequence of accepted dyadic child intervals and the sign boundary that travels with each branch row;*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose radius and midpoint arithmetic determine the displayed stopping window;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the retained endpoints and midpoint observations;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows after Q fixes the finite tolerance request;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, S, B, Q, W, R have been displayed;*

8. *H records componentwise* hsame *transport for the located interval, sign ledger, dyadic branch data, tolerance row, window rows, readback row, seal row, replay row, provenance row, and local naming row;*
9. *C records displayed* Cont *replay of the route*

$$I, S \longmapsto B, Q \longmapsto W, R \longmapsto E;$$

10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{DyadicIntermediateValue}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealIntermediateValue}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. It has no coordinate for a selected root, quotient real, real trichotomy decision, open-cover compactness argument, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.LocatedRealIntermediateValueUp.LocatedRealIntermediateValueTasteGate`
`single carrier alignment`

Theorem 2441.2 (Located real intermediate-value NameCert obligations)**.** *For an accepted* LocatedRealIntermedia *carrier*

$$L = (I, S, B, Q, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealIntermediateValue}^{\uparrow}}$ *surface consists of carrier admission for the displayed located interval, sign ledger, dyadic branch, tolerance, window, readback, seal, transport, replay, provenance, and naming rows; sign-ledger visibility through I and S; dyadic branch exactness through B and Q; finite-window readback through W and R; Real-seal exposure through E; and structural stability through H, C, P, N.*

Every obligation is internal to the displayed finite packet. In particular, the certificate cannot be discharged by selecting a root, passing to a quotient real, deciding trichotomy, invoking open-cover compactness, or using an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Carrier admission is projection from Definition 3394.1. The projection exposes exactly the located interval, sign, branch, tolerance, window, readback, seal, transport, replay, provenance, and local naming rows.

Sign-ledger visibility follows by reading S only over the located endpoint row I. The dyadic branch stage then reads B together with the tolerance row Q, so each accepted child interval is tied to displayed midpoint arithmetic and a visible sign boundary.

The finite-window stage reads W and then R. The real-facing row E is downstream of those windows, while H, C, P, N transport, replay, source, and name the same route.

Since none of the carrier coordinates stores a root selector, quotient-real equality, trichotomy oracle, compactness datum, or Real-completeness principle, none of these objects can serve as a local obligation. □

Theorem 2441.3 (Located real sign-branch route)**.** *Every Real-facing read from an accepted* $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ *packet factors through*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{IntermediateValue}^{\uparrow} \longmapsto \mathsf{DyadicIntermediateValue}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

The route reads the located endpoint row I, the sign ledger S, the branch data B, the tolerance row Q, the windows W, the readback row R, and only then the seal row E, with H, C, P, N preserving the same finite packet.

Proof. Project the accepted carrier $L = (I, S, B, Q, W, R, E, H, C, P, N)$. The endpoint and sign stages are I followed by S, so the read begins with located signs rather than a host predicate over all real points.

Apply the dyadic bisection route of Definition 2203.3. The branch row B and tolerance row Q determine the finite child-interval route before any window data is consumed.

Next read the finite windows and regular-rational readback. The rows W and R are upstream of the seal row E, so a Real-facing consumer reaches the seal only through the displayed finite route.

The structural rows H, C, P, N transport, replay, source, and name that same route. Therefore no selected root, quotient real, real trichotomy decision, open-cover compactness argument, or ambient completeness principle can be exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealIntermediateValue}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint row, an $\mathsf{IntermediateValue}^{\uparrow}$ sign ledger, a $\mathsf{DyadicIntermediateValue}^{\uparrow}$ branch row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealIntermediateValue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3394.1, Definition 3394.2, and Definition 3394.3 seed the finite located-sign route from dyadic branch data to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealIntermediateValue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a selected root, quotient real, real trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-ledger visibility, dyadic branch exactness, finite-window readback, Real-seal exposure, transport and replay stability, and provenance exhaustion for BEDC.Derived.LocatedRealIntermedia

Chapter 2442

A Concrete Naming Certificate for $\mathsf{LocatedRealLine}^{\uparrow}$

Following Bishop and Bridges, the located real line is presented as a finite interface over located real names, apartness evidence, and regular Cauchy readback, rather than as a host real-line object or quotient completion. The $\mathsf{LocatedRealLine}^{\uparrow}$ packet binds the located-name surface of chapter 1933, the positive-separation evidence of chapter 304, the terminal real seal of chapter 38, the regular rational source route of chapter 301, and the finite observation windows of chapter 126. It also reads the dyadic endpoint and tolerance ledgers of chapter 291 so L10 real-completion routes can cite one non-isolated line interface.

Definition 2442.1 (LocatedRealLine carrier)**.** *A* $\mathsf{LocatedRealLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Lambda = (L, A, Q, R, S, D, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *row presenting the point-facing located real-name surface.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *row presenting positive finite-window separation evidence available to line-facing order and metric consumers.*
3. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same regular rational source route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular Cauchy readback used by L and Q.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation schedule naming the windows inspected by the line interface.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and tolerance ledger used for located windows, apartness gaps, and regular Cauchy bounds.*
7. *H records componentwise* hsame *transport for L, A, Q, R, S, D and for the structural replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a line request through $L, A, Q, R, S, D, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealLine}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealLine}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite located real-line surface. It contains no quotient real equality, trichotomy decision, host real-line primitive, ambient completeness theorem, selected limit, countable-choice schedule, or bridge credential.

Lean4 (definition) `BEDC.Derived.LocatedRealLineUp.LocatedRealLineUp`

Theorem 2442.2 (LocatedRealLine NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealLine}^{\uparrow}$ *carrier* $\Lambda = (L, A, Q, R, S, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealLine}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located-real row, apartness row, real seal, regular rational source, stream schedule, dyadic ledger, transport, replay, provenance, and local naming rows;*
2. *classifier stability, requiring sameness to be componentwise transport of* L, A, Q, R, S, D *through the displayed* hsame *and* Cont *routes;*
3. *located point exactness, requiring every point read to pass through the* $\mathsf{LocatedReal}^{\uparrow}$ *row* L *and its scheduled regular Cauchy source rows* R, S, D*;*
4. *apartness visibility, requiring every positive gap exposed to an order or metric consumer to pass through the* $\mathsf{ApartnessReal}^{\uparrow}$ *row* A *and the same finite dyadic ledger* D*;*
5. *real-seal compatibility, requiring the* $\mathsf{Real}^{\uparrow}$ *row* Q *to retain the same* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *source surface seen by* L*;*
6. *non-escape, excluding quotient real equality, trichotomy, host real-line primitives, ambient completeness, selected limits, countable choice, Lean verification, and bridge checking as local data.*

No located real-line obligation is stored outside these rows.

Proof. Project the carrier of Definition 3395.1. The analytic rows are precisely the located-real row L, apartness row A, real seal Q, regular rational source R, stream schedule S, and dyadic ledger D.

Classifier stability is componentwise. The rows H and C transport and replay the six analytic rows, while P and N source and name the same displayed packet.

Located point exactness follows by reading L through chapter 1933. Apartness visibility follows by reading A through chapter 304. In both cases the only line-facing observations available are the scheduled regular Cauchy windows and dyadic ledgers already stored in R, S, D.

The seal row Q is terminal and shares the same R, S source route. Since no remaining coordinate contains quotient equality, trichotomy, a host real line, ambient completeness, selected limits, or countable choice, the listed rows exhaust the local certificate. □

Theorem 2442.3 (LocatedRealLine regular Cauchy real handoff)**.** *Every L10 real-completion consumer of an accepted* $\mathsf{LocatedRealLine}^{\uparrow}$ *carrier receives the finite route*

$$L, A, R, S, D \longmapsto Q \longmapsto H, C, P, N.$$

The handoff first exposes located real-name data, apartness-gap data, scheduled regular rational readback, stream windows, and dyadic tolerance accounting. Only after those rows are displayed does it expose the terminal $\mathsf{Real}^{\uparrow}$ *seal and the structural transport, replay, provenance, and local naming rows.*

Proof. Start with an accepted carrier $\Lambda = (L, A, Q, R, S, D, H, C, P, N)$. By Definition 3395.2, any consumer must read the point surface, positive-gap surface, regular Cauchy source, stream schedule, and dyadic ledger before the seal row is visible.

The located-real component L supplies the point-facing readback through the finite windows of chapter 126 and the regular source rows of chapter 301. The apartness component A supplies positive finite-window gap evidence through chapter 304.

The real seal Q is then the same terminal seal route cited by chapter 38. The dyadic ledger D remains the only endpoint, radius, and tolerance account available from chapter 291.

Repacking through H, C, P, N preserves exactly this displayed route. The carrier has no coordinate for quotient real equality, trichotomy, a host real-line primitive, ambient completeness, selected limits, countable choice, or bridge data, so the L10 handoff is exhausted by the finite packet above. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealLine}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealLine}^{\uparrow}$ packet is generated from a LocatedReal row, an ApartnessReal row, a RealUp seal, RegSeqRat readback, StreamName windows, a DyadicRatCore ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3395.1, Definition 3395.2, and Definition 3395.3 seed the Bishop-style located real-line interface for L10 real-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, host real-line primitives, ambient completeness, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located point exactness, apartness visibility, regular Cauchy readback, dyadic ledger accounting, Real seal compatibility, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.LocatedRealLineUp.

The $\mathsf{LocatedUpperBound}^{\uparrow}$ hub routes the reusable upper-bound witness between **??**, chapter 38, and the downstream chapter 1427 consumer.

Chapter 2443

A Concrete Naming Certificate for $\mathsf{LocatedUpperBound}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedUpperBound}^{\uparrow}$ packet isolates the finite upper-bound witness that a Real or Completion consumer may inspect before any least-upper-bound or completeness principle is available. It sits over the located-cut surface of chapter 404, the located-real surface of **??**, the comparison discipline of chapter 1381, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the downstream located-supremum consumer of chapter 1427. The chapter names upper-bound data as a reusable NameCert surface, rather than keeping it only as an internal row of the supremum packet.

Definition 2443.1 (LocatedUpperBound carrier)**.** *A* $\mathsf{LocatedUpperBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the located family row, read through either a* $\mathsf{LocatedCut}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *surface.*
2. *U is the upper-bound ledger row. It records the displayed bound name, the comparison windows that certify the source family lies below that bound, and the dyadic tolerances attached to those comparisons.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule listing the finite windows inspected by the upper-bound ledger.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used by the bound name and by every comparison window.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located source, upper-bound ledger, finite windows, and regular readback have been displayed.*
6. *H records componentwise* hsame *transport for F, U, W, R, E and for the structural replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an upper-bound request through F, U, W, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedUpperBound}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperBound}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite upper-bound surface. It contains no lower-approximation ledger, selected supremum, trichotomy row, quotient-cut carrier, host real equality test, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge credential.*

Definition 2443.2 (LocatedUpperBound classifier)**.** *The* $\mathsf{LocatedUpperBound}^{\uparrow}$ *classifier accepts exactly those finite packets* $B = (F, U, W, R, E, H, C, P, N)$ *whose upper-bound reads pass through the displayed source row* F*, comparison ledger* U*, finite request schedule* W*, regular rational readback* R*, and terminal real-name seal* E*. Classifier sameness is componentwise sameness of these rows through* H *and replay through* C*; no consumer-facing classifier may identify two packets by host real equality, quotient-cut equality, trichotomy, a selected supremum, countable choice, or an ambient completeness principle.*

Theorem 2443.3 (LocatedUpperBound NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUpperBound}^{\uparrow}$ *carrier* $B = (F, U, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperBound}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located source, upper-bound ledger, stream schedule, regular rational readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *classifier stability, requiring upper-bound sameness to be componentwise transport of* F, U, W, R, E *through the displayed* hsame *and* Cont *routes;*
3. *source coverage, requiring every bounded source read to pass through the located-cut or located-real surface named by* F*;*
4. *comparison exactness, requiring every upper-bound assertion to pass through the* $\mathsf{BishopRealComparison}^{\uparrow}$ *discipline named by* U *at a finite window listed in* W*;*
5. *regular readback compatibility, requiring the bound name and each comparison window to use the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route before the* $\mathsf{Real}^{\uparrow}$ *seal is exposed;*
6. *non-escape, excluding lower-approximation cofinality, selected suprema, trichotomy, quotient cuts, host real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local data.*

No upper-bound obligation is stored outside these rows.

Proof. Project the carrier of Definition 3396.1. The analytic rows are precisely the source row F, upper-bound ledger U, finite window row W, regular readback row R, and terminal real seal E.

Classifier stability is componentwise. The rows H and C transport and replay the five analytic rows, while P and N source and name the same displayed packet.

Source coverage follows by reading F through the located-cut and located-real sibling surfaces. Comparison exactness follows by reading U through the Bishop-style comparison row at a window listed in W.

The readback row R is shared by the bound name and every comparison window before the seal E is exposed. Since no remaining coordinate contains lower-approximation cofinality, selected suprema, trichotomy, quotient cuts, host equality, countable choice, ambient completeness, Lean verification, or bridge data, the listed rows exhaust the local certificate. □

Theorem 2443.4 (LocatedUpperBound real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedUpperBound}^{\uparrow}$ *carrier receives the finite route*

$$F, U, W, R \longmapsto E \longmapsto H, C, P, N.$$

The handoff first exposes the located source, upper-bound comparison ledger, finite request schedule, and regular rational readback. Only after those rows are displayed does it expose the terminal $\mathsf{Real}^{\uparrow}$ *seal and the structural transport, replay, provenance, and local naming rows.*

Proof. Start with an accepted carrier $B = (F, U, W, R, E, H, C, P, N)$. By Definition 3396.3, any Real-facing consumer must read the source row, comparison ledger, finite window schedule, and regular readback before the real seal is available.

The source row F supplies the located-cut or located-real family interface. The ledger U supplies the upper-bound comparison rows through the Bishop-style comparison discipline, and W records the finite windows inspected for those comparisons.

The readback row R is the sole route into regular rational real-name data, and E is the only terminal real seal exposed by the carrier. Repacking through H, C, P, N preserves this order of disclosure.

Because the carrier has no lower-approximation coordinate, selected supremum, trichotomy row, quotient-cut carrier, host equality test, countable-choice schedule, ambient completeness theorem, or bridge data, the displayed route exhausts every $\mathsf{Real}^{\uparrow}$-facing handoff. □

Theorem 2443.5 (LocatedUpperBound supremum route)**.** *Every* $\mathsf{LocatedSupremum}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedUpperBound}^{\uparrow}$ *carrier may use the packet only as the upstream upper-bound face. The consumer receives* $F, U, W, R, E, H, C, P, N$ *as the finite upper-bound witness, while lower-approximation cofinality, selected supremum data, and completion-facing least-upper-bound closure remain obligations of the downstream* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet.*

Proof. Inspect the carrier $B = (F, U, W, R, E, H, C, P, N)$. Its only order-facing analytic row is the upper-bound ledger U, and that row is tied to the located source F, the finite windows W, the regular readback R, and the real seal E.

Apply Definition 3396.4. It shows that any real-facing read exported from the upper-bound packet reaches E only through the displayed upper-bound route.

The downstream supremum packet in chapter 1427 additionally requires lower-approximation and cofinality rows. Those rows are absent from Definition 3396.1, so a $\mathsf{LocatedSupremum}^{\uparrow}$ consumer can read this packet only as its reusable upstream upper-bound witness. □

Theorem 2443.6 (LocatedUpperBound real-certificate route)**.** *Every accepted* $\mathsf{LocatedUpperBound}^{\uparrow}$ *packet exposes its Real-facing certificate only along the finite route from the located source row, upper-bound comparison ledger,* $\mathsf{StreamName}^{\uparrow}$ *request schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. This route is stable under the displayed* hsame *transports and* Cont *replay rows, and no Real-facing consumer can read the certificate before those rows have been displayed.*

Proof. Project the carrier of Definition 3396.1. Its Real-facing analytic rows are exactly the located source F, upper-bound comparison ledger U, finite request schedule W, regular rational readback R, and terminal real seal E.

Apply Definition 3396.3. Carrier admission, source coverage, comparison exactness, and regular readback compatibility require every upper-bound certificate read to pass through those five analytic rows before the structural rows are consumed.

Now apply Definition 3396.4. It identifies the displayed route

$$F, U, W, R \longmapsto E \longmapsto H, C, P, N$$

as the only Real-facing handoff exported by the packet.

The transport row H and continuation row C are componentwise rows of the same carrier, so they preserve and replay the route rather than adding a second certificate source. Since the carrier has no selected supremum, lower-approximation ledger, quotient-cut equality, host real equality, countable-choice schedule, ambient completeness theorem, Lean verification row, or bridge credential, the stated route exhausts the reusable Real-facing certificate. □

Theorem 2443.7 (LocatedUpperBound comparison exactness)**.** *Every accepted* $\mathsf{LocatedUpperBound}^{\uparrow}$ *packet routes each upper-bound comparison through the located-cut, located-real, Bishop-real-comparison,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows already displayed in the carrier before any supremum-facing consumer may read it. In particular, the upper-bound ledger U cannot be consumed as a detached order assertion: it must be read with the located source F, finite request schedule W, regular rational readback R, terminal seal E, and the structural rows H, C, P, N.*

Proof. Project the carrier of Definition 3396.1. The rows F, U, W, R, E are the analytic comparison route, while H, C, P, N transport, replay, source, and name the same accepted packet.

Apply Definition 3396.4. It forces every Real-facing read to expose F, U, W, R before the terminal seal E is available.

Apply Definition 3396.5. A $\mathsf{LocatedSupremum}^{\uparrow}$ consumer receives this packet only as its upstream upper-bound witness, so it may not import lower-approximation cofinality or selected supremum data from the upper-bound carrier.

Apply Definition 3396.6. The route ties the upper-bound ledger to the finite request schedule and regular rational readback before any Real-facing certificate is consumed. Since the carrier has no selected supremum, trichotomy row, quotient-cut equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle, no supremum consumer can bypass the displayed comparison rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUpperBound}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedUpperBound}^{\uparrow}$ packet is generated from a located source row, an upper-bound comparison ledger, a StreamName finite-window schedule, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUpperBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3396.1, Definition 3396.2, Definition 3396.3, Definition 3396.4, and Definition 3396.5 seed the reusable upper-bound witness for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUpperBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected suprema, trichotomy, quotient cuts, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, source coverage, comparison exactness, regular readback compatibility, Real seal handoff, supremum routing, transport stability, replay stability, and provenance exhaustion for BEDC.Derived.LocatedUpperBoundUp.

Theorem 2443.8 (LocatedSupremum upstream upper-bound face)**.** *The downstream* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet of chapter 1427 consumes an accepted* $\mathsf{LocatedUpperBound}^{\uparrow}$ *packet only as its upstream upper-bound face. Concretely, the route supplied by Definition 3396.5 offers the finite rows $F, U, W, R, E, H, C, P, N$ as the displayed upper-bound witness; lower-approximation cofinality, least-upper-bound exactness, and supremum-facing closure remain rows of* $\mathsf{LocatedSupremum}^{\uparrow}$ *rather than rows of* $\mathsf{LocatedUpperBound}^{\uparrow}$.

Proof. Read Definition 3396.5. It identifies the accepted upper-bound carrier as a reusable witness for the source family, the upper-bound ledger, finite windows, regular readback, the Real seal, and the structural transport, replay, provenance, and local naming rows.

Now compare the downstream consumer in chapter 1427. Its supremum certificate requires lower-approximation and cofinality data in addition to an upstream upper-bound face. Those additional rows are not coordinates of Definition 3396.1.

Thus every handoff from $\mathsf{LocatedUpperBound}^{\uparrow}$ into $\mathsf{LocatedSupremum}^{\uparrow}$ is exactly the forward dependency through $F, U, W, R, E, H, C, P, N$. The supremum packet must supply the remaining supremum-specific rows itself. $\square$

Chapter 2444

A Concrete Naming Certificate for $\mathsf{UniformEmbeddingCompletion}^{\uparrow}$

Following Bourbaki and Kelley on uniform embeddings and completion, the $\mathsf{UniformEmbeddingCompletion}^{\uparrow}$ packet records the finite BEDC route by which an embedding into a separated completion is consumed without quotient representatives or selected limits. It sits after the metric-completion carrier of chapter 1506, the separated comparison surface of chapter 1411, the uniform-completion route of chapter 1473, the Cauchy-name comparison of chapter 1412, and the terminal seal boundary of chapter 38. The packet names the embedding interface as displayed rows over completion input, separatedness, uniform continuity, Cauchy-equivalence stability, and Real-facing readback; it does not assert a quotient completion, choose representatives, or import ambient completeness.

Definition 2444.1 (UniformEmbeddingCompletion carrier)**.** *A* $\mathsf{UniformEmbeddingCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, S, U, Q, R, T, W, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row supplying the completion-facing metric request and its displayed finite tolerance route.*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row requiring the target-side comparison to be separated before the embedding read is public.*
3. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row exposing the entourage-facing completion presentation consumed by the embedding.*
4. *Q is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *row identifying when two source Cauchy names have the same displayed completion read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the completion, separatedness, uniform, and Cauchy-equivalence rows have been displayed.*
6. *T records the finite source-window schedule inspected by the embedding before a target read is accepted.*
7. *W records the finite target-window schedule produced by the embedding route.*
8. *A records the approximation ledger saying that matching source windows and tolerances transport to matching target windows.*

9. *H records componentwise* hsame *transport for M, S, U, Q, R, T, W, A and the structural rows.*
10. *C records displayed* Cont *replay of the route*

$$M, S, U, Q, T, A \longmapsto W \longmapsto R.$$

11. *P is the* Pkg *provenance over* UniformEmbeddingCompletion$^{\uparrow}$, MetricCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CauchySequenceEquivalence$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{UniformEmbeddingCompletion}^{\uparrow}}$ *row.*

The classifier accepts only packets whose embedding-to-completion read is exhausted by $M, S, U, Q, R, T, W, A, H, C,$ It has no coordinate for quotient representatives, selected limits, host equality of completions, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformEmbeddingCompletionUp.UniformEmbeddingCompletionTasteGate single carrier alignment`

Theorem 2444.2 (UniformEmbeddingCompletion NameCert obligations)**.** *For every accepted* UniformEmbeddingCompletion$^{\uparrow}$ *carrier*

$$E = (M, S, U, Q, R, T, W, A, H, C, P, N),$$

the local NameCert$_{\text{UniformEmbeddingCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed twelve-row packet; metric-completion exposure through M; separated-target exposure through S; uniform-completion exposure through U; Cauchy-equivalence stability through Q; terminal Real sealing through R; finite source-window exposure through T; finite target-window exposure through W; approximation transport through A; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 3397.1. The accepted packet exposes exactly the completion source, separated target, uniform completion, Cauchy-equivalence comparison, terminal seal, source and target windows, approximation ledger, and structural rows listed there.

The analytic obligations are read in the displayed order. The completion request passes through M and U, the separated target boundary is supplied by S, and the source comparison is stabilized by Q before the terminal Real-facing row R can be inspected.

The embedding content is the finite window handoff T, A, W. The source windows in T and their approximation ledger A determine the target windows in W; no step inserts a quotient representative or a selected completion point.

Finally H, C, P, N transport, replay, source, and name the same route. Since the excluded quotient, choice, host-equality, and ambient-completeness objects are absent from the carrier, they cannot appear as local NameCert obligations. □

Theorem 2444.3 (UniformEmbeddingCompletion universal route)**.** *Every completion-facing consumer of an accepted* UniformEmbeddingCompletion$^{\uparrow}$ *packet factors through the finite route*

$$M, S, U, Q, T, A \longmapsto W, R \longmapsto H, C, P, N.$$

Thus a uniformly embedded source can be read by completion consumers only through displayed metric-completion input, separatedness, uniform-completion structure, Cauchy-equivalence stability, finite source windows, approximation transport, finite target windows, the terminal Real seal, transport, replay, provenance, and local naming.

Proof. Start with an accepted carrier. The source completion row M and uniform-completion row U provide only completion-facing requests, while the separated row S restricts target comparison to the displayed separated boundary.

The Cauchy-equivalence row Q supplies the only equality-facing source comparison. It is read before the target windows are public, so a consumer cannot replace it by quotient-stream equality or host completion equality.

The universal route is the finite handoff T, A, W. The source-window schedule in T is transported by the approximation ledger A to the target-window schedule W, and the Real-facing read reaches R only after those rows have been displayed.

The structural rows H, C, P, N preserve, replay, source, and name exactly this packet. Hence every completion-facing consumer factors through the displayed route and cannot read a selected limit, quotient representative, countable-choice schedule, host completion equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEmbeddingCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformEmbeddingCompletion}^{\uparrow}$ packet is generated from MetricCompletion, SeparatedMetric, UniformCompletion, CauchySequenceEquivalence, Real, finite source windows, finite target windows, approximation transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEmbeddingCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3397.1, Definition 3397.2, and Definition 3397.3 seed the finite nonquotient route for uniformly embedded completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEmbeddingCompletion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformEmbeddingCompletionUp.UniformEmbeddingCompletionTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, selected limits, host equality of completions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-target exposure, uniform-completion exposure, Cauchy-equivalence stability, finite window transport, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformEmbeddingCompletionUp.

Chapter 2445

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion and Bourbaki on reflective subobjects, the $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ packet records the RegSeqRat-specific completion reflector boundary as finite BEDC naming data. It sits after the finite observation rows of chapter 126, the regular rational source of chapter 301, the completed real-name surface of chapter 360, the monadic completion route of chapter 378, the idempotence boundary of chapter 2381, and the extension surface of chapter 397. The packet names only the finite reflector rows visible to RegSeqRat consumers; it does not identify quotient completions, select limits, assert host equality of completed objects, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2445.1 (RegularCauchyCompletionReflector carrier)**.** *A* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, Q, E, U, I, P, H, C, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source regular Cauchy name and every completion-facing observation cut.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, exposing the regular rational readback and its displayed tolerance discipline before completion is requested.*
3. *E is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *completed real-name row reached from S, Q through the displayed completion surface rather than through a host quotient carrier.*
4. *U is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *unit and bind route specialized to the same S, Q, E rows.*
5. *I is the* $\mathsf{CompletionIdempotence}^{\uparrow}$ *boundary row recording that a second completion pass reuses the same completed surface.*
6. *P is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row for consumers whose maps are read through the displayed regular Cauchy source and the same completed real-name row.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, completed real-name rows, monad routes, idempotence boundaries, universal-property rows, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a RegSeqRat completion request through*

$$S, Q \longmapsto E \longmapsto U, I, P \longmapsto H, N.$$

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionReflector}^{\uparrow}}$ *row, with provenance read from the displayed* Pkg *rows over* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

The classifier compares accepted packets only through $S, Q, E, U, I, P, H, C, N$. It has no coordinate for quotient completion equality, selected limit representatives, host equality of completed objects, countable choice, detached $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionReflectorUp.RegularCauchyCompletionReflectorTasteGate`
`single carrier alignment`

Theorem 2445.2 (RegularCauchyCompletionReflector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *carrier*

$$R = (S, Q, E, U, I, P, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for stream windows, RegSeqRat readbacks, completed real-name rows, monad routes, idempotence boundaries, universal-property extension rows, transport, replay, provenance, and local naming;*
2. *source regularity, requiring every completion-facing read to expose S and Q before E is available;*
3. *completion admission, requiring the completed row E to be read through the displayed* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *surface;*
4. *monad handoff, requiring unit and bind consumers to use U over the same S, Q, E rows;*
5. *idempotence stability, requiring repeated completion reads to reuse I and the same completed row E;*
6. *universal-property compatibility, requiring every extension consumer to read P over the same source, completion, monad, and idempotence rows;*
7. *nonescape, excluding quotient completions, selected limits, host equality, countable choice, detached* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier. The stream window row, regular rational readback row, completed real-name row, monad route, idempotence boundary, universal-property row, transport, replay, and local naming row are exactly the displayed coordinates of R.

The source side is forced by S and Q. A completion-facing consumer has no completed row to inspect until the finite StreamName windows and the RegSeqRat readback have been displayed.

The completed row E is then read through the RealCauchyCompletion surface. The monad row U, idempotence row I, and universal-property row P all refer back to the same S, Q, E route, so none of them can introduce a separate completion object.

Finally H, C, N preserve and name the same finite packet. Since the carrier has no coordinate for quotient completions, selected limits, host equality, countable choice, detached Real completeness, Lean verification, or bridge data, the listed rows exhaust the local NameCert surface. □

Theorem 2445.3 (RegularCauchyCompletionReflector unit handoff)**.** *Let $R = (S, Q, E, U, I, P, H, C, N)$ be an accepted* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *carrier. Every unit-facing completion request factors through the finite route*

$$S \longmapsto Q \longmapsto E \longmapsto U \longmapsto H, C, N.$$

The handoff copies the displayed RegSeqRat source into the completed real-name surface by finite windows and regular readbacks. It does not supply quotient stream equality, a selected limit, host equality, countable choice, or ambient completeness.

Proof. Start with the source rows. The finite windows in S determine which parts of the regular rational source may be inspected, and Q supplies the matching RegSeqRat readback.

The completed row E is downstream of those source rows. A unit-facing request therefore reaches completion only after the finite source route has been displayed.

The monad row U records the unit handoff on that same route, and H, C, N transport, replay, and name it componentwise. No excluded host-side principle is available as a row of the packet. □

Theorem 2445.4 (RegularCauchyCompletionReflector idempotence boundary)**.** *For an accepted* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *carrier $R = (S, Q, E, U, I, P, H, C, N)$, a repeated completion read is classified by the same completed real-name row E and the same idempotence boundary I. The second read may replay S, Q, U, P, H, C, N, but it has no independent completed carrier and no quotient equality coordinate.*

Proof. Read the carrier coordinates. The only completed real-name coordinate is E, and the only idempotence coordinate is I.

A repeated completion request can therefore replay the source windows, RegSeqRat readbacks, monad handoff, universal-property row, transport, continuation, and local naming. It cannot branch to a second completed object because no such coordinate appears in R.

Thus idempotence is a boundary on the displayed completion surface, not an assertion of host quotient equality or selected-limit equality. □

Theorem 2445.5 (RegularCauchyCompletionReflector ledger nonescape)**.** *Every downstream consumer of an accepted* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *packet reads the completion reflector through*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealCauchyCompletion}^{\uparrow} \longmapsto \mathsf{CauchyCompletionMonad}^{\uparrow}, \mathsf{CompletionIdempotence}^{\uparrow}, \mathsf{Co}$$

The ledger exposes no quotient completion, selected limit representative, host equality of completed objects, countable-choice schedule, detached $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge-checking row.*

Proof. Apply Definition 3398.2. The public read begins with S, Q, then reaches the completed real-name row E, and only then consumes the monad, idempotence, and universal-property rows U, I, P.

The sibling chapters fix the same dependency route: chapter 301 supplies the regular rational source, chapter 360 supplies the completed real-name surface, and chapter 378 supplies the completion monad handoff.

The structural rows H, C, N preserve and name only that displayed route. Hence no refused host-side principle can escape through the local ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readbacks, a RealCauchyCompletion completed row, a CauchyCompletionMonad handoff, a CompletionIdempotence boundary, a CompletionUniversalProperty extension row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3398.1, Definition 3398.2, Definition 3398.3, Definition 3398.4, and Definition 3398.5 seed the RegSeqRat-specific completion reflector packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality of completed objects, countable choice, detached $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source regularity, completion admission, unit handoff, idempotence boundary, universal-property compatibility, ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionReflectorUp.

Chapter 2446

A Concrete Naming Certificate for $\mathsf{SchwartzFunction}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzFunction}^{\uparrow}$ packet records the finite test-function carrier that exposes rapidly decreasing smooth windows to Fourier and tempered-distribution consumers. It sits over the weak-derivative route of chapter 2210, the finite Fourier observation surface of chapter 124, the tempered-distribution handoff of chapter 2310, the local support and gluing surface of chapter 3369, and the scalar readback of chapter 38. The chapter names only the finite BEDC carrier for test windows, derivative orders, polynomial weights, Fourier-readiness rows, and real seals; it does not import a completed Schwartz topology, host smooth functions, unrestricted seminorm families, Plancherel, inversion, or quotient test-function equality.

2446.1 Carrier definition

Definition 2446.1 (Schwartz function carrier)**.** *A* $\mathsf{SchwartzFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, G, F, T, R, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite derivative-observation row. It records the named weak-derivative requests, multi-order labels, sign conventions, and local derivative windows read through chapter 2210.*
2. *W is the finite window row. It records the compact or bounded windows on which pointwise reads, derivative reads, and support restrictions are visible.*
3. *G is the polynomial-weight ledger. It records the displayed weight exponents and rational bounds certifying rapid decay for the derivative orders requested in D.*
4. *F is the Fourier-readiness row. It records the finite transform and coefficient windows exported to chapter 124.*
5. *T is the tempered-distribution test handoff row. It exports the test-window inventory consumed by chapter 2310.*
6. *R is the scalar readback row through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, exposing only the finite rational and real endpoints needed by derivative, weight, and transform observations.*

7. *L is the local classifier row. It admits two packets together exactly when their derivative observations, windows, polynomial-weight ledgers, Fourier rows, tempered-distribution test rows, and scalar readbacks match componentwise.*
8. *H records componentwise* hsame *transport for all displayed rows.*
9. *C records displayed* Cont *replay from a Schwartz-test request through D, W, G, F, T, R, L, H in that order.*
10. *P is the* Pkg *provenance over* $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{PartitionOfUnity}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchwartzFunction}^{\uparrow}}$ *row.*

The classifier compares only these finite rows. It has no coordinate for a completed Schwartz space, an infinite seminorm topology, host smooth-function equality, arbitrary support selection, countable choice, Plancherel, inversion, or quotient test-function equality.

Lean4 ✓ `BEDC.Derived.SchwartzFunctionUp.SchwartzFunctionTasteGate single carrier alignment`

2446.2 The certificate

Theorem 2446.2 (Schwartz function NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzFunction}^{\uparrow}$ *carrier*

$$S = (D, W, G, F, T, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for derivative observations, local windows, polynomial-weight ledgers, Fourier-readiness rows, tempered-distribution test handoff rows, scalar readbacks, classifier, transport, replay, provenance, and local naming;*
2. *derivative-window exactness, requiring every derivative read to pass through D and W before any weighted or Fourier-facing read is exposed;*
3. *rapid-decay exactness, requiring every displayed polynomial-weight bound to be read from G for a derivative order already named in D;*
4. *Fourier-readiness exactness, requiring every finite transform or coefficient request to pass through F and then through the same scalar readback row R;*
5. *tempered-distribution test exactness, requiring every distribution-facing test row to pass through T after the derivative and weight ledgers have been opened;*
6. hsame, Cont, Pkg, *and local* NameCert *stability for the rows $D, W, G, F, T, R, L, H, C, P, N$.*

No obligation outside these rows is part of the certificate.

Proof. Carrier admission is projection from Definition 3399.1. The accepted tuple displays the derivative observations, local windows, polynomial-weight ledger, Fourier-readiness row, tempered-distribution test handoff, scalar readback, classifier, transport, replay, provenance, and local naming.

The derivative gate is D together with W. A consumer cannot ask for a weighted or transform observation until the finite derivative order and the window on which it is read have both been displayed.

The rapid-decay gate is G. Its bounds are attached to the displayed derivative orders, so the proof uses no infinite seminorm family and no host smooth-function equality.

The Fourier and distribution handoffs are F and T. These rows export only the finite transform windows and test rows already admitted by D, W, G, and the endpoints pass through R before any scalar seal is read. The remaining rows L, H, C, P, N compare, transport, replay, source, and name the same finite inventory. □

Theorem 2446.3 (Schwartz function Fourier stability)**.** *Every accepted* $\mathsf{SchwartzFunction}^{\uparrow}$ *packet exported to a Fourier-facing consumer factors through*

$$D, W, G \longmapsto F \longmapsto R \longmapsto L, H, C, P, N.$$

Thus the consumer receives derivative windows, polynomial-weight ledgers, finite transform and coefficient windows, scalar readbacks, classifier, transport, replay, provenance, and local naming. It receives no completed Schwartz topology, Plancherel theorem, inversion theorem, quotient test-function equality, selected representative, countable choice, or ambient completeness principle.

Proof. Start with a Fourier-facing read. The derivative row D and window row W must be visible because each finite transform request is attached to a displayed test window and derivative order.

Read the polynomial-weight ledger G next. It is the only row that certifies the rapid-decay bound attached to the requested derivative order, so there is no appeal to an infinite seminorm topology.

The handoff to F is then finite. It records coefficient and transform windows consumable by chapter 124, and its scalar endpoints pass through R before the classifier, transport, replay, provenance, and naming rows are read. □

Theorem 2446.4 (Schwartz function tempered-distribution handoff)**.** *Every accepted* $\mathsf{SchwartzFunction}^{\uparrow}$ *packet exported to a tempered-distribution consumer factors through the displayed derivative row, local window row, polynomial-weight ledger, test handoff row, scalar readback row, classifier, transport, replay, provenance, and local naming:*

$$D, W, G \longmapsto T \longmapsto R \longmapsto L, H, C, P, N.$$

The tempered-distribution consumer therefore receives only the finite test-function rows required by chapter 2310; it receives no completed test-function space, unrestricted continuous dual, quotient test-function equality, host distribution equality, selected representative, or countable-choice schedule.

Proof. Project the accepted carrier of Definition 3399.1. The distribution-facing handoff row T is stored after the derivative, window, and polynomial-weight rows, so it cannot be read without those finite tests already being displayed.

The scalar route remains R. It exposes only the rational and real endpoints needed by the finite test row and does not identify host functions or distributions.

Finally L, H, C, P, N repack the same data as a local NameCert surface. Because no row contains a completed Schwartz topology, unrestricted dual, quotient equality, selected representative, or choice schedule, the handoff is exactly the finite test carrier consumed by the tempered-distribution packet. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzFunction}^{\uparrow}$ consumer that reaches a Fourier window, tempered-distribution test row, weak-derivative observation, or $\mathsf{Real}^{\uparrow}$ scalar seal without first reading the derivative window and polynomial-weight ledger refutes the carrier surface.

Independence witness: weakderivative, fourier, tempereddistribution, partitionofunity, regseqrat, real: none is bijective to $\mathsf{SchwartzFunction}^{\uparrow}$ because this packet jointly carries derivative observations, local windows, polynomial-weight ledgers, Fourier-readiness rows, tempered-distribution test handoff rows, scalar readbacks, classifier, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzFunction}^{\uparrow}$ packet is generated from finite derivative-observation rows, local windows, polynomial-weight ledgers, Fourier-readiness rows, tempered-distribution test handoff rows, scalar readbacks through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, a local classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3399.1, Definition 3399.2, Definition 3399.3, and Definition 3399.4 seed the finite Schwartz-test carrier over derivative windows, polynomial-weight ledgers, Fourier-readiness rows, tempered-distribution handoff rows, scalar readbacks, classifier, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed Schwartz spaces, infinite seminorm topologies, host smooth-function equality, arbitrary support selection, quotient test-function equality, Plancherel, inversion, unrestricted continuous duals, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-window exactness, rapid-decay exactness, Fourier-readiness exactness, tempered-distribution test exactness, scalar readback stability, transport stability, replay stability, and non-escape proofs for BEDC.Derived.SchwartzFunctionUp.

Chapter 2447

A Concrete Naming Certificate for $\mathsf{AsymptoticEquivalence}^{\uparrow}$

Following Hardy on divergent series and Bishop–Bridges constructive analysis, an $\mathsf{AsymptoticEquivalence}^{\uparrow}$ packet names tail-equivalence data for real-series and regular-Cauchy comparison routes by finite thresholds, displayed tail windows, and terminal Real-facing seals. It sits after the partial-sum and tail-budget surface of chapter 1581, the regular rational readback of chapter 301, the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a reusable comparison certificate for two displayed tails; it is not a quotient of series, not a selected sum, not a host limit, and not an ambient completeness principle.

Definition 2447.1 (Asymptotic equivalence carrier)**.** *An* $\mathsf{AsymptoticEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. S_0, S_1 *are the two* $\mathsf{RealSeries}^{\uparrow}$ *tail-source rows whose partial-sum or term tails are compared.*
2. R_0, R_1 *are the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows used by the two tail names.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for ratio, difference, and tail-budget inspections.*
4. T *is the finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window schedule assigning each requested precision a pair of inspected tail windows.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *comparison-seal row reached after the two readbacks and dyadic ledger have been consumed.*
6. H *records componentwise* hsame *transport for the two series rows, two regular readbacks, dyadic ledger, stream windows, terminal seal, continuation, provenance, and local naming rows.*
7. C *records the displayed* Cont *replay from each precision request through* $T, D, R_0, R_1, E, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticEquivalence}^{\uparrow}}$ *row.*

The carrier exposes only finite tail-comparison data. It has no coordinate for a selected infinite sum, quotient equality of series, host limit selection, trichotomy, countable choice, ambient Real completeness, or bridge checking.

Lean4 ✓ `BEDC.Derived.AsymptoticEquivalenceUp.AsymptoticEquivalenceTasteGate single carrier alignment`

Theorem 2447.2 (Asymptotic equivalence NameCert obligations)**.** *For an accepted* $\mathsf{AsymptoticEquivalence}^{\uparrow}$ *carrier* $A = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AsymptoticEquivalence}^{\uparrow}}$ *surface consists exactly of carrier exposure, two real-series tail-source rows, two regular-Cauchy readback rows, the shared dyadic tolerance ledger, the stream-indexed tail-window schedule, the terminal Real comparison seal, componentwise classifier transport, continuation replay, package provenance, and local naming. Each accepted precision request is classified by the finite tail window in* T *and the tolerance ledger in* D *before either regular readback may expose the terminal row* E*.*

Proof. Project the carrier tuple in Definition 3400.1. The analytic rows are $S_0, S_1, R_0, R_1, D, T, E$, and the structural rows are H, C, P, N.

For a precision request, first read the scheduled finite windows in T and the dyadic tolerance ledger D. These rows determine which tails of the two $\mathsf{RealSeries}^{\uparrow}$ sources and which regular-Cauchy readbacks may be inspected.

The classifier transport is componentwise through H, while C replays the same route from the request to the two readbacks and then to E. The provenance row P and local naming row N record only those displayed dependencies, so the NameCert surface cannot import a selected sum, quotient equality, host limit, choice schedule, or ambient completeness proof. □

Theorem 2447.3 (Asymptotic equivalence tail transfer)**.** *Let* $A = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$ *be an accepted* $\mathsf{AsymptoticEquivalence}^{\uparrow}$ *carrier. If a Real or Completion consumer reads a finite tail estimate for* S_0 *through the schedule* T *and ledger* D*, then the same accepted packet exposes the matching finite tail estimate for* S_1 *through the componentwise readback rows* R_0, R_1 *and the terminal comparison seal* E*. The transfer is stable under* hsame *transport of the carrier rows and exports no selected real representative, quotient stream equality, host convergence principle, or completed infinite tail.*

Proof. Start with the accepted schedule row T. It stores a pair of finite tail windows for each precision request, so a consumer that reads the first source tail has already displayed the matching second-source window.

Use the dyadic ledger D to compare the two inspected tails. The readback rows R_0 and R_1 then expose the regular-Cauchy data attached to the two windows, and the terminal row E records the Real-facing comparison seal reached after both readbacks are displayed.

Transport along H preserves the two series rows, two readbacks, ledger, windows, and terminal seal component by component. Replaying C therefore gives the same tail-transfer route to every downstream consumer, while the excluded selected representatives, quotient equalities, host convergence principles, and completed infinite tails remain absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticEquivalence}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AsymptoticEquivalence}^{\uparrow}$ packet is generated from two $\mathsf{RealSeries}^{\uparrow}$ tail-source rows, two $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, a shared $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ tail windows, a terminal $\mathsf{Real}^{\uparrow}$ comparison seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AsymptoticEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3400.1, Definition 3400.2, and Definition 3400.3 seed the finite tail-equivalence route over $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AsymptoticEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient equality of series, host limits, trichotomy, countable choice, ambient Real completeness, bridge checking, or a Lean theorem.

Upgrade path: A formal route can encode the eleven-row carrier and prove the finite tail-transfer and NameCert obligation surfaces.

Chapter 2448

A Concrete Naming Certificate for $\mathsf{RieszLemma}^{\uparrow}$

Following Riesz's lemma in normed linear spaces, the $\mathsf{RieszLemma}^{\uparrow}$ packet records the finite BEDC witness by which a proper closed subspace and a displayed separation tolerance expose a normed-space separation row. It sits over the norm carrier of chapter 89, the inner-product comparison surface of chapter 86, the metric observation row of chapter 57, the complete-metric boundary of chapter 128, and the Banach carrier of chapter 90. The certificate names a finite separation witness surface; it is not a quotient subspace construction, not a selected best approximation, and not an ambient compactness or completeness theorem.

Definition 2448.1 (Riesz lemma finite separation carrier)**.** *A* $\mathsf{RieszLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, Y, U, A, B, D, S, K, H, C, P, N)$$

with the following displayed rows:

1. *X is the normed-space source row, read through* $\mathsf{Norm}^{\uparrow}$ *and the vector-space carrier already visible to the packet.*
2. *Y is the displayed proper closed subspace row, named as finite membership and closure evidence rather than as a quotient carrier.*
3. *U is the unit normalization row recording the inspected vector window and its norm-one certificate.*
4. *A is the separation tolerance row, with the requested dyadic margin read through the local* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*
5. *B is the ball-avoidance row recording the displayed finite comparisons with the subspace window.*
6. *D is the metric-distance observation row, routed through* $\mathsf{Met}^{\uparrow}$ *and the norm-induced distance surface.*
7. *S is the separation witness row that names the finite vector witness after U, A, B, D have been read.*
8. *K is the completeness or Banach-facing source row, available only as a dependency witness from* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{Banach}^{\uparrow}$ *and not as a selection principle.*
9. *H stores componentwise* hsame *transports for the displayed rows.*

10. *C stores the displayed* Cont *replay route from source and subspace rows to the witness row.*
11. *P is the* Pkg *provenance over the normed source, subspace ledger, tolerance, avoidance, distance, witness, transport, replay, and local naming rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for quotient subspace distance, best-approximation selection, closed-ball compactness, countable choice, or ambient Banach-space completeness.

Lean4 ✓ `BEDC.Derived.RieszLemmaUp.RieszLemmaTasteGate single carrier alignment`

Theorem 2448.2 (Riesz lemma NameCert obligations)**.** *For every accepted* $\mathsf{RieszLemma}^{\uparrow}$ *carrier* $R = (X, Y, U, A, B, D, S, K, H, C, P, N)$*, the local NameCert surface consists of:*

1. *carrier admission for the finite normed-separation packet of Definition 3401.1;*
2. *source-row exposure through X, with the norm and metric rows read through chapter 89 and chapter 57;*
3. *subspace exposure through Y, with closure information displayed as finite ledger data rather than quotient subspace distance;*
4. *unit and tolerance exposure through U and A before any avoidance or separation row is visible;*
5. *classifier stability through B, D, S, where ball avoidance, metric observation, and separation witness rows are compared componentwise;*
6. *ledger nonescape through K, H, C, P, N, so completeness, transport, replay, provenance, and naming remain inside the same finite packet.*

These obligations do not include a quotient normed space, a nearest-point projection, a selected distance minimizer, countable choice, compactness of closed balls, or an unrestricted Banach-space separation principle.

Proof. Project the carrier rows of Definition 3401.1. The source, subspace, unit, tolerance, avoidance, distance, witness, completeness-source, transport, replay, provenance, and naming rows are the only data visible to the local classifier.

The normed-separation part is finite. The source row X supplies the normed carrier, Y supplies the displayed subspace ledger, and U, A fix the unit normalization and dyadic tolerance before any witness can be read.

The classifier stability part is read through B, D, S. These rows compare avoidance and distance observations componentwise, so the separation witness cannot be replaced by quotient distance or by a selected best approximation.

Finally K, H, C, P, N bind the route to one local certificate. Since the excluded objects are absent from the carrier, no NameCert obligation can escape through them. □

Lean4 ✓ `BEDC.Derived.RieszLemmaUp.RieszLemmaCarrier namecert obligations`

Theorem 2448.3 (Riesz lemma normed separation witness)**.** *Every consumer of an accepted* $\mathsf{RieszLemma}^{\uparrow}$ *packet that asks for the Riesz separation witness factors through*

$$X, Y, U, A, B, D, S, K, H, C, P, N.$$

The read consumes the normed source, closed-subspace ledger, unit normalization, tolerance row, ball-avoidance row, metric-distance observation, separation witness row, completeness-source row,

componentwise transport, replay, provenance, and local naming before any witness is exported. The route exports no quotient subspace distance, selected minimizer, host projection, compactness principle, countable choice, or ambient Banach-space completeness coordinate.

Proof. Begin with the NameCert obligations of Definition 3401.2. They place X, Y, U, A before the avoidance and distance rows, so the requested separation witness is grounded in displayed normed-space and subspace data.

Next read B, D, S. The avoidance row, metric observation row, and separation witness row are compared by the local classifier, which makes the witness stable under componentwise equality of the displayed packet.

Finally use the ledger rows K, H, C, P, N. They record that completeness dependencies, transport, continuation replay, provenance, and local naming stay inside the same finite BHist packet. Hence the consumer receives a finite normed separation witness rather than any of the excluded quotient, choice, projection, compactness, or ambient-completeness objects. □

Lean4 ✓ `BEDC.Derived.RieszLemmaUp.RieszLemmaCarrier normed separation witness`

Closure status for $\mathsf{NameCert}_{\mathsf{RieszLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszLemma}^{\uparrow}$ packet is generated from a normed-space source row, closed-subspace ledger, unit normalization row, dyadic tolerance, ball-avoidance row, metric-distance observation, separation witness, completeness-source dependency, componentwise transport, continuation replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RieszLemma}^{\uparrow}}$, seed)

Scope closed: Definition 3401.1, Definition 3401.2, and Definition 3401.3 bind the finite normed-space separation carrier and its witness nonescape boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RieszLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not claim quotient subspace distance, nearest-point projection, selected distance minimizers, compactness of closed balls, countable choice, full Banach-space separation, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability for the avoidance and distance rows, ledger nonescape, and local NameCert coverage for the displayed normed separation packet.

Chapter 2449

A Concrete Naming Certificate for $\mathsf{SimplicialApproximation}^{\uparrow}$

Following Brouwer, Alexander, and Spanier on the classical simplicial approximation theorem, the $\mathsf{SimplicialApproximation}^{\uparrow}$ packet records the finite combinatorial route by which a displayed continuous map is replaced by a simplicial map after a displayed subdivision. It sits beside the finite complex surface of chapter 238, the polytope realization boundary of chapter 209, the graph and modulus rows of chapter 130, the Brouwer fixed-point route of chapter 2030, and the deformation ledger of chapter 156. The packet names only the finite subdivision, vertex-image, star-containment, and handoff rows visible to BEDC consumers; it does not import host topology, open-cover compactness, quotient homotopy classes, or choice-selected approximating maps.

Definition 2449.1 (Simplicial approximation carrier)**.** *A* $\mathsf{SimplicialApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, L, S, V, F, T, B, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the source* $\mathsf{SimplicialComplex}^{\uparrow}$ *row, including the finite simplex inventory, face relation, and dimension grading.*
2. *L is the target* $\mathsf{SimplicialComplex}^{\uparrow}$ *row, read through the same finite-complex surface.*
3. *S is the subdivision ledger for K, naming the subdivided complex, the face projection back to K, and the carried simplex-refinement relation.*
4. *V is the vertex-image ledger assigning each vertex of the subdivision to a vertex of L.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed map from the polytope realization of K to the polytope realization of L.*
6. *T is the* $\mathsf{Polytope}^{\uparrow}$ *realization row, exposing the barycentric and face-containment data used to read stars and simplex interiors.*
7. *B is the finite star-containment ledger asserting that every subdivided simplex of S is sent by V into a target simplex whose open-star row contains the corresponding F-image window.*
8. *M is the Brouwer-facing handoff row, recording the finite approximation surface consumed by* $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *arguments that pass through a combinatorial subdivision.*
9. *H records the* $\mathsf{Homotopy}^{\uparrow}$ *handoff row witnessing that the simplicial map encoded by V, B is homotopic to the displayed continuous map along the visible polytope and star rows.*

10. *C records componentwise* Cont *replay from $K, L, S, V, F, T, B, M, H$ through the local certificate rows.*
11. *P is the* Pkg *provenance over* SimplicialApproximation$^{\uparrow}$, SimplicialComplex$^{\uparrow}$, Polytope$^{\uparrow}$, ContinuousMap$^{\uparrow}$, BrouwerFixedPoint$^{\uparrow}$, Homotopy$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SimplicialApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient topological space, an arbitrary open cover, a selected infinite subdivision process, a quotient homotopy class, or a host proof of compactness.

Lean4 ✓ `BEDC.Derived.SimplicialApproximationUp.SimplicialApproximationTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.SimplicialApproximationUp.SimplicialApproximationUpTasteGate single carrier alignment`

Theorem 2449.2 (SimplicialApproximationUp NameCert obligations)**.** *For every accepted* SimplicialApproximation *carrier*

$$A = (K, L, S, V, F, T, B, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SimplicialApproximation}^{\uparrow}}$ *surface consists exactly of source-complex admission, target-complex admission, subdivision admission, vertex-image admissibility, continuous-map readback, polytope realization readback, star-containment exactness, Brouwer-facing finite-topology handoff, Homotopy-facing deformation handoff, displayed continuation replay, package provenance, and local naming. No obligation is stored outside the rows of Definition 3402.1.*

Proof. Project the carrier. The source and target finite topological data are exactly K and L, while S refines only the displayed source complex and cannot introduce a new ambient space.

The map data are split into two finite ledgers. The continuous row F supplies the BEDC-visible graph and modulus surface, and the vertex-image row V supplies the candidate simplicial map. The polytope row T is the only realization surface on which both can be compared.

Star-containment exactness is therefore the boundary row B. It checks each subdivided simplex against a target simplex and records the finite containment needed by the classical simplicial approximation route.

The remaining rows do not add new analytic content. The Brouwer handoff M, Homotopy handoff H, continuation replay C, provenance P, and local name N expose where the finite approximation may be consumed. Since no other coordinate exists, the listed rows exhaust the NameCert surface. □

Theorem 2449.3 (Simplicial approximation Brouwer handoff)**.** *Every* BrouwerFixedPoint$^{\uparrow}$ *or* Homotopy$^{\uparrow}$ *consumer of an accepted* SimplicialApproximation$^{\uparrow}$ *carrier receives only the finite route*

$$K, L, S, V, F, T, B \longmapsto M, H \longmapsto C, P, N.$$

The route first exposes the source and target simplicial complexes, the displayed subdivision, the vertex-image ledger, the continuous-map row, the polytope realization row, and the star-containment ledger. Only then may a consumer read the Brouwer-facing finite-topology handoff or the Homotopy-facing deformation handoff.

Proof. Start with an accepted carrier $A = (K, L, S, V, F, T, B, M, H, C, P, N)$. By Definition 3402.2, the consumer must read K, L, S, V, F, T, B before any handoff row is visible.

For a Brouwer-facing consumer, M is the only row naming the finite approximation surface. It is already indexed by the displayed subdivision and star-containment ledger, so it cannot replace the finite route by an open-cover compactness argument or a selected host approximant.

For a Homotopy-facing consumer, H is the only deformation row. It relates the simplicial map encoded by V, B to the continuous row F through the visible polytope data T, rather than through a quotient of maps.

Repacking through C, P, N preserves exactly this finite route. Thus both downstream consumers see the same displayed subdivision, vertex, star, realization, and handoff rows, with no additional host-topology coordinate. □

Falsifiable prediction: A $\mathsf{SimplicialApproximation}^{\uparrow}$ consumer that reaches a Brouwer fixed-point or homotopy conclusion without reading the subdivision row S, vertex-image row V, polytope realization row T, and star-containment row B refutes the carrier surface.

Independence witness: simplicialcomplex, polytope, continuousmap, brouwer-fixed-point, homotopy: no listed sibling supplies the whole twelve-row packet $A = (K, L, S, V, F, T, B, M, H, C, P, N)$, because the siblings contribute finite complexes, realization data, continuous graph rows, fixed-point consumers, or deformation ledgers separately while this chapter binds them into one subdivision-and-star certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{SimplicialApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{SimplicialApproximation}^{\uparrow}$ packet is generated from source and target SimplicialComplex rows, a subdivision ledger, a vertex-image ledger, a ContinuousMap row, a Polytope realization row, a star-containment ledger, BrouwerFixedPoint and Homotopy handoff rows, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SimplicialApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3402.1, Definition 3402.2, and Definition 3402.3 seed the finite subdivision, vertex-image, star-containment, Brouwer handoff, and Homotopy handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SimplicialApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host topology, open-cover compactness, quotient homotopy classes, selected infinite subdivision processes, general Brouwer fixed-point existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subdivision stability, vertex-image admissibility, star-containment exactness, Brouwer handoff, Homotopy handoff, replay stability, provenance exhaustion, and local naming for BEDC.Derived.SimplicialApproximationUp.

Chapter 2450

A Concrete Naming Certificate for $\mathsf{MooreSmithNet}^{\uparrow}$

Following Moore–Smith and Kelley nets, the $\mathsf{MooreSmithNet}^{\uparrow}$ packet records the finite directed-net carrier that completion and convergence chapters can inspect before any limit, quotient net, or ambient completeness assertion is named. It sits over the directed-index substrate of chapter 1607, the ordinary net-convergence route of chapter 1667, the uniform-completion consumer of chapter 1473, and the filter-base surface of chapter 1601. The packet is a completion-side neighbour for the L10 directed evidence corridor; it supplies a finite net row, not a selected subnet, not a cofinal-choice operator, and not a host-level limit theorem.

Definition 2450.1 (Moore–Smith net carrier)**.** *A* $\mathsf{MooreSmithNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, V, T, F, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index surface, naming finite index vertices, displayed preorder comparisons, and upper-window witnesses consumed by every net read.*
2. *V is the net-value window, recording the finite values visible at the indices named by D.*
3. *T is the tail ledger, recording the finite late-index requests and the displayed upper-window witnesses that answer them.*
4. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *handoff row obtained from the displayed tails of D and T.*
5. *U is the completion-facing consumer row for* $\mathsf{NetConvergence}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *reads that inspect the same directed tail surface.*
6. *H records componentwise* hsame *transport for the directed index row, value window, tail ledger, filter-base handoff, completion consumer row, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a net request through D, V, T, F, U.*
8. *P is the* Pkg *provenance over* $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithNet}^{\uparrow}}$ *row.*

The carrier exports only this finite directed-net surface. It has no coordinate for quotient nets, selected limits, cofinal choice functions, ambient completeness, or host equality of net values.

Lean4 ✓ `BEDC.Derived.MooreSmithNetUp.MooreSmithNetTasteGate single carrier alignment`

Theorem 2450.2 (Moore–Smith net NameCert obligations)**.** *For an accepted* $\mathsf{MooreSmithNet}^{\uparrow}$ *carrier* $M = (D, V, T, F, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithNet}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the directed-index row, value window, tail ledger, filter-base handoff, completion consumer row, transport, replay, provenance, and local naming row;*
2. *directed-tail coverage, requiring every late-index request to read an upper-window witness from* D *and* T *before any value in* V *is consumed;*
3. *filter-base exposure, requiring the* $\mathsf{FilterBase}^{\uparrow}$ *row* F *to be assembled only from the displayed directed tails;*
4. *convergence and completion handoff, requiring* $\mathsf{NetConvergence}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *consumers to inspect the same* D, V, T, F *route before reaching* U*;*
5. *ledger refusal, stating that quotient nets, selected limits, cofinal-choice functions, ambient completeness, and host equality are not packet coordinates.*

Proof. Project the accepted carrier of Definition 3403.1. Its analytic rows are D, V, T, F, U, and its structural rows are H, C, P, N.

Directed-tail coverage is read from D and T. A consumer first names a displayed index request, then reads the upper-window witness in the directed set, and only then inspects the corresponding value window V.

The filter-base row F is downstream of the same directed tails. Since F has no independent source coordinate, the filter-facing consumer receives only the finite tail family already displayed by D, T, V.

The completion row U is reached after this route. Componentwise transport through H and replay through C preserve the same rows, while P and N name them as the local certificate surface. No listed coordinate can export quotient nets, selected limits, cofinal choice, ambient completeness, or host equality. □

Theorem 2450.3 (Moore–Smith net Cauchy completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{MooreSmithNet}^{\uparrow}$ *packet that needs Cauchy-style completion data first passes through the directed tails and filter-base handoff of chapter 3794 before the broader completion boundary of chapter 2190 may be exposed. The route reads* $D, V, T, F, U, H, C, P, N$ *as finite net data, Cauchy-filter data, and Moore–Smith completion boundary data, and it does not introduce selected limits, quotient nets, cofinal choice, ambient completeness, or host equality.*

Proof. Start with the obligations of Definition 3403.2. They force every completion-facing read to inspect the directed-index row D, value window V, tail ledger T, and filter-base handoff F before reaching the completion consumer row U.

The Cauchy completion neighbour receives exactly that tail and filter route. Thus a reader of chapter 3794 consumes displayed Moore–Smith net data as a Cauchy-style completion surface rather than as a selected limit.

Only after this Cauchy-filter route is visible can the Moore–Smith completion boundary of chapter 2190 be named. Componentwise transport, replay, provenance, and local naming remain H, C, P, N, so the route cannot add quotient nets, cofinal choice, ambient completeness, or host equality. □

Theorem 2450.4 (Moore–Smith net uniform-completion handoff)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{MooreSmithNet}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DirectedSet}^{\uparrow},\ V,\ T \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{NetConvergence}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow}.$$

The handoff exposes directed indices, displayed value windows, finite tail requests, filter-base data, and convergence-facing replay only through $D, V, T, F, U, H, C, P, N$*. It does not supply a quotient of nets, a selected completion point, a cofinal-choice function, host equality of values, or ambient uniform completeness.*

Proof. Begin with the NameCert obligations of Definition 3403.2. The directed-tail coverage row forces the consumer to read D and T before any value window can be used.

Next apply the filter-base exposure row. The handoff to $\mathsf{FilterBase}^{\uparrow}$ is assembled from those displayed tails, so it cannot introduce an external filter, ultrafilter, or quotient of net tails.

The convergence and completion handoff row then sends the same finite route to $\mathsf{NetConvergence}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ consumers. Transport and replay remain componentwise through H and C, while P, N record provenance and naming for the same packet. Thus the uniform-completion read is exhausted by the displayed directed-net carrier and cannot import selected limits, cofinal choice, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithNet}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithNet}^{\uparrow}$ packet is generated from a DirectedSetUp index row, displayed net-value windows, a finite tail ledger, a FilterBaseUp handoff row, NetConvergenceUp and UniformCompletionUp consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MooreSmithNet}^{\uparrow}}$, seed)

Scope closed: Definition 3403.1, Definition 3403.2, and Definition 3403.4 seed the finite Moore–Smith net carrier consumed by completion-side directed evidence.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MooreSmithNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient nets, cofinal choice, ambient completeness, host equality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail coverage, filter-base exposure, convergence handoff, uniform-completion handoff, transport preservation, and ledger refusal for the same finite packet.

Chapter 2451

A Concrete Naming Certificate for $\mathsf{BishopCompletionCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompletionCriterion}^{\uparrow}$ packet records the explicit criterion by which a displayed regular Cauchy route is allowed to enter a completion boundary without quotienting names or selecting limits. It sits between the modulus schedule of chapter 1438, the finite window surface of chapter 126, the regular rational readback of chapter 301, the metric completion packet of chapter 1506, the uniform completion packet of chapter 1473, and the terminal real-name seal of chapter 38. The packet is a finite NameCert criterion for completion consumers; it is not a quotient-completion construction, not a selected-representative principle, not countable choice, not open-cover compactness, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 2451.1 (Bishop completion criterion carrier)**.** *A* $\mathsf{BishopCompletionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, W, R, K, U, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *row recording the explicit tail schedule inspected by the criterion.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which source observations are read at the displayed precision requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows and tolerance schedule.*
4. *K is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row reached after M, W, R have been displayed.*
5. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row reached by the same finite completion route.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for Real-facing consumers of the criterion.*
7. *H records componentwise* hsame *transport for the modulus schedule, stream windows, regular readback, metric and uniform completion handoffs, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through M, W, R, K, U, E.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionCriterion}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionCriterion}^{\uparrow}}$ *row naming the displayed criterion and its permitted consumer reads.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for quotient limits, selected representatives, countable choice, open-cover compactness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionCriterionUp.BishopCompletionCriterionTasteGate single carrier alignment`

Theorem 2451.2 (Bishop completion criterion NameCert obligations)**.** *For every accepted* BishopCompletionCriteri *carrier $B = (M, W, R, K, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionCriterion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed modulus schedule, stream windows, regular rational readback, metric-completion handoff, uniform-completion handoff, Real seal, transport, continuation replay, provenance, and local naming row;*
2. *explicit Cauchy-modulus exposure, requiring M to be read before any completion boundary K or U is available;*
3. *finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring every completion-facing observation to pass through W and then R at the displayed precision requests;*
4. *completion-seal handoff, requiring K, U, and E to remain downstream of M, W, R and upstream only of the structural rows H, C, P, N;*
5. *ledger non-escape, refusing quotient limits, selected representatives, countable choice, open-cover compactness, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside those rows.

Proof. Carrier admission is tuple projection from Definition 3404.1. The accepted packet displays exactly $M, W, R, K, U, E, H, C, P, N$.

The analytic route first reads the explicit modulus schedule M, then the finite windows W, and then the regular rational readback R. The completion rows K and U and the Real seal E are downstream of that displayed route.

Finally H, C, P, N transport, replay, source, and name the same finite criterion. Since quotient limits, selected representatives, countable choice, open-cover compactness, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no carrier row, none can be exported by the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionCriterion}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 3404.1 and Definition 3404.2 seed the finite Bishop completion criterion route from explicit Cauchy moduli through StreamName, RegSeqRat, MetricCompletion, UniformCompletion, and Real seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionCriterion}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.BishopCompletionCriterionUp.BishopCompletionCriterionTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion, selected limits, countable choice, open-cover compactness, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, explicit modulus exposure, finite StreamName and RegSeqRat readback, completion-seal handoff, and ledger non-escape for BEDC.Derived.BishopCompletionCriterionUp.

Constructive story: A $\mathsf{BishopCompletionCriterion}^{\uparrow}$ packet is generated from a CauchyConvergenceModulus tail schedule, finite StreamName windows, RegSeqRat readback, MetricCompletion and UniformCompletion handoffs, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2452

A Concrete Naming Certificate for $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ packet records the finite criterion by which two regular-Cauchy views may be interleaved before a completion-facing consumer reads either view. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, the subsequence criterion of chapter 1552, and the product interleaving route of chapter 2172. The packet is a displayed interleaving criterion for completion consumers; it is not a quotient stream, not a choice-selected limit, and not an ambient completeness coordinate.

Definition 2452.1 (Cauchy interleaving criterion carrier)**.** *A* $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S_0, S_1, D_0, D_1, T, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows whose observations are to be interleaved.*
2. D_0 *and* D_1 *are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers attached to the two windows.*
3. T *is the finite selector schedule recording which side is read at each displayed stage.*
4. W *is the common window-extraction row obtained from the two scheduled sources and their dyadic ledgers.*
5. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reconstructed from the extracted interleaving windows.*
6. E *is the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after* $S_0, S_1, D_0, D_1, T, W, Q$ *have been displayed.*
7. H *records componentwise* hsame *transport for the two stream windows, two dyadic ledgers, selector schedule, extracted window, readback row, Real seal, continuation, provenance, and local naming rows.*
8. C *records displayed* Cont *replay through the same interleaving route.*
9. P *is the* Pkg *provenance over* $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for quotient streams, selected host limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyInterleavingCriterionUp.CauchyInterleavingCriterionTasteGate single carrier alignment`

Theorem 2452.2 (Cauchy interleaving criterion NameCert obligations)**.** *For every accepted* CauchyInterleavingCrit *carrier* $I = (S_0, S_1, D_0, D_1, T, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission, two-sided finite-window exposure, two dyadic tolerance ledgers, finite selector admission, common window extraction, regular readback handoff, Real-seal boundary exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every* $\mathsf{BishopCompletionCriterion}^{\uparrow}$ *or* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumer reads only this displayed route and receives no quotient stream, selected representative, host convergence predicate, countable-choice selector, or ambient completeness witness.*

Proof. Project the carrier of Definition 3405.1. The rows $S_0, S_1, D_0, D_1, T, W, Q, E, H, C, P, N$ are the complete displayed packet.

The analytic rows first expose the two finite stream windows and their dyadic tolerance ledgers. The selector schedule T then chooses the displayed side at each stage, and the common extraction row W records the finite window actually read by the interleaving consumer.

The regular readback Q and Real seal E are downstream of that extracted route. The structural rows H, C, P, N transport, replay, source, and name the same finite criterion, so no quotient stream or choice-selected limit can enter the local NameCert surface. □

Theorem 2452.3 (Cauchy interleaving criterion window extraction)**.** *Every accepted* $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ *packet admits a finite window extraction route*

$$(S_0, S_1, D_0, D_1, T) \longmapsto W \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

The extracted window W *is read from the two displayed* $\mathsf{StreamName}^{\uparrow}$ *rows using only the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers and the finite selector schedule* T*. Hence downstream* $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopCompletionCriterion}^{\uparrow}$, *and regular-Cauchy completion consumers cannot replace the route by a quotient of streams, a selected limit, or an ambient completeness coordinate.*

Proof. Begin with the NameCert obligations of Definition 3405.2. They force both source windows and both dyadic ledgers to be visible before the selector schedule can be consumed.

The selector schedule is finite, so each displayed stage chooses one of the two already exposed windows. The common extraction row W records exactly those finite choices, and the regular readback row Q is reached only after W has been displayed.

Finally the Real seal and structural rows replay the same route. Because the carrier has no coordinate for quotient streams, selected representatives, countable choice, host real equality, or ambient completeness, a completion-facing consumer receives only the finite extraction route shown above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInterleavingCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ packet is generated from two StreamName finite-window rows, two DyadicRatCore tolerance ledgers, a finite selector schedule, an extracted interleaving window, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyInterleavingCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 3405.1, Definition 3405.2, and Definition 3405.3 seed the finite interleaving criterion route for L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyInterleavingCriterion}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyInterleavingCriterionUp.CauchyInterleavingCriterionTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient-stream equality, selected limits, countable choice, host real equality, ambient Real completeness, or a completed-real binary operation.

Upgrade path: Obligation closure requires carrier admission, selector-window coverage, dyadic ledger compatibility, regular readback handoff, Real-seal nonescape, and TasteGate field faithfulness for BEDC.Derived.CauchyInterleavingCriterionUp.

Chapter 2453

A Concrete Naming Certificate for $\mathsf{LocatedRealModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealModulus}^{\uparrow}$ packet records the finite modulus surface that lets a located real answer bounded precision requests without becoming a quotient real or a trichotomy oracle. It sits over the located-real carrier of chapter 1933, the dyadic precision ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the density-support route of chapter 1809. It also refines the convergence-modulus discipline of chapter 1438 for the Phase Real and Completion context of chapter 9238.

Definition 2453.1 (LocatedRealModulus carrier)**.** *A* $\mathsf{LocatedRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, D, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *row whose located interval and endpoint enclosure data answer the precision request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger recording the requested radius, endpoint slack, and comparison budget.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened from the located real at the displayed precision.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite window and dyadic tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, D, W, R have been displayed.*
6. *H stores componentwise* hsame *transport for the located-real row, dyadic ledger, finite window, regular readback, real seal, replay route, provenance, and local naming row.*
7. *C stores the displayed* Cont *replay from a precision request through L, D, W, R to the seal row E and to downstream completion consumers.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealModulus}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, trichotomy, a selected limiting representative, countable choice, host completeness, or an ambient order oracle.

Lean4 ✓ `BEDC.Derived.LocatedRealModulusUp.LocatedRealModulusTasteGate single carrier alignment`

Theorem 2453.2 (LocatedRealModulus NameCert obligations)**.** *For an accepted* $\mathsf{LocatedRealModulus}^{\uparrow}$ *carrier* $M = (L, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, located-real row exposure, dyadic precision-ledger exactness, finite stream-window coverage, regular rational readback compatibility, real-seal non-escape, componentwise transport, continuation replay, provenance, and local naming for the packet of Definition 3406.1.*

Proof. Carrier admission is projection from the displayed tuple. The analytic rows are L, D, W, R, E, and the structural rows are H, C, P, N.

The located-real row L supplies the enclosure surface, while D records the radius and comparison budget for the request. The stream row W and readback row R are opened only at that displayed budget, so the window coverage and rational readback are tied to the same dyadic ledger.

The seal row E is downstream of those reads. Transport and replay preserve the same order through H and C, while P and N add provenance and naming without introducing quotient equality, trichotomy, selected limits, choice, or ambient completeness. □

Theorem 2453.3 (LocatedRealModulus dyadic-window coverage)**.** *Every precision request accepted by a* $\mathsf{LocatedRealModulus}^{\uparrow}$ *packet must display the dyadic ledger* D *before opening the finite stream window* W*, and must display the window* W *before reading the regular rational row* R*. Thus a* $\mathsf{RealSeparability}^{\uparrow}$ *or* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *consumer receives a covered dyadic-window route*

$$D \longmapsto W \longmapsto R$$

inside the same BHist *packet, not a detached density choice, an infinite selector, or a host convergence proof.*

Proof. Start with the carrier inventory of Definition 3406.1. The dyadic ledger precedes the finite-window and readback rows in the accepted packet.

Use the local obligations of Definition 3406.2. They require dyadic precision exactness, window coverage, and regular rational readback compatibility to be certified for the same packet.

The separability and convergence-modulus consumers can therefore cite the displayed route only as finite coverage data. Since the packet contains no density selector, infinite choice schedule, quotient equality, or host convergence coordinate, none can be exported with the covered window. □

Theorem 2453.4 (LocatedRealModulus real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Real and Completion consumer of an accepted* $\mathsf{LocatedRealModulus}^{\uparrow}$ *packet must pass through*

$$L, D, W, R, E, H, C, P, N$$

in that order before the real seal E *is read. The handoff preserves the located-real enclosure, dyadic precision ledger, stream window, and regular readback as visible rows, and it exports no host real equality, trichotomy, selected representative, countable-choice schedule, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the located-real row first. It supplies the enclosure and locatedness data inherited from chapter 1933.

Next read the dyadic-window route of Definition 3406.3. The precision ledger, finite stream window, and regular rational readback are already fixed before the seal row is available.

Finally replay the handoff through C and transport it through H. The provenance and local naming rows record the same packet, so the terminal $\mathsf{Real}^{\uparrow}$ seal is a downstream read of finite modulus data rather than an appeal to quotient completion, choice, trichotomy, selected representatives, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealModulus}^{\uparrow}$ packet is generated from a displayed LocatedRealUp row, a DyadicRatCore precision ledger, a StreamName finite-window row, a RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3406.1, Definition 3406.2, Definition 3406.3, and Definition 3406.4 seed the finite located-modulus route over LocatedReal, DyadicRatCore, StreamName, RegSeqRat, RealUp, RealSeparability, and CauchyConvergenceModulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, trichotomy, selected limits, countable choice, host completeness, or an ambient RealUp completeness theorem.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-window coverage, regular readback compatibility, real-seal handoff, transport stability, continuation replay, provenance, and local naming for BEDC.Derived.LocatedRealModulusUp.

Chapter 2454

A Concrete Naming Certificate for $\mathsf{MonotoneBoundedSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ packet records the finite carrier surface for a monotone sequence of constructive real names together with an explicit boundedness ledger. It sits between the $\mathsf{Real}^{\uparrow}$ rows of chapter 38, the bounded sequence discipline of chapter 1415, the limit interface of chapter 1413, the tail-modulus handoff of chapter 1438, and the located monotone convergence route of chapter 3373. The packet names the data available before a constructive monotone-convergence consumer asks for a limit; it does not smuggle a completed limit into the source carrier.

Definition 2454.1 (MonotoneBoundedSequence carrier)**.** *A* $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, R, O, B, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Real}^{\uparrow}$ *source-row family for the sequence values, read only through the finite sequence schedule admitted by the packet.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger recording the inspected indices and observation windows for each displayed sequence value.*
3. *R is the real-readback row that ties each scheduled observation in W to the corresponding* $\mathsf{Real}^{\uparrow}$ *source row in S.*
4. *O is the monotonicity ledger, listing the finite comparison rows by which the packet certifies that later scheduled values do not move below earlier scheduled values.*
5. *B is the boundedness ledger, read through the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *surface, which records the common real bound and the finite comparisons keeping every inspected source row below that bound.*
6. *T is the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *handoff row exposed to downstream convergence consumers when the monotonicity and boundedness ledgers have been inspected together.*
7. *H records componentwise* hsame *transport for the source rows, stream windows, real readbacks, monotonicity ledger, boundedness ledger, modulus handoff, replay route, provenance, and local naming row.*
8. *C records displayed* Cont *replay from a convergence request through $S, W, R, O, B, T, H, P, N$.*

9. *P is the* Pkg *provenance over* MonotoneBoundedSequence$^\uparrow$, Real$^\uparrow$, BoundedRealSequence$^\uparrow$, RealSequenceLimit$^\uparrow$, CauchyConvergenceModulus$^\uparrow$, LocatedMonotoneConvergence$^\uparrow$, StreamName$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{MonotoneBoundedSequence}^\uparrow}$ *row.*

The classifier compares accepted packets only through

$$S, W, R, O, B, T, H, C, P, N.$$

It has no coordinate for quotient limits, countable choice, trichotomy, selected representatives, or ambient Real$^\uparrow$ *completeness.*

Theorem 2454.2 (MonotoneBoundedSequence NameCert obligations)**.** *For every accepted* MonotoneBoundedSequ *carrier*

$$M = (S, W, R, O, B, T, H, C, P, N),$$

the local NameCert$_{\text{MonotoneBoundedSequence}^\uparrow}$ *surface consists exactly of the finite rows for carrier admission, source-row scheduling, stream-window readback, monotonicity-ledger admission, boundedness-ledger admission,* CauchyConvergenceModulus$^\uparrow$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Each obligation reads the same* Real$^\uparrow$ *source rows and the same* StreamName$^\uparrow$ *windows before the boundedness ledger or modulus handoff is exposed. No obligation may appeal to quotient limits, countable choice, trichotomy, selected representatives, or ambient* Real$^\uparrow$ *completeness.*

Proof. Project the carrier in Definition 3407.1. Carrier admission exposes precisely the rows $S, W, R, O, B, T, H, C, P, N$, so every source value is read as a scheduled Real$^\uparrow$ row through the displayed stream windows.

The order-facing rows are then forced to use the same source schedule. The monotonicity ledger O compares only scheduled values from S, W, R, while the boundedness ledger B is the BoundedRealSequence$^\uparrow$ read of the same scheduled source rows against a common bound.

The convergence-facing handoff comes last. The CauchyConvergenceModulus$^\uparrow$ row T may be exposed only after the monotonicity and boundedness ledgers have both been inspected, and the RealSequenceLimit$^\uparrow$ and LocatedMonotoneConvergence$^\uparrow$ consumers can read only that displayed handoff.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the excluded quotient, choice, trichotomy, representative-selection, and ambient-completeness coordinates do not occur in the carrier, they cannot occur among the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.MonotoneBoundedSequenceUp.TasteGate.MonotoneBoundedSequenceTasteGate single carrier alignment`

Theorem 2454.3 (MonotoneBoundedSequence scheduled-window factorization)**.** *Let*

$$M = (S, W, R, O, B, T, H, C, P, N)$$

be an accepted MonotoneBoundedSequence$^\uparrow$ *carrier. Every consumer that reads the monotonicity ledger O, boundedness ledger B, and* CauchyConvergenceModulus$^\uparrow$ *row T must factor those reads through the same* RealSequenceSpace$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, *and* Real$^\uparrow$ *schedule S, W, R before any* LocatedSupremum$^\uparrow$ *or* LocatedMonotoneConvergence$^\uparrow$ *read is exposed. The factorization exports one displayed finite sequence schedule, not quotient limits, selected representatives, countable choice, trichotomy, or ambient* Real$^\uparrow$ *completeness.*

Proof. Project the carrier in Definition 3407.1. The rows S, W, R are the only sequence-value route available to the packet: S lists the source rows, W records the finite stream windows, and R ties those windows to the real readback surface.

Apply Definition 3407.2. It forces the order-facing rows to consume the same source schedule, so O cannot compare a different sequence surface and B cannot introduce a second boundedness schedule.

The modulus row T is downstream of that shared route. Reading it as a $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ handoff therefore uses the same RealSequenceSpace, StreamName, RegSeqRat, and Real rows before any located-supremum or located-monotone-convergence consumer is allowed to inspect the packet.

Since the carrier has no coordinate for quotient limits, selected representatives, countable choice, trichotomy, or ambient real completeness, the shared-window route cannot export any of those objects. □

Theorem 2454.4 (MonotoneBoundedSequence finite limit boundary)**.** *Let*

$$M = (S, W, R, O, B, T, H, C, P, N)$$

be an accepted $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ *carrier. Every* $\mathsf{RealSequenceLimit}^{\uparrow}$ *or* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *consumer of M must first read the* $\mathsf{Real}^{\uparrow}$ *source rows,* $\mathsf{StreamName}^{\uparrow}$ *windows, monotonicity ledger, boundedness ledger,* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *through the same finite surface. The consumer receives a limit-boundary route for monotone bounded data, not a quotient limit, countable-choice-selected tail, trichotomy decision, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a limit-facing consumer. By Definition 3407.1, the only available sequence data are the scheduled $\mathsf{Real}^{\uparrow}$ source rows S, their $\mathsf{StreamName}^{\uparrow}$ windows W, and the readback row R.

Apply Definition 3407.2. The monotonicity ledger O and boundedness ledger B are attached to that same scheduled source surface, and the modulus row T is available only after both ledgers have been displayed.

The $\mathsf{RealSequenceLimit}^{\uparrow}$ route may therefore inspect a finite tail-boundary surface, and the $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ route may inspect the same bounded monotone handoff before reaching its located-supremum data. Neither route can replace the packet by a completed real limit or a host-level sequence theorem.

The structural rows H, C, P, N preserve this boundary under transport, replay, provenance, and naming. The absent quotient-limit, choice, trichotomy, representative, and ambient-completeness coordinates remain absent for every downstream consumer. □

Theorem 2454.5 (MonotoneBoundedSequence located convergence source)**.** *Let*

$$M = (S, W, R, O, B, T, H, C, P, N)$$

be an accepted $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ *carrier. Every* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *consumer of M must read the same source rows S, stream windows W, real readback row R, monotonicity ledger O, boundedness ledger B,* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *handoff T, transport row H, replay row C, provenance row P, and local naming row N before any* $\mathsf{LocatedSupremum}^{\uparrow}$ *or terminal* $\mathsf{Real}^{\uparrow}$ *seal row is exposed. Thus the located monotone convergence route consumes the displayed bounded monotone source surface rather than a second limit object, quotient representative, choice-selected tail, or ambient completeness theorem.*

Proof. Project the carrier of Definition 3407.1. The tuple exposes exactly the rows $S, W, R, O, B, T, H, C, P, N$, so a located convergence consumer has no other source coordinate to inspect.

Apply Definition 3407.2. The monotonicity ledger, boundedness ledger, and $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ handoff are all attached to the same scheduled source rows and stream windows.

Use Definition 3407.4. It places every $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ read downstream of the displayed source rows, order ledgers, modulus handoff, transport, replay, provenance, and local name.

The located monotone convergence packet can therefore consume only this source route before it reaches a $\mathsf{LocatedSupremum}^{\uparrow}$ handoff or a terminal real seal. Since the carrier has no coordinate for a second limit object, quotient representative, choice-selected tail, or ambient completeness theorem, none can be exposed by the handoff. □

Theorem 2454.6 (MonotoneBoundedSequence Cauchy-modulus frontier)**.** *Let*

$$M = (S, W, R, O, B, T, H, C, P, N)$$

be an accepted $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ *carrier. Every completion-facing consumer that uses the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *handoff row* T *must first expose the shared* $\mathsf{Real}^{\uparrow}$ *source rows* S*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the readback row* R*, the monotonicity ledger* O*, the boundedness ledger* B*, the transport row* H*, the replay row* C*, the provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{MonotoneBoundedSequence}^{\uparrow}}$ *row* N*. The handoff therefore exports a finite Cauchy-modulus frontier for the displayed bounded monotone source, not a quotient limit, choice-selected tail, trichotomy decision, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 3407.1. The row T is not an independent limit object; it is one coordinate of the displayed tuple $S, W, R, O, B, T, H, C, P, N$.

Apply Definition 3407.2. The $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ handoff is admitted only through the same source rows, stream windows, readback, monotonicity ledger, and boundedness ledger that support the local naming surface.

Use Definition 3407.4 and Definition 3407.5. Together they place every completion-facing or located-convergence read downstream of the displayed carrier surface and before any terminal limit seal.

The structural rows H, C, P, N preserve that route under componentwise transport, replay, provenance, and local naming. Since the carrier has no coordinate for quotient limits, choice-selected tails, trichotomy decisions, selected representatives, or ambient real completeness, the modulus frontier cannot export any of those objects. □

Falsifiable prediction: Every accepted $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ consumer that claims access to a convergence boundary must display the Real source rows, StreamName windows, monotonicity ledger, boundedness ledger, CauchyConvergenceModulus handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert before any RealSequenceLimit or LocatedMonotoneConvergence read is inspected.

Independence witness: boundedrealsequence, realsequencelimit, cauchyconvergencemodulus, locatedmonotoneconvergence, real: $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a monotonicity ledger, boundedness ledger, and finite modulus handoff before any limit-facing consumer may read the source sequence.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneBoundedSequence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneBoundedSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3407.1, Definition 3407.2, Definition 3407.4, and Definition 3407.5 seed the finite source carrier, local obligation surface, limit-boundary route, and located-convergence source handoff for monotone bounded real sequences.

Formal verification: FormalStatus(NameCert$_{\text{MonotoneBoundedSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient limits, countable choice, trichotomy, selected representatives, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, monotonicity-ledger admission, boundedness-ledger admission, CauchyConvergenceModulus handoff, transport replay, provenance, and local naming for BEDC.Derived.MonotoneBoundedSequenc

Constructive story: A MonotoneBoundedSequence$^{\uparrow}$ packet is generated from Real source rows, StreamName windows, real readback, monotonicity and boundedness ledgers, a CauchyConvergenceModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2455

A Concrete Naming Certificate for $\mathsf{AiryFunction}^{\uparrow}$

Following Airy and Olver on the classical Airy differential equation, the $\mathsf{AiryFunction}^{\uparrow}$ packet records the finite certificate route by which Airy-function reads are named through a displayed scalar ODE, coefficient recurrences, real-series windows, and terminal real-name seals. It consumes the real endpoint discipline of chapter 38, the finite partial-sum and tail surface of chapter 1581, the ODE source of chapter 193, and the Picard local-flow route of chapter 1888. The packet is not a host entire-function primitive, an asymptotic expansion theorem, a selected global solution object, or an ambient analytic-completeness claim.

Definition 2455.1 (Airy function carrier)**.** *An* $\mathsf{AiryFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, I, K, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the scalar ODE row for the Airy equation $y'' - xy = 0$, read through the local* $\mathsf{Ode}^{\uparrow}$ *source and its displayed derivative, vector-field, and state-window ledgers.*
2. *I is the initial-data row. It records the chosen Airy branch by finitely displayed values for $y(0)$ and $y'(0)$, including the branch tags that distinguish the standard* Ai *and* Bi *reads when such a distinction is requested.*
3. *K is the coefficient-recurrence row. It records the finite recurrence ledger by which coefficient windows for the Airy power series are generated from D and I.*
4. *T is the* $\mathsf{RealSeries}^{\uparrow}$ *term-stream row, listing the finite partial-sum windows, tail requests, and shared threshold rows used by the requested Airy read.*
5. *S is the local Picard or ODE nonescape row, ensuring that the inspected series and flow windows stay inside the displayed scalar state window supplied by* $\mathsf{PicardLindelof}^{\uparrow}$*.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for coefficients, partial sums, initial values, and endpoint requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the ODE, initial-data, recurrence, series, nonescape, and readback rows have been displayed.*
8. *H records componentwise* hsame *transport for the ODE row, initial data, recurrence ledger, series windows, nonescape row, readbacks, Real seal, replay, provenance, and local name.*

9. *C records displayed* Cont *replay from an Airy request through the ODE row, initial data, coefficient recurrence, real-series windows, Picard nonescape, regular readbacks, and the Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{AiryFunction}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AiryFunction}^{\uparrow}}$ *row.*

The carrier exports only this finite route. It has no coordinate for a host entire function, global analytic continuation, asymptotic sector decomposition, selected zero set, quotient function equality, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.AiryFunctionUp.AiryFunctionTasteGate single carrier alignment`

Theorem 2455.2 (Airy function NameCert obligations)**.** *For every accepted* $\mathsf{AiryFunction}^{\uparrow}$ *carrier* $A = (D, I, K, T, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AiryFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed ODE, initial-data, recurrence, real-series, nonescape, readback, Real-seal, transport, replay, provenance, and local naming rows;*
2. *ODE compatibility, requiring D to be the only scalar Airy equation row read by the packet;*
3. *initial-data compatibility, requiring I to supply the branch-determining values consumed by the recurrence ledger;*
4. *recurrence exactness, requiring K to generate every inspected coefficient window from D and I before any series read is exposed;*
5. *real-series visibility, requiring T to expose partial sums, tail thresholds, and endpoint requests only through the* $\mathsf{RealSeries}^{\uparrow}$ *surface;*
6. *local-flow nonescape, requiring S to bind the inspected ODE and series windows to the Picard local-flow route;*
7. *endpoint sealing, requiring R and E to read every requested coefficient, partial sum, and Airy endpoint through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows;*
8. *structural preservation, requiring H, C, P, N to transport, replay, source, and name exactly the displayed rows and no external analytic object.*

No Airy-function obligation is stored outside these rows.

Proof. Project the carrier of Definition 3408.1. The ODE row D and initial-data row I are visible before any recurrence or series row can be inspected, so the requested branch is fixed inside the packet.

The coefficient and series obligations are then finite ledger checks. The recurrence row K supplies the inspected coefficient windows, and the $\mathsf{RealSeries}^{\uparrow}$ row T supplies only the partial sums, tail thresholds, and endpoint requests listed in the packet.

The local-flow and endpoint rows close the analytic route. The nonescape row S keeps the inspected windows inside the displayed Picard or ODE state window, while R and E provide regular rational readback and the terminal real-name seal.

Finally H, C, P, N transport, replay, source, and name the same finite data. Since the carrier has no coordinate for a host entire function, asymptotic sector, selected zero set, quotient function equality, or ambient completeness theorem, the local NameCert surface has no obligation row for such an object. □

Theorem 2455.3 (Airy function real-series handoff)**.** *Every Real-facing read from an accepted* $\mathsf{AiryFunction}^{\uparrow}$ *carrier factors through*

$$D, I \longmapsto K \longmapsto T, S \longmapsto R, E \longmapsto H, C, P, N.$$

Thus a consumer receives the displayed Airy ODE row, branch initial data, coefficient recurrence ledger, finite real-series windows, local nonescape row, regular readback, and terminal real seal, but receives no host entire-function primitive or global analytic continuation datum.

Proof. Start with an accepted packet $A = (D, I, K, T, S, R, E, H, C, P, N)$. The only ODE and branch data available to a consumer are D and I, so a Real-facing read begins at the displayed Airy equation and its carried initial values.

The recurrence row K is the next forced coordinate. It generates the inspected coefficient windows from the ODE and branch data before the $\mathsf{RealSeries}^{\uparrow}$ row T exposes partial sums or tail thresholds.

The nonescape and endpoint rows are downstream. The row S keeps the displayed series and local-flow windows inside the accepted ODE route, and R, E provide the regular readback and terminal $\mathsf{Real}^{\uparrow}$ seal.

The structural rows H, C, P, N preserve and name only that route. Hence the handoff cannot introduce a host entire function, a global continuation object, an asymptotic sector decomposition, a selected zero set, or quotient function equality. □

Falsifiable prediction: Every $\mathsf{AiryFunction}^{\uparrow}$ read factors through one displayed Airy ODE row, one branch initial-data row, one coefficient-recurrence ledger, one $\mathsf{RealSeries}^{\uparrow}$ partial-sum and tail surface, one Picard nonescape row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: real, realseries, ode, picard-lindelof: $\mathsf{AiryFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an Airy ODE row, branch initial data, coefficient recurrence, real-series windows, local-flow nonescape, regular readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AiryFunction}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AiryFunction}^{\uparrow}$ packet is generated from a displayed Airy ODE row, branch initial data, coefficient-recurrence ledger, RealSeriesUp partial-sum and tail rows, Picard nonescape data, RegSeqRat readbacks, RealUp endpoint seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AiryFunction}^{\uparrow}}$, seed)

Scope closed: Definition 3408.1, Definition 3408.2, and Definition 3408.3 seed the finite Airy-function certificate surface over displayed ODE, branch, recurrence, series, nonescape, readback, and real endpoint rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AiryFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host entire functions, global analytic continuation, asymptotic expansions, selected zero sets, quotient function equality, ambient analytic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ODE compatibility, branch-data compatibility, recurrence exactness, real-series visibility, nonescape, endpoint sealing, and structural preservation for BEDC.Derived.AiryFunctionUp.

Chapter 2456

A Concrete Naming Certificate for $\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, the $\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}$ packet names the finite comparison surface between a Cauchy presentation of the real line and a located lower-upper presentation. It sits between the Cauchy path of chapter 38, chapter 301, chapter 126, and chapter 291, and the located path of **??**, chapter 404, chapter 1446, and chapter 1447. The packet compares finite observation windows only; it does not add quotient cuts, host real equality, countable choice, trichotomy, or an ambient completeness principle.

Definition 2456.1 (Cauchy-located equivalence carrier)**.** *A* $\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (C, L, U, W, R, D, E, H, Ct, P, N)$$

with the following rows:

1. *C is the displayed* $\mathsf{Real}^{\uparrow}$ *Cauchy seal, read through the regular rational and stream-name surface of* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*;*
2. *L is the located lower-observation row, read through* $\mathsf{LowerReal}^{\uparrow}$ *and the lower side of* $\mathsf{LocatedCut}^{\uparrow}$*;*
3. *U is the located upper-observation row, read through* $\mathsf{UpperReal}^{\uparrow}$ *and the upper side of* $\mathsf{LocatedCut}^{\uparrow}$*;*
4. *W is the shared finite-window ledger comparing Cauchy tails, dyadic tolerances, lower observations, and upper observations;*
5. *R records the regular-sequence readback from C into the window ledger;*
6. *D records the dyadic-rational tolerance and endpoint rows consumed by W;*
7. *E records the two handoff routes: Cauchy data to located observations, and located observations back to a Cauchy seal;*
8. *H stores componentwise* hsame *transport for all displayed rows;*
9. *Ct stores the displayed* Cont *replay routes used by the two handoffs and by shared-window comparison;*
10. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{UpperReal}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, L, U, W, R, D, E, H, Ct, P, N$. No coordinate stores quotient-cut equality, host real equality, selected limits, trichotomy, countable choice, or a global completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyLocatedRealEquivalenceUp.TasteGate.CauchyLocatedRealEquivalenceTasteGate single carrier alignment`

Theorem 2456.2 (Cauchy-located equivalence NameCert obligations)**.** *For every accepted* CauchyLocatedRealEqui *carrier $Q = (C, L, U, W, R, D, E, H, Ct, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the Cauchy seal, lower and upper located observations, shared-window ledger, regular readback, dyadic tolerance row, handoff row, transport, continuation, provenance, and local naming row;*
2. *Cauchy-to-located handoff, requiring reads from C through R, D, W, E, H, Ct before lower and upper observations are exported as L, U;*
3. *located-to-Cauchy handoff, requiring compatible lower and upper observations in L, U to pass through the same shared windows W, D, E, H, Ct before the Cauchy seal C is read;*
4. *classifier stability under shared finite windows, requiring agreement on W, R, D, E, H, Ct to preserve both directions of comparison;*
5. $\mathsf{Real}^{\uparrow}$*-seal nonescape, excluding quotient cuts, host real equality, selected limits, trichotomy, countable choice, and ambient completeness from the exported comparison.*

No obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3409.1. The row list displays exactly the Cauchy seal, the lower and upper located observations, the shared-window ledger, the regular and dyadic readback rows, the handoff row, and the structural rows H, Ct, P, N.

For the Cauchy-to-located handoff, read C through the regular sequence row R and the dyadic row D. The shared-window ledger W is the only place where Cauchy tail information is compared with lower and upper observations, and E records the finite route from that comparison to L, U.

For the located-to-Cauchy handoff, begin with compatible reads in L and U. The same ledger W and dyadic row D supply the finite tolerance comparison, while E and Ct replay the route back to the Cauchy seal C.

Classifier stability is componentwise. Agreement on the shared-window, readback, tolerance, handoff, transport, and continuation rows preserves the two handoff routes because no other classifier coordinate is available.

Finally, the provenance and naming rows mention only the listed sibling chapters and BEDC support rows. Since quotient cuts, host real equality, selected limits, trichotomy, countable choice, and ambient completeness are not coordinates of Q, the $\mathsf{Real}^{\uparrow}$ seal cannot export them through this packet. □

Theorem 2456.3 (Cauchy-located equivalence finite handoff)**.** *Every accepted* $\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}$ *carrier $Q = (C, L, U, W, R, D, E, H, Ct, P, N)$ routes comparison between the Cauchy* $\mathsf{Real}^{\uparrow}$ *seal and the located* $\mathsf{LowerReal}^{\uparrow}$-$\mathsf{UpperReal}^{\uparrow}$ *observations through the finite surface*

$$C, L, U, W, R, D, E, H, Ct, P, N.$$

The route may be consumed by $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, *and* $\mathsf{UpperReal}^{\uparrow}$ *readers, but it exports no quotient-cut equality, host real equality, selected limit, trichotomy, countable choice, or ambient completeness.*

Proof. Start with the carrier obligations. They force both directions of comparison to use W, R, D, E, H, Ct, so a consumer cannot jump directly from a Cauchy seal to a located cut or from a located cut to a Cauchy seal.

The Cauchy siblings supply the source rows C, R, D, while the located siblings supply L, U and their cut-facing reads. The handoff row E is the only coordinate that compares the two sides, and the continuation row Ct is the only replay route.

Nonescape follows from the final obligation of Definition 3409.2. Since the forbidden data are absent from the carrier, the finite handoff cannot export them to either side of the comparison. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}$ packet is generated from a Cauchy $\mathsf{Real}^{\uparrow}$ seal, lower and upper located observations, shared finite windows, regular and dyadic readback rows, two handoff routes, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3409.1, Definition 3409.2, and Definition 3409.3 seed the finite comparison surface between Cauchy and located real presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLocatedRealEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient cuts, host real equality, selected limits, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, both handoff directions, shared-window classifier stability, and Real-seal nonescape for BEDC.Derived.CauchyLocatedRealEquivalenceUp.

$\mathsf{Cauchy}^{\uparrow}$ is an L10 route whose regular-sequence, finite-window, dyadic-tolerance, and terminal seal reads are supplied through chapter 301, chapter 126, chapter 291, and chapter 38.

Chapter 2457

A Concrete Naming Certificate for $\mathsf{CauchyRealLocator}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRealLocator}^{\uparrow}$ packet records the finite locator surface by which a displayed Cauchy real answers Real-facing precision and side-location requests. It refines the modulus route of chapter 1423 and chapter 292, reads finite observations through chapter 126, uses the regular rational handoff of chapter 301, records dyadic tolerances through chapter 291, and reaches the terminal seal of chapter 38. The packet is a traditional constructive-analysis locator object reconstructed as finite NameCert data; it does not select a host limit, identify quotient streams, invoke countable choice, decide trichotomy, use open-cover compactness, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2457.1 (Cauchy real locator carrier)**.** *A* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule row. It records the displayed RealCauchyModulus and CauchyModulus threshold data used for every locator request.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the locator at the requested precision and side test.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the positive dyadic scale, comparison cells, and slack budget for the displayed windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected windows into regular rational data before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *locator seal. It records only the Real-facing locator boundary delivered after M, S, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the modulus schedule, stream windows, dyadic ledger, regular readback, terminal locator seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a locator request through M, S, D, Q, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$*, RealCauchyModulus, CauchyModulus,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $M, S, D, Q, R, H, C, P, N$. It has no coordinate for host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

Theorem 2457.2 (Cauchy real locator NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier*

$$L = (M, S, D, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the modulus schedule, finite stream windows, dyadic tolerance ledger, regular rational readback, terminal Real locator seal, transport, replay, provenance, and local naming;*
2. *modulus exactness, requiring every locator request to use the displayed row M rather than an independent threshold, host convergence theorem, or selected limit;*
3. *window and tolerance compatibility, requiring the inspected windows in S to be compared only through the dyadic ledger D;*
4. *RegSeqRat readback, requiring the rational data consumed by the locator seal to pass through the displayed row Q;*
5. *route ordering, requiring R to be read only after M, S, D, Q have been displayed;*
6. *nonescape, excluding host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, and bridge checking.*

No local locator obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3410.1. The accepted packet displays exactly the modulus schedule, finite windows, dyadic ledger, regular readback, terminal locator seal, and structural rows.

Modulus exactness is forced by the single coordinate M. Every locator request reads its threshold from this row, so the packet has no second convergence witness, hidden host completeness theorem, or selected limit coordinate.

Window and tolerance compatibility are supplied by S and D. The stream row exposes only finite windows, while the dyadic row records the positive scale, comparison cells, and slack budget used to interpret those windows.

The readback and ordering clauses follow from Q and R. The regular rational row is the only rational readback coordinate, and the terminal Real locator seal occurs downstream of M, S, D, Q.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier inventory contains no row for host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 2457.3 (Cauchy real locator modulus route)**.** *Every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier factors each locator request through the displayed finite route*

$$M \longmapsto S, D \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

Thus the request reaches the $\mathsf{Real}^{\uparrow}$ *locator seal only through the visible modulus schedule, finite stream windows, dyadic tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*

Proof. Begin with an accepted carrier $L = (M, S, D, Q, R, H, C, P, N)$ and a displayed locator request. The only threshold coordinate available to the request is M, so the modulus schedule is read first.

The finite observation step is next. The request opens the window row S and interprets its tolerance through D, whose dyadic ledger records the positive scale and comparison cells.

The rational handoff is then forced through Q. No independent stream or host rational approximation is present in the carrier, so the locator request reaches the Real-facing boundary only after the regular rational readback has been displayed.

Finally the terminal row R is consumed and the structural rows H, C, P, N preserve the same route. This proves the stated factorization and excludes a bypass through selected limits, quotient streams, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. □

Theorem 2457.4 (Cauchy real locator Real seal nonescape)**.** *For an accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier* $L = (M, S, D, Q, R, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *locator-seal read reaches* R *only after the displayed rows* M, S, D, Q *have been consumed. The seal exports no host Real equality, quotient stream representative, selected limit, countable-choice selector, trichotomy branch, open-cover compactness witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Inspect the terminal coordinate of the carrier. The only Real-facing locator seal is R, and it is listed after the modulus schedule, stream-window, dyadic-ledger, and regular-readback rows.

Apply the obligation surface of Definition 3410.2. It requires route ordering through M, S, D, Q before R can be read by a Real-facing consumer.

The structural rows preserve this boundary. The hsame transports and Cont replay keep the same displayed packet, while Pkg provenance and local naming record only that route.

Because no excluded coordinate appears in L, the terminal seal cannot export host Real equality, quotient representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. Any consumer asking for one of those principles must leave the local carrier. □

Theorem 2457.5 (Cauchy real locator four-object exit)**.** *Every accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *Real-facing locator read factors through exactly the four L10 exit objects named by Definition 3412.8: the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *locator seal. In carrier coordinates, any accepted read of* $L = (M, S, D, Q, R, H, C, P, N)$ *uses* S, D, Q, R *as the four object faces and uses* M, H, C, P, N *only as the modulus schedule, transport, replay, provenance, and local naming support. It exports no quotient stream equality, host Real equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier tuple. The row S is the finite $\mathsf{StreamName}^{\uparrow}$ window, D is the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, Q is the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and R is the terminal $\mathsf{Real}^{\uparrow}$ locator seal.

The modulus route theorem Definition 3410.3 fixes the order of consumption. A locator request reads the schedule M, opens the finite windows S, interprets them through the dyadic ledger D, passes through the regular readback Q, and only then reaches R.

The Real-seal nonescape theorem Definition 3410.4 supplies the boundary condition for the terminal read. It rules out every Real-facing bypass that would identify quotient streams, appeal to host Real equality, choose a limit, branch by trichotomy, use open covers, or import ambient completeness.

Finally compare this carrier projection with Definition 3412.8. The four object faces are exactly S, D, Q, R, while M, H, C, P, N supply only schedule, transport, replay, provenance, and naming support. Hence an accepted locator read has the claimed four-object L10 exit route and no additional exported coordinate. □

Theorem 2457.6 (Cauchy real locator induction route)**.** *For an accepted* $\mathsf{CauchyRealLocator}^{\uparrow}$ *carrier* $L = (M, S, D, Q, R, H, C, P, N)$*, every locator-side read available to induction is obtained by the finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

The induction step reads finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal rows without deciding trichotomy and without choosing a host limit.*

Proof. Project the carrier of Definition 3410.1. The modulus schedule M is the only threshold source, so a locator-side induction step begins by reading the same schedule used in the modulus route.

The finite observation is then S interpreted through D. The stream row exposes only bounded windows, while the dyadic row supplies the tolerance scale and comparison cells needed to use those windows.

The rational and Real-facing parts follow through Q and R. The modulus route theorem Definition 3410.3 fixes this order, and the four-object exit theorem Definition 3410.5 identifies S, D, Q, R as the four L10 exit faces.

Finally H, C, P, N preserve the route by transport, replay, provenance, and local naming. Since the carrier has no coordinate for trichotomy or selected host limits, the induction route cannot decide a side by trichotomy or choose a limit outside the displayed locator data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3410.1, Definition 3410.2, Definition 3410.3, Definition 3410.4, Definition 3410.5, and Definition 3410.6 seed the finite locator route over Cauchy modulus schedules, StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, and the Real locator seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Real equality, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, window and tolerance compatibility, RegSeqRat readback, route ordering, nonescape, and local NameCert registration for BEDC.Derived.CauchyRealLocatorUp.

Constructive story: A $\mathsf{CauchyRealLocator}^{\uparrow}$ packet is generated from a RealCauchyModulusUp and CauchyModulusUp schedule row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a terminal RealUp locator seal, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2458

A Concrete Naming Certificate for CauchyRealLocatorPointwiseInduction$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet records the finite-window induction route used by Cauchy real locators. It is a sibling of the locator surface of chapter 3410 and the finite schedule discipline of chapter 126: a pointwise induction step opens one displayed stream window, reads its dyadic tolerance ledger, passes through the regular rational readback of chapter 301, and returns to the same Real-facing locator seal of chapter 38. The packet is not an induction principle over all host streams, a quotient-real equality theorem, a countable-choice selector, or an ambient completeness assertion.

The dependency route is substantive: before the packet exports pointwise locator induction, it consumes the rational interval enclosure surface of chapter 4202 together with the RegSeqRat window handoff of chapter 301. Thus each pointwise branch is read as rational interval enclosure plus regular Cauchy window data, not as a decorative citation to neighboring chapters.

Definition 2458.1 (Cauchy real locator pointwise induction carrier)**.** *A* CauchyRealLocatorPointwiseInduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* CauchyRealLocator$^{\uparrow}$ *row, carrying the locator modulus, finite-window, dyadic, regular-rational, and Real seal data.*
2. *W is the* StreamName$^{\uparrow}$ *pointwise window row selected for the current locator request.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare the pointwise window with the requested side test.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row exposed after the window and dyadic tolerance have been displayed.*
5. *R is the terminal* Real$^{\uparrow}$ *locator seal reached by the pointwise readback.*
6. *B is the finite induction-branch ledger, recording the base window and successor-window handoff over the displayed rows W, D, Q, R.*
7. *H records componentwise* hsame *transport for the locator source, window, dyadic tolerance, regular readback, Real seal, branch ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay for each pointwise induction step.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2458.2 (Cauchy real locator pointwise induction regularity-witness route)**.** *Every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier consumes the finite regularity-witness surface of chapter 1158 before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the pointwise branch first opens the displayed $\mathsf{StreamName}^{\uparrow}$ *window W, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q through the regularity-witness route, and only then reaches the terminal Real locator seal R.*

Proof. Project the carrier. The only rows available before the Real seal are the locator source L, the displayed window W, the dyadic tolerance D, and the regular-rational readback Q.

Now use the sibling regularity-witness surface. Its displayed route supplies the same finite window, tolerance ledger, and RegSeqRat readback before the Real seal handoff, so the pointwise branch can inspect regularity evidence without opening a host stream representative.

Finally read R and the structural rows B, H, C, P, N. These rows record, transport, replay, source, and name the already displayed route, so the pointwise induction packet depends on the regularity witness before it reaches the Real-facing locator seal. □

Theorem 2458.3 (Cauchy real locator pointwise window induction)**.** *For every accepted* CauchyRealLocatorPointwi *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

each pointwise locator step factors through the finite route

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B, H, C, P, N.$$

The base and successor cases of the induction ledger B may inspect only the displayed $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *locator seal supplied by the same* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row.*

Proof. Project the accepted carrier. The source row L is the only Cauchy real locator coordinate, so every pointwise step begins by reading the displayed locator packet of chapter 3410.

The induction window is then opened through W. The dyadic tolerance row D is the only comparison surface attached to that window, and the regular rational readback Q is available only after the window and dyadic rows have been displayed.

The terminal read reaches R and is then recorded by the branch ledger B. The base branch and each successor branch therefore preserve the same finite route rather than selecting a host stream representative.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness, the displayed route exhausts the pointwise induction surface. □

Theorem 2458.4 (Cauchy real locator pointwise induction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *obligations are exactly carrier admission for the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row* L*, pointwise* $\mathsf{StreamName}^{\uparrow}$ *window admission for* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility for* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for* Q*,* $\mathsf{Real}^{\uparrow}$ *locator-seal ordering for* R*, finite base and successor branch admission for* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4225.1. The tuple displays the locator source, pointwise window, dyadic tolerance, regular-rational readback, real seal, branch ledger, and structural rows.

The source and window obligations are read from L and W. The dyadic tolerance row D is the only comparison surface attached to that pointwise window, and the readback row Q can be inspected only after those rows are displayed.

The real-seal ordering obligation is the row R, downstream of Q. The branch ledger B records the finite base and successor handoff over the same displayed rows rather than over a host stream representative.

The rows H, C, P, N transport, replay, source, and name the packet. Since no other coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 2458.5 (Cauchy real locator pointwise window stability)**.** *Let*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier. Replacing the locator source,* $\mathsf{StreamName}^{\uparrow}$ *pointwise window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal by displayed componentwise* hsame *rows, and replaying the replacement through* C*, preserves the admissible pointwise induction route*

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B.$$

Thus the base and successor branches of the finite induction ledger remain attached to the same locator source and cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and use Definition 4225.3. Every pointwise step already factors through the displayed locator source, window, dyadic tolerance, regular-rational readback, real seal, and branch ledger.

The componentwise replacement is recorded by H. It transports the locator source, window, tolerance, readback, seal, branch ledger, replay, provenance, and local name without adding another induction coordinate.

The replay row C then carries the transported rows through the same pointwise route. The branch ledger B therefore continues to read the base window and successor-window handoff over W, D, Q, R.

The carrier has no row for any excluded host or quotient object, so row exhaustion shows that the transported packet preserves exactly the admissible pointwise induction route. □

Theorem 2458.6 (Cauchy real locator pointwise branch exhaustion)**.** *For every accepted* CauchyRealLocatorPointw *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

every base or successor branch read in B is exhausted by the displayed rows $L, W, D, Q, R, H, C, P, N$. Such a branch read cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The branch ledger B is downstream of the locator source L, pointwise window W, dyadic tolerance row D, regular-rational readback Q, and terminal real seal R.

Use pointwise window induction from Definition 4225.3. It forces both the base branch and each successor branch to read the same finite route $L \longmapsto W, D \longmapsto Q \longmapsto R$ before B records the branch.

Use window stability from Definition 4225.5. The transport row H and replay row C preserve that route under displayed componentwise replacement, while P, N only source and name the packet.

Row exhaustion completes the claim. No coordinate of I stores host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so no base or successor branch can export any of those objects. □

Theorem 2458.7 (Cauchy real locator pointwise induction sibling route)**.** *Every accepted* CauchyRealLocatorPointw *read must pass through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38 before the branch ledger is public. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the rows L, W, D, Q, R are exactly that sibling route, and B, H, C, P, N can only record, transport, replay, source, and name the displayed route.

Proof. Project the carrier rows $L, W, D, Q, R, B, H, C, P, N$ from Definition 4225.1. The source row L is read through the Cauchy real locator certificate, while W is the finite StreamName window attached to the current pointwise request.

The dyadic tolerance row D is then consumed through the DyadicRatCore certificate, and Q is the RegSeqRat readback of that displayed window and tolerance data. The terminal row R is the Real-facing locator seal reached after those rows are visible.

Apply Definition 4225.3 and Definition 4225.4. They force the pointwise induction route and the local NameCert obligations to use exactly the rows L, W, D, Q, R before the branch ledger can be inspected.

Finally use Definition 4225.5 and Definition 4225.6. The transport, replay, provenance, and local naming rows preserve the same sibling route and exhaust the branch surface, so the public branch ledger has no alternate dependency edge outside the listed chapters. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4225.1, Definition 4225.3, Definition 4225.4, Definition 4225.5, and Definition 4225.6 seed the finite pointwise induction route over CauchyRealLocator, StreamName, DyadicRatCore, RegSeqRat, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window induction, dyadic tolerance compatibility, RegSeqRat readback, Real seal ordering, and local NameCert registration for BEDC.Derived.CauchyRealLocatorPointwiseInductionUp.

Constructive story: A CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet is generated from a CauchyRealLocator source row, one StreamName pointwise window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp locator seal, a finite induction-branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2459

A Concrete Naming Certificate for $\mathsf{CauchySequenceAlgebra}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ packet records the finite algebra route by which two regular rational Cauchy source rows are added or multiplied before any $\mathsf{Real}^{\uparrow}$ consumer reads the sealed result. It sits between the regular source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic ledger of chapter 291, the addition route of chapter 1695, the product route of chapter 461, and the terminal real-name seal of chapter 38. The packet gives later Real algebra and CauchyRealField consumers one BEDC-native finite dependency for binary Cauchy algebra; it does not import quotient Cauchy classes, host real arithmetic, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2459.1 (CauchySequenceAlgebra carrier)**.** *A* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observations supply the left and right inputs.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite window pairs in which the two source rows are inspected at the same requested tolerance scale.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row. It stores the displayed endpoint arithmetic, slack conversions, tolerance comparisons, addition-budget entries, and product-budget entries used by the accepted binary operation request.*
4. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the summed endpoint row, finite addition ledger, and resulting regular readback.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the product endpoint row, product-error ledger, magnitude-budget entries, and resulting regular readback.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is exposed only after the chosen operation row A or M has displayed its regular readback.*
7. *H records componentwise* hsame *transport for the two source rows, synchronized windows, dyadic budgets, operation rows, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a binary algebra request through $X, Y, W, D, A, M, S, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, A, M, S, H, C, P, N$. The carrier has no coordinate for quotient-stream equality, host real addition or multiplication, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2459.2 (CauchySequenceAlgebra NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier*

$$G = (X, Y, W, D, A, M, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation budgets,* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route,* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *source-window synchronization, requiring every operation request to inspect X and Y through the same displayed window row W before any endpoint arithmetic is read;*
3. *dyadic-budget exactness, requiring every addition or product endpoint row to consume only the displayed tolerance, slack, comparison, and magnitude-budget entries of D;*
4. *operation-route separation, requiring A to carry only the addition route and M to carry only the product route, while both routes consume the same source, window, and dyadic-budget rows;*
5. *Real seal handoff, requiring S to be exposed only after the selected operation route has produced its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
6. *transport and replay stability, requiring H and C to preserve the full route $X, Y, W, D, A, M, S, P, N$ without adding a quotient stream, host operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.*

No CauchySequenceAlgebra NameCert obligation is stored outside these rows.

Proof. Carrier exposure is row projection from Definition 3708.1. The displayed coordinates are exactly the two source rows X, Y, synchronized windows W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Source-window synchronization is forced by the single window coordinate W. Both source reads must pass through that coordinate before the dyadic operation budget is available, so the carrier has no second window service for either input.

Dyadic-budget exactness and operation-route separation are read from D, A, M. The row D supplies the finite arithmetic budgets, the row A consumes those budgets for addition, and the row M consumes those budgets for product. Since A and M are distinct rows with the same upstream inputs, neither route can borrow an unrecorded host operation.

Finally, the Real seal and structural rows close the finite route. The seal S is downstream of the operation readback, while H, C, P, N only transport, replay, package, and name the displayed rows. The excluded quotient, host arithmetic, selected-limit, choice, trichotomy, and ambient-completeness data have no carrier coordinate. □

Theorem 2459.3 (CauchySequenceAlgebra Real-field handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *binary algebra read reaches field-facing data only through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *routes, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In particular the handoff exports regular Cauchy addition and multiplication readbacks before the final Real seal, and it exports no quotient stream, host real arithmetic, selected limit, trichotomy, countable-choice datum, or ambient completeness principle.*

Proof. Project the carrier of Definition 3708.1. The only field-facing source data are the two regular rational Cauchy rows X, Y, the synchronized window W, and the dyadic operation budget D.

Read the operation rows before the final Real seal. The addition route is A, the product route is M, and both routes consume the same source, window, and budget rows named in Definition 3708.2.

The terminal consumer then reads S only after one of those operation routes has produced its $\mathsf{RegSeqRat}^{\uparrow}$ readback. Transport, replay, provenance, and local naming in H, C, P, N preserve that route. Since the carrier has no coordinate for quotient streams, host arithmetic, selected limits, trichotomy, countable choice, or ambient completeness, no Real-field handoff can export any of those objects. □

Theorem 2459.4 (CauchySequenceAlgebra operation route)**.** *Every* $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProdu}$ $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier reads binary algebra data only through the displayed route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N.$$

Consequently the consumer obtains the two regular source rows, synchronized stream windows, dyadic operation budgets, the addition route, the product route, the terminal Real seal handoff, transport, replay, provenance, and local naming, and obtains no quotient Cauchy class, host real operation, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a downstream algebra request. By Definition 3708.1, the only source coordinates are X and Y, and the only synchronized window coordinate available to both sources is W.

The operation budget is then forced through D. Addition reads the route row A, product reads the route row M, and both rows are displayed downstream of the same sources, windows, and dyadic budgets named in Definition 3708.2.

The Real-facing handoff is last. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyRealField}^{\uparrow}$ consumer can read the seal S only after an operation route has produced its regular readback, and the rows H, C, P, N preserve that same finite route. No coordinate remains from which a quotient Cauchy class, host operation, selected limit, countable choice, trichotomy, or ambient completeness principle could be exported. □

Theorem 2459.5 (CauchySequenceAlgebra route non-escape)**.** *Let* $G = (X, Y, W, D, A, M, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier. Any algebraic fact exported from* G *is a rowwise consequence of the displayed regular source rows, synchronized windows, dyadic operation budgets, operation routes, Real seal, transport, replay, provenance, and local naming rows. It is not a quotient Cauchy class, host real addition, host real multiplication, selected limit, countable-choice datum, trichotomy datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The data-bearing coordinates are exactly X, Y, W, D, A, M, S, and the structural coordinates are exactly H, C, P, N.

An exported addition fact must use A after the source, window, and dyadic-budget rows have been displayed. An exported product fact must use M after the same upstream rows have been displayed. A Real-facing algebra fact must then pass through the seal row S.

The structural rows preserve only that route. Componentwise hsame transport and displayed Cont replay cannot create a host operation or a quotient relation, while provenance and local naming record only the finite packet. Thus every exported algebraic fact is confined to the listed rows, and each excluded principle has no entry point. □

Theorem 2459.6 (CauchySequenceAlgebra remainder-estimate handoff)**.** *Let*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

be an accepted CauchySequenceAlgebra$^{\uparrow}$ *carrier. Any downstream* CauchyRemainderEstimate$^{\uparrow}$ *read for an addition or product result factors first through the same finite binary-algebra route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N$$

and then through the finite tail-estimate rows of chapter 3991. The handoff exports the displayed source rows, synchronized windows, dyadic operation budgets, selected addition or product route, terminal Real seal, transport, replay, provenance, local naming, finite tail threshold, admitted tail windows, regular readback, and tail-diameter boundary rows. It exports no quotient Cauchy class, host real operation, selected limit, countable-choice datum, trichotomy datum, or ambient Real$^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier G. By Definition 3708.2, every binary algebra read exposes only the source rows X, Y, synchronized window W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Apply Definition 3708.4 to the downstream addition or product request. The result route must pass through A for addition or M for product, and in either case it uses the same upstream X, Y, W, D rows before reaching the seal S.

Now apply Definition 3708.5. No part of that binary-algebra route can introduce a quotient Cauchy class, host real operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.

The remainder-estimate consumer therefore begins from the regular readback already displayed by the operation route and then uses the sibling surface chapter 3991. That surface supplies the finite threshold, admitted tail windows, regular readback, tail-diameter boundary, transport, replay, provenance, and local naming rows for CauchyRemainderEstimate$^{\uparrow}$. Composing these two finite routes gives the stated handoff and leaves every excluded principle without a carrier coordinate. □

Closure status for NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 3708.1, Definition 3708.2, Definition 3708.3, Definition 3708.4, Definition 3708.5, and Definition 3708.6 seed the finite binary algebra route over RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, CauchyRemainderEstimate$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, host real operations, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-window synchronization, dyadic-budget exactness, operation-route separation, Real seal handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchySequenceAlgebraUp.

Constructive story: A CauchySequenceAlgebra$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, synchronized StreamName$^{\uparrow}$ windows, one DyadicRatCore$^{\uparrow}$ operation-budget ledger, RegularCauchyAddition$^{\uparrow}$ and RegularCauchyProduct$^{\uparrow}$ route rows, a Real$^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The Cauchy$^{\uparrow}$ gateway reads its completion-facing source through chapter 126, chapter 301, chapter 291, and chapter 38 before any terminal seal is public.

Theorem 2459.7 (Cauchy L10 sibling route)**.** *The Cauchy packet family exported by this hub is consumed through the L10 route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}.$$

Concretely, the finite-window surface of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the completion boundary of chapter 1506 are sibling inputs to the Cauchy carriers rather than hidden ambient structure.

Proof. Read any Cauchy carrier exported by the hub through its finite observation rows. The stream coordinate supplies the inspected windows, the regular-rational coordinate supplies the numerical readback, and the dyadic coordinate supplies the tolerance budget.

The Real-facing seal is reached only after those rows have been displayed. When a completion consumer is present, it receives the same displayed route through the metric-completion boundary.

Thus the hub's Cauchy packet family is attached to the Real and MetricCompletion siblings by visible L10 rows, with no quotient representative, selected limit, countable-choice schedule, host real equality, or ambient completeness coordinate added by the route. □

The Cauchy$^{\uparrow}$ route consumes the L10 sibling chapters before the real locator and sequence algebra inputs are read. In particular, the regular-rational source of chapter 301, the finite stream windows of chapter 126, and the terminal seal of chapter 38 are already part of the displayed dependency spine for every downstream Cauchy locator or algebra consumer. The completion-side consumer in chapter 1937 reads the same RegSeqRat, StreamName, and RealUp spine before exposing its functorial completion route.

Theorem 2459.8 (Cauchy L10 four-object seal route)**.** *Every accepted* Cauchy$^{\uparrow}$ *Real-facing seal route used by the current L10 phase factors through the four displayed sibling faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Concretely, the finite window family of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38 are the only Real-facing sibling rows exported by the route. The supporting rows are the displayed BHist *carrier data, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *registration.*

Proof. Read the route through the existing CauchyRealLocator carrier and its Real-seal nonescape theorem. The carrier exposes a finite StreamName window row, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, and a terminal RealUp locator seal before any Real-facing consumer can read the packet.

Project those four named faces. The StreamName row supplies only inspected finite windows, the DyadicRatCore row supplies the tolerance and comparison budget, the RegSeqRat row supplies the rational readback, and the RealUp row supplies the terminal seal.

The structural rows preserve this factorization. The BHist data name the carried packet, hsame transports the displayed coordinates, Cont replays the same route, Pkg records provenance, and NameCert records the local accepted surface.

Since the carrier has no coordinate for quotient streams, host equality, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported by the Cauchy Real-facing seal route. □

Chapter 2460

A Concrete Naming Certificate for $\mathsf{Cauchy}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{Cauchy}^{\uparrow}$ packet records the ordinary constructive Cauchy-real carrier as finite BEDC naming data. It sits above the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational sequence surface of chapter 301, and the terminal seal of chapter 38. The packet is not a quotient construction of reals; it is a finite route by which a modulus, rational readback, transport, replay, provenance, and local naming row become visible before any $\mathsf{Real}^{\uparrow}$ consumer can read the Cauchy object.

Definition 2460.1 (Cauchy carrier)**.** *A* $\mathsf{Cauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, recording the finite windows of rational approximants inspected by the carrier.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the positive dyadic scale, comparison cells, and slack conversions used to interpret each requested window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence row, exposing the rational readback consumed downstream.*
4. *M is the modulus row, recording the displayed threshold assignment used by Cauchy requests and refusing any hidden convergence theorem.*
5. *Q is the modulus/readback compatibility row, requiring the stream window, dyadic tolerance, regular rational sequence, and modulus rows to agree at every displayed precision request.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, exposed only after S, D, R, M, Q have been displayed.*
7. *H records componentwise* hsame *transport for the stream, dyadic, regular-sequence, modulus, compatibility, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Cauchy request through $S, D, R, M, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $S, D, R, M, Q, E, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyUp.CauchyCarrier`

Theorem 2460.2 (Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *carrier*

$$X = (S, D, R, M, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window stability, dyadic tolerance exactness, regular-rational readback, displayed modulus admission, modulus/readback compatibility,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 3413.1.*

Proof. Carrier admission is projection from Definition 3413.1. The accepted packet displays precisely the stream, dyadic, regular-sequence, modulus, compatibility, seal, transport, replay, provenance, and local naming rows.

The stability and exactness obligations are rowwise. The stream row supplies only finite windows, the dyadic row supplies only displayed tolerance cells, the regular-sequence row supplies only rational readback, and the modulus row supplies only the visible threshold assignment.

The compatibility row Q binds these four data rows before any $\mathsf{Real}^{\uparrow}$ seal can be consumed. The structural rows H, C, P, N then transport, replay, source, and name the same route without adding quotient equality, selected limits, host real equality, choice, trichotomy, compactness, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCarrier namecert obligations`

Theorem 2460.3 (Cauchy modulus readback route)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *consumer route factors through the displayed path*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus a precision request reads finite $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the explicit modulus row, the compatibility row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the* $\mathsf{Real}^{\uparrow}$ *seal-facing boundary.*

Proof. Begin with an accepted carrier $X = (S, D, R, M, Q, E, H, C, P, N)$ and a displayed precision request. The only finite observations available to the request are the windows in S, and their tolerance scale is read through D.

The request next reads the explicit modulus row M. The compatibility row Q is the only coordinate that relates the chosen window, tolerance, threshold, and regular-rational readback, so the route cannot bypass it.

After Q is displayed, the consumer may read the $\mathsf{RegSeqRat}^{\uparrow}$ row R and then the terminal $\mathsf{Real}^{\uparrow}$ seal-facing row E. The rows H, C, P, N preserve this same route under transport, replay, provenance, and local naming.

Since the carrier has no quotient, selected-limit, host equality, countable-choice, trichotomy, open-cover, or ambient-completeness coordinate, the displayed route is the whole public Cauchy readback surface. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusReadbackRoute`

Theorem 2460.4 (Cauchy StreamName RegSeqRat window)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet exposes its* $\mathsf{RegSeqRat}^{\uparrow}$ *row only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and modulus/readback compatibility row. Thus a regular rational read of* $X = (S, D, R, M, Q, E, H, C, P, N)$ *must factor through* S, D, M, Q *before it can inspect* R*.*

Proof. Project the carrier of Definition 3413.1. The row S is the only finite observation surface, D is the only displayed tolerance surface, and M is the only modulus row available to the packet.

Apply Definition 3413.2 to identify Q as the compatibility row binding stream windows, dyadic tolerances, regular rational readback, and modulus data. Then apply Definition 3413.3: the displayed route reads S, D, M and Q before R.

The carrier has no quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient completeness coordinate. Hence the stated window and compatibility rows exhaust the public access path to $\mathsf{RegSeqRat}^{\uparrow}$. □

Theorem 2460.5 (Cauchy finite-tail criterion)**.** *Let*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

be an accepted $\mathsf{Cauchy}^{\uparrow}$ *carrier. Suppose every displayed finite* $\mathsf{StreamName}^{\uparrow}$ *window admitted by* S *and every dyadic tolerance cell admitted by* D *satisfy the tail bound named by the modulus row* M*, and suppose the compatibility row* Q *identifies those windows with the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*. Then every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of* X *is routed through the same finite tail ledger*

$$S, D, M \longmapsto Q \longmapsto R$$

before the $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed. The criterion exports no selected limit, quotient stream equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3413.1. The only rows available for a tail read are the finite StreamName window row S, the DyadicRatCore tolerance row D, the modulus row M, the compatibility row Q, the RegSeqRat readback row R, and the terminal seal row E.

Induct over the displayed window list retained by S. The empty window has no readback outside the recorded tolerance ledger. In the successor step, the new inspected position is checked against the dyadic cell in D and the threshold supplied by M, so the same finite tail bound remains attached to the extended window.

Apply Definition 3413.4. It forces any access to R through the displayed S, D, M, Q route. Apply Definition 3413.3 to identify Q as the point where the window, tolerance, modulus, and readback rows are jointly inspected.

Finally use Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal E is downstream of the regular rational readback, so no Real-facing consumer can bypass the finite tail ledger. Since the carrier has no selected-limit, quotient-stream, countable-choice, trichotomy, or ambient-completeness coordinate, the displayed finite induction exhausts the criterion. □

Definition 2460.6 (Cauchy finite-window modulus carrier)**.** *The finite-window modulus carrier associated to an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet is the displayed handoff surface*

$$W = (S, D, M, Q, R, E, H, C, P, N)$$

read from the carrier of Definition 3413.1. Its rows have the following roles:

1. *S records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by a tail request.*

2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cells and slack conversions attached to those windows.*
3. *M records the explicit modulus threshold row used to accept later-window requests.*
4. *Q records the compatibility row tying each displayed window, dyadic tolerance, modulus threshold, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*
5. *R records the regular-rational readback exposed only after S, D, M, Q have been displayed.*
6. *E records the downstream* $\mathsf{Real}^{\uparrow}$ *seal-facing row.*
7. *H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *naming for the same finite route.*

The carrier admits only these displayed coordinates. It has no coordinate for quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2460.7 (Cauchy finite-window tail induction)**.** *Let $W = (S, D, M, Q, R, E, H, C, P, N)$ be the finite-window modulus carrier of Definition 3413.6. Every accepted tail request obtained by extending the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row preserves the dyadic tolerance row D, the modulus threshold row M, the compatibility row Q, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed. Thus the induction route is*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E$$

with H, C, P, N transporting, replaying, sourcing, and naming the same displayed handoff.

Proof. Project the underlying accepted Cauchy carrier through Definition 3413.1 and read it in the window/modulus order specified by Definition 3413.6. The only tail-request rows available are $S, D, M, Q, R, E, H, C, P, N$.

Induct over the displayed $\mathsf{StreamName}^{\uparrow}$ windows retained by S. The empty window has no tolerance request outside D and no readback outside the route named by Definition 3413.4.

For the successor step, the new inspected window is accepted only through the dyadic cell in D and the threshold supplied by M. Apply Definition 3413.5 to keep the same finite tail ledger attached to the extended request.

The compatibility row Q is then the unique displayed row where the window, dyadic tolerance, modulus threshold, and regular readback are jointly inspected. Apply Definition 3413.3 to place R after Q and E after R.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. Since none of the rows supplies quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the induction cannot expose any such principle. □

Theorem 2460.8 (Cauchy RegSeqRat handoff obligation)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet must factor through the finite-window modulus carrier of Definition 3413.6 and the tail-induction route of Definition 3413.7. In particular, the consumer reads S, D, M, Q before R, and any Real-facing use reads E only after that* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Begin with an accepted Cauchy packet and project its rows by Definition 3413.1. The carrier supplies finite stream windows, dyadic tolerances, a modulus row, a compatibility row, regular-rational readback, a terminal Real-facing seal, and structural transport, replay, provenance, and naming rows.

Apply Definition 3413.4. It forces access to the $\mathsf{RegSeqRat}^{\uparrow}$ row through the displayed S, D, M, Q route, so no consumer can inspect R independently of the finite window and tolerance data.

Next apply Definition 3413.5 and Definition 3413.7. These identify the finite tail ledger and show that accepted extensions preserve the dyadic tolerance, modulus threshold, compatibility, and regular readback rows before the Real seal is exposed.

Finally use Definition 3413.3. The structural rows H, C, P, N transport and name the same handoff, while the carrier contains no quotient-stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every $\mathsf{RegSeqRat}^{\uparrow}$ consumer factors through the stated finite-window induction surface. □

Theorem 2460.9 (Cauchy RegSeqRat Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the terminal real seal. In the notation of Definition 3413.1, the seal-facing route is*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

It does not expose quotient streams, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project $X = (S, D, R, M, Q, E, H, C, P, N)$ from Definition 3413.1. The seal row E is declared terminal and seal-facing; it is not an independent source of Cauchy data.

Use Definition 3413.3 to order the displayed read. The route reaches R after S, D, M, Q and reaches E only after R has been displayed.

Finally apply Definition 3413.2. The rows H, C, P, N transport, replay, source, and name the same route, so they cannot insert quotient representatives, selected limits, host equality, countable choice, trichotomy, or ambient completeness between $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. □

Theorem 2460.10 (Cauchy modulus transport stability)**.** *Let*

$$X = (S, D, R, M, Q, E, H, C, P, N)$$

and

$$X' = (S', D', R', M', Q', E', H', C', P', N')$$

be accepted $\mathsf{Cauchy}^{\uparrow}$ *packets. Suppose the stream row, dyadic tolerance row, modulus row, modulus/readback compatibility row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, replay row, provenance row, and local naming row are transported componentwise by the displayed* hsame *data in* H *and* H'*, and suppose both packets are replayed through the same displayed* Cont *route. Then the public Cauchy readback route*

$$S, D, M \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

is the same BEDC route as

$$S', D', M' \longmapsto Q' \longmapsto R' \longmapsto E' \longmapsto H', C', P', N'.$$

In particular, componentwise transport of the modulus/readback surface cannot introduce quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, or ambient completeness.

Proof. Project both accepted packets through Definition 3413.1. The only visible coordinates are the stream, dyadic tolerance, regular-rational readback, modulus, compatibility, seal, transport, replay, provenance, and local naming rows.

Apply Definition 3413.3 to X and to X'. The two projected routes must read their displayed stream, dyadic, and modulus rows before their compatibility rows, and the shared Cont replay identifies these reads through the componentwise hsame data.

Next use Definition 3413.4. Access to R and R' is forced through the transported S, D, M, Q and S', D', M', Q' rows, so no other regular-rational readback path is available.

Finally apply Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal remains downstream of the transported $\mathsf{RegSeqRat}^{\uparrow}$ rows, and the structural rows H, C, P, N and H', C', P', N' only transport, replay, source, and name that path. Since neither carrier contains quotient streams, selected limits, host equality, choice, trichotomy, or ambient completeness, the two displays name the same BEDC route. □

Theorem 2460.11 (Cauchy uniform-modulus Real seal)**.** *For an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet*

$$X = (S, D, R, M, Q, E, H, C, P, N),$$

any uniform-modulus consumer of the explicit modulus row M *that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must read* S, D, M, Q *before* R*, and* R *before* E*. The route contains no quotient stream equality, selected limit, countable choice, trichotomy, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet through Definition 3413.1. The explicit modulus row M is packaged with the finite stream window S, the dyadic tolerance row D, the compatibility row Q, the regular rational readback R, and the terminal seal-facing row E.

Apply Definition 3413.3. It forces a precision request to read S, D, M and then Q before any regular-rational row can be inspected.

Next apply Definition 3413.9. The $\mathsf{Real}^{\uparrow}$ seal row E is downstream of R, so a uniform-modulus consumer cannot reach the seal before the regular rational readback has been displayed.

Finally use Definition 3413.10. Componentwise transport and the displayed Cont replay preserve the same route for every accepted consumer, and the carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, metric-completeness data, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 2460.12 (Cauchy root filter-completion anchor)**.** *Every Cauchy root consumer that first reaches the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *surface of chapter 1569 must already have read the Cauchy core route, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route remains inside componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

Proof. Project the root hub through its Cauchy core child. The core route exposes the stream-window, tolerance, readback, transport, replay, provenance, and naming rows before any completion-facing consumer can inspect the root packet.

Now read the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ chapter. Its completion handoff consumes the same finite windows and regular rational readback before the terminal Real seal is visible, so the root consumer cannot enter through a detached filter object.

The structural rows preserve the path. Componentwise hsame transport and displayed Cont replay keep the consumer inside the Cauchy root packet, while Pkg provenance and the local $\mathsf{NameCert}$ row record that no quotient filter, selected limit, countable-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is exported. □

Theorem 2460.13 (Cauchy L10 child dependency route)**.** *Every finite-window read exported by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by sibling L10 chapters only after it passes through the child routes displayed in this chapter. The regular-rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-facing route of chapter 1569 read the* $\mathsf{Cauchy}^{\uparrow}$ *packet through finite stream windows, dyadic tolerance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. No child route exports quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the hub through its child files. The core carrier in chapter 3413 displays the stream-window, dyadic tolerance, regular readback, transport, replay, provenance, and naming rows before any downstream consumer can inspect a Cauchy object.

The sibling dependency spine then sends those rows to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The cited regular-rational and Real chapters consume only the displayed finite route; they do not receive a quotient stream, selected limit, choice schedule, trichotomy oracle, host equality coordinate, or ambient completeness proof.

The completion-facing consumer follows the same rows through the Cauchy-filter completion surface. Because the hub contains only child inputs and each child route exposes finite BHist and NameCert data, the L10 dependency path is connected through sibling chapters rather than through an unstated top-level object. □

Theorem 2460.14 (Cauchy RegSeqRat and completion forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *finite-window packet consumed by* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *factors through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The route exports no quotient streams, selected limits, choice schedules, host equality, or ambient completeness.*

Proof. Start with the child dependency route above. It already displays the finite stream-window, dyadic tolerance, regular readback, Real-seal, transport, replay, provenance, and naming rows before any L10 consumer reads a Cauchy packet.

The regular rational and Real consumers are the first forward users. The chapters chapter 301 and chapter 38 read only the displayed finite windows, readback rows, tolerance rows, and terminal seal.

The completion consumer reads the same route through chapter 1506. A metric-completion request can inspect Cauchy data only after the finite windows, tolerances, readbacks, Real seal, transport, replay, provenance, and local naming rows have been displayed.

The excluded objects have no row in this finite route. Thus quotient streams, selected limits, choice schedules, host equality, and ambient completeness cannot be exported by the forward handoff. □

The L10 route consumes $\mathsf{Cauchy}^{\uparrow}$ through the finite-window surface of chapter 126, the regular readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal seal rows of chapter 38. These four child dependencies keep the Cauchy packet attached to finite stream windows, regular rational evidence, dyadic budgets, and the Real seal before any L10 consumer may read it.

Every $\mathsf{Cauchy}^{\uparrow}$ read used by Real and completion consumers factors through the same horizontal lattice: finite observation windows from chapter 126, regular-rational readback from chapter 301, dyadic tolerance rows from chapter 291, and the terminal seal of chapter 38. Downstream

consumers therefore receive a displayed finite-window route before they may treat the packet as Real-facing Cauchy data.

Theorem 2460.15 (Cauchy finite-window modulus pullback)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *modulus read pulls back to the same finite* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row of chapter 291, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any consumer can inspect a Cauchy value. In the notation of Definition 3413.1, the pullback route is*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

No quotient stream equality, selected limit, host real equality, countable-choice coordinate, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row is available along this route.*

Proof. Project the accepted carrier through Definition 3413.1. The finite stream window S, dyadic tolerance row D, modulus row M, compatibility row Q, regular-rational readback R, and terminal Real seal E are the only rows available before the structural rows are read.

Apply Definition 3413.2. It identifies the local $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ surface with stream-window stability, dyadic tolerance exactness, regular-rational readback, displayed modulus admission, modulus/readback compatibility, Real seal ordering, transport, replay, provenance, and local naming.

Now use Definition 3413.3. A precision request first reads S, D, M, Q, then reaches R, and only then reaches E. The route is sharpened by Definition 3413.4, which keeps the $\mathsf{RegSeqRat}^{\uparrow}$ row behind the displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, modulus, and compatibility rows.

Finally apply Definition 3413.9. The terminal Real seal is reached only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback has been displayed. Thus every accepted modulus read pulls back to the same four L10 sibling rows before a consumer sees a Cauchy value, and none of the excluded quotient, selected-limit, choice, order, compactness, or completeness coordinates can be inserted. □

Theorem 2460.16 (Regular-Cauchy modulus pullback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of the* $\mathsf{Cauchy}^{\uparrow}$ *finite-window modulus route obtains a dyadic tolerance schedule that is cofinal with the route displayed in Definition 3413.15. In the notation of Definition 3413.1, the consumer may read*

$$S, D, M, Q \longmapsto R \longmapsto E$$

only as a regular-rational handoff: the $\mathsf{Real}^{\uparrow}$ *seal is reached after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, not before it. The route exports no quotient stream equality, selected limit, host real equality, choice principle, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 3413.15. It fixes the finite route from the StreamName window S, dyadic tolerance row D, modulus row M, and compatibility row Q into the regular-rational readback R, and only then into the terminal Real seal E.

Project the route at the $\mathsf{RegSeqRat}^{\uparrow}$ boundary. A RegSeqRat-facing consumer reads the dyadic tolerance row D through the same finite windows S and compatibility row Q, so its tolerance requests are bounded by a cofinal schedule already displayed by the Cauchy modulus route.

Transport the schedule through the regular-rational classifier row. The readback row R is the first row that presents the schedule as regular-rational data, and the Real seal E is reachable only after that readback has been displayed.

Thus the pullback is cofinal at the RegSeqRat surface and terminal at the Real seal. Since the carrier has no coordinate for quotient stream equality, selected limits, host equality, choice,

trichotomy, or Real completeness, none of those principles can be inserted into the consumer route. □

Theorem 2460.17 (Cauchy finite-window pullback uniqueness)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing Cauchy modulus consumer accepted by the* $\mathsf{Cauchy}^{\uparrow}$ *packet must factor through the same finite route*

$$S, D, M, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

displayed in Definition 3413.15. The consumer cannot replace this route by quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3413.1. The only rows visible to a modulus consumer are the finite StreamName window, dyadic tolerance ledger, modulus row, compatibility row, RegSeqRat readback, Real seal, and the structural rows.

Apply Definition 3413.2. It identifies the local NameCert surface with precisely those rows, so there is no second carrier coordinate from which an alternative Real-facing route could be read.

Use Definition 3413.3. A precision request reaches R only after S, D, M, Q have been displayed, and it reaches the terminal seal E only after the regular-rational readback has been displayed.

Finally apply Definition 3413.15 and Definition 3413.16. The first theorem fixes the finite pullback route to the L10 sibling rows, while the second shows that every RegSeqRat-facing consumer receives the same cofinal handoff. Hence any Real-facing Cauchy modulus consumer factors through the displayed route and gains no quotient, selected-limit, choice, host-equality, or completeness coordinate. □

Every completion-facing consumer of the $\mathsf{Cauchy}^{\uparrow}$ hub reads the finite Cauchy packet through chapter 301 and chapter 38 before any Real seal is exposed to completion rows. The route first displays the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the dyadic tolerance ledger, then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal, and only then lets Cauchy completion consumers inspect the same BHist, hsame, Cont, Pkg, and local NameCert rows. Thus the hub records a structural dependency route, not quotient stream equality, selected limits, countable choice, host real equality, or ambient Real completeness.

Theorem 2460.18 (Cauchy RegSeqRat Real forward dependency)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *source-window read consumed by a Real-facing downstream chapter must pass through the regular rational readback of chapter 301 and the terminal real-name seal of chapter 38 before any* $\mathsf{Real}^{\uparrow}$*-facing seal is exposed. The route reads only displayed finite windows, regular rational tail data, componentwise transport, replay, provenance, and local naming; it exports no selected limit, quotient stream equality, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Cauchy carrier route in Definition 3413.1. Its source-window reads are displayed before the regular rational readback and terminal real seal rows are available.

Use the regular readback and real-seal routes already named by the Cauchy child files. They order downstream consumption through $\mathsf{RegSeqRat}^{\uparrow}$ and then $\mathsf{Real}^{\uparrow}$, with the structural rows transporting and naming the same finite windows.

Since the hub exposes only child-file surfaces and no independent carrier coordinate, a Real-facing consumer can cite $\mathsf{Cauchy}^{\uparrow}$ only through that forward dependency route. The read therefore reaches chapter 301 and chapter 38 before any Real-facing seal is exposed. □

Theorem 2460.19 (Cauchy located-uniform filter forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *route whose explicit modulus row is consumed by a located or uniform Cauchy filter completion must pass through the displayed carrier route*

$$S, D, M, Q, R, E, H, C, P, N$$

of Definition 3413.1, then through chapter 1661 or chapter 1694, before any $\mathsf{Real}^{\uparrow}$ *seal-facing completion row is exported. The forward route has no quotient stream equality, selected limit, countable choice, metric-completeness datum, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host equality.*

Proof. Start with the explicit modulus readback of the Cauchy carrier. By Definition 3413.3, a precision request reads the finite StreamName row S, the DyadicRatCore row D, the explicit modulus row M, and the compatibility row Q before it can inspect the regular rational row R.

Apply Definition 3413.9. The seal-facing row E is downstream of R, so a Real-facing completion consumer cannot bypass the regular rational readback.

Now use Definition 3413.11. Any uniform-modulus consumer of M that reaches a $\mathsf{Real}^{\uparrow}$ seal preserves the same ordering S, D, M, Q before R and R before E.

The remaining completion-neighbour branch is supplied only by the sibling chapters chapter 1661 and chapter 1694. These chapters consume the already displayed Cauchy route as located or uniform filter evidence; neither adds quotient stream equality, selected limits, choice, metric-completeness data, ambient completeness, or host equality to the core Cauchy carrier. □

Theorem 2460.20 (Cauchy route to CauchyCriterion)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *hub's finite route is consumed by chapter 392 through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The route exports no detached completion carrier, quotient sequence equality, selected modulus outside the displayed rows, countable-choice schedule, or host completeness principle.*

Proof. Read the hub through its existing finite siblings. The $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows provide the only Cauchy data visible to downstream criteria.

The structural rows hsame, Cont, Pkg, and NameCert transport, replay, source, and name that same finite route. Therefore the Cauchy criterion consumer receives exactly the displayed BEDC rows and no external completion or choice object. □

Theorem 2460.21 (Cauchy hub Bishop completion forward route)**.** *The regular-source material routed by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by chapter 1639 through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The forward route exports no detached Cauchy representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness principle.*

Proof. Read the Cauchy hub through its regular-source children. Those children expose dyadic tolerance arithmetic, finite stream windows, regular rational readback, and the terminal real seal as $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

The Bishop regular Cauchy completion chapter consumes exactly that L10-facing route. Its completion read is mediated by the same finite BHist carrier discipline, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Since the hub route contains no detached representative, quotient stream equality, selected limit, countable-choice schedule, or ambient real completeness coordinate, the forward edge to the Bishop completion packet is precisely the displayed finite dependency route. □

Chapter 2461

A Concrete Naming Certificate for $\mathsf{FiniteSimplicialChain}^{\uparrow}$

Following Eilenberg–Steenrod and the standard finite presentation of simplicial homology, the $\mathsf{FiniteSimplicialChain}^{\uparrow}$ packet records the BEDC route from a finite $\mathsf{SimplicialComplex}^{\uparrow}$ carrier to the chain groups and boundary rows consumed by $\mathsf{Homology}^{\uparrow}$. It sits over the simplex inventory of chapter 238, the finite enumeration surface of chapter 112, and the additive carrier rows of chapter 42; it supplies $\mathsf{Homology}^{\uparrow}$ and $\mathsf{PersistentHom}^{\uparrow}$ with a displayed finite chain-complex source rather than an implicit classical complex.

Definition 2461.1 (Finite simplicial chain carrier)**.** *A* $\mathsf{FiniteSimplicialChain}^{\uparrow}$ *carrier over a finite* $\mathsf{SimplicialComplex}^{\uparrow}$ *packet is a finite* BHist *tuple*

$$C = (K, F, A, G, B, Z, H, T, P, N)$$

with the following displayed rows:

1. *K is the source* $\mathsf{SimplicialComplex}^{\uparrow}$ *row, including the finite simplex inventory, face relation, and dimension grading.*
2. *F is the* $\mathsf{FinSet}^{\uparrow}$ *enumeration row for oriented simplex generators in each displayed dimension.*
3. *A is the* $\mathsf{AbGroup}^{\uparrow}$ *row for finite integer combinations of oriented simplex generators, with addition and inverse read componentwise.*
4. *G is the grading row assigning each chain generator to its simplex dimension.*
5. *B is the boundary ledger sending an oriented n-simplex to the alternating finite face sum in dimension $n-1$.*
6. *Z is the square-zero cancellation ledger, pairing each codimension-two face occurrence with the opposite occurrence obtained by deleting the two vertices in the other order.*
7. *H records componentwise* hsame *transport for simplex inventories, generator enumerations, additive rows, grading rows, boundary rows, cancellation rows, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from K, F, A, G, B, Z, H to the chain-complex source read by* $\mathsf{Homology}^{\uparrow}$*.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteSimplicialChain}^{\uparrow}$*,* $\mathsf{SimplicialComplex}^{\uparrow}$*,* $\mathsf{FinSet}^{\uparrow}$*,* $\mathsf{AbGroup}^{\uparrow}$*,* $\mathsf{Homology}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteSimplicialChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite chain module, a host quotient group, a selected orientation convention outside F, an ambient topological realization, or a homology computation not routed through B and Z.

Lean4 ✓ `BEDC.Derived.FiniteSimplicialChainUp.TasteGate.FiniteSimplicialChainTasteGate single carrier alignment`

Theorem 2461.2 (Finite simplicial chain boundary square-zero)**.** *For every accepted* $\mathsf{FiniteSimplicialChain}^{\uparrow}$ *carrier $C = (K, F, A, G, B, Z, H, T, P, N)$, the displayed boundary row B composes with itself to the zero row of the* $\mathsf{AbGroup}^{\uparrow}$ *chain carrier. Equivalently, every* $\mathsf{Homology}^{\uparrow}$ *consumer receives a chain-complex source whose boundary-square obstruction is discharged by the finite cancellation ledger Z before cycles and boundaries are compared.*

Proof. Project the carrier of Definition 3414.1. The simplex source K and finite generator enumeration F make every boundary expansion a finite face list, and the additive row A is the only group operation available for collecting those face terms.

Apply the boundary ledger B once to an oriented simplex. The result is the alternating sum of its displayed codimension-one faces. Applying B again expands each face into codimension-two faces, still inside the finite enumeration supplied by F.

The cancellation ledger Z pairs the term obtained by deleting vertex i and then vertex j with the term obtained by deleting j and then i. The two terms have the same codimension-two face row under hsame and opposite signs in the $\mathsf{AbGroup}^{\uparrow}$ carrier, so they add to the zero row.

Since all codimension-two occurrences are exhausted by these pairs, the second boundary has no unpaired summand. The continuation, provenance, and local naming rows T, P, N repack the same finite cancellation into the $\mathsf{Homology}^{\uparrow}$ source surface, so no host chain module or external quotient argument is used. □

Falsifiable prediction: A $\mathsf{Homology}^{\uparrow}$ or $\mathsf{PersistentHom}^{\uparrow}$ consumer using $\mathsf{FiniteSimplicialChain}^{\uparrow}$ must display the source $\mathsf{SimplicialComplex}^{\uparrow}$ row, finite generator enumeration, additive chain carrier, boundary ledger, square-zero cancellation ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: simplicialcomplex, finset, abgroup, homology: $\mathsf{FiniteSimplicialChain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries simplex inventory, oriented generator enumeration, additive chain rows, boundary rows, square-zero cancellation, Homology-facing replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSimplicialChain}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSimplicialChain}^{\uparrow}$ packet is generated from a finite SimplicialComplex row, FinSet generator enumeration, AbGroup additive chain rows, grading, a finite alternating boundary ledger, codimension-two cancellation pairs, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteSimplicialChain}^{\uparrow}}$, seed)

Scope closed: Definition 3414.1 and Definition 3414.2 seed the finite simplicial chain carrier and its square-zero boundary route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteSimplicialChain}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.FiniteSimplicialChainUp.TasteGate.FiniteSimplicialChainTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close singular chains, infinite chain complexes, host quotient homology, selected geometric realization, or bridge checking.

Upgrade path: Obligation closure requires finite generator enumeration, additive chain stability, boundary exactness, square-zero cancellation, Homology handoff, replay stability, provenance exhaustion, and local naming for BEDC.Derived.FiniteSimplicialChainU

Chapter 2462

A Concrete Naming Certificate for $\mathsf{RealModulusCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealModulusCriterion}^{\uparrow}$ packet records the finite criterion by which an explicit Cauchy modulus makes a regular rational stream ready for a $\mathsf{Real}^{\uparrow}$ convergence read. It sits between the convergence schedule of chapter 1438, the sequence-limit consumer of chapter 1413, the regular rational names of chapter 301, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the real-name seal of chapter 38.

Definition 2462.1 (Real modulus criterion carrier)**.** *A* $\mathsf{RealModulusCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, S, Q, W, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. M *is the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *row naming the explicit tail schedule.*
2. S *is the sequence-source row inspected by the modulus.*
3. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback exposed by the scheduled tails.*
4. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family used to read each tail comparison.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the modulus requests.*
6. L *is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *consumer row reached only after* M, S, Q, W, D *have been displayed.*
7. E *is the* $\mathsf{Real}^{\uparrow}$ *convergence-readiness seal exported to real-name consumers.*
8. H *records componentwise* hsame *transport for the analytic rows and the structural rows.*
9. C *records displayed* Cont *replay from the tolerance request through the modulus, windows, regular readback, sequence-limit consumer, and real seal.*
10. P *is the* Pkg *provenance over* $\mathsf{RealModulusCriterion}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. N *is the local* $\mathsf{NameCert}_{\mathsf{RealModulusCriterion}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient completion, selected representatives, countable choice, trichotomy, host sequence convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealModulusCriterionUp.RealModulusCriterionTasteGate single carrier alignment`

Theorem 2462.2 (Real modulus criterion NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RealModulusCriterion}^{\uparrow}}$ *surface for Definition 3415.1 consists exactly of carrier exposure for R, explicit modulus exposure through M, sequence-source exposure through S, regular rational readback through Q, finite window exposure through W, dyadic tolerance exposure through D, sequence-limit handoff through L, real convergence-readiness through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed packet $R = (M, S, Q, W, D, L, E, H, C, P, N)$. The analytic route is finite: a tolerance request reads the modulus row M, the source row S, the regular rational row Q, the window row W, and the dyadic row D before it reaches L and E.

The rows H, C, P, N preserve and name that same route. Componentwise hsame transport keeps each analytic coordinate in its displayed sibling surface, while Cont replay records the order in which the consumer reads the modulus, windows, regular name, sequence-limit row, and real seal.

No excluded object is a row of the carrier. Therefore the listed rows exhaust the seed NameCert obligations for the explicit real-modulus criterion. □

Theorem 2462.3 (Real modulus criterion completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealModulusCriterion}^{\uparrow}$ *packet must pass through*

$$\mathsf{CauchyConvergenceModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RealSequenceLimit}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

in the displayed carrier order before treating the packet as convergence-ready for real-name use. The handoff supplies a finite criterion for explicit Cauchy-modulus convergence; it does not supply quotient completion, a selected limiting representative, countable choice, trichotomy, or an ambient completeness theorem.

Proof. Start with the carrier definition. The modulus row M and dyadic ledger D identify the tolerance request, while W and Q expose the finite tail windows and regular rational readback needed by the request.

Next read the sequence-limit and real-seal rows. The row L is reached only after the modulus, window, dyadic, and regular readback rows have been displayed, and E is the resulting $\mathsf{Real}^{\uparrow}$ readiness boundary.

Finally apply the structural rows. Transport, replay, provenance, and local naming can only preserve the displayed route, so a completion-facing consumer cannot bypass the criterion through quotient completion, representative selection, countable choice, trichotomy, host convergence, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusCriterion}^{\uparrow}$ packet is generated from an explicit CauchyConvergenceModulus row, a sequence source, RegSeqRat readback, finite StreamName windows, DyadicRatCore tolerance rows, a RealSequenceLimit consumer row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealModulusCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 3415.1, Definition 3415.2, and Definition 3415.3 declare the finite explicit-modulus criterion connecting $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealModulusCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, countable choice, trichotomy, host sequence convergence, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, explicit modulus exposure, sequence-limit handoff, real-seal nonescape, and completion-facing criterion readiness.

Chapter 2463

A Concrete Naming Certificate for $\mathsf{CauchyFilterCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyFilterCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed filter base becomes acceptable Cauchy-filter data for the L10 completion route. It sits after the finite $\mathsf{FilterBase}^{\uparrow}$ interface of chapter 1601, the Cauchy-filter surface of chapter 333, and the completion-facing routes of chapter 1506 and chapter 1473; it never replaces them by quotient filters, choice-selected limits, or host completeness.

Definition 2463.1 (Cauchy filter criterion carrier)**.** *A* $\mathsf{CauchyFilterCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, K, M, U, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row naming the finite base packets and directed-refinement witnesses that may be inspected by a completion consumer.*
2. *K is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row recording that the displayed base is Cauchy only through finite entourage or ball requests.*
3. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row reached only after B, K, W, R, D, E have been displayed.*
4. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row exposing the same Cauchy-filter route to entourage-facing completion consumers.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family used when the criterion is read sequentially.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the sequential windows and tolerance requests.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds every displayed Cauchy request.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal read by real-name consumers after the filter, window, regular-rational, and dyadic rows have been displayed.*
9. *H records componentwise* hsame *transport for the filter-base, Cauchy-filter, completion, sequential, tolerance, real-seal, and structural rows.*
10. *C records displayed* Cont *replay from a filter-base request through Cauchy-filter evidence, sequential readback, tolerance accounting, completion handoff, and real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterCriterion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, K, M, U, W, R, D, E, H, C, P, N$. There is no coordinate for quotient filter equality, selected representatives, countable choice, host-side limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyFilterCriterionUp.CauchyFilterCriterionTasteGate single carrier alignment`

Theorem 2463.2 (Cauchy filter criterion NameCert obligations)**.** *For the carrier of Definition 3416.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCriterion}^{\uparrow}}$ *surface consists exactly of carrier exposure for F, finite filter-base exposure through B, Cauchy-filter exposure through K, metric-completion handoff through M, uniform-completion handoff through U, sequential window exposure through W, regular rational readback through R, dyadic tolerance exposure through D, real-name sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed packet $F = (B, K, M, U, W, R, D, E, H, C, P, N)$. The base row B supplies only the finite directed interface of chapter 1601, and the Cauchy row K reads that interface before any completion-facing coordinate is visible.

The sequential rows then bind the criterion to the real-name route. The window row W, regular readback row R, and dyadic tolerance row D are displayed before the real seal E or either completion handoff can be consumed.

Finally the structural rows H, C, P, N transport, replay, source, and name exactly these coordinates. Since quotient filters, selected representatives, countable choice, host limits, and ambient completeness are not rows of the carrier, no further NameCert obligation remains. □

Theorem 2463.3 (Cauchy filter criterion real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterCriterion}^{\uparrow}$ *carrier must pass through*

$$\mathsf{FilterBase}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

in the displayed carrier order before reading the completion handoff rows M or U. The handoff supplies a finite Cauchy-filter criterion for the completion route; it does not supply quotient filters, choice-selected limits, selected representatives, countable choice, host completeness, or an ambient real-limit operator.

Proof. Start with the finite base route. The consumer first reads B and can narrow requests only through the displayed directed-refinement surface supplied by Definition 1601.3.

Next read the Cauchy and sequential rows. The row K witnesses the Cauchy-filter condition over the same base, while W, R, D translate inspected requests into finite windows, regular rational readback, and dyadic tolerance accounting.

The terminal seal and completion handoffs are downstream of those rows. Thus E, M, U can only expose the real-name and completion-facing boundaries after the displayed filter-base criterion has been replayed by C and transported by H.

No excluded principle is carried by P or N. The packet therefore feeds the L10 real and completion route without quotient filters, selected limits, countable choice, host completeness, or a hidden ambient limit object. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterCriterion}^{\uparrow}$ packet is generated from a FilterBaseUp row, a CauchyFilterUp row, MetricCompletionUp and UniformCompletionUp handoff rows, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3416.1, Definition 3416.2, and Definition 3416.3 seed the finite criterion by which a displayed FilterBase and CauchyFilter route may feed Real, MetricCompletion, and UniformCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterCriterion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyFilterCriterionUp.CauchyFilterCriterionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient filters, choice-selected limits, selected representatives, countable choice, host completeness, bridge checking, or an ambient real-limit operator.

Upgrade path: Obligation closure requires Cauchy-filter criterion exposure, completion handoff nonescape, real-seal readiness, and ledger-refusal proofs for BEDC.Derived.CauchyFilterCriterionUp.

Chapter 2464

A Concrete Naming Certificate for $\mathsf{UniformConvergence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformConvergence}^{\uparrow}$ packet records uniform tail control before any $\mathsf{UniformLimit}^{\uparrow}$ consumer reads a $\mathsf{Real}^{\uparrow}$ seal. It sits over the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, the pointwise limiting surface of chapter 2314, the uniform-limit route of chapter 463, the continuous-map graph rows of chapter 130, and the terminal real-name seal of chapter 38. The chapter names the generic finite tail ledger used by later completion and limit consumers; it is not a selected limit, a supremum norm construction, countable choice, quotient equality of functions, host completeness, or open-cover compactness.

Definition 2464.1 (Uniform convergence carrier)**.** *A* $\mathsf{UniformConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, W, Q, R, T, H, C, P, N)$$

with the following displayed rows:

1. *F is the displayed function-family or sequence source. Each source entry is read only through the finite windows named by the packet.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation-window ledger. It records the parameter windows, index windows, and tolerance-request windows inspected by the consumer.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed finite comparisons attached to F and W.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback has displayed the scheduled comparisons.*
5. *T is the uniform tail schedule. For each requested tolerance row it records one threshold row shared by every displayed observation window in W.*
6. *H records componentwise* hsame *transport for the source, window ledger, readback, real seal, tail schedule, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from any limit-facing consumer request through F, W, T, Q, R in that order.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{UniformConvergence}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier has no coordinate for a selected limiting function, a host supremum norm, quotient equality of functions, countable choice, ambient completeness, or open-cover compactness.

Lean4 ✓ `BEDC.Derived.UniformConvergenceUp.TasteGate.UniformConvergenceTasteGate single carrier alignment`

Theorem 2464.2 (Uniform convergence NameCert obligations)**.** *For every accepted* $\mathsf{UniformConvergence}^{\uparrow}$ *carrier*

$$U = (F, W, Q, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source row, finite* $\mathsf{StreamName}^{\uparrow}$ *observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seals, uniform tail schedule, transports, continuations, provenance, and local naming;*
2. *uniform tail coverage, requiring every requested tolerance row to read the single threshold recorded in T before any limiting read is exposed;*
3. *real-seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *seal in R to remain downstream of the readback row Q and the schedule row T;*
4. $\mathsf{UniformLimit}^{\uparrow}$ *handoff, requiring each endpoint-facing consumer to factor through $F, W, Q, R, T, H, C, P, N$ before forming a limiting read;*
5. *transport and replay stability, requiring H and C to preserve the displayed source, window, readback, seal, and tail rows componentwise;*
6. *excluded rows, ruling out selected limits, host supremum norms, quotient equality of functions, countable choice, ambient completeness, open-cover compactness, and any hidden pointwise-only threshold.*

No uniform-convergence obligation is stored outside these rows.

Proof. Project the accepted packet $U = (F, W, Q, R, T, H, C, P, N)$. The carrier exposes exactly the displayed source, finite observation windows, regular rational readbacks, real seals, uniform tail schedule, and structural rows.

Uniformity is supplied by T. A tolerance request first selects a single threshold row in that ledger, and the same row must serve every displayed observation window in W before any readback is admitted.

The real seal is then downstream of the regular rational route. The row Q is the only readback channel attached to the scheduled comparisons, and the seal row R becomes visible only after Q has displayed those comparisons through the tail schedule.

The endpoint handoff follows by the displayed route order. A $\mathsf{UniformLimit}^{\uparrow}$ consumer receives F, W, T, Q, R and then the structural rows H, C, P, N; there is no carrier coordinate from which it can read a selected limit, host supremum norm, quotient equality, choice row, ambient completeness theorem, open-cover compactness argument, or pointwise-only threshold. □

Theorem 2464.3 (Uniform convergence UniformLimit handoff)**.** *Every* $\mathsf{UniformLimit}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformConvergence}^{\uparrow}$ *carrier reads*

$$F, W, Q, R, T, H, C, P, N$$

before forming the limiting read. Thus the limiting route is forced through the displayed source, finite observation windows, regular rational readbacks, real seals, uniform tail schedule, componentwise transport, continuation replay, provenance, and local naming. It receives no selected limit, host supremum norm, quotient function equality, countable-choice schedule, ambient completeness theorem, open-cover compactness principle, or hidden pointwise-only threshold.

Proof. Start with a limit-facing consumer request. By Definition 3417.1, the request first reads the source row F through the finite observation windows W.

The uniform tail schedule T then supplies the common threshold for the requested tolerance. The readback row Q is attached to that scheduled comparison, and the real seal row R is reachable only after the readback has displayed it.

Finally H, C, P, N transport, replay, source, and name the same route. Since every coordinate available to the consumer occurs in the displayed packet, the limiting read cannot be formed from a selected limit, host supremum norm, quotient function equality, countable-choice schedule, ambient completeness theorem, open-cover compactness principle, or hidden pointwise-only threshold. □

Falsifiable prediction: An accepted $\mathsf{UniformConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{UniformLimit}^{\uparrow}$ endpoint or $\mathsf{Real}^{\uparrow}$ seal without first reading $F, W, Q, R, T, H, C, P, N$ refutes the carrier surface.

Independence witness: streamname, regseqrat, pointwise-limit, uniformlimit, continuousmap, real: none is bijective to $\mathsf{UniformConvergence}^{\uparrow}$ because this packet jointly carries a displayed source, finite observation windows, regular readbacks, real seals, one uniform tail schedule, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3417.1, Definition 3417.2, and Definition 3417.3 seed the finite uniform tail ledger over displayed sources, StreamName windows, RegSeqRat readbacks, Real seals, and UniformLimit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformConvergenceUp.TasteGate.UniformConvergenceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim selected limits, host supremum norms, quotient equality of functions, countable choice, ambient completeness, open-cover compactness, or bridge checking.

Upgrade path: Obligation closure requires uniform tail coverage, real-seal non-escape, UniformLimit handoff, transport and replay stability, and excluded-row coverage for BEDC.Derived.UniformConvergenceUp.

Constructive story: A $\mathsf{UniformConvergence}^{\uparrow}$ packet is generated from a displayed function-family or sequence source, finite StreamName observation windows, RegSeqRat readbacks, RealUp seals, one uniform tail schedule, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Chapter 2465

A Concrete Naming Certificate for $\mathsf{BishopApproximationSequence}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{BishopApproximationSequence}^{\uparrow}$ packet records a finite naming surface for approximation sequences whose visible observations are dyadic schedules, finite stream windows, and regular-rational readbacks. It sits between the dyadic arithmetic of chapter 291, the finite stream surface of chapter 126, the regular-rational route of chapter 301, the terminal real-name seal of chapter 38, and the convergence-modulus discipline of chapter 1438. The packet gives Real and Completion consumers a named approximation-sequence interface without adding quotient sequence equality, countable choice, trichotomy, a selected host limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2465.1 (BishopApproximationSequence carrier)**.** *A* $\mathsf{BishopApproximationSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, W, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and bracket row, storing the dyadic precision requests and the finite arithmetic witnesses used by the approximation schedule;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, storing the finite sequence windows whose entries are inspected by the consumer;*
3. *W is the window-synchronization row that binds the dyadic tolerances in D to the stream observations in S;*
4. *M is the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *row, storing the finite modulus witnesses used to compare later windows with earlier requested tolerances;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that repacks the accepted windows as regular rational readback data;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, W, M, R have been displayed;*
7. *H records the componentwise* hsame *transports for the dyadic row, stream row, window row, modulus row, regular handoff, real seal, continuation routes, provenance, and local naming row;*
8. *C records the displayed* Cont *routes that replay tolerance reads, stream-window reads, modulus reads, regular-rational handoff, and real-seal readback;*

9. *P is the* Pkg *provenance over* $\mathsf{BishopApproximationSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopApproximationSequence}^{\uparrow}}$ *row.*

The accepted carrier stores no quotient sequence equality, no selected infinite subsequence, no host real equality test, no countable-choice functional, no trichotomy row, and no ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.BishopApproximationSequenceUp.BishopApproximationSequenceTasteGate single carrier alignment`

Theorem 2465.2 (BishopApproximationSequence NameCert obligations)**.** *For an accepted packet $A = (D, S, W, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopApproximationSequence}^{\uparrow}}$ *obligations are exactly the following finite rows:*

1. *carrier admission: the accepted object is the displayed packet with dyadic tolerances, finite stream windows, synchronized window data, convergence modulus, regular-rational handoff, real seal, transports, continuations, provenance, and local naming;*

2. *dyadic-window coherence: every precision request in D is attached to a displayed window in S through the synchronization row W;*

3. *modulus coverage: every accepted tolerance request reads a finite witness in M before any regular-rational or real-name observation is exported;*

4. *regular handoff stability: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R reads only the synchronized windows and modulus witnesses carried by D, S, W, M;*

5. *classifier transport: the componentwise transports in H preserve the dyadic row, stream row, synchronization row, modulus row, regular handoff, real seal, continuation replay, provenance, and local naming row;*

6. *ledger exhaustion: every Real or Completion consumer must pass through one of $D, S, W, M, R, E, H, C, P, N$ before reading any approximation-sequence observation.*

No obligation may call on quotient sequence equality, a selected host limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier row by row. Carrier admission is immediate from the displayed BHist packet, and dyadic-window coherence reads only the tolerance row D, stream row S, and synchronization row W.

For modulus coverage, inspect a tolerance request in D. The row M supplies the finite convergence witness attached to that request, and the route into R is available only after the synchronized window has been displayed.

Classifier transport and ledger exhaustion are structural. The transport row H moves only the displayed coordinates, while C replays only the displayed tolerance, window, modulus, regular handoff, and seal routes. Since the carrier contains no quotient equality, selected limit, choice functional, trichotomy row, host equality test, or completeness coordinate, none of those principles can enter the local obligations. □

Theorem 2465.3 (BishopApproximationSequence RegSeqRat handoff)**.** *Let $A = (D, S, W, M, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopApproximationSequence}^{\uparrow}$ *packet. Every regular-rational read exported by A factors through a displayed dyadic tolerance in D, a finite stream window in S, the synchronization*

row W, and a convergence-modulus witness in M before the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R is available. The route is stable under the transports in H and the replay routes in C.*

Proof. Begin with a regular-rational consumer of the packet. The carrier makes R the only regular-rational handoff coordinate, and R is downstream of the dyadic, stream-window, synchronization, and modulus rows.

Apply Definition 3418.2. Its dyadic-window coherence and modulus coverage rows force every tolerance request to pass through D, S, W, M before a regular read is exposed.

The transports in H preserve each displayed coordinate, and the continuations in C replay only the same route. Thus the regular-rational read cannot detach from the finite approximation schedule or use quotient sequence equality, countable choice, trichotomy, host equality, selected limits, or ambient completeness. □

Theorem 2465.4 (BishopApproximationSequence Real seal nonescape)**.** *Let $A = (D, S, W, M, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopApproximationSequence}^{\uparrow}$ *packet. No* $\mathsf{Real}^{\uparrow}$*-facing consumer can bypass the dyadic tolerance row D, finite stream row S, synchronization row W, convergence-modulus row M, regular handoff R, terminal seal E, transports H, replays C, provenance P, and local name N to obtain quotient sequence equality, a selected host limit, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the accepted carrier. The only terminal real-name coordinate is E, and it is displayed after the dyadic tolerance row, finite stream row, synchronization row, modulus row, and regular-rational handoff.

Use Definition 3418.3. Every regular-rational approximation read has already passed through D, S, W, M before reaching R, so the route into E is a finite route through the named rows.

The rows H and C can transport and replay only displayed coordinates, while P and N record the same package and local name. Because the carrier contains none of the excluded objects, the Real-facing seal cannot export quotient equality, selected limits, choice, trichotomy, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopApproximationSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopApproximationSequence}^{\uparrow}$ packet is generated from dyadic tolerances, finite stream windows, a synchronization row, a convergence-modulus row, RegSeqRat readback, a RealUp seal, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopApproximationSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3418.1, Definition 3418.2, Definition 3418.3, and Definition 3418.4 present the finite approximation-sequence certificate surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopApproximationSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient sequence equality, selected host limits, countable choice, trichotomy, host real equality, arbitrary least-upper-bound completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, dyadic-window coherence, modulus coverage, regular handoff stability, classifier transport, ledger exhaustion, and real-seal nonescape for the displayed packet.

Chapter 2466

A Concrete Naming Certificate for $\mathsf{LaxMilgram}^{\uparrow}$

Following Lax and Milgram and the variational treatment in Evans, the $\mathsf{LaxMilgram}^{\uparrow}$ packet records the finite BEDC surface for coercive variational solvability. It is read as a neighbour of the Hilbert and Sobolev certificates of chapter 91 and chapter 440, with its pairing row anchored in the bilinear-form chapter chapter 146 and its bounded action surface anchored in chapter 1644. The packet names only the displayed variational handoff; it does not add a choice-selected solution operator or an ambient PDE existence theorem.

Definition 2466.1 (Lax-Milgram carrier)**.** *A* $\mathsf{LaxMilgram}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, B, F, C, S, T, P, N)$$

with the following displayed rows:

1. *H is the Hilbert/Sobolev domain row, read through the* $\mathsf{Hilbert}^{\uparrow}$ *surface and, when a weak-form PDE consumer is present, through the* $\mathsf{Sobolev}^{\uparrow}$ *weak-derivative ledger;*
2. *B is the* $\mathsf{BilinForm}^{\uparrow}$ *row naming the bilinear pairing together with its boundedness and coercivity evidence as finite classifier rows;*
3. *F is the bounded functional row, read through the same bounded-linear-operator surface used by* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *consumers;*
4. *C records the coercivity and boundedness constants as displayed ledger entries rather than as real-number selectors outside the packet;*
5. *S is the solution handoff row: it exposes the single variational response row certified by the equation $B(S, v) = F(v)$ for displayed test rows v in H;*
6. *T stores the* hsame *transport and* Cont *replay rows for the domain, bilinear form, bounded functional, constants, and solution handoff;*
7. *P is the* Pkg *provenance over* $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{BilinForm}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LaxMilgram}^{\uparrow}}$ *evidence.*

The carrier has no coordinate for a choice-selected global inverse, a quotient representative, a completed PDE solution space beyond the cited Sobolev row, or a host theorem asserting existence outside the displayed variational packet.

Lean4 ✓ `BEDC.Derived.LaxMilgramUp.LaxMilgramTasteGate single carrier alignment`

Theorem 2466.2 (Lax-Milgram NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LaxMilgram}^{\uparrow}}$ *surface for the carrier of Definition 3419.1 consists of exactly five finite obligations:*

1. *domain admission, requiring H to be read through the displayed* $\mathsf{Hilbert}^{\uparrow}$ *row and any weak-form consumer through the* $\mathsf{Sobolev}^{\uparrow}$ *ledger;*
2. *bilinear-form admission, requiring B to expose only the* $\mathsf{BilinForm}^{\uparrow}$ *pairing row together with boundedness and coercivity ledger entries;*
3. *functional admission, requiring F to be read through the bounded functional surface supplied by* $\mathsf{BoundedLinearOperator}^{\uparrow}$*;*
4. *variational handoff exactness, requiring every solution-facing read to pass through S and the displayed equation row $B(S, v) = F(v)$ for admitted test rows v;*
5. *transport and replay stability, requiring T, P, N to preserve the same domain, bilinear, functional, constant, and handoff rows under componentwise* hsame*, displayed* Cont*, provenance, and local naming.*

Proof. Project the carrier rows. The domain, bilinear form, functional, constant ledger, handoff, transport, provenance, and local naming evidence are the full visible inventory of K.

Use the cited sibling certificates for each analytic dependency. The Hilbert and Sobolev rows supply the domain-facing reads, the bilinear-form row supplies the pairing and its boundedness/coercivity classifier, and the bounded-linear-operator surface supplies the functional row.

Finally inspect a solution-facing consumer. It can reach only the handoff row S and the displayed variational equation against admitted test rows. The transport, replay, provenance, and naming rows preserve that finite route and add no external selector. □

Theorem 2466.3 (Lax-Milgram variational handoff)**.** *Every PDE, Sobolev, Hilbert, or variational consumer of an accepted* $\mathsf{LaxMilgram}^{\uparrow}$ *packet receives only the displayed route*

$$H \longmapsto B \longmapsto F \longmapsto C \longmapsto S \longmapsto T, P, N.$$

The consumer may use the certified variational response row and its equation against admitted test rows, but it receives no choice-selected solution operator, no quotient representative, no host inverse map, no ambient compactness principle, and no PDE solution space beyond the finite Sobolev or Hilbert rows already cited.

Proof. Begin with the NameCert obligations. They force any consumer to read the domain, bilinear form, functional, constant ledger, and handoff rows in the order displayed by the carrier.

The Sobolev and Hilbert dependencies identify the domain surface, while the bilinear-form and bounded-linear-operator dependencies identify the pairing and functional surfaces. These reads are certificate rows, not host analytic constructions.

It remains to inspect the handoff. The row S is available only as the variational response named by $B(S, v) = F(v)$ for displayed tests v. Since no other solution coordinate is present in the carrier, the listed selector, quotient, inverse, compactness, and ambient PDE objects cannot be exported. □

Theorem 2466.4 (Lax-Milgram energy-minimizer handoff)**.** *An accepted* $\mathsf{LaxMilgram}^{\uparrow}$ *packet exposes its variational solution row as an energy-minimizer handoff only through the Hilbert/Sobolev*

domain row of chapter 91 and chapter 440, the $\mathsf{BilinForm}^{\uparrow}$ *coercive pairing row of chapter 146, and the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *functional row of chapter 1644. The handoff is the finite route*

$$H \longmapsto B \longmapsto F \longmapsto C \longmapsto S,$$

with T, P, N *preserving transport, replay, provenance, and local naming. It exports no selected inverse operator, no quotient representative of a solution class, and no ambient PDE existence theorem.*

Proof. Project the carrier of Definition 3419.1. The only domain coordinate is H, so an energy read starts from the Hilbert row and, for weak-form consumers, the Sobolev ledger named by the sibling chapters.

The energy pairing is then forced through B and C. The bilinear-form sibling supplies the coercive pairing row, while the constant ledger records the displayed boundedness and coercivity data. No inverse operator is stored in these rows.

The forcing term is the row F supplied through the bounded-linear-operator surface. The variational response row S can therefore be read as an energy-minimizer handoff only after the domain, pairing, constant, and functional rows have been displayed.

Finally T, P, N transport, source, and name the same finite route. Since the carrier has no coordinate for a selected inverse operator, quotient representative, or ambient PDE existence theorem, none of those objects can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LaxMilgram}^{\uparrow}}$.

Constructive story: A $\mathsf{LaxMilgram}^{\uparrow}$ packet is generated from a Hilbert or Sobolev domain row, a bilinear-form row with boundedness and coercivity ledgers, a bounded functional row, a solution handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LaxMilgram}^{\uparrow}}$, seed)

Scope closed: Definition 3419.1, Definition 3419.2, and Definition 3419.3 seed the finite variational certificate surface consumed by Sobolev, Hilbert, PDE, and bounded-operator routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LaxMilgram}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a choice-selected solution operator, quotient representative, host inverse map, ambient compactness principle, or full PDE existence theorem.

Upgrade path: Obligation closure requires checked carrier admission, bilinear boundedness and coercivity rows, bounded functional admission, solution handoff exactness, transport, replay, provenance, and local naming for the displayed packet.

Chapter 2467

A Concrete Naming Certificate for $\mathsf{BanachAlaoglu}^{\uparrow}$

Following Banach and Alaoglu, the $\mathsf{BanachAlaoglu}^{\uparrow}$ packet records the finite weak-star dual-ball window that functional-analysis consumers can inspect before any unrestricted compactness theorem is available. It sits over the Banach source row of chapter 90, the bounded-linear-functional surface supplied by chapter 1644, the scalar norm readback of chapter 1500, the terminal real seal of chapter 38, and the finite product compactness handoff of **??**. The chapter names only finite windows in the weak-star dual ball; it does not claim unrestricted Tychonoff compactness, ultrafilter arguments, host weak-star compactness, quotient function spaces, or selected cluster points.

The weak-star window also reads the locally convex seminorm-neighborhood discipline of chapter 3386 before any dual-ball compactness route is exposed.

Definition 2467.1 (Banach-Alaoglu finite weak-star dual-ball carrier)**.** *A* $\mathsf{BanachAlaoglu}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, L, W, S, R, F, T, C, P, N)$$

with the following displayed rows:

1. *B is the Banach source row, read through the displayed* $\mathsf{Banach}^{\uparrow}$ *carrier and its norm, metric, regular-Cauchy, and completion ledgers.*
2. *L is the bounded-linear functional family row, whose members are read as* $\mathsf{BoundedLinearOperator}^{\uparrow}(B, \mathsf{Real}^{\uparrow})$ *coordinates with displayed operator bounds.*
3. *W is the finite weak-star seminorm-window row, listing the finitely many source probes and scalar tolerances allowed in the present observation.*
4. *S is the dual-ball bound row, recording the shared scalar bound on the displayed functionals through* $\mathsf{NormedRealLine}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readbacks.*
5. *R is the Real and normed-real readback row for all scalar values, scalar bounds, and seminorm tolerances exposed by the window.*
6. *F is the finite-product handoff row, sending the displayed scalar coordinate window to the finite* $\mathsf{TychonoffFiniteProduct}^{\uparrow}$ *compactness surface.*
7. *T records componentwise* hsame *transport for the Banach source, functional family, weak-star window, scalar readbacks, finite-product handoff, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a weak-star window request through $B, L, W, S, R, F, T, P, N$.*
9. *P is the* Pkg *provenance over* BanachAlaoglu$^{\uparrow}$, Banach$^{\uparrow}$, BoundedLinearOperator$^{\uparrow}$, NormedRealLine$^{\uparrow}$, Real$^{\uparrow}$, TychonoffFiniteProduct$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BanachAlaoglu}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted Tychonoff compactness, ultrafilter or choice arguments, host weak-star compactness, quotient function spaces, selected cluster points, ambient dual-space compactness, Lean verification, or standard bridge data.

Lean4 ✓ `BEDC.Derived.BanachAlaogluUp.BanachAlaogluTasteGate single carrier alignment`

Theorem 2467.2 (Banach-Alaoglu NameCert obligations)**.** *For the carrier of Definition 3420.1, the local* NameCert$_{\text{BanachAlaoglu}^{\uparrow}}$ *surface consists of exactly six finite obligations:*

1. *Banach source admission, requiring B to be read through the displayed source row of chapter 90;*
2. *bounded-linear-functional admission, requiring each coordinate of L to pass through the bounded-linear-operator surface of chapter 1644;*
3. *finite weak-star window admission, requiring W to expose only finitely many source probes and scalar tolerances;*
4. *scalar readback admission, requiring S and R to read all bounds and scalar values through chapter 1500 and chapter 38;*
5. *finite-product handoff exactness, requiring every compactness-facing read to pass through F and the finite product surface of* **??***;*
6. *transport, replay, provenance, and local naming stability, requiring T, C, P, N to preserve the same finite route under componentwise* hsame*, displayed* Cont*, package provenance, and local naming.*

Proof. Project the carrier rows. The displayed Banach source, bounded-linear functional family, finite weak-star window, scalar bound and readback rows, finite-product handoff, transport, replay, provenance, and local naming rows exhaust the visible inventory of A.

The source and functional obligations are read from the cited sibling certificates. The Banach row supplies the normed source data, and the bounded-linear-operator row supplies the finite bounded-functional surface into the scalar real line.

The weak-star content is only the finite row W. Its probes and tolerances are read through S and R, so every scalar comparison remains inside the displayed normed-real and Real readbacks.

Finally inspect a compactness-facing consumer. It may reach only the finite-product row F after the displayed scalar coordinates have been exposed. Since no unrestricted product, ultrafilter, quotient function space, or selected cluster-point row is present, the certificate closes only the finite weak-star window. □

Theorem 2467.3 (Banach-Alaoglu finite dual-ball handoff)**.** *Every accepted* BanachAlaoglu$^{\uparrow}$ *packet exports the route*

$$B, L, W, S, R \longmapsto F \longmapsto T, C, P, N$$

to any duality, compactness, or functional-analysis consumer. The consumer receives a finite weak-star dual-ball window and the corresponding finite product compactness handoff, but receives no unrestricted Tychonoff compactness theorem, no ultrafilter or choice argument, no host weak-star compactness claim, no quotient function space, and no selected cluster point.

Proof. Begin with an accepted packet and a consumer request. The request first reads the Banach source row B and the bounded-linear functional row L, so the functional data is already confined to displayed source and scalar surfaces.

The finite weak-star window W then selects the only probes and scalar tolerances that may be inspected. Rows S and R translate those displayed values and bounds through the normed-real and Real readback interfaces.

Only after these rows are present can the consumer reach F. That row is the finite-product handoff, not an unrestricted product theorem or a compactness assertion over an entire host dual ball.

The structural rows T, C, P, N preserve and replay the same finite route. Because the carrier contains no selector, quotient function space, ultrafilter, or unrestricted compactness coordinate, the exported handoff is exactly the finite weak-star dual-ball window named above. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachAlaoglu}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachAlaoglu}^{\uparrow}$ packet is generated from a Banach source row, a bounded-linear functional family row, finite weak-star seminorm windows, Real and normed-real scalar readbacks, a finite-product handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachAlaoglu}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3420.1, Definition 3420.2, and Definition 3420.3 seed the finite weak-star dual-ball window consumed by later compactness and duality routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachAlaoglu}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted Tychonoff compactness, ultrafilter or choice arguments, host weak-star compactness, quotient function spaces, selected cluster points, ambient dual-space compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-linear functional family admission, finite weak-star window exactness, scalar readback admission, finite-product handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.BanachAlaogluUp.

Chapter 2468

A Concrete Naming Certificate for $\mathsf{MonotoneCauchySequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{MonotoneCauchySequence}^{\uparrow}$ packet records the finite carrier surface for a monotone regular rational source whose tail windows are already prepared for constructive real completion. It sits between the $\mathsf{Real}^{\uparrow}$ rows of chapter 38, the regular sequence discipline of $\mathsf{RegSeqRat}^{\uparrow}$, the $\mathsf{StreamName}^{\uparrow}$ window ledgers, the dyadic comparison rows of $\mathsf{DyadicRatCore}^{\uparrow}$, and the limit-facing boundary of chapter 1413. The packet names the Cauchy tail surface available before a completion consumer asks for a completed real.

Definition 2468.1 (MonotoneCauchySequence carrier)**.** *A* $\mathsf{MonotoneCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, R, D, O, T, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule for the inspected sequence windows.*
2. *W is the stream-window ledger recording the finite index intervals and tail requests visible to the packet.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that ties each scheduled window to a regular rational approximation.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row used to compare rational approximants inside common dyadic windows.*
5. *O is the monotonicity ledger, listing the finite comparison rows by which later inspected approximants do not move below earlier inspected approximants.*
6. *T is the tail-threshold row, assigning each requested precision a displayed tail window and dyadic comparison bound.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row that exposes the regular Cauchy source to real-name consumers without choosing a host limit.*
8. *H records componentwise* hsame *transport for the stream schedule, window ledger, regular readback, dyadic comparisons, monotonicity ledger, tail threshold, real seal, replay route, provenance, and local naming row.*
9. *C records displayed* Cont *replay from a convergence request through $S, W, R, D, O, T, A, H, P, N$.*

10. *P is the* Pkg *provenance over* MonotoneCauchySequence$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealSequenceLimit$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MonotoneCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through

$$S, W, R, D, O, T, A, H, C, P, N.$$

It has no coordinate for quotient streams, selected host limits, host real equality, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchySequenceUp.MonotoneCauchySequenceTasteGate single carrier alignment`

Theorem 2468.2 (MonotoneCauchySequence NameCert obligations)**.** *For every accepted* MonotoneCauchySequenc *carrier*

$$M = (S, W, R, D, O, T, A, H, C, P, N),$$

the local NameCert$_{\text{MonotoneCauchySequence}^{\uparrow}}$ *surface consists exactly of the finite rows for carrier admission, stream-window scheduling, regular rational readback, dyadic comparison, monotonicity-ledger admission, tail-threshold admission,* Real$^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Each obligation reads the same* StreamName$^{\uparrow}$ *windows and the same* RegSeqRat$^{\uparrow}$ *source rows before the tail threshold or real seal is exposed. No obligation may appeal to quotient streams, selected host limits, host real equality, countable choice, trichotomy, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 3421.1. Carrier admission exposes precisely the rows $S, W, R, D, O, T, A, H, C, P, N$, so every inspected approximation is read as a scheduled regular rational row through the displayed stream windows.

The order-facing and Cauchy-facing rows use the same source schedule. The monotonicity ledger O compares only approximants exposed by S, W, R, D, while the tail-threshold row T assigns each requested precision a finite window and dyadic comparison bound over the same readback surface.

The real-facing seal comes after those rows. The Real$^{\uparrow}$ seal A may be exposed only from the regular rational source, dyadic comparison row, monotonicity ledger, and tail threshold already present in the carrier, and a RealSequenceLimit$^{\uparrow}$ consumer can read only that displayed seal.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the excluded quotient, host-limit, host-equality, choice, trichotomy, and ambient-completeness coordinates do not occur in the carrier, they cannot occur among the local NameCert obligations. □

Theorem 2468.3 (MonotoneCauchySequence tail-window boundary)**.** *Let*

$$M = (S, W, R, D, O, T, A, H, C, P, N)$$

be an accepted MonotoneCauchySequence$^{\uparrow}$ *carrier. Every* RealSequenceLimit$^{\uparrow}$ *or completion-facing consumer of M must first read the* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *comparisons, monotonicity ledger, tail-threshold row,* Real$^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *through the same finite surface. The consumer receives a monotone Cauchy tail-window route, not a quotient stream, selected host limit, host real equality, countable-choice tail, trichotomy decision, or ambient* Real$^{\uparrow}$ *completeness theorem.*

Proof. Start with a limit-facing or completion-facing consumer. By Definition 3421.1, the only available sequence data are the scheduled $\mathsf{StreamName}^{\uparrow}$ windows S, W, the regular rational readback row R, and the dyadic comparison row D.

Apply Definition 3421.2. The monotonicity ledger O and tail-threshold row T are attached to that same scheduled source surface, and the $\mathsf{Real}^{\uparrow}$ seal A is available only after both the dyadic comparison and tail threshold have been displayed.

The $\mathsf{RealSequenceLimit}^{\uparrow}$ route may therefore inspect a finite monotone Cauchy boundary before reaching any real-name consumer. A completion-facing route receives the same boundary through the real seal, not a completed quotient stream or selected host limit.

The structural rows H, C, P, N preserve this boundary under transport, replay, provenance, and naming. The absent quotient-stream, host-limit, host-equality, choice, trichotomy, and ambient-completeness coordinates remain absent for every downstream consumer. □

Falsifiable prediction: Every accepted $\mathsf{MonotoneCauchySequence}^{\uparrow}$ consumer that claims access to a completion or limit boundary must display the StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, monotonicity ledger, tail threshold, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert before any RealSequenceLimit or completion read is inspected.

Independence witness: real, regseqrat, streamname, dyadicratcore, realsequencelimit: MonotoneCauchySequence is not bijective to any listed sibling because it jointly carries monotonicity, regular rational readback, dyadic tail thresholds, and a real seal before any limit-facing consumer may read the source sequence.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneCauchySequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3421.1, Definition 3421.2, and Definition 3421.3 seed the finite source carrier, local obligation surface, and tail-window boundary for monotone Cauchy sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected host limits, host real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, stream-window scheduling, regular readback, dyadic comparison, monotonicity-ledger admission, tail-threshold admission, real sealing, transport replay, provenance, and local naming for BEDC.Derived.MonotoneCauchySequenceUp.

Constructive story: A $\mathsf{MonotoneCauchySequence}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, monotonicity and tail-threshold ledgers, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2469

A Concrete Naming Certificate for MetaCICCandidateSetSNHandoff$^{\uparrow}$

The MetaCICCandidateSetSNHandoff$^{\uparrow}$ packet realizes the candidate-set strong-normalization handoff of chapter 9383 as finite NameCert data. It is narrower than the candidate-set normalization surface of chapter 2320: this packet records exactly the route from Candidate and CandidateSet membership evidence to a closed typed term strong-normalization export, with beta-closure and no-infinite-reduction kept visible. It sits beside the MetaCIC critical path of chapter 765, the closed substitution boundary of chapter 527, the finite trace evaluator of chapter 818, the kernel category surface of chapter 488, and the halting distinction packet of chapter 491.

Definition 2469.1 (MetaCIC candidate-set SN handoff carrier)**.** *A* MetaCICCandidateSetSNHandoff$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, S, T, B, E, N, R, C, P, L)$$

with the following displayed rows:

1. *A is the Candidate row, naming the reducibility-candidate evidence admitted by the normalization audit map.*
2. *S is the CandidateSet membership row, recording finite membership, soundness, and the selected candidate-set witness consumed by the handoff.*
3. *T is the closed typed term evidence row, recording the empty-context term, its type, and the closedness evidence to which the candidate-set row is attached.*
4. *B is the beta-closure row, exposing the one-step beta stability supplied by the same CandidateSet route.*
5. *E is the strong-normalization export row, read only after A, S, T, B have all been displayed.*
6. *N is the no-infinite-reduction projection row obtained from the exported strong-normalization evidence.*
7. *R records componentwise* hsame *transport for candidate, candidate-set, closed-term, beta-closure, export, no-infinite, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a closed-term request through CandidateSet membership, beta closure, strong-normalization export, and no-infinite-reduction projection.*

9. *P is the* Pkg *provenance over* $\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}$*, Candidate, CandidateSet, closed typed term evidence, beta-closure evidence, strong-normalization export,* BHist, hsame, Cont, Pkg*, and* NameCert *rows.*

10. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, S, T, B, E, N, R, C, P, L$. It has no coordinate for candidate-free strong normalization, closed subject reduction, global confluence, host evaluator normalization, quotient conversion equality, or a proof-producing oracle outside the displayed handoff.

Theorem 2469.2 (MetaCIC candidate-set SN handoff obligations)**.** *For every accepted* MetaCICCandidateSetSNHa *carrier $H = (A, S, T, B, E, N, R, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}}$ *surface consists exactly of carrier admission; Candidate evidence through A; CandidateSet membership, soundness, and witness exposure through S; closed typed term evidence through T; beta-closure stability through B; strong-normalization export through E; no-infinite-reduction projection through N; componentwise transport through R; displayed replay through C; provenance through P; and local naming through L.*

Proof. Project the accepted carrier of Definition 3422.1. The visible rows are exactly $A, S, T, B, E, N, R, C, P, L$.

The positive route begins with A and S. Candidate evidence and CandidateSet membership are displayed before the closed typed term row can be read as a normalization input.

The closed-term and beta rows are T and B. They keep the empty-context typing, closedness, and one-step beta stability attached to the same CandidateSet witness.

The export rows are E and N. Strong normalization is exported only after A, S, T, B are present, and no-infinite-reduction is only a projection from that export. The transport, replay, provenance, and naming rows preserve the same handoff, so no excluded host route can appear in the NameCert surface. □

Theorem 2469.3 (MetaCIC candidate-set SN export nonescape)**.** *Every public strong-normalization or no-infinite-reduction read exported by an accepted* $\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}$ *packet factors through*

$$A, S \longmapsto T, B \longmapsto E, N \longmapsto R, C, P, L.$$

Thus a closed typed term consumer receives the route only as CandidateSet membership, closed-term, beta-closure, and SN export NameCert data, not as an unconditional theorem over all closed MetaCIC terms.

Proof. Read the source rows A and S. They name the candidate evidence and CandidateSet membership that the normalization audit map requires for the public closed-term route.

Next read T and B. The closed typed term row and beta-closure row attach the term and its local reduction stability to the same finite evidence route.

Finally read E, N, R, C, P, L. The strong-normalization export and no-infinite projection are downstream of the candidate-set source, while transport, replay, provenance, and local naming preserve that order. Since the carrier has no coordinate for candidate-free strong normalization, closed subject reduction, global confluence, host evaluator normalization, quotient conversion equality, or a proof-producing oracle, no consumer can escape the displayed route. □

Theorem 2469.4 (MetaCIC candidate-set SN export factorization)**.** *For every accepted* MetaCICCandidateSetSNH *carrier*

$$H = (A, S, T, B, E, N, R, C, P, L),$$

each strong-normalization export row factors through the displayed order

$$A \longmapsto S \longmapsto T \longmapsto B \longmapsto E \longmapsto N \longmapsto R \longmapsto C \longmapsto P \longmapsto L.$$

Thus the export is mediated first by Candidate evidence, then CandidateSet membership, closed typed term evidence, beta-closure stability, strong-normalization export, no-infinite projection, transport, replay, provenance, and local NameCert rows.

Proof. Project the accepted carrier of Definition 3422.1. The rows are displayed as $A, S, T, B, E, N, R, C, P, L$, and the local classifier compares accepted packets only through those coordinates.

The candidate-mediated source is A followed by S. The closed typed term row T and beta-closure stability row B can be read only as part of the same finite CandidateSet handoff.

The export itself is then E, with N only as the no-infinite-reduction projection from that export. The nonescape theorem Definition 3422.3 rules out a candidate-free or host-oracle route for these public reads.

Finally the structural rows R, C, P, L transport, replay, source, and name the same route. This gives the stated factorization and keeps the strong-normalization export inside the local NameCert surface. □

Theorem 2469.5 (MetaCIC candidate-set SN TasteGate route)**.** *Every strong-normalization export from an accepted* $\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}$ *carrier*

$$H = (A, S, T, B, E, N, R, C, P, L)$$

passes through Candidate evidence A, CandidateSet membership S, closed typed term evidence T, beta-closure stability B, no-infinite-reduction projection N, componentwise transport R, replay C, provenance P, and the local NameCert row L. These rows are exactly the field projections that a future TasteGate field-faithful instance for $\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}$ *must preserve when it exposes the strong-normalization export E.*

```
Lean4 ✓  BEDC.Derived.MetaCICCandidateSetSNHandoffUp.MetaCICCandidateSetSNHandoffTasteGate
single carrier alignment
```

Proof. Project the accepted carrier using Definition 3422.1. The field inventory is $A, S, T, B, E, N, R, C, P, L$, and the classifier compares accepted packets only through those displayed coordinates.

Apply Definition 3422.4. It orders the SN export through Candidate evidence, CandidateSet membership, closed typed term evidence, beta-closure, export, no-infinite projection, transport, replay, provenance, and local naming.

The TasteGate field-faithful requirement therefore has no additional field to preserve and no license to merge fields. Preserving the handoff means preserving each of $A, S, T, B, E, N, R, C, P, L$ as a displayed projection.

Since the carrier has no coordinate for candidate-free strong normalization, host evaluator normalization, quotient conversion equality, or an external proof oracle, the same field-faithful route is the only route available to any SN export consumer. □

Falsifiable prediction: A closed typed term read that reaches $\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}$ strong-normalization export without displaying CandidateSet membership, closed typed term evidence, beta-closure stability, and the SN export row fails the carrier surface.

Independence witness: metaciccriticalpath, closedtermsubstitutionboundary, finitetraceevaluator, kernelcategory, haltingdistinction: none is bijective because $\mathsf{MetaCICCandidateSetSNHandoff}^{\uparrow}$

binds Candidate evidence, CandidateSet membership, closed typed term evidence, beta closure, SN export, no-infinite projection, transport, replay, provenance, and local NameCert rows in one finite handoff packet.

The Lean follow-up is `BEDC.Derived.MetaCICCandidateSetSNHandoffUp`. Its TasteGate surface must provide Nontrivial MetaCICCandidateSetSNHandoff$^{\uparrow}$ and FieldFaithful MetaCICCandidateSetSNHandoff$^{\uparrow}$ instances that keep $A, S, T, B, E, N, R, C, P, L$ as separate displayed fields.

Closure status for NameCert$_{\text{MetaCICCandidateSetSNHandoff}^{\uparrow}}$.

Constructive story: A MetaCICCandidateSetSNHandoff$^{\uparrow}$ packet is generated from Candidate evidence, CandidateSet membership, closed typed term evidence, beta-closure evidence, strong-normalization export, no-infinite-reduction projection, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICCandidateSetSNHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 3422.1, Definition 3422.2, Definition 3422.3, and Definition 3422.4 seed the finite candidate-set strong-normalization handoff surface.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICCandidateSetSNHandoff}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unconditional MetaCIC strong normalization, closed subject reduction, global confluence, host evaluator normalization, quotient conversion equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked Candidate evidence, CandidateSet membership, closed typed term evidence, beta-closure stability, SN export, no-infinite projection, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.MetaCICCandidateSetSNHandoffUp.

Chapter 2470

A Concrete Naming Certificate for $\mathsf{FilterConvergence}^{\uparrow}$

Following Kelley and Bourbaki on filter convergence, the $\mathsf{FilterConvergence}^{\uparrow}$ packet records the finite convergence interface needed by the L10 completion route. It sits between the finite $\mathsf{CauchyFilter}^{\uparrow}$ surface of chapter 333, the regular directed-tail surface of chapter 1445, the window discipline of chapter 126, the ambient metric interface of chapter 57, and the terminal real-name seal of chapter 38. The packet names convergence toward a displayed target point through visible tail events and tolerance rows; it does not quotient filters, select host limits, invoke countable choice, hide cofinal tails, or assume ambient real completeness.

Definition 2470.1 (FilterConvergence carrier)**.** *A* $\mathsf{FilterConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, X, T, V, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the visible* $\mathsf{CauchyFilter}^{\uparrow}$ *row. It stores the finite filterbase requests and refinement evidence from which convergence may be read.*
2. *X is the target point row over* $\mathsf{Met}^{\uparrow}$*. It records the displayed point classifier, distance observations, and metric-law ledger used by every neighborhood request.*
3. *T is the finite tail-event schedule. Each row names a filter event requested around the target point and the finite stage at which that event is inspected.*
4. *V is the Metric/Real tolerance row. It matches the metric ball or entourage demand around X with the rational and real-facing tolerance data read by the convergence request.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is available only after the filter row, target point row, tail schedule, and tolerance row have all been displayed.*
6. *H records componentwise* hsame *transport for B, X, T, V, E and for the structural rows below.*
7. *C records displayed* Cont *replay from filterbase refinement to tail events, from target-point neighborhoods to tolerance windows, and from tolerance windows to the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{FilterConvergence}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, X, T, V, E, H, C, P, N$. There is no coordinate for quotient filters, selected host limits, hidden cofinal tails, countable-choice schedules, host equality of target points, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.FilterConvergenceUp.FilterConvergenceTasteGate single carrier alignment`

Theorem 2470.2 (FilterConvergence NameCert obligations)**.** *For every accepted* $\mathsf{FilterConvergence}^{\uparrow}$ *carrier $F = (B, X, T, V, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FilterConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission, visible filter exposure through B, target-point exposure through X, finite tail-event exposure through T, Metric/Real tolerance readback through V, terminal Real seal handoff through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

These obligations bind the convergence route

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

without adding quotient filters, selected limits, hidden cofinal tails, countable choice, host target equality, or ambient real completeness.

Proof. Project the carrier of Definition 3423.1. The packet exposes exactly the visible filter row, target point row, tail-event schedule, tolerance row, Real seal, and structural rows.

The filter and target rows are read first. The row B supplies only finite filterbase requests, while X supplies the metric target point and its displayed neighborhood observations.

The tail schedule and tolerance row then bind convergence to finite data. The schedule T lists the filter events inspected around X, and V ties each such event to the Metric and Real tolerance windows consumed by the request.

Finally E, H, C, P, N seal, transport, replay, source, and name the same ordered route. Since the excluded objects are absent from the carrier, no further local NameCert obligation can be exported. □

Theorem 2470.3 (FilterConvergence tail stability)**.** *Let $F = (B, X, T, V, E, H, C, P, N)$ be an accepted* $\mathsf{FilterConvergence}^{\uparrow}$ *carrier. Any two displayed tail events in T that are read around the same target point row X admit a later displayed filterbase refinement inside B whose Metric/Real tolerance data is still the row V and whose terminal seal is still E.*

Consequently tail refinement is stable under componentwise hsame *transport, displayed* Cont *replay, package provenance, and local naming through H, C, P, N. The stability claim does not use quotient filters, selected host limits, countable choice, hidden cofinal tails, host target equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with two tail events in the finite schedule T. Because both events are carrier rows, they are already tied to the same visible filterbase row B and the same target point row X.

Use the directed refinement surface read from B. The later filterbase row is displayed inside the packet, so the proof never passes to an external cofinal family or quotient filter.

Read the tolerance row next. The row V is the only Metric/Real tolerance interface attached to the scheduled tail events, and H, C transport and replay that same interface to the later refinement.

The Real seal is therefore unchanged. Since E is downstream from B, X, T, V, and P, N only source and name those coordinates, the excluded choice, limit, hidden-tail, equality, and completeness principles cannot enter the tail-stability route. □

Theorem 2470.4 (FilterConvergence Real seal handoff)**.** *Every completion-facing or Real-facing consumer of an accepted* $\mathsf{FilterConvergence}^{\uparrow}$ *packet must read the displayed convergence route*

$$B \longmapsto X \longmapsto T \longmapsto V \longmapsto E$$

before the Real seal is available. In BEDC terms, the consumer passes through the visible $\mathsf{CauchyFilter}^{\uparrow}$ *row, the target* $\mathsf{Met}^{\uparrow}$ *point row, the* $\mathsf{StreamName}^{\uparrow}$ *tail-event schedule, and the Metric/Real tolerance row before it reaches* $\mathsf{Real}^{\uparrow}$*.*

The handoff supplies a finite convergence interface for $\mathsf{RegularCauchyFilter}^{\uparrow}$ *and downstream completion-limit uniqueness arguments. It supplies no quotient filter, selected host limit, countable-choice schedule, hidden cofinal tail, host equality of target points, or ambient real-completeness principle.*

Proof. Start with the visible filter row B. A consumer can inspect only the finite filterbase requests and refinements recorded by the packet.

Next read the target and schedule rows. The row X supplies the metric target point and neighborhood observations, while T records the finite tail events that answer those neighborhood requests.

The tolerance and seal rows are downstream. The row V matches those tail events with the Metric and Real tolerance windows, and E seals the compatible readback only after that route has been replayed.

Thus every Real-facing consumer receives the same ordered route through $B, X, T, V, E, H, C, P, N$. Since no excluded principle is a carrier coordinate, the handoff is a finite convergence certificate rather than an ambient completeness assertion. □

Theorem 2470.5 (Filter convergence directed-net index)**.** *Any* $\mathsf{FilterConvergence}^{\uparrow}$ *packet that consumes* $\mathsf{MooreSmithNet}^{\uparrow}$ *data must expose the* $\mathsf{DirectedSet}^{\uparrow}$ *index row and the* $\mathsf{FilterBase}^{\uparrow}$ *handoff before any* $\mathsf{NetConvergence}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer reads convergence. The convergence route therefore passes through displayed directed indices, directed tails, and filterbase refinement data, not through host cofinal selectors, quotient net indices, hidden tail predicates, or ambient convergence relations.*

Proof. Project the filter-convergence carrier of Definition 3423.1. The visible filter row B, target row X, tail schedule T, tolerance row V, and seal row E are the only convergence-facing coordinates.

Read the Moore–Smith net carrier through chapter 3403. Its displayed route exposes a $\mathsf{DirectedSet}^{\uparrow}$ index row before the $\mathsf{FilterBase}^{\uparrow}$ handoff and before any $\mathsf{NetConvergence}^{\uparrow}$ or $\mathsf{UniformCompletion}^{\uparrow}$ consumer is named.
