Only after that comparison can the terminal Real seal E and universal-property uniqueness row U be consumed. The structural rows H, C, P, N transport, replay, source, and name the same route, leaving no carrier coordinate for quotient equality, selected representatives, host equality, countable choice, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}}$.

Constructive story: A RegularCauchyCompletionSeparation$^{\uparrow}$ packet is generated from two regular Cauchy completion-name rows, a shared DyadicRatCore tolerance ledger, finite StreamName windows, a RegSeqRat comparison row, a terminal RealUp seal, a CauchyCompletionUniversalProperty uniqueness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionSeparation}^{\uparrow}}$, seed)

Scope closed: Definition 3839.1, Definition 3839.2, and Definition 3839.3 seed the quotient-free separation surface for displayed regular Cauchy completion names.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionSeparation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, host sequence equality, countable choice over tails, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-tolerance exactness, finite-window routing, regular-rational comparison, terminal seal handoff, universal-property uniqueness routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionSeparationUp.

Chapter 2868

A Concrete Naming Certificate for WRRHotspotCube$^{\uparrow}$

The WRRHotspotCube$^{\uparrow}$ packet realizes the purine-suffix hotspot cube of Definition 9462.1780, the reassignment count of Definition 9462.1781, and the highest-scoring cube certificate of Definition 9462.1783 as finite BEDC NameCert data. It consumes the DNA boundary-tile source of chapter 3393, the six-boundary coverage surface of chapter 3470, the finite trigger algebra of chapter 3478, the trigger-energy partition packet of chapter 3806, and the trigger-blocker duality packet of chapter 3801. The packet names C_{WRR} as finite cube, layer, transfer-square, count, and refusal data; it is not a biological causal model, stochastic evolutionary law, exhaustive code table, or hidden codon semantics.

Definition 2868.1 (WRR hotspot cube carrier)**.** *A* WRRHotspotCube$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (V, A, L, T, M, Q, H, C, P, N)$$

with the following displayed rows:

1. *V is the eight-vertex row for $C_{\mathrm{WRR}} = \{\mathrm{UAA}, \mathrm{UAG}, \mathrm{UGA}, \mathrm{UGG}, \mathrm{AAA}, \mathrm{AAG}, \mathrm{AGA}, \mathrm{AGG}\}$.*
2. *A is the six-bit atlas row recording the free coordinates b_1^s, b_2^f, b_3^f and fixed coordinates $b_1^f = 0$, $b_2^s = 1$, and $b_3^s = 1$.*
3. *L is the layer-classifier row recording the $\mathrm{U} \times R \times R$ and $\mathrm{A} \times R \times R$ layers and the standard $3 + 2 + 2 + 1$ pattern.*
4. *T is the transfer-square row for $\{\mathrm{UGA}, \mathrm{UGG}, \mathrm{AGA}, \mathrm{AGG}\}$ and its Stop/Trp/Arg transition surface.*
5. *M is the reassignment-count ledger recording the codon counts $8, 10, 15, 0, 3, 0, 8, 8$ and total 52.*
6. *Q is the Q_3 score row recording that the displayed cube is the unique highest-scoring axis-aligned cube among the 160 displayed candidates.*
7. *H records componentwise* hsame *transport for vertex, atlas, layer, transfer-square, count, score, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source hotspot-cube vision through $V, A, L, T, M, Q, H, P, N$.*
9. *P is the* Pkg *provenance over* WRRHotspotCube$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgebra$^{\uparrow}$, TriggerEnergyPartition$^{\uparrow}$, TriggerBlockerDuality$^{\uparrow}$, *the source hotspot-cube vision,* BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}$ *row.*
The carrier has no coordinate for biochemical mechanism, evolutionary ancestry, exhaustive biological coverage, stochastic causality, host codon semantics, or an unlisted reassignment table.

Lean4 ✓ `BEDC.Derived.WRRHotspotCubeUp.WRRHotspotCubeTasteGate single carrier alignment`

Theorem 2868.2 (WRR hotspot cube NameCert obligations)**.** *For every accepted* $\mathsf{WRRHotspotCube}^{\uparrow}$ *carrier* $W = (V, A, L, T, M, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}$ *surface consists exactly of vertex exposure, six-bit atlas exposure, layer-classifier exposure, transfer-square exposure, reassignment-count ledger exactness,* Q_3 *score-row exposure, componentwise transport, continuation replay, package provenance, and local naming through the displayed rows* $V, A, L, T, M, Q, H, C, P, N$*.*

Proof. Project the carrier of Definition 3840.1. The vertex row V and atlas row A name the finite cube, while L and T expose the two layer and transfer-square classifiers already displayed in the source vision.

The count and score rows are finite ledgers. The row M records the eight codon-level reassignment counts and their total, and Q records the comparison against the displayed family of axis-aligned Q_3 cubes.

Transport, replay, provenance, and local naming preserve exactly those rows. Since the carrier has no coordinate for biochemical mechanism, evolutionary ancestry, stochastic causality, exhaustive biological coverage, hidden codon semantics, or an unlisted table, the listed rows exhaust the NameCert obligations. □

Theorem 2868.3 (WRR hotspot cube dependency handoff)**.** *Every downstream trigger-spectrum consumer of an accepted* $\mathsf{WRRHotspotCube}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{SixBoundaryTileCoverage}^{\uparrow},\ \mathsf{WindowCoverageTriggerAlgebra}^{\uparrow},\ \mathsf{TriggerEnergyPartition}^{\uparrow},$$

The handoff exposes the cube vertices, atlas coordinates, layer classifier, transfer square, reassignment count ledger, and highest-score row before any consumer treats the hotspot cube as a finite NameCert packet.

Proof. The provenance row P lists the sibling dependency surface. The DNA boundary-tile packet supplies the source codon-window rows, the six-boundary coverage packet supplies the finite coverage coordinates, and the trigger algebra supplies the finite support and coverage-trigger readback.

The trigger-energy partition and trigger-blocker duality packets then supply the partition and blocker rows used by trigger-spectrum consumers. Only after those sibling rows are visible can V, A, L, T, M, Q be read as the hotspot-cube NameCert surface.

The structural rows H, C, P, N preserve and name the same route. Therefore the handoff is a finite dependency chain, not a biological mechanism, stochastic law, or hidden codon table. □

Falsifiable prediction: Any accepted $\mathsf{WRRHotspotCube}^{\uparrow}$ consumer that changes one of the eight displayed vertex rows or one of the count entries $8, 10, 15, 0, 3, 0, 8, 8$ must change the total-count row M or reject the packet.

Independence witness: dna-window-six-boundary-tile, six-boundary-tile-coverage, window-coverage-trigger-algebra, trigger-energy-partition, trigger-blocker-duality: none is bijective with $\mathsf{WRRHotspotCube}^{\uparrow}$ because this packet jointly carries the WRR vertex cube, six-bit atlas row, layer classifier, transfer square, reassignment-count ledger, highest-score row, transport, replay, provenance, and local naming.

The Lean follow-up for this chapter must provide `Nontrivial WRRHotspotCubeUp` and `FieldFaithful WRRHotspotCubeUp` TasteGate instances under `BEDC.Derived.WRRHotspotCubeUp`, preserving $V, A, L, T, M, Q, H,$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}$.

Constructive story: A $\mathsf{WRRHotspotCube}^{\uparrow}$ packet is generated from eight WRR cube vertices, six-bit atlas coordinates, layer-classifier rows, transfer-square rows, reassignment-count ledgers, highest-score rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3840.1, Definition 3840.2, Definition 3840.3, the falsifiable prediction, and the independence witness seed the finite WRR hotspot cube packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close biochemical causality, evolutionary ancestry, exhaustive biological coverage, stochastic semantics, hidden codon semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, vertex exposure, atlas exposure, layer and transfer-square classifier exactness, count-ledger exactness, highest-score row exposure, Nontrivial WRRHotspotCubeUp, and FieldFaithful WRRHotspotCubeUp for BEDC.Derived.WRRHotspotCubeUp.

Chapter 2869

A Concrete Naming Certificate for $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$

Bishop–Bridges nested interval/regular Cauchy construction treats a decreasing located interval chain with a displayed diameter schedule as finite approximation data before any real point is read. The $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ packet records that handoff as a NameCert route from the nested-interval theorem surface of chapter 2308 and the located endpoint surface of chapter 394 through the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It names the L10 route from nested interval data to regular Cauchy real names; it is not an interval-intersection oracle, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2869.1 (Nested Cauchy interval-selection carrier)**.** *A* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *source row, exposing the finite descending interval windows, containment rows, and diameter controls.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row, recording located lower and upper endpoint reads for the inspected intervals.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare interval diameter bounds with the requested regular Cauchy precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which endpoint and midpoint observations are requested.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy handoff row extracted from the nested interval windows and tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for interval, located endpoint, dyadic tolerance, stream-window, regular readback, real seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a nested interval request through located endpoint reads, dyadic tolerances, stream windows, regular readback, and real seal handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$, $\mathsf{NestedIntervalTheorem}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $I, L, D, W, R, E, H, C, P, N$. It has no coordinate for a completed host intersection point, a quotient real representative, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedCauchyIntervalSelectionUp.NestedCauchyIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 2869.2 (Nested Cauchy interval-selection NameCert obligations)**.** *For every accepted* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ *carrier $S = (I, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}}$ *surface consists exactly of carrier admission for the displayed rows, nested-interval exposure through I, located endpoint exposure through L, dyadic tolerance exactness through D, finite-window exposure through W, regular Cauchy handoff through R, terminal real seal confinement through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3841.1. The rows $I, L, D, W, R, E, H, C, P, N$ are exactly the data visible to the local classifier.

The interval source and located endpoint rows are separate. The source row I carries the descending windows and diameter controls, while L carries the endpoint locatedness evidence needed to read those windows as rational approximation data.

The regular Cauchy handoff is downstream. The tolerance ledger D converts displayed diameter bounds into requested precision rows, the window row W supplies finite observations, and R packages the resulting observations as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

The real seal and structural rows do not add a hidden selector. The row E is reached only after I, L, D, W, R have been replayed, and H, C, P, N preserve and name the same route. Hence the excluded host intersection, quotient representative, choice, trichotomy, compactness, and ambient-completeness coordinates are absent from the NameCert surface. □

Theorem 2869.3 (Nested Cauchy interval-selection regular Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{NestedIntervalTheorem}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exports a regular Cauchy name read from displayed interval windows and diameter controls, not a completed intersection point or a host equality of real presentations.

Proof. Begin with an accepted carrier $S = (I, L, D, W, R, E, H, C, P, N)$. A regular Cauchy request first reads the nested interval theorem row I and the located endpoint row L.

Next the request consumes the dyadic tolerance ledger D and finite-window row W. These rows identify which displayed interval prefix supplies the requested Cauchy precision.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is then read as the regular Cauchy handoff. A $\mathsf{Real}^{\uparrow}$ consumer may proceed to E, but only through the same route and the structural rows H, C, P, N.

Since no carrier coordinate names a completed host intersection point, quotient real representative, countable-choice schedule, trichotomy split, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the handoff remains choice-free and finite. □

Falsifiable prediction: Every accepted $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ read exposes NestedIntervalTheorem rows, LocatedInterval endpoint rows, DyadicRatCore tolerance rows, StreamName finite windows, a RegSeqRat handoff, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any Real-facing consumer can use the packet.

Independence witness: nested-interval-theorem, locatedinterval, regseqrat, dyadicratcore, streamname, real: $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the nested interval source, located endpoint evidence, dyadic tolerance ledger, finite-window route, regular Cauchy handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ packet is generated from a NestedIntervalTheorem source row, a LocatedInterval endpoint row, a DyadicRatCore tolerance ledger, StreamName finite windows, a RegSeqRat regular Cauchy handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3841.1, Definition 3841.2, and Definition 3841.3 seed the finite route from nested interval data to regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, host interval intersection, quotient real equality, selected limit points, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, nested interval exposure, located endpoint exposure, dyadic tolerance exactness, regular Cauchy handoff, Real seal confinement, and field-faithful TasteGate evidence for BEDC.Derived.NestedCauchyIntervalSelectionUp.

Chapter 2870

A Concrete Naming Certificate for $\mathsf{BoundaryPressureLedger}^{\uparrow}$

The $\mathsf{BoundaryPressureLedger}^{\uparrow}$ packet realizes the outer-boundary degree and pressure rows of Definition 9462.1298, Definition 9462.1300, and Definition 9462.1305 as finite BEDC NameCert data. It sits after the median-closure carrier of chapter 3545, the six-boundary trigger coverage route of chapter 3470, the boundary-trigger closure packet of chapter 3508, and the coverage algebra of chapter 3478. The packet records pressure rows for inactive boundary codons before any trigger or class-pressure consumer may use them; it is not a biological stochastic model, an empirical fitness claim, a hidden codon table, or an unrestricted boundary enumerator.

Definition 2870.1 (Boundary-pressure ledger carrier)**.** *A* $\mathsf{BoundaryPressureLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, O, D, P, A, K, H, C, Q, N)$$

with the following displayed rows:

1. *S is the reassigned support row naming the displayed* 13*-codon support $\mathcal{R}$.*
2. *O is the outer-boundary row, listing exactly the inactive codons at Hamming distance one from $\mathcal{R}$.*
3. *D is the boundary-degree ledger, recording $d_{\partial}(z)$ for each displayed boundary codon z.*
4. *P is the boundary-pressure ledger, recording $P_{\partial}(z)$ from the displayed support-neighbor weights.*
5. *A is the aggregate class-pressure row, grouping boundary codons by standard-code class while preserving degree and pressure totals.*
6. *K is the high-pressure corner row naming the inactive envelope corners and the first completion frontier consumed by boundary-closure readers.*
7. *H records componentwise* hsame *transport for support, outer-boundary, degree, pressure, aggregate, corner, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-pressure request through $S, O, D, P, A, K, H, Q, N$.*
9. *Q is the* Pkg *provenance over* $\mathsf{BoundaryPressureLedger}^{\uparrow}$*,* $\mathsf{MedianClosure}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$*,* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}$ *row.*

The carrier accepts pressure reads only through $S, O, D, P, A, K, H, C, Q, N$. It has no coordinate for a pressure-row bypass, hidden biological semantics, stochastic selection dynamics, empirical likelihood, or a boundary row outside the displayed finite ledger.

Lean4 ✓ `BEDC.Derived.BoundaryPressureLedgerUp.BoundaryPressureLedgerTasteGate single carrier alignment`

Theorem 2870.2 (Boundary-pressure ledger NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryPressureLedger}^{\uparrow}$ *carrier* $B = (S, O, D, P, A, K, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}$ *surface consists exactly of support admission through* S*, outer-boundary exposure through* O*, degree-ledger exactness through* D*, pressure-ledger exactness through* P*, class-pressure aggregation through* A*, inactive-corner and completion-frontier readback through* K*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* Q*, and local naming through* N*.*

Proof. Project the carrier of Definition 3842.1. Its visible pressure data are exactly the rows $S, O, D, P, A, K, H, C, Q, N$.

The source support and boundary rows are finite. The row S names the reassigned support, and O lists the inactive codons at Hamming distance one from that support.

The degree and pressure rows are downstream of the same source. The row D counts displayed support neighbors for each boundary codon, while P sums the displayed support-neighbor weights. The aggregate row A groups those same entries by class without changing their provenance.

The corner, transport, replay, provenance, and naming rows preserve the ledger. Because no coordinate bypasses D and P, a consumer cannot obtain pressure data from hidden biological semantics, stochastic selection dynamics, empirical likelihood, or an unrestricted boundary enumerator. □

Lean4 ✓ `BEDC.Derived.BoundaryPressureLedgerUp.BoundaryPressureLedgerNamecertObligations`

Theorem 2870.3 (Boundary-pressure trigger handoff)**.** *Every boundary-trigger or class-pressure consumer of an accepted* $\mathsf{BoundaryPressureLedger}^{\uparrow}$ *packet factors through*

$$S \longmapsto O \longmapsto D \longmapsto P \longmapsto A \longmapsto K \longmapsto H, C, Q, N.$$

In particular, any consumer preserving $\mathsf{MedianClosure}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$*, and* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *provenance must read the degree and pressure ledgers before it can use high-pressure inactive boundary codons.*

Proof. Begin with a boundary-trigger request. The provenance row Q names the median-closure and boundary-trigger siblings, but the request cannot read those siblings as pressure rows unless the local support row S and outer-boundary row O have first been displayed.

The pressure data then pass through D and P. Degree is counted from displayed support neighbors, and pressure is the displayed weighted sum over the same neighbor relation.

The aggregate and corner rows are read only after the degree and pressure ledger. The row A groups class totals, while K names the inactive envelope corners and completion-frontier entries consumed by boundary-closure readers.

Finally H, C, Q, N transport, replay, source, and name the same finite route. Thus a pressure-row bypass would refute the packet: it would use high-pressure boundary data without passing through the displayed degree and pressure ledgers. □

Falsifiable prediction: A pressure-row bypass refutes $\mathsf{BoundaryPressureLedger}^{\uparrow}$: any accepted boundary-trigger consumer that reaches high-pressure inactive codons without first reading $S, O, D, P, A, K, H, C, Q$ is outside the packet.

Independence witness: median-closure, six-boundary-tile-coverage, dna-boundary-trigger-closure, window-coverage-trigger-algebra: $\mathsf{BoundaryPressureLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the outer-boundary row, degree ledger, pressure ledger, class aggregation, inactive-corner frontier, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.BoundaryPressureLedgerUp.TasteGate` must provide explicit $\mathsf{Nontrivial\ BoundaryPressureLedger}^{\uparrow}$ and $\mathsf{FieldFaithful\ BoundaryPressureLedger}^{\uparrow}$ instances preserving $S, O, D, P, A, K, H, C, Q, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryPressureLedger}^{\uparrow}$ packet is generated from a reassigned support row, an outer-boundary row, boundary-degree and boundary-pressure ledgers, class-pressure aggregation, inactive-corner frontier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3842.1, Definition 3842.2, and Definition 3842.3 seed the finite pressure-ledger route for DNA boundary-trigger consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, biological stochastic semantics, empirical likelihood, hidden codon semantics, unrestricted boundary enumeration, or pressure-row bypasses.

Upgrade path: Obligation closure requires checked support admission, outer-boundary exposure, degree-ledger exactness, pressure-ledger exactness, class aggregation, trigger handoff, Nontrivial BoundaryPressureLedgerUp, and FieldFaithful BoundaryPressureLedgerUp for BEDC.Derived.BoundaryPressureLedgerUp.

Chapter 2871

A Concrete Naming Certificate for $\mathsf{CompletionAdjoint}^{\uparrow}$

Following Mac Lane and Bishop–Bridges, the $\mathsf{CompletionAdjoint}^{\uparrow}$ packet records the Cauchy completion reflector as a finite adjunction certificate. It sits after the reflector surface of chapter 1585, the functorial completion surface of chapter 423, the universal extension ledger of chapter 397, the reflective-subcategory boundary of chapter 1793, the regular rational and stream-window interfaces of chapter 126 and chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the displayed unit, counit, and universal-property rows; it is not a quotient completion, a selected limit object, an ambient reflective subcategory theorem, or an appeal to countable choice.

Definition 2871.1 (Completion adjoint carrier)**.** *A* $\mathsf{CompletionAdjoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, F, U, V, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row from chapter 1585, recording the source-to-complete handoff through the Cauchy completion reflector surface.*
2. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row from chapter 423, carrying the functorial source, regular-Cauchy, seal, and classifier data.*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row from chapter 397, recording extension existence, extension uniqueness, and unit compatibility for the same displayed source.*
4. *V is the* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$ *visibility row from chapter 1793: it records that complete objects are read through the reflected completion surface, not through a host subcategory object.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule for completion requests, approximating maps, unit reads, and counit reads.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular Cauchy names inspected by F and by the universal-property row U.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for all approximation and triangle reads used by the unit-counit ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after R, F, U, V, S, Q, D have been displayed.*

9. *H records componentwise* hsame *transport for the reflector, functor, universal-property, reflective-subcategory, stream, readback, dyadic, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from any completion-adjunction consumer through the rows R, F, U, V, S, Q, D, E and then through the structural rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CompletionAdjoint}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected limits, host reflective subcategories, functor extensionality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompletionAdjointUp.CompletionAdjointTasteGate single carrier alignment`

Theorem 2871.2 (Completion adjoint NameCert obligations)**.** *For every accepted* $\mathsf{CompletionAdjoint}^{\uparrow}$ *carrier $A = (R, F, U, V, S, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the twelve displayed rows; reflector exposure through R; functorial completion exposure through F; universal-property exposure through U; reflective-subcategory visibility through V; finite request scheduling through S; regular rational readback through Q; dyadic tolerance accounting through D; terminal RealUp sealing through E; componentwise transport through H; continuation replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier rows. The adjunction-facing data are precisely the reflector row R, the functor row F, the universal-property row U, the reflective-subcategory visibility row V, and the finite analytic rows S, Q, D, E.

Read the structural rows separately. The transport row H preserves those displayed rows componentwise, while C replays the same route for completion-adjunction consumers.

The provenance and naming rows P, N attach the packet to the cited completion, stream, regular-readback, dyadic, and Real certificates. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 2871.3 (Completion adjoint unit-counit ledger)**.** *Every unit or counit read exported by an accepted* $\mathsf{CompletionAdjoint}^{\uparrow}$ *carrier factors through the finite route*

$$R, F, U, V \longrightarrow S, Q, D \longrightarrow E, H, C, P, N.$$

The unit side reads the source-to-completion handoff through the reflector and functor rows, while the counit side reads the complete-object return through the universal-property and reflective-subcategory visibility rows. Both sides use the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the structural ledger is inspected.*

Proof. Start with the rows R, F, U, V. They are the only coordinates in the packet that can name the reflector, functor, extension, uniqueness, and reflected-object handoff needed by an adjunction consumer.

Next read S, Q, D, E. These rows supply finite request schedules, regular rational readback, dyadic tolerance accounting, and the terminal Real seal for both the unit-facing and counit-facing directions.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same displayed ledger, so the unit and counit routes cannot escape to a quotient completion, selected limit, host reflective subcategory, functor-extensional equality, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionAdjoint}^{\uparrow}$ packet is generated from CauchyCompletionReflector, CauchyCompletionFunctor, CompletionUniversalProperty, CauchyCompletionReflectiveSubcategory, StreamName, RegSeqRat, DyadicRatCore, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3843.1, Definition 3843.2, and Definition 3843.3 seed the finite adjunction certificate for Cauchy completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, selected limits, host reflective subcategories, functor extensionality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, reflector exposure, functorial completion exposure, universal-property compatibility, unit-counit ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompletionAdjointUp.

Chapter 2872

A Concrete Naming Certificate for UniformEquicontinuityModulus$^{\uparrow}$

Following Arzela–Ascoli and Bishop–Bridges equicontinuity arguments, the UniformEquicontinuityModulus$^{\uparrow}$ packet records the finite-net route by which a compact source and a finite family of continuous maps expose one shared modulus before any open-cover compactness or choice principle is read. It consumes compact-metric data from chapter 129, total-bounded finite nets from chapter 127, continuous-map graph and pointwise modulus rows from chapter 130, compact uniform-continuity handoff data from chapter 3444, and the downstream modulus surface of chapter 369. The certificate is a finite uniform-equicontinuity route for compact-window consumers, not a selected subcover, not a family-choice functional, and not ambient completeness of the codomain.

Definition 2872.1 (UniformEquicontinuityModulus carrier)**.** *A* UniformEquicontinuityModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, T, F, W, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing only the compact metric carrier, distance ledger, and compact finite-net surface used by the family.*
2. *T is the* TotallyBounded$^{\uparrow}$ *finite-net row over the same source, listing inspected centers and dyadic source-radius budgets.*
3. *F is the finite family of* ContinuousMap$^{\uparrow}$ *rows whose pointwise modulus and graph rows are inspected at the centers named by T.*
4. *W is the finite target-window row, recording the common tolerance window and the family indices admitted by the packet.*
5. *M is the exported* UniformModulus$^{\uparrow}$ *row, obtained by a finite fold over the centerwise and familywise modulus witnesses displayed by F against T and W.*
6. *H records componentwise* hsame *transport for the compact source, finite-net, continuous-family, window, folded-modulus, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a compact-window consumer through K, T, F, W, M and then through the structural rows.*

8. *P is the* Pkg *provenance over* UniformEquicontinuityModulus$^{\uparrow}$, CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, ContinuousMap$^{\uparrow}$, HeineCantor$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{UniformEquicontinuityModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected finite subcovers, countable choice over the family, quotient equality of maps, host real trichotomy, or ambient codomain completeness.

Lean4 ✓ `BEDC.Derived.UniformEquicontinuityModulusUp.UniformEquicontinuityModulusTasteGate`
`single carrier alignment`

Theorem 2872.2 (UniformEquicontinuityModulus NameCert obligations)**.** *For every accepted* UniformEquicontinuityModulus$^{\uparrow}$ *carrier $U = (K, T, F, W, M, H, C, P, N)$, the local* NameCert$_{\text{UniformEquicontinuityModulus}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the finite packet $K, T, F, W, M, H, C, P, N$;*
2. *finite-window classifier: every family and target-tolerance read is confined to the displayed window row W and the listed* ContinuousMap$^{\uparrow}$ *rows in F;*
3. *compact finite-net exactness: the only compactness data read by the classifier are the* CompactMetric$^{\uparrow}$ *source row K and the* TotallyBounded$^{\uparrow}$ *finite-net row T;*
4. *uniform-modulus export: the shared modulus row M is obtained by the finite fold over the centerwise pointwise-modulus rows in F and the compact finite-net route already exposed by K, T;*
5. *non-escape: no accepted consumer receives an open-cover compactness object, selected subcover, family-choice functional, quotient map equality, host real trichotomy, or ambient completeness theorem.*

Proof. Project the carrier row by row. The analytic data available before the exported modulus are exactly the compact source K, the finite-net inventory T, the finite continuous-family rows F, and the common target window W.

The compact finite-net exactness clause follows from the route through K and T. Since T lists the centers and radius budgets as finite data, the classifier never needs an open-cover subcover or a choice over covers.

The uniform-modulus export is then the finite fold stored in M. Each fold input is a pointwise modulus row from F at a center named by T and a tolerance named by W; the Heine–Cantor handoff supplies the compact-window reading of those rows, while the final row is presented to the UniformModulus$^{\uparrow}$ surface.

Finally read the structural rows. The transport row H, replay row C, provenance row P, and local naming row N preserve the same finite route and contain no coordinate for the excluded cover, choice, equality, trichotomy, or completeness data. □

Falsifiable prediction: An accepted UniformEquicontinuityModulus$^{\uparrow}$ read is refuted if it exports a shared family modulus without displaying the compact source row, total-bounded finite-net row, finite continuous-family rows, target-window row, folded modulus row, transport, replay, provenance, and local naming rows.

Independence witness: compactmetric, totallybounded, continuousmap, heine-cantor, uniformmodulus: none alone is bijective with UniformEquicontinuityModulus$^{\uparrow}$ because the packet jointly records a compact source, finite net, finite continuous family, common target window, folded uniform modulus, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEquicontinuityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ packet is generated from CompactMetric source data, TotallyBounded finite nets, ContinuousMap family rows, a common finite target window, a finite folded UniformModulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEquicontinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3844.1 and Definition 3844.2 seed the compact finite-net route from a finite continuous family to a shared UniformModulus consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEquicontinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable family choice, quotient equality of maps, host real trichotomy, ambient codomain completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window classification, compact finite-net exactness, uniform-modulus export, transport, replay, provenance, and local naming for BEDC.Derived.UniformEquicontinuityModulusUp.

Chapter 2873

A Concrete Naming Certificate for $\mathsf{LimitSpace}^{\uparrow}$

Following Kelley and Bishop–Bridges convergence-space and limit-space terminology, the $\mathsf{LimitSpace}^{\uparrow}$ packet records the finite interface by which a displayed Cauchy-filter or filter-base row is read against an observation schedule, a dyadic tolerance ledger, a regular rational readback, and a terminal real limit seal. It consumes the Cauchy-filter surface of chapter 333, the finite observation schedule of chapter 126, the dyadic tolerance core of chapter 291, the regular rational route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a convergence-space interface, not a quotient filter, selected limit, host equality of convergent objects, or ambient completeness theorem.

Definition 2873.1 (LimitSpace carrier)**.** *A* $\mathsf{LimitSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, S, D, R, L_0, H, C, P, N)$$

with the following displayed rows:

1. *F is a* $\mathsf{CauchyFilter}^{\uparrow}$ *or filter-base row, carrying the finite filter requests and Cauchy-stability witnesses permitted at this limit-space site;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule that records which finite windows of F are inspected;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the scheduled and tolerated observations into regular rational data;*
5. *L_0 is the* $\mathsf{Real}^{\uparrow}$ *limit-seal row reached only after F, S, D, R have been displayed;*
6. *H records componentwise* hsame *transport for the filter, schedule, tolerance, readback, limit seal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from a convergence request through F, S, D, R, L_0, H, P, N;*
8. *P is the* Pkg *provenance over* $\mathsf{LimitSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable choice, host equality of convergent filters, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge evidence.*

Lean4 ✓ `BEDC.Derived.LimitSpaceUp.LimitSpaceTasteGate single carrier alignment`

Theorem 2873.2 (LimitSpace NameCert obligations)**.** *For every accepted* $\mathsf{LimitSpace}^{\uparrow}$ *carrier*

$$L = (F, S, D, R, L_0, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Cauchy-filter or filter-base row, StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, Real limit seal, transport, replay, provenance, and local naming row;*
2. *filter-source exposure, requiring every limit-space consumer to read F before any scheduled observation, tolerance comparison, readback, or limit seal is inspected;*
3. *schedule and tolerance discipline, requiring S and D to determine the finite windows and dyadic budgets used by the readback row;*
4. *regular readback discipline, requiring R to be downstream of F, S, D and upstream of the terminal seal;*
5. *limit-seal non-escape, requiring the* $\mathsf{Real}^{\uparrow}$ *row L_0 to be read only as a seal for the displayed readback route;*
6. *structural preservation through H, C, P, N;*
7. *refusal of quotient filters, selected limits, countable choice, host equality of convergent filters, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge evidence.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3845.1. The tuple displays exactly the Cauchy-filter or filter-base source, finite schedule, dyadic tolerance ledger, regular rational readback, real limit seal, and structural rows.

The source obligation is first. A convergence consumer cannot reach a scheduled observation or terminal seal without reading F, because no other row carries filter-source data.

The schedule and tolerance obligations are then forced by S and D. They determine the finite windows and dyadic budgets that the regular readback row may inspect, so R is downstream of the displayed observation discipline rather than a separate selected representative.

Finally L_0 is exposed only as the real seal for that readback route, while H, C, P, N preserve, replay, source, and name the same finite packet. Since the excluded principles have no carrier coordinate, they cannot become NameCert obligations. □

Theorem 2873.3 (LimitSpace Cauchy-filter consumer route)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LimitSpace}^{\uparrow}$ *carrier factors through the displayed route*

$$F \longmapsto S, D \longmapsto R \longmapsto L_0 \longmapsto H, C, P, N.$$

The consumer first reads the Cauchy-filter or filter-base row, then the StreamName schedule and DyadicRatCore tolerance ledger, then the RegSeqRat readback, and only then the Real limit seal. The route exports no quotient filter, no selected limit, no host equality of convergent filters, no countable-choice schedule, and no ambient completeness theorem.

Proof. Project the accepted carrier. The first row F is the only source for Cauchy-filter or filter-base data, so every filter-facing read starts there.

The next step is the finite observation discipline. The schedule row S names the inspected windows and the tolerance row D names the dyadic budgets attached to them; without those two rows the regular readback row has no displayed finite request to answer.

The readback and seal rows are downstream. The row R converts the scheduled observations into regular rational data, and L_0 seals the resulting route as a $\mathsf{Real}^{\uparrow}$ limit row without selecting an external limit object.

The structural rows H, C, P, N preserve and name the same route. Because the carrier contains no quotient-filter coordinate, selected-limit coordinate, host equality row, choice schedule, or ambient completeness row, every accepted consumer factors through the displayed path. □

Falsifiable prediction: An accepted $\mathsf{LimitSpace}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ limit seal without first displaying the $\mathsf{CauchyFilter}^{\uparrow}$ or filter-base row, the $\mathsf{StreamName}^{\uparrow}$ schedule, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger refutes the carrier surface.

Independence witness: cauchyfilter, streamname, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{LimitSpace}^{\uparrow}$ because this packet jointly carries a filter-source row, observation schedule, tolerance ledger, regular readback, terminal limit seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LimitSpace}^{\uparrow}$ packet is generated from a CauchyFilter or filter-base row, StreamName observation schedule, DyadicRatCore tolerance ledger, RegSeqRat readback row, Real limit seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$, seed)

Scope closed: Definition 3845.1, Definition 3845.2, and Definition 3845.3 seed the finite convergence-space interface from CauchyFilter rows through StreamName, DyadicRatCore, RegSeqRat, and Real limit-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality of convergent filters, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-source exposure, schedule and tolerance discipline, regular readback discipline, Real limit-seal non-escape, and structural preservation for BEDC.Derived.LimitSpaceUp.

$\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ reads compactness-facing finite-window criteria through chapter 129, chapter 127, and chapter 3844 before its Arzela–Ascoli and completion consumers inspect the local rows.

Chapter 2874

A Concrete Naming Certificate for $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$

Following Kolmogorov–Riesz and Frechet compactness in constructive finite-window form, the $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet records the BEDC route by which compact metric control, total boundedness, uniform equicontinuity, completion readiness, and terminal Real readbacks are named as one compactness-facing criterion. It sits after the compact-metric surface of chapter 129, the total-bounded source of chapter 127, the uniform-equicontinuity modulus of chapter 3844, the complete-metric handoff of chapter 128, and the terminal real-name seal of chapter 38. Its compactness route also consumes bounded-set rows from chapter 1757, equicontinuous-sequence rows from chapter 4356, and finite-net compact-metric product rows from chapter 1822. The carrier names finite net and completion rows only; it does not assert open-cover compactness, choose subsequences, select subcovers, or import ambient completeness outside the displayed packet.

As a carrier dependency, the packet consumes the compactness route through chapter 129, the equicontinuity-family route through chapter 413, and the real and metric boundary routes through chapter 38 and chapter 57. These rows are part of the $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$ admission surface: a compactness consumer must see the compact metric source, family-equicontinuity ledger, Real readback seal, and metric carrier before the Frechet–Kolmogorov criterion row is exported.

Definition 2874.1 (Frechet-Kolmogorov compactness carrier)**.** *A* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, E, Q, C, S, R, H, A, P, N)$$

with the following rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the displayed metric and compactness-facing finite-net interface.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *row recording the finite ε-net budget consumed by the criterion.*
3. *E is the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *row binding a shared modulus to the same finite windows.*
4. *Q is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion boundary row, used only after the finite net and modulus rows are visible.*
5. *C is the compactness-criterion row relating the metric, total-bounded, equicontinuity, and completion rows as one finite BEDC route.*

6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger for the inspected net cells, modulus requests, and Cauchy-readback windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance comparisons.*
8. *H records componentwise* hsame *transport for all displayed source, net, modulus, completion, readback, and naming rows.*
9. *A records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, T, E, Q, C, S, R, H, A, P, N$. It has no coordinate for an open-cover compactness theorem, selected subsequence, selected subcover, quotient completion equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2874.2 (Frechet-Kolmogorov compactness NameCert obligations)**.** *For every accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier $K = (M, T, E, Q, C, S, R, H, A, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCor}}$ *surface consists exactly of compact-metric source exposure through M; total-bounded finite-net exposure through T; uniform-modulus exposure through E; completion-boundary exposure through Q; criterion compatibility through C; finite-window and rational readback exposure through S, R; componentwise transport through H; displayed replay through A; provenance through P; and local naming through N.*

Proof. Project the accepted carrier. The coordinates are precisely the compact-metric source, total-bounded net, uniform-modulus, completion-boundary, criterion, finite-window, readback, transport, replay, provenance, and naming rows.

Read the source rows in order. The compact-metric row gives the metric-facing carrier; the total-bounded row supplies finite nets over that metric; the uniform-equicontinuity row uses the same windows; and the completion row is reached only through those displayed finite controls.

The structural rows H, A, P, N transport, replay, source, and name that same route. Since no carrier coordinate names a selected subsequence, selected subcover, open-cover compactness proof, quotient equality, or ambient completeness theorem, the listed rows exhaust the local certificate surface. □

Theorem 2874.3 (Frechet-Kolmogorov compactness total-bounded handoff)**.** *Every compactness-facing consumer of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier must read the total-bounded row T through the compact-metric source M and the uniform-modulus row E before it inspects the StreamName and RegSeqRat readback rows S, R. Thus finite-net evidence is exported as a displayed BEDC handoff, not as a choice-selected dense set or an unrecorded cover refinement.*

Proof. Begin with the compact-metric source row. It fixes the metric and the carrier surface on which the total-bounded net is meaningful.

The total-bounded row then exposes the finite net budget, while the uniform-modulus row forces all later compactness requests to use the same finite tolerance windows. Only after those rows are visible can the StreamName and RegSeqRat rows read the inspected windows and rational tolerances.

Therefore the consumer receives a finite-net handoff through M, T, E, S, R and not a selected dense subset, a selected subcover, or an unrecorded refinement outside the packet. □

Theorem 2874.4 (Frechet-Kolmogorov compactness sibling route)**.** *Every compactness-facing export of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier consumes the compactness, total-boundedness, and equicontinuity sibling surfaces before it exports compactness of the function family. The route enters through the* $\mathsf{CompactMetric}^{\uparrow}$ *source of chapter 129, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row of chapter 127, and the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *row of chapter 3844; it may then hand the assembled finite-window criterion to the Arzela–Ascoli finite-net surface of chapter 7576. The packet exports no open-cover compactness proof, selected subsequence, selected subcover, quotient completion equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier and NameCert obligations. The rows M, T, E are respectively the compact-metric source, total-bounded finite-net budget, and uniform-equicontinuity modulus, so no compactness-facing read can begin outside those sibling surfaces.

Use the total-bounded handoff. It forces finite-net evidence through the compact-metric source and the shared modulus before StreamName and RegSeqRat readbacks are inspected.

Finally use the completion boundary theorem. The row Q can be consumed only after the compactness, total-boundedness, and equicontinuity rows are visible, and the structural rows H, A, P, N preserve the same finite route for any Arzela–Ascoli or completion-facing consumer. □

Theorem 2874.5 (Frechet-Kolmogorov compactness Arzela-Ascoli dependency)**.** *Every Arzela–Ascoli-facing consumer of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier first reads the* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows already exposed by the carrier. The Arzela–Ascoli finite-net surface may consume this route, but it does not bypass the compact-metric source, total-bounded handoff, uniform-modulus row, completion boundary, finite windows, rational readback, or Real seal.*

Proof. Apply the sibling route of Definition 3846.4. It already directs compactness-facing exports through the CompactMetric, TotallyBounded, and UniformEquicontinuityModulus sibling surfaces before any Arzela–Ascoli finite-net consumer receives the assembled criterion.

Use the total-bounded handoff of Definition 3846.3. The finite-net budget is read through the compact-metric source and shared modulus before the StreamName and RegSeqRat rows expose inspected windows and rational tolerance comparisons.

Finally apply the completion boundary of Definition 3846.6. The CompleteMetric row and Real-facing seal remain downstream boundaries over the same finite data, so an Arzela–Ascoli-facing consumer cannot obtain open-cover compactness, a selected subsequence, a selected subcover, quotient completion equality, or ambient Real completeness outside the displayed route. □

Theorem 2874.6 (Frechet-Kolmogorov compactness completion boundary)**.** *The completion-facing part of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier is confined to the displayed row* Q *after the compact-metric source, total-bounded net, and uniform-modulus rows have been read. It may hand a downstream completion consumer a finite Cauchy-window boundary, but it does not claim quotient completion equality, a selected limit representative, sequential compactness, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the route through M, T, E first. These rows supply the metric source, finite-net budget, and shared modulus required before any completion boundary can be inspected.

The completion row Q is therefore a boundary row over already displayed finite data. The readback rows S, R and the structural rows H, A, P, N keep the same route visible under windowing, rational comparison, transport, replay, provenance, and naming.

Because the carrier contains no quotient-equality, selected-limit, sequential-compactness, open-cover, or ambient-completeness coordinate, a completion consumer cannot obtain any of those objects from the local packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet is generated from a CompactMetric source row, a TotallyBounded finite-net row, a UniformEquicontinuityModulus row, a CompleteMetric boundary row, StreamName finite windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3846.1, Definition 3846.2, Definition 3846.3, Definition 3846.4, Definition 3846.5, and Definition 3846.6 seed the finite compactness criterion over compact-metric, total-bounded, uniform-modulus, completion-boundary, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness, selected subsequences, selected subcovers, quotient completion equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, uniform-modulus compatibility, completion-boundary nonescape, readback stability, transport, replay, provenance, and local naming for BEDC.Derived.FrechetKolmogoro

Theorem 2874.7 (Frechet-Kolmogorov finite-window compactness handoff)**.** *Every accepted* FrechetKolmogorovCo *compactness read that is exported to a finite-net or compact-metric consumer must route through the displayed boundedness row, finite translation-modulus row, tail-cutoff row, finite-net extraction row,* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{Met}^{\uparrow}$ *distance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$ *row before compactness is public. In carrier notation the handoff refines the local route*

$$M, T, E, Q, C, S, R, H, A, P, N$$

by requiring boundedness, translation control, tail cutoff, finite nets, Real readback, rational readback, and metric-distance rows to be visible before the consumer can use the compactness criterion. The handoff exports no ambient compactness theorem, open-cover compactness, countable choice, selected subsequence, selected subcover, quotient completion equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the local NameCert obligations of Definition 3846.2. They force the compact-metric source M, total-bounded finite-net row T, uniform-modulus row E, completion boundary Q, finite-window row S, readback row R, and structural rows H, A, P, N to be displayed before a compactness-facing consumer receives the packet.

Read the additional finite-window controls through the same route. The boundedness row is supplied by the bounded-set dependency already named in the chapter introduction, the finite translation-modulus and tail-cutoff rows are consumed as uniform-window controls, and the finite-net extraction row is read through the total-bounded handoff of Definition 3846.3. The $\mathsf{Met}^{\uparrow}$ distance rows and the $\mathsf{Real}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}$ readbacks attach the tolerance comparisons to the displayed windows.

Finally apply the completion boundary of Definition 3846.6. The structural rows only transport, replay, source, and locally name the same finite handoff, so no coordinate remains for ambient compactness, open-cover compactness, countable choice, selected subsequences, selected subcovers, quotient completion equality, or ambient Real completeness. □

The finite compactness route of $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ feeds the Arzela–Ascoli finite-modulus criterion of chapter 3568 only after the compact metric source of chapter 129, the finite-net

discipline of chapter 127, and the uniform-equicontinuity modulus of chapter 3844 have been displayed. A compact-uniform-continuity consumer therefore receives compact metric, total-bounded, uniform-modulus, completion, transport, replay, provenance, and local NameCert rows, not an open-cover compactness theorem or a selected subsequence.

Theorem 2874.8 (Frechet–Kolmogorov Arzela–Ascoli dependency route)**.** *Every accepted* FrechetKolmogorovComp *compactness read consumes the equicontinuity and finite-subfamily surface of chapter 412 before it exports compactness for function families. The Frechet–Kolmogorov packet therefore routes compact metric data, total-bounded finite nets, bounded-family rows, Arzela–Ascoli equicontinuity rows, transport, replay, provenance, and local* NameCert *naming as one displayed dependency chain.*

Proof. Project the carrier through the local Frechet–Kolmogorov route. The compact source and finite-net rows are visible before any family compactness conclusion is offered to a downstream consumer.

Now read the Arzela–Ascoli sibling. Its equicontinuity and finite-subfamily surface supplies the function-family control that the Frechet–Kolmogorov packet consumes before exporting compactness.

The structural rows only transport, replay, source, and name this chain. Hence the dependency is horizontal and finite, not an ambient compactness theorem or a selected subsequence principle. □

Theorem 2874.9 (Frechet–Kolmogorov Arzela–Ascoli compact handoff)**.** *Every accepted* FrechetKolmogorovComp *handoff to an Arzela–Ascoli consumer must first display the compact-metric finite nets of chapter 129, the total-bounded finite-net rows of chapter 127, and the equicontinuity surface of chapter 412. The exported compactness packet is therefore a finite* BHist *route through compact metric, total-boundedness, Arzela–Ascoli finite-window selection, transport, replay, provenance, and local* NameCert *rows.*

Proof. Read the accepted Frechet–Kolmogorov carrier through its compact metric source. The compact-metric row fixes the metric-facing source, while the total-bounded row supplies the finite nets that any compactness-facing consumer can inspect.

Next read the Arzela–Ascoli dependency. Its equicontinuity and finite-window rows are consumed after those compact metric and total-bounded rows, so the function-family compactness conclusion is not detached from the finite net budget.

The remaining rows only preserve the displayed route. Componentwise hsame transport, Cont replay, provenance, and local naming keep the handoff inside the same finite packet, excluding selected subsequences, open-cover compactness, and ambient completeness. □

Theorem 2874.10 (Frechet–Kolmogorov downstream Arzela–Ascoli link)**.** *Every Arzela–Ascoli finite-net consumer of an accepted* FrechetKolmogorovCompactness$^{\uparrow}$ *packet must first read the* CompactMetric$^{\uparrow}$ *source row, the* TotallyBounded$^{\uparrow}$ *finite-net row, the* UniformEquicontinuityModulus$^{\uparrow}$ *row, the* CompleteMetric$^{\uparrow}$ *completion boundary, the* StreamName$^{\uparrow}$ *observation windows, the* RegSeqRat$^{\uparrow}$ *readback rows, and the* Real$^{\uparrow}$ *seal rows carried by the displayed dependency route. The handoff exports no selected subsequence, selected subcover, open-cover compactness theorem, quotient completion equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the existing Frechet–Kolmogorov carrier through the compactness dependency route. The compact metric source and total-bounded finite-net rows are visible before any function-family compactness read is offered downstream.

Read the Arzela–Ascoli-facing rows next. The dependency route of Definition 3846.8 and the compact handoff of Definition 3846.9 require the uniform-equicontinuity modulus before the finite-net consumer receives the family surface.

Finally inspect the completion and real-readback side. The compact metric total-bounded dependency of Definition 3846.11 keeps the $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows attached to the same finite route. Since no route theorem supplies a selected subsequence, selected subcover, open-cover compactness theorem, quotient completion equality, or ambient completeness coordinate, the downstream Arzela–Ascoli link exports only the displayed finite lattice. □

Theorem 2874.11 (Compact metric total-bounded dependency)**.** *The* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *criterion consumes the compact-metric source of chapter 129 and the total-bounded finite-net budget of chapter 127 before it reads the uniform-equicontinuity row of chapter 3844 and the completion boundary of chapter 128. Thus the later StreamName, RegSeqRat, and Real readbacks remain attached to displayed finite metric and net data, rather than to an unrecorded compactness principle.*

The $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet exposes a real-sequence compactness read only after its compact-metric finite-net rows, bounded-function-family rows, and Arzela–Ascoli finite-window rows have all been displayed. Thus every downstream compactness consumer first passes through the compact source of chapter 129, the bounded family surface of chapter 3522, and the Arzela–Ascoli route of chapter 412; before real-sequence compactness readback, it also consumes the finite epsilon-net chain of chapter 8049. The Frechet–Kolmogorov carrier then contributes only the finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows that assemble those dependencies into the real-sequence compactness read.

Theorem 2874.12 (Frechet-Kolmogorov locally convex boundedness route)**.** *Every* $\mathsf{FrechetKolmogorovCompactnes}$ *consumer that reads compactness through locally convex bounded sets must factor through the finite route*

$$\mathsf{LocallyConvexSpace}^{\uparrow}, \mathsf{FrechetSpace}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{TotallyBounded}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer must expose the locally convex seminorm row of chapter 3386, the Frechet metric completion row of chapter 3495, the compact metric row of chapter 129, the total bounded row of chapter 127, and the terminal Real seal row of chapter 38 before it may treat a bounded family as Frechet-Kolmogorov compactness data.

Proof. Start with the locally convex seminorm row. It supplies the bounded-set requests that a functional-analysis consumer is allowed to ask of the packet.

The Frechet metric completion row then turns those seminorm requests into a displayed metric-completion boundary. The compact metric row and total bounded row refine that boundary into finite compactness data, so the consumer sees nets and metric windows rather than an ambient bounded-set compactness theorem.

Finally the Real seal row records the scalar readback used by the seminorm and metric estimates. Since each step is an exposed row in the displayed route, no consumer can bypass the seminorm, completion, compact metric, total bounded, or Real-seal surfaces by appealing to host boundedness or selected compactness data. □

Theorem 2874.13 (Frechet–Kolmogorov metric-completion functor route)**.** *Every* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier must first read the compact-metric source of chapter 129, the total-bounded finite-net surface of chapter 127, the uniform-equicontinuity modulus of chapter 3844, the complete-metric boundary of chapter 128, the StreamName window rows of chapter 126, the RegSeqRat readback of chapter 301, and the Real seal of*

chapter 38. The route exports a displayed compactness-to-completion handoff only; it exports no quotient completion equality, selected compact limit, selected subsequence, selected subcover, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the carrier of Definition 3846.1. Its compactness-facing source rows are the compact metric row, the total-bounded finite-net row, the uniform-modulus row, and the completion boundary row.

Apply the sibling route of Definition 3846.16. It keeps the compact metric, total-bounded, uniform-equicontinuity, RegSeqRat, and Real-seal rows visible as one dependency lattice before any compactness conclusion is exported.

Finally apply the completion boundary of Definition 3846.6. A $\mathsf{MetricCompletionFunctor}^{\uparrow}$ consumer can only repackage that displayed boundary through StreamName and RegSeqRat readbacks, so quotient completion equality, selected compact limits, and ambient completeness are outside the exported surface. □

The $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet is read through a substantive compactness sibling lattice rather than as a detached compactness kernel: its equicontinuity branch consumes the finite-modulus Arzela–Ascoli route of chapter 412, its compact source consumes the $\mathsf{CompactMetric}^{\uparrow}$ total-bounded finite-net rows of chapter 129, and its completion handoff is routed through the MetricCompletion completion surface of chapter 1506. These references keep compact metric, total-bounded finite nets, completion, transport, replay, provenance, and local NameCert rows visible before any compactness-facing consumer reads the Frechet–Kolmogorov packet.

Theorem 2874.14 (Frechet-Kolmogorov Sobolev compact-embedding forward link)**.** *Every Sobolev-family consumer that reaches the* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *packet through a compact-embedding route must first display the* $\mathsf{Sobolev}^{\uparrow}$ *source rows, the* $\mathsf{CompactEmbedding}^{\uparrow}$ *handoff of chapter 7166, and the compact-metric and total-bounded rows of chapter 129 and chapter 127. The Frechet–Kolmogorov packet may then consume the finite StreamName, RegSeqRat, completion-boundary, transport, replay, provenance, and local NameCert rows exposed by those siblings, but it does not replace the compact-embedding handoff with selected subsequences, open-cover compactness, quotient function equality, or ambient Real completeness.*

Proof. Start from the compact-embedding side. The $\mathsf{CompactEmbedding}^{\uparrow}$ chapter exposes a finite handoff from Sobolev source windows into compact and complete target rows, so a Sobolev-family read arrives with displayed source, target, readback, transport, replay, provenance, and naming data.

Use the Frechet–Kolmogorov compactness carrier and its sibling route. The rows $M, T, E, Q, S, R, H, A, P, N$ already require compact-metric source exposure, total-bounded finite nets, completion boundary, finite-window readback, rational comparison, transport, replay, provenance, and local naming before compactness-facing data are exported.

The forward link is therefore a dependency route, not a new compactness principle. The Frechet–Kolmogorov consumer reads the Sobolev and compact-embedding siblings as displayed rows and then reuses the compact-metric and total-bounded surfaces, leaving selected subsequences, open-cover compactness, quotient function equality, and ambient Real completeness outside the packet. □

Theorem 2874.15 (Frechet–Kolmogorov hub dependency index)**.** *The hub route for* FrechetKolmogorovCompactne *reads the* $\mathsf{CompactMetric}^{\uparrow}$ *source rows, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net rows, the Arzela–Ascoli finite-modulus rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback rows, the* $\mathsf{Real}^{\uparrow}$ *terminal boundary rows, and the*

MetricCompletion$^{\uparrow}$ *sibling rows before any Frechet–Kolmogorov compactness consumer can inspect the local compactness packet. Thus the top-level input boundary records the same dependency lattice that the child certificates expose: compact metric source, total-bounded budget, finite-modulus equicontinuity, regular rational comparison, Real boundary, completion handoff, transport, replay, provenance, and local* NameCert *data.*

Proof. Read the hub as an ordered certificate boundary. Its child files first expose the name certificate spine and then the compact-metric, total-bounded, Arzela–Ascoli, locally convex, and metric-completion routes.

The rational and Real rows are read through the same sibling lattice. The RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ surfaces supply readback and terminal boundary data before the compactness consumer opens the Frechet–Kolmogorov packet.

Consequently a consumer cannot bypass the sibling rows at the hub boundary. The hub records the dependency lattice directly while leaving all theorem content in child files. □

The FrechetKolmogorovCompactness$^{\uparrow}$ dependency lattice reads compactness only after its sibling surfaces are visible: the compact metric source of chapter 129, the finite-family control supplied by chapter 412, the completion-facing transport of chapter 1506, the regular rational tolerance readback of chapter 301, the terminal real seal of chapter 38, and the tightness ledger of chapter 3795. This makes compactness a displayed route through compact metric, equicontinuity, completion, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and tightness rows, rather than an ambient subsequence selector, open-cover oracle, or quotient completion equality.

Theorem 2874.16 (Frechet–Kolmogorov compactness sibling route)**.** *The* FrechetKolmogorovCompactness$^{\uparrow}$ *packet consumes the Arzela–Ascoli finite-modulus route of chapter 3568 as its equicontinuity-facing compactness control, and it consumes the local seminorm-to-completion route recorded in Definition 3846.12 as its locally convex boundedness control. Together with the compact metric surface of chapter 129, the total-bounded surface of chapter 127, the equicontinuity radius source of chapter 3844, the compact metric total-bounded source of chapter 4055, the regular rational readback of chapter 301, and the Real seal of chapter 38, these sibling reads keep the compact metric, total-bounded, uniform-equicontinuity, locally convex seminorm, Frechet metric, RegSeqRat, and Real-seal rows visible as one finite dependency lattice rather than as an ambient function-space compactness theorem.*

Proof. Read the compact metric and total-bounded rows first. The compactness-facing consumer must pass through the displayed compact metric packet and its total-bounded control before any finite-cover or subsequence conclusion is available.

Next read the equicontinuity and local boundedness rows. The Arzela–Ascoli finite-modulus route supplies the uniform-equicontinuity control, while the locally convex boundedness route supplies the seminorm-to-completion control.

Finally read the completion, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ seal rows. Since each consumer opens these sibling rows before the compactness conclusion, the packet exports a finite dependency lattice rather than an ambient function-space compactness principle. □

Theorem 2874.17 (Frechet–Kolmogorov bounded-tail compactness route)**.** *An accepted* FrechetKolmogorovCompa *consumer may read total-bounded compactness only after it has exposed both the Arzela–Ascoli finite-modulus route and the locally convex boundedness route. The read passes through* CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *and the displayed completion boundary of Definition 3846.6; it does not use open-cover compactness, selected subsequences, or an ambient choice of compact limit points.*

Proof. Start with the sibling route of Definition 3846.16. It orders the compact metric, total-bounded, Arzela–Ascoli finite-modulus, locally convex seminorm, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows as one dependency lattice.

Next apply the locally convex boundedness route of Definition 3846.12. It supplies the bounded finite-tail control needed before the Frechet metric can be read through the completion surface.

Finally combine the total-bounded handoff of Definition 3846.3 with the completion boundary of Definition 3846.6. The handoff gives finite total-bounded data, and the boundary keeps the completion read in $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ form, so no open-cover compactness principle or selected subsequence is introduced. □

Theorem 2874.18 (Frechet–Kolmogorov sibling dependency witness)**.** *Every accepted* FrechetKolmogorovCompact *carrier witnesses a substantive dependency on the compact metric, total-bounded, and Arzela–Ascoli finite-modulus sibling chapters. The compactness criterion may be consumed only after the compact source of chapter 129, the finite-net surface of chapter 127, and the Arzela–Ascoli finite-modulus route of chapter 3568 have all been displayed together with the local carrier rows of Definition 3846.1.*

Proof. Read the compact source first. The row M in Definition 3846.1 is a $\mathsf{CompactMetric}^{\uparrow}$ source row, so the criterion has no compactness-facing read until the displayed compact metric packet is available.

Read the total-bounded surface next. The row T supplies the finite-net budget consumed by the criterion, and the theorem Definition 3846.3 forces that budget to pass through the same compact metric source before any readback rows are inspected.

Read the Arzela–Ascoli finite-modulus route as the equicontinuity-facing control. The sibling route of Definition 3846.16 binds the Arzela–Ascoli finite-modulus chapter to the same finite compactness route, so the equicontinuity row cannot be replaced by an ambient function-space compactness theorem.

Finally the local transport, replay, provenance, and naming rows H, A, P, N keep those sibling dependencies on the same packet. Thus the Frechet–Kolmogorov chapter records a dependency lattice over compact metric, total boundedness, and Arzela–Ascoli finite modulus rather than a kernel-only compactness assertion. □

Theorem 2874.19 (Frechet–Kolmogorov orphan compact metric lattice)**.** *The compactness-facing export of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *packet is not a kernel-only assertion. Before it exposes the local compactness criterion, the consumer must read the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *control row, the Arzela–Ascoli finite-modulus route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row as sibling dependencies of the same carrier.*

Proof. Start with the dependency witness of Definition 3846.18. It already forces the compact metric, total-bounded, and Arzela–Ascoli finite-modulus rows to be displayed with the local carrier rows.

Now read the sibling route of Definition 3846.16. That route places the uniform-equicontinuity, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows in the same finite lattice rather than letting the criterion stand as an isolated kernel compactness claim.

Finally apply the total-bounded handoff of Definition 3846.3. The finite-net budget must pass through the compact metric source before readback rows are inspected, so the local compactness criterion is exposed only after the compact-metric dependency lattice is visible. □

The FrechetKolmogorovCompactness$^{\uparrow}$ packet consumes the compact-metric total-bounded route from chapter 129 and the finite extraction route of chapter 412 before it can export a compactness criterion. Thus the compact metric source, finite extraction surface, transport rows, replay rows, and local NameCert data are visible as horizontal dependencies rather than as an isolated compactness kernel. The FrechetKolmogorovCompactness$^{\uparrow}$ packet consumes the finite total-bounded and completion rows of chapter 129 before it exports compactness data to the equicontinuity and finite-subfamily surface of chapter 412. This route keeps compact metric source data, finite nets, completion readiness, Arzela–Ascoli family control, transport, replay, provenance, and local NameCert rows visible together, rather than treating Frechet–Kolmogorov compactness as an isolated compactness oracle.

Theorem 2874.20 (Frechet–Kolmogorov top sibling pointer)**.** *Every finite-window criterion exported by* FrechetKolmogorovCompactness$^{\uparrow}$ *must first display the compact metric source of chapter 129, the total-bounded finite-net surface of chapter 127, and the Arzela–Ascoli finite-modulus route of chapter 3568. The top-level route therefore exposes the sibling lattice before any Frechet–Kolmogorov compactness consumer reads the local carrier.*

Theorem 2874.21 (Frechet–Kolmogorov tightness dependency route)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *compactness read must expose the compact metric source of chapter 129, the total-bounded finite-net surface of chapter 127, the Arzela–Ascoli finite-modulus route of chapter 3568, and the locally-convex boundedness and tightness rows before the local carrier is consumed. The dependency route therefore records Frechet–Kolmogorov compactness as a finite lattice read over compact metric, total boundedness, equicontinuity-modulus, and tightness data, not as an ambient compactness oracle.*

Theorem 2874.22 (Frechet–Kolmogorov tightness route)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *compactness read must display the* CompactMetric$^{\uparrow}$ *source row, the* TotallyBounded$^{\uparrow}$ *finite-net row, the* UniformEquicontinuityModulus$^{\uparrow}$ *control row, the* CompleteMetric$^{\uparrow}$ *boundary row, the* RegSeqRat$^{\uparrow}$ *rational readback row, the* Real$^{\uparrow}$ *seal, and the local tightness and boundedness rows before it exports compactness of the family. The route is a finite* BHist/Cont/Pkg *ledger over compact metric, total-bounded, equicontinuity, completion, regular-rational, real, tightness, boundedness, transport, replay, provenance, and local* NameCert *data; it is not an ambient compactness oracle, a selected subsequence, a selected subcover, or quotient completion equality.*

Proof. Read the carrier of Definition 3846.1. Its source rows already expose CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, UniformEquicontinuityModulus$^{\uparrow}$, CompleteMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ as the visible compactness route.

Now combine the total-bounded handoff of Definition 3846.3 with the sibling route of Definition 3846.4. Those results force the finite-net, equicontinuity, and completion-facing rows to remain visible before any compactness export is read.

The tightness and boundedness rows are therefore local dependency rows in the same ledger. They do not introduce a hidden subsequence choice, a hidden subcover, or an equality in a quotient completion, because the structural rows transport and replay only the displayed finite packet. □

The compactness export of FrechetKolmogorovCompactness$^{\uparrow}$ is read through a compact-metric finite-net source together with the Arzela–Ascoli equicontinuity and tightness rows. The compact metric source fixes the finite-net budget; the Arzela–Ascoli sibling supplies the function-family tightness surface; the local replay rows then expose compactness only after both pieces have been displayed.

Theorem 2874.23 (Frechet–Kolmogorov compact-metric tightness route)**.** *Every accepted* FrechetKolmogorovCom *consumer that exports compactness for function-family windows must first read the compact-metric finite-net data of chapter 129 and the equicontinuity/tightness rows of chapter 412. The export is therefore a finite dependency route through compact metric source rows, finite-net coverage rows, Arzela–Ascoli tightness rows, transport, replay, provenance, and local* NameCert *data, not a selected subsequence, open-cover compactness theorem, quotient function-family equality, or ambient completeness principle.*

Proof. Project the Frechet–Kolmogorov carrier through its compactness-facing rows. The compact metric source supplies the finite-net data that any downstream compactness read must inspect before it can speak about a family window.

Next read the Arzela–Ascoli sibling route. Its equicontinuity and tightness rows are consumed after the compact-metric finite nets and before the local compactness export, so the function-family conclusion remains tied to displayed finite data.

Finally project the structural rows. Componentwise hsame transport, displayed Cont replay, provenance, and local naming preserve exactly the compact-metric and tightness route, leaving no coordinate for a hidden subsequence, open-cover theorem, quotient equality of families, or ambient completeness principle. □

Theorem 2874.24 (Frechet–Kolmogorov Lp-tail dependency route)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *consumer that reads compactness through Lp tails must first pass through the displayed sibling route*

CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, MetricCompletion$^{\uparrow}$, LpSpace/LpTail, BHist, hsame, Cont, Pkg, N

The exported compactness row is therefore a finite compact-metric, total-bounded, completion-facing, and Lp-tail dependency route, not an ambient compactness oracle, a selected subsequence, a selected subcover, or quotient completion equality.

Proof. Project the accepted carrier of Definition 3846.1. Its compactness-facing read already begins with the compact metric source and the finite-net budget, so any Lp-tail consumer must inherit those rows before reading a tail estimate.

Apply the total-bounded handoff of Definition 3846.3. It keeps the finite-net row visible before the StreamName, RegSeqRat, and Real readbacks are inspected.

Now use the completion boundary and the existing sibling route of Definition 3846.4. The Lp-space and Lp-tail rows can only be attached after the displayed MetricCompletion$^{\uparrow}$ handoff has been routed through the same finite BHist/Cont/Pkg ledger.

Route exhaustion gives the stated dependency chain. No row in the carrier supplies an unrecorded compactness principle, selected subsequence, selected subcover, or quotient-completion equality, so the Lp-tail compactness export is exactly the displayed sibling route. □

Theorem 2874.25 (Frechet–Kolmogorov Lp-tail localization)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *compactness read that localizes through an Lp-tail estimate consumes that estimate only after the compact-metric total-bounded route, tightness route, and Lp-tail dependency route have been displayed. Equivalently, the localized read factors through Definition 3846.11, Definition 3846.22, and Definition 3846.24; it does not introduce an ambient compactness oracle, selected subsequence, selected subcover, quotient completion equality, or hidden Lp-tail selector.*

Proof. Start with the compact-metric total-bounded route. It keeps the compact metric source and finite-net surface visible before a compactness-facing consumer may inspect downstream rows.

Next use the tightness route. Tightness and boundedness remain local dependency rows in the same finite ledger, so a tail estimate cannot bypass the displayed $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, completion, readback, transport, replay, provenance, and local naming route.

Finally apply the Lp-tail dependency route. It attaches the $\mathsf{LpSpace/LpTail}$ row only after the compact-metric, total-bounded, and completion-facing rows have been routed through the same finite $\mathsf{BHist/Cont/Pkg}$ ledger. Thus Lp-tail localization is a local factorization through the existing sibling routes, not a new compactness principle or choice-selected tail object. □

The operator-tail compactness route for $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ is read only after a bounded-linear-operator source from chapter 1644, an equicontinuous-sequence surface from chapter 4356, and the existing compact-metric, total-bounded, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route have been displayed. A consumer that starts from operator-tail compactness therefore reaches the Frechet–Kolmogorov packet through bounded operator rows, equicontinuity rows, compact-metric finite nets, total-bounded coverage, regular-rational readback, and the terminal Real seal, not through an ambient compactness theorem or a selected subsequence.

Theorem 2874.26 (Frechet–Kolmogorov upstream dependency lattice)**.** *Every* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *compactness read must pass through the compact metric, totally bounded,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, Arzela–Ascoli finite-modulus, and Lp-tail localization rows before any compactness conclusion is exported. The exported route is therefore a finite dependency lattice over the displayed carrier rows, not an ambient compactness oracle, selected subsequence, selected subcover, quotient completion equality, or host completeness principle.*

Proof. Start with the local carrier and the compact metric total-bounded dependency of Definition 3846.11. It forces the compact metric source and total-bounded finite-net budget to appear before later StreamName, RegSeqRat, and Real readbacks are inspected.

Next read the Arzela–Ascoli side through Definition 3846.8 and Definition 3846.9. Those routes keep finite-modulus and finite-window function-family data downstream of the compact metric and total-bounded rows.

Now apply the completion and rational-readback routes, Definition 3846.13 and Definition 3846.16. They keep the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows attached to the same displayed finite lattice.

Finally use the Lp-tail routes, Definition 3846.24 and Definition 3846.25. These place tail localization after compact-metric, total-bounded, completion-facing, and rational-readback rows. The stated lattice follows because no cited carrier row supplies a hidden compactness principle or selected limiting object. □

Chapter 2875

A Concrete Naming Certificate for $\mathsf{RationalBracketing}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalBracketing}^{\uparrow}$ packet records the finite rational lower-and-upper bracket surface used before a real-name consumer reads an approximation. It sits after the rational density surface of chapter 1409, the Archimedean bound surface of chapter 3372, the dyadic tolerance core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the displayed bracket endpoints, tolerance rows, finite observation windows, nesting ledger, and downstream regular-Cauchy handoff; it is not a trichotomy principle, quotient real equality theorem, limit selector, or ambient completeness assertion.

Definition 2875.1 (Rational bracketing carrier)**.** *A* $\mathsf{RationalBracketing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, D, S, R, E, N, H, C, P, A)$$

with the following displayed rows:

1. *L is the rational lower-endpoint row supplied through the* $\mathsf{RationalDensityReal}^{\uparrow}$ *surface.*
2. *U is the rational upper-endpoint row supplied through the same rational-density surface.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the displayed bracket width with the requested precision.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observations used to inspect L, U, and D.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row exported by the bracket window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, D, S, R have been displayed.*
7. *N is the nesting ledger recording that later bracket windows refine earlier ones by moving the lower row upward, moving the upper row downward, or preserving an endpoint already inside the requested tolerance.*
8. *H records componentwise* hsame *transport for lower endpoint, upper endpoint, dyadic tolerance, stream window, regular readback, real seal, nesting, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a bracketing request through $L, U, D, S, R, E, N, H, P, A$.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalBracketing}^{\uparrow}$, $\mathsf{RationalDensityReal}^{\uparrow}$, $\mathsf{RealArchimedeanProperty}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *A is the local* $\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $L, U, D, S, R, E, N, H, C, P, A$. It has no coordinate for trichotomy, quotient real equality, selected limits, hidden real representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RationalBracketingUp.RationalBracketingTasteGate single carrier alignment`

Theorem 2875.2 (Rational bracketing NameCert obligations)**.** *For every accepted* $\mathsf{RationalBracketing}^{\uparrow}$ *carrier $B = (L, U, D, S, R, E, N, H, C, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}$ *surface consists exactly of lower-endpoint exposure through L, upper-endpoint exposure through U, dyadic width and tolerance exactness through D, finite-window exposure through S, regular rational readback through R, terminal real-name sealing through E, nesting-ledger visibility through N, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through A.*

Proof. Project the carrier of Definition 3847.1. Its visible approximation data are exactly the endpoint rows L, U, the tolerance row D, the finite-window row S, the readback row R, and the real seal row E.

The endpoint and tolerance rows are separate. The rational-density surface supplies L and U, while the Archimedean and dyadic rows supply the bounded comparison budget used to certify that the bracket width is below the requested tolerance.

The nesting ledger is downstream of those rows. It records refinement between displayed windows, but it does not add a new real representative, a trichotomy split, or a selected limiting endpoint.

Finally H, C, P, A transport, replay, source, and name the same finite surface. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 2875.3 (Rational bracketing window nesting)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalBracketing}^{\uparrow}$ *packet factors through a finite nested-bracket route*

$$\mathsf{RationalDensityReal}^{\uparrow} \longmapsto \mathsf{RealArchimedeanProperty}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Re}$$

For any later accepted window, the consumer must read the same lower endpoint, upper endpoint, dyadic tolerance, stream observation, regular readback, real seal, nesting, transport, replay, provenance, and local naming rows before using the narrowed bracket. The route exports nested rational brackets, not trichotomy, quotient real equality, selected limits, or ambient completeness.

Proof. Begin with an accepted carrier $B = (L, U, D, S, R, E, N, H, C, P, A)$. A bracketing request first reads the rational lower and upper endpoint rows L, U together with the Archimedean bound information named in the provenance row.

Next the request reads D and S. The dyadic ledger specifies the precision budget, while the stream row records the finite observations used to inspect the current bracket.

The regular rational readback R and real seal E are available only after those rows have been displayed. A later window can be consumed only through the nesting ledger N, which compares the later endpoints with the earlier displayed endpoints under the same dyadic budget discipline.

Thus every downstream read remains inside the finite route named in the theorem. No step introduces trichotomy, quotient real equality, a selected limiting endpoint, countable choice, hidden real representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{RationalBracketing}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without first reading rational lower and upper endpoint rows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{StreamName}^{\uparrow}$ finite window, nesting evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence is outside the packet.

Independence witness: rational-density-real, real-archimedean-property, dyadicratcore, streamname, regseqrat, real: $\mathsf{RationalBracketing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rational lower and upper endpoint rows, dyadic width budgets, finite observation windows, regular readback, terminal Real sealing, nesting, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalBracketing}^{\uparrow}$ packet is generated from rational lower and upper endpoint rows, an Archimedean boundedness context, a DyadicRatCore tolerance ledger, StreamName finite windows, a RegSeqRat readback row, a RealUp seal, a nesting ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3847.1, Definition 3847.2, and Definition 3847.3 seed the finite rational-bracket route from density and Archimedean rows to regular rational readback and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, trichotomy, quotient real equality, selected limits, hidden real representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked lower and upper endpoint exposure, dyadic width exactness, finite-window exposure, nesting stability, regular readback, Real seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.RationalBracketingUp.

Chapter 2876

A Concrete Naming Certificate for $\mathsf{RealModulusExtraction}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy data, the $\mathsf{RealModulusExtraction}^{\uparrow}$ packet records the finite BEDC surface by which an explicit regular Cauchy modulus is exposed before a $\mathsf{Real}^{\uparrow}$ seal is read. It sits on the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names modulus extraction as displayed finite NameCert data; it does not import quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2876.1 (RealModulusExtraction carrier)**.** *A* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radius, denominator budget, and comparison ledger for each requested precision.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, recording the finite windows inspected before a modulus answer is emitted.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *witness row, recording regular rational Cauchy data exposed by the scheduled windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *T records componentwise* hsame *transport for the dyadic tolerance, schedule, regularity, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a precision request through D, then through S, R, and finally to the seal row E.*
7. *P is the* Pkg *provenance over* $\mathsf{RealModulusExtraction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}$ *row.*

The carrier has no coordinate for an implicit analytic modulus, quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealModulusExtractionUp.RealModulusExtractionTasteGate single carrier alignment`

Theorem 2876.2 (RealModulusExtraction NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier* $M = (D, S, R, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}$ *surface consists exactly of dyadic tolerance exposure through* D*, finite schedule exposure through* S*, regular Cauchy witness exposure through* R*, terminal Real sealing through* E*, componentwise transport through* T*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier coordinates. The dyadic tolerance row D, schedule row S, regular witness row R, and seal row E are the analytic-facing rows of the packet.

The structural rows do not add analytic assumptions. Transport through T is componentwise, replay through C follows the displayed precision route, provenance through P records the sibling chapters named above, and N supplies the local NameCert row. Since no further coordinate is present, the listed rows exhaust the obligation surface. □

Theorem 2876.3 (RealModulusExtraction regular Cauchy handoff)**.** *Every regular Cauchy handoff exported by an accepted* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The extracted modulus is therefore read as dyadic tolerance data, finite schedule data, and regular rational witness data before the Real seal is available.

Proof. Begin with a precision request. The carrier first exposes the dyadic tolerance row D, so the requested radius and denominator budget are displayed before any stream window is inspected.

The schedule row S then supplies the finite windows, and the regular witness row R reads the rational Cauchy data inside those windows. Only after this displayed route has been replayed by C does the seal row E become available to a $\mathsf{Real}^{\uparrow}$ consumer.

Thus the handoff is the finite sibling route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not an implicit analytic assumption. □

Theorem 2876.4 (RealModulusExtraction Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier is exhausted by the rows* D, S, R, E, T, C, P, N*. In particular, the read exports no quotient stream equality, selected representative, countable-choice schedule, host real equality, implicit analytic modulus, or ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Use the obligation surface of Definition 3848.2. A Real-facing consumer can inspect only the dyadic tolerance, finite schedule, regular witness, seal, transport, replay, provenance, and local naming rows.

The nonescape claim follows from the carrier boundary. None of the excluded objects appears as a coordinate of M, and the replay row C only preserves the displayed precision route through D, S, R, E. Hence every Real seal read remains inside the finite NameCert packet. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusExtraction}^{\uparrow}$ read exposes dyadic tolerance, finite schedule, regular Cauchy witness, Real seal, transport, replay, provenance, and local NameCert rows before any modulus answer is exported.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RealModulusExtraction}^{\uparrow}$ is not bijective to any listed sibling because it carries the dyadic tolerance row, schedule row, regular

witness row, terminal seal row, componentwise transport, displayed replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusExtraction}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName schedule row, RegSeqRat regular witness row, RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3848.1, Definition 3848.2, Definition 3848.3, and Definition 3848.4 seed the finite modulus-extraction route from regular Cauchy data to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic schedule coverage, regular Cauchy handoff, Real seal nonescape, and a Lean carrier formalization for BEDC.Derived.RealModulusExtractionUp.

Chapter 2877

A Concrete Naming Certificate for $\mathsf{CauchyStability}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy data, the $\mathsf{CauchyStability}^{\uparrow}$ packet names the finite stability route used when displayed transport changes a Cauchy presentation but not the Real-facing read. It sits on the StreamName windows of chapter 126, the dyadic tolerance core of chapter 291, the regular rational sequence route of chapter 301, the Cauchy equivalence boundary of chapter 1820, and the terminal real-name seal of chapter 38. The packet records stability of displayed Cauchy data; it is not quotient equality, selected representatives, countable choice over tails, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2877.1 (CauchyStability carrier)**.** *A* $\mathsf{CauchyStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are two regular Cauchy source rows whose rational observations are opened only through* $\mathsf{RegSeqRat}^{\uparrow}$ *and finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *M is the shared tail-modulus comparison row relating the two source rows at each displayed precision request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the transported source observations.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row recording the regular rational readback after A, B, M, D have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached through the displayed* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *boundary.*
6. *H records componentwise* hsame *transport for the source, modulus, dyadic, regular-readback, equivalence, seal, replay, package, and naming rows.*
7. *C records displayed* Cont *replay from a Cauchy-stability request through $A, B, M, D, R, E, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyStability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient sequence equality, selected limits, hidden representatives, countable-choice tail selection, host real equality, or an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.CauchyStabilityUp.CauchyStabilityUp`
Lean4 ✓ `BEDC.Derived.CauchyStabilityUp.CauchyStabilityTasteGate single carrier alignment`

Theorem 2877.2 (CauchyStability NameCert obligations)**.** *For every accepted* $\mathsf{CauchyStability}^{\uparrow}$ *carrier* $S = (A, B, M, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular Cauchy source rows, shared tail-modulus comparison, dyadic tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *stability of the transported readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming through the rows* $A, B, M, D, R, E, H, C, P, N$*.*

Proof. Project the carrier of Definition 3849.1. The only source data are the rows A and B, and the only comparison data between them are the shared tail-modulus row M and dyadic tolerance ledger D.

The regular-rational readback R is downstream from those rows, so stability is read as a finite $\mathsf{RegSeqRat}^{\uparrow}$ handoff rather than as equality of host sequences. The displayed $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ boundary is consumed before the terminal seal E can be read.

Transport and replay use H and C componentwise. The package and naming rows P, N source the same finite route, and the excluded quotient, selected-limit, hidden-representative, choice, host-equality, and completeness data have no carrier coordinate. □

Theorem 2877.3 (CauchyStability Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyStability}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the terminal seal E *is consumed. Thus displayed transport may change the finite Cauchy presentation only through the stored* $A, B, M, D, R, H, C, P, N$ *rows, and the Real-facing boundary receives no quotient equality, selected representative, hidden tail family, countable-choice selector, host real equality, or ambient completeness coordinate.*

Proof. Start with a Real-facing request. The carrier first exposes the finite StreamName windows attached to A and B, together with the shared modulus comparison M.

The dyadic ledger D translates those windows into displayed tolerance observations. The regular-rational handoff R then repacks the inspected observations as $\mathsf{RegSeqRat}^{\uparrow}$ data.

Only after this readback does the packet enter the displayed $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ boundary and then the seal E. The rows H, C, P, N transport, replay, source, and name that same route, leaving no hidden Real-facing coordinate beyond the listed sibling surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyStability}^{\uparrow}$ packet is generated from two regular Cauchy source rows, a shared tail-modulus comparison row, dyadic tolerance rows, a RegSeqRat handoff, a CauchyEquivalenceSetoid boundary, a RealUp seal, displayed hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$, seed)

Scope closed: Definition 3849.1, Definition 3849.2, and Definition 3849.3 seed the displayed stability route for Cauchy data under transport before the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of Cauchy presentations, selected representatives, hidden tails, countable choice over moduli, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-modulus comparison, RegSeqRat stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyStabilityUp.

Chapter 2878

A Concrete Naming Certificate for $\mathsf{CauchySequenceTailFilter}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki–Kelley filterbase terminology, the $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ packet records the finite route by which a Bishop Cauchy sequence supplies tail-filter data for completion-facing consumers. It sits between the sequence-side evidence of $\mathsf{BishopCauchySequence}^{\uparrow}$, the filter carrier of chapter 333, the finite stream schedule of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet names tail neighborhoods generated by displayed sequence windows; it does not select a limit, quotient streams, choose subsequences, decide trichotomy, or assert ambient real completeness.

Definition 2878.1 (Cauchy sequence tail-filter carrier)**.** *A* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, B, F, C, D, Q, R, E, H, K, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule whose finite windows are the only sequence observations visible to the carrier.*
2. *B is the* $\mathsf{BishopCauchySequence}^{\uparrow}$ *row certifying that the displayed sequence windows satisfy the Bishop Cauchy modulus requests read by the packet.*
3. *F is the Frechet-tail filterbase row generated by tails of S: a basic tail is named by a displayed index threshold together with the windows beyond that threshold.*
4. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility row saying that every admitted tail-basic row is a Cauchy-filter neighborhood request over the same displayed windows and thresholds.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording dyadic scales, rational comparisons, and exhaustion data used to pass from sequence tails to filterbase requests.*
6. *Q is the finite tail-query ledger pairing each tolerance request with the stream windows and tail threshold used by B, F, C, D.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for consumers that read the same tail evidence as regular rational names.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, B, F, C, D, Q, R have been displayed.*

9. *H stores componentwise* hsame *transport for the stream windows, Bishop Cauchy row, tail-filterbase row, Cauchy-filter compatibility row, dyadic tolerance ledger, tail-query ledger, regular handoff, Real seal, continuation replay, provenance, and local name.*
10. *K stores displayed* Cont *replay from each tolerance request through the stream window, tail threshold, filterbase row, Cauchy-filter compatibility row, regular handoff, and seal row.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BishopCauchySequence}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}$ *row.*

The classifier accepts a packet only when every tail-basic row in F is generated from the displayed stream schedule S, every Cauchy-filter compatibility read in C uses the Bishop Cauchy evidence B and dyadic ledger D, and every completion-facing read factors through Q, R, E, H, K, P, N. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceTailFilterUp.CauchySequenceTailFilterTasteGate single carrier alignment`

Theorem 2878.2 (Cauchy sequence tail-filter NameCert obligations)**.** *For every accepted* CauchySequenceTailFilter *carrier $T = (S, B, F, C, D, Q, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}$ *obligations are exactly carrier admission, finite stream-window classification, Bishop Cauchy tail coverage, Frechet-tail filterbase generation,* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility, dyadic tolerance-ledger exhaustion,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal nonescape,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local naming row. These obligations are discharged by the displayed route*

$$S \longmapsto B \longmapsto F \longmapsto C \longmapsto D \longmapsto Q \longmapsto R \longmapsto E$$

together with H, K, P, N.

The obligation surface exports no quotient stream, selected limit, choice principle, trichotomy row, open-cover compactness object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchySequenceTailFilterUp.CauchySequenceTailFilterCarrier namecert obligations`

Proof. Project the carrier of Definition 3850.1. The only sequence observations are the finite $\mathsf{StreamName}^{\uparrow}$ windows in S, and the only Cauchy evidence for those windows is the Bishop row B.

Read the tail-filter rows next. The Frechet-tail row F names basic tails by displayed thresholds, while the compatibility row C checks those basic tails against the $\mathsf{CauchyFilter}^{\uparrow}$ surface. The dyadic ledger D and tail-query ledger Q account for the tolerance requests used in that check.

The regular and real-facing rows are downstream. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R and $\mathsf{Real}^{\uparrow}$ seal E are available only after the stream, Bishop, tail-filterbase, Cauchy-filter, dyadic, and query rows have been displayed.

Finally apply the structural rows. Componentwise transport H, continuation replay K, provenance P, and the local name N preserve the same finite route, and the carrier definition supplies no coordinate for quotient streams, selected limits, choice, trichotomy, open-cover compactness, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ completion-facing read factors through the displayed $\mathsf{StreamName}^{\uparrow}$ windows, Bishop Cauchy row, Frechet-tail filterbase row,

CauchyFilter$^{\uparrow}$ compatibility row, dyadic tolerance ledger, RegSeqRat$^{\uparrow}$ handoff, and Real$^{\uparrow}$ seal before any tail consumer is allowed to read the packet.

Independence witness: cauchyfilter, streamname, regseqrat, dyadicratcore, real: CauchySequenceTailFilter$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries sequence-window evidence, Bishop Cauchy tail coverage, tail-filterbase generation, filter compatibility, dyadic tolerance accounting, regular-rational handoff, real-seal routing, transport, continuation replay, provenance, and local naming.

Closure status for NameCert$_{\text{CauchySequenceTailFilter}^{\uparrow}}$.

Constructive story: A CauchySequenceTailFilter$^{\uparrow}$ packet is generated from finite stream windows, a Bishop Cauchy sequence row, a Frechet-tail filterbase row, a CauchyFilter compatibility row, a dyadic tolerance ledger, a tail-query ledger, a RegSeqRat handoff, a Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchySequenceTailFilter}^{\uparrow}}$, seed)

Scope closed: Definition 3850.1 and Definition 3850.2 seed the finite sequence-to-tail-filter carrier from StreamName windows through Bishop Cauchy evidence, tail filterbase rows, CauchyFilter compatibility, dyadic tolerance accounting, RegSeqRat handoff, and the Real seal.

Formal verification: FormalStatus(NameCert$_{\text{CauchySequenceTailFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, choice principles, trichotomy, open-cover compactness, ambient Real$^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, tail-filterbase generation, CauchyFilter compatibility, dyadic ledger exhaustion, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local NameCert rows for BEDC.Derived.CauchySequenceTailFilterUp.

Chapter 2879

A Concrete Naming Certificate for CauchySequenceTailFilterCompletion$^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki–Kelley filter terminology, the CauchySequenceTailFilte packet records the finite bridge by which sequence-tail filters are read as Cauchy-filter completion data before any quotient completion point or selected limit is available. It sits after the sequence-tail route of chapter 3850, the completion-facing carrier of chapter 1569, and the saturated filter surface of chapter 333. The chapter names only the displayed finite handoff from tail-filter evidence to completion readback; it does not assert ambient real completeness, quotient-filter equality, selected representatives, countable choice, trichotomy, or host equality of completed points.

Definition 2879.1 (Cauchy sequence tail-filter completion carrier)**.** *A* CauchySequenceTailFilterCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (T, F, C, D, W, R, E, H, K, P, N)$$

with the following visible rows:

1. *T is the* CauchySequenceTailFilter$^{\uparrow}$ *row naming the sequence-generated tail-filter data from chapter 3850.*
2. *F is the* CauchyFilter$^{\uparrow}$ *row that reads the same tail-filter neighborhoods as saturated Cauchy-filter requests.*
3. *C is the* CauchyFilterCompletion$^{\uparrow}$ *row whose completion-facing consumer is allowed to inspect only the displayed filter route.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to compare the tail thresholds with completion precision requests.*
5. *W is the finite family of* StreamName$^{\uparrow}$ *windows exposed by the tail-filter row before the completion consumer reads R or E.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row extracted from the same windows, dyadic tolerances, and filter requests.*
7. *E is the terminal* Real$^{\uparrow}$ *seal reached only after T, F, C, D, W, R have been displayed.*
8. *H stores componentwise* hsame *transport for the tail-filter, Cauchy-filter, completion, dyadic, window, readback, seal, replay, provenance, and local naming rows.*

9. *K stores displayed* Cont *replay from a sequence-tail request through Cauchy-filter compatibility, completion handoff, finite windows, dyadic tolerance, regular readback, and the Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}$ *row.*

The classifier accepts X only when every completion-facing read first opens the sequence-tail row T, then the Cauchy-filter row F, then the completion row C, and only then the dyadic, window, readback, and Real-seal rows D, W, R, E. It has no coordinate for quotient filters, selected limits, countable-choice selectors, host real equality, trichotomy, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySequenceTailFilterCompletionUp.CauchySequenceTailFilterCompletionTasteGate`
`single carrier alignment`

Theorem 2879.2 (Cauchy sequence tail-filter completion NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *carrier $X = (T, F, C, D, W, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}$ *obligations are exactly carrier admission, sequence-tail source admission,* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff, dyadic tolerance exactness, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local naming row. These obligations are discharged by the displayed route*

$$T \longmapsto F \longmapsto C \longmapsto D, W \longmapsto R \longmapsto E$$

together with H, K, P, N.

The obligation surface exports no quotient filter, selected limit, host equality, countable-choice selector, trichotomy row, open-cover compactness object, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or detached completion coordinate.*

Proof. Project the carrier of Definition 3851.1. The public rows are exactly $T, F, C, D, W, R, E, H, K, P, N$, so carrier admission exposes a sequence-tail source, a Cauchy-filter compatibility row, a completion handoff, a finite tolerance and window route, a regular readback, a Real seal, and the structural rows.

Read the source and filter rows first. The row T supplies the finite tail-filter data generated from sequence windows, while F reads that data as the Cauchy-filter surface used by completion-facing consumers. The row C is downstream of those two rows and does not replace them by a quotient filter or selected limit.

Next inspect the completion readback route. The dyadic ledger D and window row W are the only precision and observation rows available before the regular readback R and the terminal seal E are consumed.

Finally apply the structural rows. Transport H, replay K, provenance P, and the local name N preserve the same route, and the carrier definition supplies no coordinate for quotient filters, selected limits, choice, trichotomy, open-cover compactness, host equality, or ambient completeness. □

Theorem 2879.3 (Cauchy sequence tail-filter completion Real handoff)**.** *Let $X = (T, F, C, D, W, R, E, H, K, P, N)$ be an accepted* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *packet. Every Real-facing or completion-facing consumer that reads the terminal seal factors through*

$$T, F, C, D, W, R \longmapsto E \longmapsto H, K, P, N.$$

Thus the $\mathsf{Real}^{\uparrow}$ *seal is available only after the sequence-tail filter, Cauchy-filter compatibility, Cauchy-filter completion row, dyadic tolerance ledger, finite stream windows, and regular rational readback have been displayed.*

Proof. Start with a consumer of the terminal seal. Carrier projection gives access to E only as the seal row of the accepted packet X.

Replay the continuation row K. The request consumes the sequence-tail source T, the Cauchy-filter row F, the completion row C, the dyadic tolerance ledger D, the finite windows W, and the regular readback R before E is available.

The structural rows preserve this order. Transport through H, provenance through P, and naming through N record the same route, so the consumer has no available coordinate for a selected completion point, quotient-filter equality, host real equality, choice, or ambient completeness. □

Theorem 2879.4 (Cauchy sequence tail-filter completion filterbase nonescape)**.** *Let* $X = (T, F, C, D, W, R, E, H, K$ *be an accepted* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *packet. No accepted completion read can bypass the displayed sequence-tail filter row* T *or the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *when it reaches the completion row* C*, the regular readback* R*, or the seal row* E*.*

Consequently every filterbase-dependent completion read is confined to the finite route

$$T_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}, F_{\mathsf{CauchyFilter}^{\uparrow}} \longmapsto C_{\mathsf{CauchyFilterCompletion}^{\uparrow}} \longmapsto D, W, R, E, H, K, P, N.$$

Detached filterbases, quotient filters, selected limits, free tolerance parameters, countable-choice selectors, and ambient completeness principles are outside the accepted packet.

Proof. Inspect the carrier of Definition 3851.1. The only source for filterbase-dependent data is T, and the only Cauchy-filter compatibility row is F.

Apply the obligation surface of Definition 3851.2. It requires the completion handoff C to read after T and F, then requires D, W, R, E to remain downstream of that handoff.

The Real handoff of Definition 3851.3 keeps terminal consumers on the same route. Since H, K, P, N only transport, replay, source, and name the displayed rows, no detached filterbase or excluded completion object can be introduced later. □

Falsifiable prediction: Every accepted $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ completion read opens the displayed $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ row, $\mathsf{CauchyFilter}^{\uparrow}$ row, $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row, dyadic tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal before any consumer may inspect the packet as completion data.

Independence witness: cauchy-sequence-tail-filter, cauchyfilter, cauchyfiltercompletion, dyadicratcore, streamname, regseqrat, real: $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries sequence-tail source data, Cauchy-filter compatibility, completion handoff, dyadic tolerance accounting, finite stream windows, regular readback, Real-seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ packet is generated from a CauchySequenceTailFilter row, a CauchyFilter row, a CauchyFilterCompletion row, dyadic tolerance data, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3851.1, Definition 3851.2, Definition 3851.3, and Definition 3851.4 seed the finite sequence-tail-filter bridge into CauchyFilterCompletion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchySequenceTailFilterCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, selected completion representatives, countable choice, trichotomy, open-cover compactness, host equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, sequence-tail source admission, CauchyFilter compatibility, CauchyFilterCompletion handoff, dyadic tolerance exactness, StreamName window exposure, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local NameCert rows for BEDC.Derived.CauchySequenceTailFilterCompletion

Chapter 2880

A Concrete Naming Certificate for $\mathsf{LocalizedCauchyRate}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocalizedCauchyRate}^{\uparrow}$ packet records localized convergence-rate evidence as finite BEDC rows before a Real or Completion consumer reads a regular Cauchy name. It sits over the tail-bound route of chapter 2071, the regular tail-bound route of chapter 3743, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the oscillation ledger of chapter 448. The packet is a localized rate ledger; it does not choose quotient stream representatives, selected limits, trichotomy decisions, ambient completeness, or global convergence-speed functions.

Definition 2880.1 (Localized Cauchy rate carrier)**.** *A* $\mathsf{LocalizedCauchyRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, D, T, R, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected rational stream segment.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the local dyadic budgets used by the packet.*
3. *T is the* $\mathsf{CauchyTailBound}^{\uparrow}$ *row displaying the tail-bound witness for the requested local tolerance window.*
4. *R is the* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *row recording the regular tail-bound strengthening consumed by regular Cauchy readers.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, tying the window and tail-bound rows to regular rational sequence data.*
6. *Q is the* $\mathsf{CauchyOscillation}^{\uparrow}$ *row, recording the local oscillation bound checked against the same window and dyadic budget.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after W, D, T, R, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for windows, tolerances, tail bounds, regular readback, oscillation, real seal, replay, provenance, and naming.*
9. *C records displayed* Cont *replay from a localized rate request through $W, D, T, R, S, Q, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LocalizedCauchyRate}^{\uparrow}$, $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{RegularCauchyTailBound}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyOscillation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, D, T, R, S, Q, E, H, C, P, N$. The carrier has no coordinate for a selected rate outside T and R, quotient stream equality, an external limit selector, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocalizedCauchyRateUp.LocalizedCauchyRateTasteGate single carrier alignment`

Theorem 2880.2 (Localized Cauchy rate NameCert obligations)**.** *For every accepted* $\mathsf{LocalizedCauchyRate}^{\uparrow}$ *carrier $L = (W, D, T, R, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $W, D, T, R, S, Q, E, H, C, P, N$;*
2. *window localization: every rate read starts with the finite* $\mathsf{StreamName}^{\uparrow}$ *row W and the dyadic tolerance ledger D;*
3. *tail-bound visibility: the* $\mathsf{CauchyTailBound}^{\uparrow}$ *row T and* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *row R are displayed before any regular rational readback is consumed;*
4. *regular readback: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row S reads the same window, dyadic budget, and tail-bound rows;*
5. *oscillation compatibility: the* $\mathsf{CauchyOscillation}^{\uparrow}$ *row Q checks the local oscillation bound against the same budget and tail window;*
6. *real handoff: the* $\mathsf{Real}^{\uparrow}$ *seal E is reachable only after W, D, T, R, S, Q have been displayed;*
7. *ledger nonescape: H, C, P, N export no selected rate, quotient representative, host limit, trichotomy decision, countable-choice schedule, ambient completeness theorem, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 3852.1. The accepted rows are exactly $W, D, T, R, S, Q, E, H, C, P, N$, so carrier admission exposes only finite windows, dyadic budgets, tail bounds, regular readback, oscillation, a real seal, and structural rows.

The localized rate route begins with W and D. These rows name the finite stream segment and the tolerance budget, so the tail-bound rows cannot be read as global convergence-speed functions.

Next read T and R. The ordinary Cauchy tail-bound row supplies the requested local tail witness, while the regular tail-bound row records the strengthening needed by a regular Cauchy consumer. The readback row S consumes those same displayed rows, and Q checks the matching oscillation bound.

Finally E, H, C, P, N seal and transport the route. Since none of these rows adds a selector, quotient representative, trichotomy decision, countable-choice schedule, ambient completeness theorem, or bridge certificate, the listed obligations exhaust the local surface. □

Theorem 2880.3 (Localized Cauchy rate Real-completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LocalizedCauchyRate}^{\uparrow}$ *packet factors through*

$$W \longmapsto D \longmapsto T \longmapsto R \longmapsto S \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

In particular, a consumer preserving the $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{RegularCauchyTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *routes must read the localized tail-bound ledger before it can treat the stream as a real-facing regular Cauchy name.*

Proof. Begin with a Real-facing request. The finite stream row W and dyadic ledger D determine the local tolerance window that the request may inspect.

The tail-bound handoff then passes through T and R. The first row gives the Cauchy tail witness at the displayed tolerance, and the second row exposes the regular tail-bound strengthening required by regular rational readback.

The readback and oscillation rows are downstream of the same data. The row S reads the regular rational sequence through the displayed window and tail-bound rows, while Q confirms that the local oscillation bound uses the same budget.

Only after those rows have been displayed may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so any Real or Completion consumer bypassing T and R lies outside the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{LocalizedCauchyRate}^{\uparrow}$ read is refuted if a Real or Completion consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ seal without displaying StreamName windows, DyadicRatCore budgets, CauchyTailBound and RegularCauchyTailBound rows, RegSeqRat readback, CauchyOscillation compatibility, transport, replay, provenance, and local naming.

Independence witness: cauchy-tail-bound, regular-cauchy-tail-bound, dyadicratcore, streamname, regseqrat, real, cauchy-oscillation: none alone is bijective with $\mathsf{LocalizedCauchyRate}^{\uparrow}$ because the packet jointly records localized windows, dyadic budgets, ordinary and regular tail-bound rows, regular rational readback, oscillation compatibility, terminal Real sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalizedCauchyRate}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore budgets, CauchyTailBound and RegularCauchyTailBound rows, RegSeqRat readback, CauchyOscillation compatibility, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3852.1, Definition 3852.2, and Definition 3852.3 seed the finite localized convergence-rate ledger consumed by Real and Completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected rates, quotient stream representatives, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked window localization, tail-bound visibility, regular readback, oscillation compatibility, Real handoff, ledger nonescape, and local naming for BEDC.Derived.LocalizedCauchyRateUp.

Chapter 2881

A Concrete Naming Certificate for $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$

Following Bishop–Bridges compact metric continuity, the $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ packet records the finite route from compact source data and pointwise continuity rows through finite oscillation partitions to a displayed uniform-modulus output. It sits over the compact-metric source of chapter 129, the metric carrier of chapter 57, the continuous-map surface of chapter 130, the finite oscillation partition row of chapter 3800, the oscillation modulus boundary of chapter 2224, and the uniform-modulus consumer of chapter 369. The packet names a compact-uniform handoff; it does not select an external modulus, identify host functions, choose points from a cover, assert quotient equality, or import ambient compactness.

Definition 2881.1 (Finite oscillation uniform-modulus carrier)**.** *A* $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, A, B, O, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, carrying the compact-metric carrier, finite cover data, and metric distance rows inspected by the packet.*
2. *M is the metric compatibility row tying the compact source to the distance comparisons used by oscillation estimates.*
3. *A is the continuous-map pointwise row, exposing source, target, graph, and local continuity evidence for the displayed map.*
4. *B is the* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *row, listing the finite partition cells and their source-side cover witnesses.*
5. *O is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row, recording the oscillation bound attached to each partition cell and requested tolerance.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row obtained by folding the finite oscillation bounds into one tolerance-only precision ledger.*
7. *H records componentwise* hsame *transport for compact, metric, continuous-map, partition, oscillation, uniform-modulus, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a compact-uniform-continuity request through $K, M, A, B, O, U, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, A, B, O, U, H, C, P, N$. The carrier has no coordinate for an external modulus selector, host function equality, point choice from a cover, quotient representation, ambient compactness theorem, or bridge certificate.

`single carrier alignment`

Theorem 2881.2 (Finite oscillation uniform-modulus NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ *carrier $F = (K, M, A, B, O, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformM}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $K, M, A, B, O, U, H, C, P, N$;*
2. *compact source exposure: K and M display the compact-metric source and distance comparisons used by the packet;*
3. *continuity visibility: the pointwise continuous-map row A is read before any oscillation cell is accepted;*
4. *finite partition exactness: B lists the finite oscillation partition cells and their cover witnesses;*
5. *oscillation-bound compatibility: O attaches each partition cell to the requested tolerance through the same metric and continuity rows;*
6. *uniform-modulus output: U is the only exported tolerance-only precision ledger and is obtained after B and O are displayed;*
7. *ledger nonescape: H, C, P, N export no external modulus selector, host function equality, point choice from a cover, quotient representation, ambient compactness theorem, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FiniteOscillationUniformModulusUp.FiniteOscillationUniformModulusNameCertObligatio`

Proof. Project the carrier in Definition 3853.1. Its accepted rows are exactly $K, M, A, B, O, U, H, C, P, N$, so carrier admission exposes compact source data, metric comparisons, continuous-map evidence, finite partition rows, oscillation bounds, a uniform-modulus output, and structural rows only.

The compact and continuity clauses are read first. The compact source row K and metric row M supply the finite cover and distance comparisons, while A supplies the pointwise continuity evidence used on each displayed cell.

The partition route then reads B and O. The finite oscillation partition row lists the cells, and the oscillation-modulus row binds each cell to the requested tolerance through the same compact, metric, and continuity data.

Finally the output row U records the uniform-modulus ledger obtained from the finite oscillation bounds. The transport, replay, provenance, and naming rows preserve that displayed route and contain no coordinate for the excluded selector, host equality, point choice, quotient representation, ambient compactness theorem, or bridge certificate. □

Lean4 ✓ `BEDC.Derived.FiniteOscillationUniformModulusUp.FiniteOscillationUniformModulusCarrier`
`namecert obligations`

Theorem 2881.3 (Finite oscillation compact-uniform handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ *packet factors through*

$$K \longmapsto M \longmapsto A \longmapsto B \longmapsto O \longmapsto U \longmapsto H, C, P, N.$$

In particular, a consumer preserving compact-metric, continuous-map, finite oscillation partition, oscillation modulus, and uniform-modulus provenance must read the finite oscillation partition and its oscillation bounds before exporting the tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ *row.*

Proof. Begin with a compact-uniform request. The rows K and M display the compact source and metric comparisons, so the request is tied to finite source-side data rather than to an ambient compactness theorem.

The continuous-map row A supplies the pointwise continuity evidence used on partition cells. After that, B displays the finite oscillation partition, including the cells and cover witnesses read by the source-side request.

The oscillation row O binds those cells to the requested tolerance. Since O is downstream of K, M, A, B, it cannot be read as a detached modulus or host-level continuity theorem.

The uniform-modulus row U is then the only exported tolerance-only precision ledger. The structural rows H, C, P, N transport and name the same finite route, so any compact-uniform consumer reaching U without B and O bypasses the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying compact source rows, metric comparisons, continuous-map evidence, finite oscillation partitions, oscillation-modulus bounds, transport, replay, provenance, and local naming.

Independence witness: compactmetric, metricspace, continuousmap, finite-oscillation-partition, oscillation-modulus, uniformmodulus: none alone is bijective with $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ because the packet jointly carries compact source data, metric comparisons, pointwise continuity rows, finite partition cells, oscillation bounds, uniform-modulus output, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ packet is generated from compact-metric source rows, metric comparison rows, ContinuousMap pointwise rows, finite oscillation partition rows, oscillation-modulus bounds, a UniformModulus output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3853.1, Definition 3853.2, and Definition 3853.3 seed the finite oscillation route from compact local control to a uniform-modulus output.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FiniteOscillationUniformModulusUp.FiniteOscillationUniformModulusCarrier\_namecert\_obl`

Bridge status: none

Not claimed: This chapter does not close external modulus selectors, host function equality, point choice from covers, quotient representations, ambient compactness, or bridge checking.

Upgrade path: Obligation closure requires checked compact source exposure, continuity visibility, finite partition exactness, oscillation-bound compatibility, uniform-modulus output, ledger nonescape, and local naming for BEDC.Derived.FiniteOscillationUnifo

Chapter 2882

A Concrete Naming Certificate for $\mathsf{FubiniFiniteRectangle}^{\uparrow}$

Following Fubini and Bishop-style finite integration, the $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ packet records a bounded finite-product rectangle computation as BEDC data before either iterated-integral route may be read. It sits over the measure row of chapter 92, the integral row of chapter 123, the product rows of chapter 2000, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the Real seal of chapter 38. The chapter names the finite rectangle surface only; it does not assert sigma-finite Fubini, Tonelli, quotient function equality, selected representatives, countable choice, or ambient measure completeness.

Definition 2882.1 (Fubini finite rectangle carrier)**.** *A* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, M, I, P, A, B, D, S, E, H, C, Q, N)$$

with the following displayed rows:

1. *R is the finite product-rectangle row, listing the source rectangles and their cell tags.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *row assigning the displayed finite measure data used by the cells of R.*
3. *I is the* $\mathsf{Integral}^{\uparrow}$ *row for cellwise finite integration over the same rectangle table.*
4. *P is the* ***??*** *row tying the two coordinate directions to the same finite rectangle cells.*
5. *A is the first-then-second iterated-integral route, reading the first coordinate cells before folding the second coordinate.*
6. *B is the second-then-first iterated-integral route, reading the second coordinate cells before folding the first coordinate.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the common finite error budget used by both iterated routes.*
8. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the displayed finite sums.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, M, I, P, A, B, D, S have been displayed.*
10. *H records componentwise* hsame *transport for rectangle cells, measure rows, integral rows, product rows, both iterated routes, tolerance ledgers, rational readback, Real seal, replay, provenance, and naming.*

11. *C records displayed* Cont *replay from a finite-rectangle integration request through* $R, M, I, P, A, B, D, S, E, H, Q,$
12. *Q is the* Pkg *provenance over* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, *??*, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, I, P, A, B, D, S, E, H, C, Q, N$. It has no coordinate for quotient function equality, selected representatives, countable choice, ambient completion of a measure space, or an infinite summability principle.

Lean4 ✓ `BEDC.Derived.FubiniFiniteRectangleUp.FubiniFiniteRectangleTasteGate single carrier alignment`

Theorem 2882.2 (Fubini finite rectangle NameCert obligations)**.** *For every accepted* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *carrier $F = (R, M, I, P, A, B, D, S, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $R, M, I, P, A, B, D, S, E, H, C, Q, N$;*
2. *rectangle visibility: R and P display the finite product cells before either iterated route is read;*
3. *measure and integral compatibility: M and I attach measure and integral rows to the same finite cell table;*
4. *route symmetry: A and B read the same cells in opposite coordinate order and share the tolerance row D;*
5. *rational readback: S reads the finite sums produced by both routes through regular rational data;*
6. *Real sealing: E is reached only after both iterated routes, the dyadic ledger, and regular rational readback have been displayed;*
7. *ledger nonescape: H, C, Q, N export no sigma-finite theorem, Tonelli theorem, quotient function equality, selected representative, countable-choice schedule, ambient measure completeness, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FubiniFiniteRectangleUp.FubiniFiniteRectangleNamecertObligations`

Proof. Project the carrier of Definition 3854.1. The accepted rows are exactly $R, M, I, P, A, B, D, S, E, H, C, Q, N$, so carrier admission exposes a finite rectangle table, its measure and integral rows, two displayed iterated routes, a dyadic ledger, rational readback, a Real seal, and structural rows.

The finite rectangle route starts with R and P. These rows fix the cell table and the coordinate-product reading, so neither iterated route may introduce a new domain or a hidden product object.

Next read M, I, A, B, D, S. The measure and integral rows are attached to the same finite cells. The two iterated routes fold those cells in opposite coordinate order, while the dyadic ledger and regular rational readback force both routes to use the same finite tolerance and sum data.

Finally E, H, C, Q, N seal and transport the same displayed computation. Since none of these rows adds sigma-finite measure structure, Tonelli data, quotient function equality, selected representatives, countable choice, ambient measure completeness, or a bridge certificate, the listed obligations exhaust the local surface. □

Theorem 2882.3 (Fubini finite rectangle iterated-integral nonescape)**.** *Every iterated-integral consumer of an accepted* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *packet factors through*

$$R \longmapsto M \longmapsto I \longmapsto P \longmapsto A, B \longmapsto D \longmapsto S \longmapsto E \longmapsto H, C, Q, N.$$

Thus a consumer may cite equality of the two finite rectangle reads only through the displayed cells, measure rows, integral rows, product row, both iterated routes, dyadic tolerance ledger, regular rational readback, Real seal, hsame*,* Cont*,* Pkg*, and local* NameCert *rows. It obtains no sigma-finite Fubini theorem, Tonelli theorem, quotient function equality, selected representative, countable-choice schedule, or ambient measure-completeness principle.*

Proof. Begin with an iterated-integral request. The finite rectangle row R and product row P identify the only cells and coordinate directions available to the request.

The measure and integral rows M and I then bind the computation to that same table. The first-then-second route A and second-then-first route B are therefore two readings of the displayed finite cell data rather than appeals to an ambient product-measure theorem.

The dyadic ledger D and regular rational readback S force both route totals through the same finite tolerance and sum surface. Only after those rows have been displayed may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed.

The structural rows H, C, Q, N transport and name the same finite route. Since the packet contains no row for sigma-finite Fubini, Tonelli, quotient function equality, selected representatives, countable choice, or ambient measure completeness, no iterated-integral consumer can obtain such data from the accepted carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}$.

Constructive story: A $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ packet is generated from finite product rectangle cells, displayed Measure and Integral rows, a Product row, first-then-second and second-then-first iterated routes, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3854.1, Definition 3854.2, and Definition 3854.3 seed the finite rectangle iterated-integral packet over displayed product cells and common tolerance readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-finite Fubini, Tonelli, quotient function equality, selected representatives, countable choice, ambient measure completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked rectangle visibility, measure-integral compatibility, route symmetry, regular rational readback, Real sealing, ledger nonescape, and local naming for BEDC.Derived.FubiniFiniteRectangleUp.

Chapter 2883

A Concrete Naming Certificate for $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$

The $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ packet realizes the disk-dynamics fixed-end reading of section 9463.5 in chapter 9463 as finite disk metric, boundary, flow, and provenance rows. It sits after the metric-read surface of chapter 3474, the boundary-geodesic packet of chapter 3491, the finite routed-flow carrier of chapter 195, the disk-coordinate surface of chapter 377, and the disk phase-transport route of chapter 3455. The packet names a finite geodesic-flow surface; it does not complete the hyperbolic disk, quotient ideal endpoints, choose a global geodesic representative, or identify observer expansion with a physical spacetime law.

Definition 2883.1 (Hyperbolic geodesic-flow carrier)**.** *A* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (U, M, B, T, D, F, J, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row for the finite source and target observations inspected by the flow.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *B is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *boundary row, recording the finite far-end incidence used by the route.*
4. *T is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *transport row carrying reversible disk-surface movement and fiber provenance.*
5. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *routed-flow row, displaying the finite step relation read as geodesic-flow evolution.*
6. *F is the fixed-end row stating that the boundary far-end commitment is preserved along the displayed route.*
7. *J is the classifier-stability row for disk coordinates, metric reads, boundary incidence, phase transport, routed flow, and fixed-end data.*
8. *A is the audit row tying U, M, B, T, D, F, J to the hyperbolic observer-expansion vision and to its sibling concrete packets.*
9. *H records componentwise* hsame *transport for disk-coordinate, metric, boundary, phase-transport, routed-flow, fixed-end, classifier-stability, audit, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a geodesic-flow request through* $U, M, B, T, D, F, J, A, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, M, B, T, D, F, J, A, H, C, P, N$. *The carrier has no coordinate for a completed hyperbolic disk, quotient ideal-boundary equality, a selected global geodesic, a host analytic flow, physical cosmology, or observer substance.*

Lean4 ✓ `BEDC.Derived.HyperbolicGeodesicFlowUp.HyperbolicGeodesicFlowTasteGate single carrier alignment`

Theorem 2883.2 (Hyperbolic geodesic-flow NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *carrier* $G = (U, M, B, T, D, F, J, A, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlow}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet* $U, M, B, T, D, F, J, A, H, C, P, N$;
2. *disk and metric visibility:* U *and* M *display disk coordinates and hyperbolic metric reads before any flow row is exported;*
3. *boundary incidence:* B *supplies the finite far-end data consumed by the geodesic route;*
4. *phase and flow routing:* T *and* D *display the reversible phase-transport route and finite routed-flow relation;*
5. *fixed-end stability:* F *and* J *preserve boundary far-end and classifier readings along the displayed route;*
6. *audit provenance:* A, H, C, P, N *source, transport, replay, package, and name the same finite rows;*
7. *ledger nonescape: no row exports a completed disk, quotient ideal-boundary equality, selected global geodesic, host analytic flow, physical cosmology, observer substance, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.HyperbolicGeodesicFlowUp.HyperbolicGeodesicFlowNamecertObligations`

Proof. Project the carrier of Definition 3856.1. The accepted rows are exactly $U, M, B, T, D, F, J, A, H, C, P, N$, so carrier admission exposes finite disk observations, metric reads, boundary incidence, transport, routed flow, fixed-end data, classifier stability, audit provenance, and structural rows only.

The route begins with U and M. These rows bind the computation to displayed disk and metric data, so the flow cannot import a completed hyperbolic plane or an ambient analytic model.

Next read B, T, D, F, J. Boundary incidence supplies the finite far-end, phase transport and routed flow display the movement, and fixed-end plus classifier-stability rows keep the same boundary commitment through the route.

Finally A, H, C, P, N audit, transport, replay, source, and name the finite packet. Since none of these rows adds quotient ideal-boundary equality, selected global geodesics, host analytic flow, physical cosmology, observer substance, or a bridge certificate, the listed obligations exhaust the local surface. □

Theorem 2883.3 (Hyperbolic geodesic-flow fixed-end nonescape)**.** *Every geodesic-flow consumer of an accepted* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *packet factors through*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicGeodesicBoundary}^{\uparrow} \longmapsto \mathsf{PoincareDiskPhaseTransport}^{\uparrow} \longmapsto \mathsf{DynSyster}$$

Thus a consumer may read disk coordinates, hyperbolic metric data, finite boundary incidence, phase transport, routed flow, fixed-end stability, classifier preservation, audit provenance, transport, replay, package sourcing, and local naming. It obtains no completed hyperbolic disk, quotient ideal-boundary equality, selected global geodesic, host analytic flow, physical cosmology, or observer substance.

Proof. Begin with a geodesic-flow request. The disk-coordinate row U and metric-read row M give the only geometric data available to the request.

The boundary row B supplies finite far-end incidence. The transport row T and routed-flow row D then display movement through certified phase transport and finite flow data, rather than through a host geodesic-flow theorem.

The fixed-end and classifier rows F, J preserve the boundary commitment and the sibling classifiers along the displayed route. The audit and structural rows A, H, C, P, N preserve that same finite packet.

No carrier coordinate names a completed hyperbolic disk, quotient ideal-boundary equality, selected global geodesic, host analytic flow, physical cosmology, or observer substance. Therefore a geodesic-flow consumer cannot escape the displayed finite route. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ read is refuted if a geodesic-flow consumer obtains a completed disk, quotient ideal-boundary equality, a selected global geodesic, or a host analytic flow without displaying UnitDisk coordinates, HyperbolicMetric reads, HyperbolicGeodesicBoundary incidence, PoincareDiskPhaseTransport routing, DynSystem flow rows, fixed-end stability, transport, replay, provenance, and local naming.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-boundary, dynsystem, unitdisk, poincare-disk-phase-transport: none is bijective to $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ because the packet jointly carries disk observations, metric reads, boundary incidence, reversible phase transport, finite routed flow, fixed-end stability, classifier preservation, audit provenance, transport, replay, package sourcing, and local NameCert rows.

The Lean TasteGate for this packet will require explicit $\mathsf{Nontrivial}\ \mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ instances. Those instances must keep $U, M, B, T, D, F, J, A, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ packet is generated from UnitDisk disk-coordinate rows, HyperbolicMetric reads, HyperbolicGeodesicBoundary incidence, PoincareDiskPhaseTransport rows, DynSystem routed-flow rows, fixed-end stability, classifier preservation, audit provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3856.1, Definition 3856.2, and Definition 3856.3 seed the finite geodesic-flow packet over disk metric, boundary, flow, and provenance rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic disks, quotient ideal-boundary equality, selected global geodesics, host analytic flows, physical cosmology, observer-substance readings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk visibility, metric-read visibility, boundary incidence, phase-flow routing, fixed-end stability, TasteGate nontriviality, field faithfulness, ledger nonescape, and local naming for BEDC.Derived.HyperbolicGeodesic

Chapter 2884

A Concrete Naming Certificate for $\mathsf{LocatedSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedSequence}^{\uparrow}$ packet records the finite surface by which a sequence is read through located windows before it is consumed as regular rational, located real, or real-facing data. It sits after the finite stream observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the located-real boundary of **??**, and the terminal real-name seal of chapter 38. The chapter isolates the generic located-sequence carrier used by later completion and compact-uniform-continuity routes; it does not choose a quotient stream, a selected limit, a trichotomy decision, countable choice, or ambient real completeness.

Definition 2884.1 (Located sequence carrier)**.** *A* $\mathsf{LocatedSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, D, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, exposing exactly the finite sequence windows that may be inspected by a consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the inspected stream windows as regular rational sequence data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used when located windows are compared, tightened, or handed to a modulus consumer.*
4. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *window row, recording the located interval or ball evidence available at the displayed sequence indices.*
5. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream, regular rational, dyadic, and located-real rows have been projected.*
6. *H records componentwise* hsame *transport for stream windows, regular rational readback, dyadic tolerances, located-real windows, real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite sequence request through*

$$S, D, L \longmapsto R \longmapsto Q.$$

8. *P is the* Pkg *provenance over* $\mathsf{LocatedSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSequence}^{\uparrow}}$ *row.*

The classifier accepts only packets in which the displayed stream windows, dyadic tolerance budgets, located-real windows, regular rational readback, and real seal describe one finite route. It has no coordinate for quotient streams, selected representatives, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedSequenceUp.TasteGate.LocatedSequenceTasteGate single carrier alignment`

Theorem 2884.2 (Located sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSequence}^{\uparrow}$ *carrier* $A = (S, R, D, L, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequence}^{\uparrow}}$ *surface consists exactly of stream-window admission, regular rational readback, dyadic tolerance accounting, located-real window coverage, real-seal routing, componentwise transport, continuation replay, package provenance, and local naming through the rows* $S, R, D, L, Q, H, C, P, N$*. Consumers from* $\mathsf{LocatedSequenceModulus}^{\uparrow}$, $\mathsf{LocatedSequenceLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *may read the packet only through those displayed rows.*

Proof. Project the carrier of Definition 3857.1. The sequence is visible only through S, and every tolerance-facing comparison is visible only through the dyadic row D and the located-real row L.

The readback row R repacks the same inspected windows as $\mathsf{RegSeqRat}^{\uparrow}$ data. The real seal Q is downstream of S, D, L, R, so a real-facing consumer reaches it only after replaying the displayed located route.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Since the carrier has no coordinate for quotient streams, selected representatives, host equality, trichotomy, countable choice, or ambient completeness, the listed NameCert rows are exhaustive. □

Theorem 2884.3 (Located sequence regular rational readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedSequence}^{\uparrow}$ *carrier must read*

$$S, D, L \longmapsto R \longmapsto Q \longmapsto H, C, P, N.$$

Thus regular rational readback is a displayed finite route from stream windows and located dyadic tolerances to the real seal, not a selected quotient stream, not host real equality, not a trichotomy principle, and not ambient real completeness.

Proof. Begin with a consumer request for regular rational or real-facing data. The packet exposes sequence observations only through S, and each located precision request is accounted for by D and L.

The row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ readback surface. Therefore a located-real or real-facing consumer reaches the terminal seal Q only after the finite route through S, D, L, R has been displayed.

The structural rows H, C, P, N preserve that route by transport, replay, source, and local naming. No excluded analytic object is present in the tuple, so no downstream consumer can extract one from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedSequence}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, LocatedReal windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{LocatedSequence}\uparrow}$, seed)

Scope closed: Definition 3857.1, Definition 3857.2, and Definition 3857.3 seed the finite located-sequence surface for the L10 StreamName-to-RegSeqRat-to-Real route.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedSequence}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, host real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window coverage, dyadic tolerance accounting, located-real window stability, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSequenceUp.

Chapter 2885

A Concrete Naming Certificate for $\mathsf{CauchyModulusExtractor}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyModulusExtractor}^{\uparrow}$ packet records the finite operation that reads an accepted effective Cauchy sequence and exposes the explicit modulus row required by regular-Cauchy and real-completion consumers. It sits over the source certificate of chapter 1705, the fast-threshold selector of chapter 1781, the ordinary modulus schedule of chapter 292, the finite-window service of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet is a displayed extraction route from explicit Cauchy evidence to a Real-facing handoff; it is not quotient stream equality, a host-selected limit, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 2885.1 (Cauchy modulus extractor carrier)**.** *A* $\mathsf{CauchyModulusExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (E, F, M, S, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the accepted* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *source row whose explicit-modulus coordinate is to be read.*
2. *F is the* $\mathsf{FastCauchyModulus}^{\uparrow}$ *threshold row used when the consumer requests a fast or doubled-window presentation of the same precision query.*
3. *M is the extracted* $\mathsf{CauchyModulus}^{\uparrow}$ *row, displayed before any finite stream window or regular rational readback is consumed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the stage selected from M and, when needed, refined by F.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the precision query, slack rows, comparison budgets, and tolerance conversions attached to the extracted stage.*
6. *Q is the precision-query row whose requested tolerance is routed through E, F, M, S, D.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row exposed only after the source, extractor, finite-window, and dyadic rows have been displayed.*
8. *H records componentwise* hsame *transport for the source, fast selector, extracted modulus, finite window, dyadic ledger, query, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a regular-Cauchy or Real-facing request through $E, F, M, S, D, Q, R, H, P, N$*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusExtractor}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{FastCauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusExtractor}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite explicit-modulus extraction packet. It has no coordinate for quotient stream equality, host-selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyModulusExtractorUp.CauchyModulusExtractorTasteGate single carrier alignment`

Theorem 2885.2 (Cauchy modulus extractor NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusExtractor}^{\uparrow}$ *carrier $X = (E, F, M, S, D, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusExtractor}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed effective Cauchy source, fast threshold selector, extracted modulus, finite stream window, dyadic tolerance ledger, precision query, regular and Real handoff, transport, replay, provenance, and local naming rows;*
2. *source exposure, requiring the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *row E to be read before M is exported;*
3. *modulus extraction, requiring M to be the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *row exposed from E for the same precision query Q;*
4. *threshold compatibility, requiring F to refine only the same selected threshold row, either directly or through the doubled-window route;*
5. *finite-window and dyadic accounting, requiring S and D to be downstream of M and F before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read is consumed;*
6. *handoff nonescape, requiring R to expose only the regular rational readback or Real seal certified by E, F, M, S, D, Q;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No extractor obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3858.1. The accepted packet displays exactly the source effective Cauchy row, the fast selector, the extracted modulus, finite windows, the dyadic ledger, the precision query, the regular and Real handoff, and the structural rows.

Source exposure uses Definition 1705.2. The explicit modulus row is part of the accepted $\mathsf{EffectiveCauchySequence}^{\uparrow}$ carrier surface, so an extractor cannot export M before it has read the source row E.

Threshold compatibility is supplied by Definition 1781.4 and Definition 1781.5. The row F selects the direct fast threshold or the doubled-window threshold for the same query Q, and it creates no third selector coordinate.

The finite-window and dyadic rows then follow chapter 126 and chapter 291. The handoff row R is downstream of that route, while H, C, P, N transport, replay, package, and name the same rows. Hence the listed obligations exhaust the local certificate surface. □

Theorem 2885.3 (Cauchy modulus extractor stage determinacy)**.** *Let $X = (E, F, M, S, D, Q, R, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusExtractor}^{\uparrow}$ *carrier. For the displayed precision query Q, every inspected* $\mathsf{StreamName}^{\uparrow}$ *window row S is opened at the stage determined by the extracted* $\mathsf{CauchyModulus}^{\uparrow}$ *row M together with the fast-threshold row F. Thus two accepted reads with the same transported E, F, M, Q, H, C, P, N rows cannot diverge on the stage used by S or on the dyadic tolerance ledger D.*

Proof. Project the accepted carrier. The only coordinates that mention stage selection are E, F, M, Q together with the downstream window and ledger rows S, D.

The source theorem Definition 1705.3 places every regular rational read behind the explicit modulus row carried by E. The extractor reads that row as M for the same query Q.

The fast-modulus theorems Definition 1781.4 and Definition 1781.5 then determine whether the direct threshold or doubled threshold is used, and identify the corresponding S and D rows.

Since the carrier has no additional selector coordinate, transported agreement of E, F, M, Q, H, C, P, N forces the same selected stage, the same finite window, and the same dyadic ledger. □

Theorem 2885.4 (Cauchy modulus extractor Real handoff nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusExtractor}^{\uparrow}$ *carrier $X = (E, F, M, S, D, Q, R, H, C, P, N)$ must first read the finite route*

$$E \longmapsto M, F, Q \longmapsto S, D \longmapsto R \longmapsto H, C, P, N.$$

Consequently the handoff exports no quotient stream equality, host-selected limit, countable-choice schedule, trichotomy principle, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, hidden stream read, Lean verification row, or bridge datum.*

Proof. Start from a regular-Cauchy or Real-facing consumer. The carrier definition exposes the handoff only as the row R, downstream of E, F, M, S, D, Q.

Apply Definition 1705.5. The effective source row E permits a Real-facing read only after its explicit modulus, finite windows, dyadic ledger, and regular rational handoff have been displayed.

Apply Definition 3858.3. The extractor route fixes the stage row used by S and the tolerance account stored in D before the handoff row is consumed.

The structural rows H, C, P, N preserve that route and contain no excluded analytic or verification coordinate. Therefore the regular-rational or Real handoff cannot escape the displayed extraction packet. □

Falsifiable prediction: Every $\mathsf{CauchyModulusExtractor}^{\uparrow}$ regular or Real-facing read factors through an EffectiveCauchySequence source row, an extracted CauchyModulus row, a FastCauchyModulus threshold row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat and RealUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: effective-cauchy-sequence, fast-cauchy-modulus, cauchymodulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyModulusExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source effective-Cauchy row, extracted modulus, fast threshold selector, finite window, dyadic ledger, regular and Real handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusExtractor}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3858.1, Definition 3858.2, Definition 3858.3, and Definition 3858.4 seed the finite explicit-modulus extraction route from EffectiveCauchySequence$^{\uparrow}$ through FastCauchyModulus$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyModulusExtractor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host-selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, modulus extraction, threshold compatibility, finite-window and dyadic accounting, handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusExtractorUp.

Constructive story: A CauchyModulusExtractor$^{\uparrow}$ packet is generated from an EffectiveCauchySequence source row, a FastCauchyModulus threshold row, an extracted CauchyModulus row, finite StreamName windows, a DyadicRatCore tolerance ledger, a precision query, a RegSeqRat and RealUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2886

A Concrete Naming Certificate for $\mathsf{RealArithmeticProgression}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealArithmeticProgression}^{\uparrow}$ packet records the textbook arithmetic progression route $a, a+d, a+2d, \ldots$ as finite BEDC data before any completed real-analysis theorem is read. It sits over the terminal real-name seal of chapter 38, the regular rational readback surface of chapter 301, the finite stream-window discipline of chapter 126, and the finite dyadic arithmetic ledgers of chapter 291. The packet supplies a constructive L10 sequence object for later finite-window sequence and series arguments; it is not a host function, not an infinite completed sum, not a quotient-real equality, not trichotomy, and not an ambient completeness principle.

Definition 2886.1 (Real arithmetic progression carrier)**.** *A* $\mathsf{RealArithmeticProgression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (a, d, S, R, D, H, C, P, N)$$

with the following displayed rows:

1. *a is the initial* $\mathsf{Real}^{\uparrow}$ *row, read through its displayed regular-rational name rather than through a host real value;*
2. *d is the common-difference* $\mathsf{Real}^{\uparrow}$ *row, read through the same real-name boundary;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule listing the indices currently requested from the progression;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose nth window is obtained by the displayed finite arithmetic route for $a + nd$;*
5. *D is the finite dyadic arithmetic ledger recording the repeated addition budget, tolerance scale, and endpoint readbacks used by the requested windows;*
6. *H records componentwise* hsame *transport for the initial real row, common-difference row, schedule, regular-rational readback, dyadic ledger, continuation, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from a finite index request through S, then through the dyadic ledger D, the regular-rational readback R, and the endpoint real rows a, d;*
8. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArithmeticProgression}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a host function $\mathbb{N} \to \mathbb{R}$, quotient equality of real representatives, selected limits, infinite sums, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealArithmeticProgressionUp.RealArithmeticProgressionTasteGate single carrier alignment`

Theorem 2886.2 (Real arithmetic progression NameCert obligations)**.** *For every accepted* RealArithmeticProgressio *carrier $A = (a, d, S, R, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealArithmeticProgression}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the initial real row a, common-difference row d, finite schedule S, regular-rational readback R, dyadic arithmetic ledger D, transport, continuation, provenance, and local naming row;*
2. *finite-window exactness, requiring each inspected index to be replayed through S before the arithmetic readback R is exposed;*
3. *arithmetic-ledger exactness, requiring the displayed row D to account for the finite repeated-addition route from a and d to every requested readback;*
4. *real-name routing, requiring every downstream* $\mathsf{Real}^{\uparrow}$ *or sequence-facing consumer to reach the progression through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *rows;*
5. *transport stability, requiring componentwise* hsame *transport to preserve the same initial row, common-difference row, schedule, readback, and dyadic ledger;*
6. *ledger refusal, excluding host functions, completed infinite sums, quotient-real equality, trichotomy, selected limits, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 3859.1. This exposes exactly the rows $a, d, S, R, D, H, C, P, N$ and no detached operation row.

Replay the continuation C at a finite index request. The request first passes through the $\mathsf{StreamName}^{\uparrow}$ schedule S, then reads the repeated-addition ledger D, and only then exposes the $\mathsf{RegSeqRat}^{\uparrow}$ readback R tied to the endpoint rows a and d.

Transport by H is componentwise, so changing representative histories preserves the same initial real row, common-difference row, finite schedule, arithmetic ledger, readback, replay route, provenance, and local naming row. The provenance row P cites only the displayed Real, regular-rational, stream, dyadic, and kernel surfaces.

Since the tuple has no coordinate for a host sequence function, quotient-real equality, infinite sum, trichotomy decision, selected limit, or ambient completeness theorem, those exits cannot be read as local $\mathsf{NameCert}_{\mathsf{RealArithmeticProgression}^{\uparrow}}$ obligations. □

Lean4 ✓ `BEDC.Derived.RealArithmeticProgressionUp.RealArithmeticProgressionNameCertObligations`

Closure status for $\mathsf{NameCert}_{\mathsf{RealArithmeticProgression}^{\uparrow}}$.

Constructive story: A $\mathsf{RealArithmeticProgression}^{\uparrow}$ packet is generated from an initial Real row, a common-difference Real row, a finite StreamName schedule, a RegSeqRat readback, a DyadicRatCore repeated-addition ledger, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealArithmeticProgression}^{\uparrow}}$, seed)

Scope closed: Definition 3859.1 and Definition 3859.2 seed the finite arithmetic-progression route from $\mathsf{Real}^{\uparrow}$ endpoints through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealArithmeticProgression}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completeness of $\mathsf{Real}^{\uparrow}$, trichotomy, quotient-real equality, host functions $\mathbb{N} \to \mathbb{R}$, selected limits, infinite sums, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exactness, arithmetic-ledger exactness, real-name routing, transport stability, and ledger refusal for the same packet.

Chapter 2887

A Concrete Naming Certificate for $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real names, the $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ packet records the finite readback ledger through which a regular Cauchy presentation is reflected into completion-facing consumers. It sits after the regular rational source of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the reflector surface of chapter 1585, and the extension boundary of chapter 397. The ledger exposes a BEDC-native reflection route for completion consumers without quotient streams, selected limits, host real equality, countable choice, or ambient completeness.

Definition 2887.1 (Regular Cauchy reflection ledger carrier)**.** *A* $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, W, D, R, K, U, J, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the regular rational Cauchy readback.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which the source row is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the regular Cauchy read.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from Q, W, D.*
5. *K is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row recording the reflector-facing handoff from the displayed regular Cauchy route.*
6. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row consumed by completion-facing maps.*
7. *J is the reflection ledger row: it records that the same Q, W, D, R source route feeds both K and U.*
8. *H records componentwise* hsame *transport for Q, W, D, R, K, U, J and the local naming row.*
9. *C records displayed* Cont *replay of the route*
$$Q, W, D \longmapsto R \longmapsto K, U \longmapsto J, H, P, N.$$
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionLedger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, W, D, R, K, U, J, H, C, P, N$. It has no coordinate for quotient stream classes, selected completion limits, host equality of real names, countable-choice schedules, hidden cofinal tails, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyReflectionLedgerUp.RegularCauchyReflectionLedgerTasteGate`
`single carrier alignment`

Theorem 2887.2 (Regular Cauchy reflection ledger NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ *carrier $L = (Q, W, D, R, K, U, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReflection}}$ *surface consists exactly of carrier admission; regular rational source exposure through Q; finite stream exposure through W; dyadic tolerance exposure through D; terminal real sealing through R; reflector handoff through K; universal-property extension through U; reflection ledger binding through J; componentwise transport through H; displayed replay through C; provenance through P; local naming through N; and non-escape from quotient streams, selected limits, host real equality, countable choice, hidden cofinal tails, or ambient completeness.*

Proof. Carrier admission is projection from Definition 3860.1. The accepted packet exposes exactly the regular rational source, finite stream schedule, dyadic tolerance ledger, real seal, reflector handoff, universal-property extension row, reflection ledger, transport, replay, provenance, and local name.

The source route is finite. Rows Q, W, D determine the regular Cauchy read before R can be consumed, so the packet never begins from a quotient stream class or a selected limit representative.

The completion-facing route is read only after the real seal is displayed. Rows K and U expose the reflector and universal-property surfaces, while J records that both surfaces use the same Q, W, D, R source route.

Rows H, C, P, N transport, replay, source, and name the same ledger. Since no excluded host-side coordinate exists in the carrier, the listed rows exhaust the local $\mathsf{NameCert}$ surface. □

Theorem 2887.3 (Regular Cauchy reflection ledger universal handoff)**.** *Every completion-facing read of an accepted* $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyCompletionReflector}^{\uparrow}, \mathsf{CompletionUniversalProperty}$$

The handoff keeps the regular Cauchy source, finite observation schedule, dyadic tolerance ledger, terminal real seal, reflector row, universal-property row, transport, replay, provenance, and local naming inside one finite packet. It exports no quotient stream, selected limit, host real equality, countable-choice schedule, hidden cofinal tail, or ambient completeness witness.

Proof. Start with the displayed source rows. The regular rational readback Q is inspected through the finite windows W and the dyadic tolerance ledger D, and only then reaches the real seal R.

The reflector and universal-property rows are downstream of that same source route. The row K records the reflector-facing handoff, while U records the extension-facing handoff for completion consumers.

The ledger row J binds the two completion reads to the same Q, W, D, R route. The structural rows H, C, P, N transport, replay, source, and name that binding, so every completion-facing consumer remains inside the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ consumer that reaches a completion-facing reflector or universal-property row while omitting any of the regular rational source, finite stream schedule, dyadic tolerance ledger, terminal real seal, reflection ledger, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchycompletionreflector, completionuniversalproperty: none is bijective because $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ jointly carries the source readback, finite observation schedule, tolerance ledger, real seal, reflector handoff, universal-property handoff, reflection binding, transport, replay, provenance, and local NameCert rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionLedger}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3860.1, Definition 3860.2, and Definition 3860.3 seed the finite regular-Cauchy reflection ledger over RegSeqRat, StreamName, DyadicRatCore, Real, CauchyCompletionReflector, CompletionUniversalProperty, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionLedger}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyReflectionLedgerUp.RegularCauchyReflectionLedgerTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, hidden cofinal tails, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular source exposure, tolerance exactness, reflector handoff, universal-property handoff, ledger binding, structural transport, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.RegularCauchyReflectionLedgerUp.

Constructive story: A $\mathsf{RegularCauchyReflectionLedger}^{\uparrow}$ packet is generated from a regular rational source row, finite stream windows, dyadic tolerance data, a terminal Real seal, a CauchyCompletionReflector row, a CompletionUniversalProperty row, a reflection ledger row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 2888

A Concrete Naming Certificate for $\mathsf{TubeLemma}^{\uparrow}$

Following Munkres and Kelley on product topology and compact neighbourhoods, the $\mathsf{TubeLemma}^{\uparrow}$ packet records the finite BEDC surface for the tube lemma: when a slice around a compact factor lies inside an open product-neighbourhood row, a displayed neighbourhood in the other factor suffices for the whole compact slice. It sits over the product topology certificate of chapter 2000, the generated-open topology rows of chapter 88, the compact finite-cover surface of chapter 60, and the finite-cover siblings such as chapter 1596 and chapter 3430. The chapter names only the finite tube-neighbourhood carrier and its local obligations; it does not assert product compactness, quotient equality of product points, selected neighbourhood bases, or ambient open-cover compactness beyond the displayed compact row.

Definition 2888.1 (Tube lemma carrier)**.** *A* $\mathsf{TubeLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, K, O, U, V, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Topology}^{\uparrow}$ *row naming the first factor.*
2. *Y is the source* $\mathsf{Topology}^{\uparrow}$ *row naming the second factor.*
3. *K is the* $\mathsf{Compact}^{\uparrow}$ *row for the compact slice inside the second factor.*
4. *O is the* ***??*** *open-neighbourhood row containing the displayed slice.*
5. *U is the finite family of product-open rows read from O along the compact slice.*
6. *V is the resulting neighbourhood row in the first factor.*
7. *F is the finite-cover row over K that justifies replacing the family U by one displayed tube neighbourhood.*
8. *H records componentwise* hsame *transport for the two topology rows, compact row, product-open row, finite family, tube neighbourhood, finite-cover row, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a slice-neighbourhood request through $X, Y, K, O, U, V, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{TubeLemma}^{\uparrow}$*,* ***??****,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{TubeLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, K, O, U, V, F, H, C, P, N$. It has no coordinate for global product compactness, a host topological theorem, quotient equality of product points, an arbitrary open-cover selector, or a detached neighbourhood basis.

Lean4 ✓ `BEDC.Derived.TubeLemmaUp.TubeLemmaTasteGate single carrier alignment`

Theorem 2888.2 (Tube lemma NameCert obligations)**.** *For every accepted* $\mathsf{TubeLemma}^{\uparrow}$ *carrier $T = (X, Y, K, O, U, V, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TubeLemma}^{\uparrow}}$ *surface is exhausted by carrier admission, topology-row exposure for both factors, compact-slice exposure through K, product-open exposure through O, finite product-neighbourhood family exposure through U, tube-neighbourhood exposure through V, finite-cover justification through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3861.1. The accepted tuple exposes the two topology rows, the compact slice row, the product-open row, the finite product-neighbourhood family, the resulting tube neighbourhood, and the finite-cover row.

The compactness use is local to K and F. The finite family U is read from the displayed product-open neighbourhood O along the compact slice, and F records the finite-cover handoff that permits one neighbourhood row V in the first factor to cover the whole slice.

Finally transport and replay preserve the same finite route. Since H, C, P, N contain only componentwise transport, continuation replay, provenance, and naming, they cannot add product compactness, quotient product equality, selected bases, or an arbitrary open-cover selector. The listed rows therefore exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{TubeLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{TubeLemma}^{\uparrow}$ packet is generated from two topology rows, a compact slice row, a product-open neighbourhood row, a finite product-neighbourhood family, a tube neighbourhood row, a finite-cover row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TubeLemma}^{\uparrow}}$, seed)

Scope closed: Definition 3861.1 and Definition 3861.2 seed the finite tube-neighbourhood packet over product topology, compact slice, generated-open, and finite-cover rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TubeLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close product compactness, arbitrary open-cover compactness, quotient equality of product points, selected neighbourhood bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked topology-row exposure, compact-slice exposure, product-open exposure, finite-cover justification, tube-neighbourhood exactness, transport replay, provenance exhaustion, and local naming for BEDC.Derived.TubeLemmaUp.

Chapter 2889

A Concrete Naming Certificate for $\mathsf{FilterLimitBasis}^{\uparrow}$

Following Kelley and Bourbaki on filters, convergence, and completion by directed neighbourhood data, the $\mathsf{FilterLimitBasis}^{\uparrow}$ packet records the finite basis interface used when a completion consumer asks for limit evidence before reading a terminal real-name seal. It sits after the Cauchy-filter completion boundary of chapter 1569, the Cauchy-filter surface of chapter 333, the limit boundary of chapter 1558, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a traditional finite filter-basis route for limit reads; it is not a quotient filter, selected limit, host real equality, ultrafilter argument, countable-choice selector, or ambient completeness theorem.

Definition 2889.1 (FilterLimitBasis carrier)**.** *A* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, F, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion-boundary row whose accepted reads are still tied to finite Cauchy-filter data.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row exposing the saturated finite-filter surface consumed by the basis request.*
3. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *limit-boundary row, read only after the same filter and basis data have been displayed.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by the basis request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the readback at the requested precision.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after Q, F, L, W, R, D have been replayed.*
8. *H records componentwise* hsame *transport for completion, filter, limit, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a limit-basis request through $Q, F, L, W, R, D, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, F, L, W, R, D, E, H, C, P, N$. There is no coordinate for quotient filters, host filter equality, ultrafilters, selected limits, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCarrier field projection round trip`

Theorem 2889.2 (FilterLimitBasis NameCert obligations)**.** *For every accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier $B = (Q, F, L, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for the displayed Cauchy-filter completion row, Cauchy-filter row, limit-boundary row, finite stream window, regular rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming row;*
2. *completion-basis exposure, requiring every completion-facing read to consume Q and F before it consults L, W, R, D, or E;*
3. *limit compatibility, requiring the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *row L to use the same displayed filter, window, readback, and dyadic tolerance route;*
4. *Real handoff, requiring the terminal seal E to remain downstream of Q, F, L, W, R, D and the structural rows H, C, P, N;*
5. *ledger refusal, excluding quotient filters, host filter equality, ultrafilters, selected limits, countable-choice schedules, ambient completeness, and bridge certificates.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisNameCertObligations`

Proof. Project the carrier of Definition 3862.1. The displayed rows are exactly $Q, F, L, W, R, D, E, H, C, P, N$, so carrier admission exposes only finite completion, filter, limit, window, readback, tolerance, seal, transport, replay, provenance, and naming data.

The completion-basis route starts with Q and F. These rows force the request to pass through the accepted Cauchy-filter completion boundary and the saturated Cauchy-filter surface before any limit-facing row can be inspected.

Next read L, W, R, D. The limit boundary consumes the same finite stream windows, regular rational readback, and dyadic tolerance ledger, so the packet has one displayed basis route rather than two unrelated filter presentations.

Finally the terminal seal E and the structural rows H, C, P, N preserve the same route. Since quotient filters, host equality, ultrafilters, selected limits, countable-choice schedules, ambient completeness, and bridge certificates are absent from the carrier, the listed obligations exhaust the local surface. □

Theorem 2889.3 (FilterLimitBasis CauchyFilterCompletion handoff)**.** *Every* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier factors through the finite route*

$$Q, F, L, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus a completion-facing read receives the displayed Cauchy-filter completion boundary, the saturated filter surface, the limit boundary, finite stream windows, regular rational readback, dyadic tolerance accounting, the terminal real-name seal, componentwise transport, replay, provenance, and local naming. It receives no quotient filter, ultrafilter, selected limit, host real equality, countable-choice selector, ambient completeness theorem, or bridge certificate.

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCauchyFilterCompletionHandoff`

Proof. Begin with a completion-facing consumer of B. The carrier admits the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row Q only together with the finite filter and limit rows F, L.

Replay the displayed continuation row C. The request consumes Q and F, then passes through the limit row L, finite windows W, regular readback R, and dyadic tolerance ledger D before the terminal seal E is available.

The structural rows do not create an additional completion object. Transport through H, provenance through P, and local naming through N record the same finite route, so every $\mathsf{CauchyFilterCompletion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives only that route. □

Theorem 2889.4 (FilterLimitBasis limit compatibility)**.** *Let $B = (Q, F, L, W, R, D, E, H, C, P, N)$ be an accepted $\mathsf{FilterLimitBasis}^{\uparrow}$ carrier. The limit-boundary row L, finite-window row W, regular readback row R, and dyadic tolerance row D are read from the same displayed filter-basis data exposed by Q and F. In particular, a limit-facing consumer cannot replace the filter of F with a second host filter, detach W from the displayed basis request, or read R, D as tolerance evidence for a different filter presentation.*

↪ variant `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasis limit compatibility`
↪ variant `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCarrier limit compatibility`

Proof. Project the carrier of Definition 3862.1. Its only completion and filter coordinates are Q and F, and its only limit-facing coordinates are L, W, R, D.

Apply the NameCert obligations of Definition 3862.2. The limit-compatibility row requires L to use the same displayed filter, window, readback, and dyadic tolerance route rather than a detached filter presentation.

Finally read the handoff theorem Definition 3862.3. Every completion-facing consumer follows the finite route Q, F, L, W, R, D before the terminal seal appears, so L, W, R, D remain tied to the filter-basis data already exposed by Q and F. □

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisLimitCompatibility`

Theorem 2889.5 (FilterLimitBasis ledger refusal)**.** *For every accepted $\mathsf{FilterLimitBasis}^{\uparrow}$ carrier $B = (Q, F, L, W, R, D, E, H, C, P, N)$, the local ledger has no coordinate for quotient filters, host filter equality, ultrafilters, selected limits, countable-choice schedules, ambient completeness, or bridge certificates. Any request for one of those objects is therefore refused by the absence of a carrier row and cannot be recovered from $Q, F, L, W, R, D, E, H, C, P, N$.*

Proof. Inspect the carrier definition. The displayed tuple contains completion, filter, limit, window, readback, tolerance, seal, transport, replay, provenance, and local naming rows, and no row with the requested quotient, ultrafilter, selected-limit, choice, completeness, or bridge role.

Apply Definition 3862.2. Its ledger-refusal clause lists exactly those excluded objects and states that the local NameCert surface stores no obligation outside the displayed rows.

The handoff theorem Definition 3862.3 then identifies every completion-facing and Real-facing read with the route through $Q, F, L, W, R, D, E, H, C, P, N$. Since the route has no additional ledger coordinate, the excluded objects remain refused for every accepted packet. □

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCarrier ledger refusal`

Theorem 2889.6 (FilterLimitBasis Real handoff stability)**.** *Let $B = (Q, F, L, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier. Componentwise transport of the displayed rows $Q, F, L, W, R, D, E, H, C, P,$ preserves the terminal* $\mathsf{Real}^{\uparrow}$ *handoff of Definition 3862.3. In particular, any transported completion-facing or Real-facing read still factors through the same finite route*

$$Q, F, L, W, R, D \longmapsto E \longmapsto H, C, P, N$$

and cannot create quotient filters, selected limits, ultrafilters, countable-choice schedules, host filter equality, host real equality, or ambient completeness.

Proof. Start with the carrier definition Definition 3862.1. Its visible rows are exactly $Q, F, L, W, R, D, E, H, C, P, N,$ and the transport row H is componentwise over those rows rather than over an ambient filter quotient or a selected limit.

Apply the NameCert obligations of Definition 3862.2. They require completion-basis exposure through Q, F, limit compatibility through L, W, R, D, Real handoff through E, and structural replay through H, C, P, N.

Finally use the handoff theorem Definition 3862.3. Since the transported packet has the same displayed coordinates and no additional carrier row, the terminal $\mathsf{Real}^{\uparrow}$ handoff remains downstream of Q, F, L, W, R, D and cannot acquire quotient filters, selected limits, ultrafilters, countable-choice schedules, host equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisRealHandoffStability`

Theorem 2889.7 (FilterLimitBasis scoped route)**.** *Every accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *packet exposes completion-facing limit evidence only through the finite route*

$$\mathsf{CauchyFilterCompletion}^{\uparrow} \longrightarrow \mathsf{CauchyFilter}^{\uparrow} \longrightarrow \mathsf{CauchyFilterLimit}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRa}$$

followed by the structural hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *rows. Equivalently, in the carrier notation of Definition 3862.1, every completion-facing, limit-facing, or Real-facing read must pass through $Q, F, L, W, R, D, E, H, C, P, N$ in that order before it is exported as limit-basis evidence.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisScopedRoute`

Proof. Start with the NameCert obligations of Definition 3862.2. They make carrier admission, completion-basis exposure, limit compatibility, Real handoff, and ledger refusal the only local obligation rows.

Apply the CauchyFilterCompletion handoff of Definition 3862.3. It forces every completion-facing and Real-facing consumer through Q, F, L, W, R, D before the terminal seal E and the structural rows are available.

Next use the limit compatibility theorem Definition 3862.4. The $\mathsf{CauchyFilterLimit}^{\uparrow}$ row L, finite window row W, regular readback row R, and dyadic tolerance row D remain attached to the same displayed filter-basis data exposed by Q and F.

Finally apply Real handoff stability from Definition 3862.6. Componentwise transport preserves the same route through H, C, P, N, so the scoped route is exactly the displayed completion, filter, limit, stream, regular-rational, dyadic, Real, and structural sequence. □

Theorem 2889.8 (FilterLimitBasis window-basis exhaustion)**.** *Every accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *request must expose the completion row* Q*, the Cauchy-filter row* F*, the limit-boundary row* L*, the finite-window row* W*, the regular readback row* R*, and the dyadic tolerance row* D *before it may read the terminal seal* E*. Only after that finite basis has been displayed may the request continue through* H, C, P, N*. Consequently the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*, and* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *rows are all visible before any* $\mathsf{Real}^{\uparrow}$ *consumer can inspect the seal.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisWindowBasisExhaustion`

Proof. Project the carrier of Definition 3862.1. Its visible order places Q, F, L, W, R, D before the terminal seal row E, and then records transport, replay, provenance, and local naming as H, C, P, N.

Apply the NameCert obligations of Definition 3862.2. The completion-basis row forces Q, F to be read first, the limit-compatibility row ties L, W, R, D to that same request, and the Real handoff row keeps E downstream of those finite rows.

Finally use Definition 3862.4 and Definition 3862.6. They preserve the same displayed basis under limit-facing and transported Real-facing reads, so no $\mathsf{Real}^{\uparrow}$ consumer can reach the seal before the StreamName, RegSeqRat, DyadicRatCore, CauchyFilter, and CauchyFilterLimit rows are visible. □

Theorem 2889.9 (FilterLimitBasis window induction)**.** *Let* $B = (Q, F, L, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier, and let* Λ *be a finite replay ledger whose entries are finite window reads or structural transports of the displayed rows. Induction on* Λ *preserves the following invariant: every* $\mathsf{Real}^{\uparrow}$*-facing consumer exposes* Q, F, L, W, R, D *before* E*, and every later replay through* H, C, P, N *preserves that same basis route. Thus no induction step can introduce a quotient filter, ultrafilter, selected limit, countable-choice schedule, host filter equality, host real equality, or ambient completeness premise.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisWindowInduction`

Proof. For the empty ledger, apply Definition 3862.8. The terminal seal is available only after Q, F, L, W, R, D have been displayed, and the remaining rows are exactly the structural route H, C, P, N.

For the induction step, assume the finite prefix of Λ preserves the displayed basis route. If the next entry is a finite window read, use Definition 3862.4: the rows L, W, R, D remain tied to the same filter-basis data exposed by Q and F.

If the next entry is a structural transport or replay, use Definition 3862.6. Componentwise transport of $Q, F, L, W, R, D, E, H, C, P, N$ keeps the $\mathsf{Real}^{\uparrow}$ handoff downstream of the same finite basis and does not create an additional carrier coordinate.

The carrier of Definition 3862.1 has no row for quotient filters, ultrafilters, selected limits, choice schedules, host equality, or ambient completeness. Therefore the invariant holds for every finite ledger Λ. □

Theorem 2889.10 (FilterLimitBasis finite-prefix StreamName consumption)**.** *Let* $B = (Q, F, L, W, R, D, E, H, C,$ *be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier. Every accepted request that reaches the terminal row* E *first consumes the finite prefix StreamName windows* W*, the RegSeqRat readback row* R*, and the DyadicRatCore tolerance row* D *through the same* Q, F, L *basis route. Consequently a Real or completion-facing read cannot replace the displayed finite-prefix route by a quotient filter, a selected limit, an ambient completeness row, or a detached stream representative.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisFinitePrefixStreamConsumption`

Proof. Project the carrier of Definition 3862.1. The only route to E is the displayed chain through Q, F, L, W, R, D followed by the structural rows H, C, P, N.

Apply Definition 3862.8. It forces every Real-facing or completion-facing request to expose Q, F, L, W, R, D before the terminal seal is read.

Then apply Definition 3862.9. Finite replay of the request preserves the same basis route through every prefix of the ledger, so W, R, D remain tied to the same Cauchy-filter completion, Cauchy-filter, and limit-boundary rows.

Since Definition 3862.1 has no coordinate for quotient filters, selected limits, detached stream representatives, or ambient completeness, none of those objects can be introduced before the E handoff. □

Theorem 2889.11 (FilterLimitBasis real-window exhaustion)**.** *Let $B = (Q, F, L, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier exposing the completion-basis row, limit-compatibility row,* $\mathsf{Real}^{\uparrow}$ *handoff-stability row, and finite-window induction row. Then every limit-basis consumer must expose a finite window tuple through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before it may read terminal* $\mathsf{Real}^{\uparrow}$ *evidence. In particular, the consumer has no route through quotient filters, selected limits, ultrafilters, countable-choice schedules, host filter equality, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisRealWindowExhaustion`

Proof. First apply Definition 3862.3. It sends every completion-facing or Real-facing request through the displayed route $Q, F, L, W, R, D, E, H, C, P, N$, so the terminal seal is not available before the completion and filter rows have been read.

Next apply Definition 3862.4. The limit boundary L remains tied to the same finite window row W, regular readback row R, and dyadic tolerance row D exposed by Q and F.

Then use Definition 3862.6 and Definition 3862.9. Transport and finite replay preserve the same route for every ledger prefix, so the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows exhaust the visible window before terminal Real evidence is read.

The carrier definition has no row for quotient filters, selected limits, ultrafilters, countable-choice schedules, host equalities, or ambient completeness. Therefore any consumer using one of those objects has left the accepted $\mathsf{FilterLimitBasis}^{\uparrow}$ packet rather than reading its real-window exhaustion surface. □

Theorem 2889.12 (FilterLimitBasis obligation-closure readiness)**.** *Let $B = (Q, F, L, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier. The carrier admission of Definition 3862.1, the local NameCert obligations of Definition 3862.2, the CauchyFilterCompletion handoff of Definition 3862.3, the limit-compatibility row of Definition 3862.4, the ledger refusal of Definition 3862.5, the Real handoff stability of Definition 3862.6, the window-basis exhaustion of Definition 3862.8, the window induction of Definition 3862.9, and the real-window exhaustion of Definition 3862.11 jointly provide the paper-side obligation surface needed to move the chapter from seed closure toward obligation closure.*

The readiness surface is still finite BEDC data: it records only the displayed completion row, Cauchy-filter row, limit-boundary row, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise transport, replay, provenance, and local NameCert rows. It introduces no quotient filter, selected limit, ultrafilter, countable-choice schedule, host equality, ambient Real completeness, or bridge certificate.

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisObligationClosureReadiness`

Proof. Project the carrier row of Definition 3862.1. The only available coordinates are $Q, F, L, W, R, D, E, H, C, P, N$ so any obligation-closure package must be assembled from those finite rows.

Apply Definition 3862.2, Definition 3862.3, and Definition 3862.4. These rows supply carrier admission, the completion-facing route, and the condition that the limit boundary uses the same finite filter-basis data.

Next apply Definition 3862.5, Definition 3862.6, and Definition 3862.8. They keep the terminal Real seal downstream of the displayed basis and exclude quotient, choice, ultrafilter, host-equality, ambient-completeness, and bridge coordinates.

Finally use Definition 3862.9 and Definition 3862.11. Finite replay preserves the same window route through every ledger prefix, so the chapter has the paper-side obligation surface required for the next closure step without adding any object outside the accepted $\mathsf{FilterLimitBasis}^{\uparrow}$ carrier. □

Theorem 2889.13 (FilterLimitBasis scope exactness)**.** *Let $B = (Q, F, L, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier. Every consumer read exported by the local limit-basis surface factors through the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row Q, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F, the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *row L, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *row N before any limit-basis export is read. The scope contains no selected limit, quotient filter, ultrafilter, countable-choice schedule, host filter equality, host real equality, or ambient real-completeness premise.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisScopeExactness`

Proof. Read the carrier rows in order. The completion row Q and Cauchy-filter row F determine the finite filter-basis request, and the limit-boundary row L attaches the requested limit evidence to that same basis.

The finite-prefix material then fixes the observation route. By Definition 3862.10, the windows W, regular readback R, and dyadic tolerance ledger D are consumed before the terminal $\mathsf{Real}^{\uparrow}$ seal E can be inspected.

The structural rows preserve exactness rather than adding new objects. Componentwise hsame transport in H and displayed Cont replay in C keep every consumer read on the same route, while P and N record only provenance and local naming.

Therefore any exported limit-basis read has passed through $Q, F, L, W, R, D, E, H, C, P, N$. The refused objects have no carrier coordinate and no replay edge, so selected limits, quotient filters, countable choice, and ambient real completeness cannot be smuggled into the scope. □

Theorem 2889.14 (FilterLimitBasis scoped obligation)**.** *For an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier $B = (Q, F, L, W, R, D, E, H, C, P, N)$, the obligation surface is scoped exactly by the displayed route through* $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *rows. Every completion-facing, limit-facing, or Real-facing read must pass through those rows, and no quotient filter, selected limit, ultrafilter, countable-choice schedule, host filter equality, host real equality, ambient completeness, or bridge certificate is part of the scope.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisScopedObligation`

Proof. Start from the carrier of Definition 3862.1. It displays precisely the rows $Q, F, L, W, R, D, E, H, C, P, N$, so the candidate scope is already bounded by the completion boundary, Cauchy-filter surface, limit

boundary, window, readback, tolerance, Real seal, transport, replay, provenance, and local naming data.

Apply the NameCert obligations and the CauchyFilterCompletion handoff, Definition 3862.2 and Definition 3862.3. They force every completion-facing consumer through Q, F, L, W, R, D before E and keep H, C, P, N attached to the same finite route.

Use limit compatibility, window induction, and real-window exhaustion from Definition 3862.4, Definition 3862.9, and Definition 3862.11. These theorems preserve the same route for limit-facing and Real-facing reads, so the scoped obligation is exactly the displayed L10 completion route and contains no additional host or bridge coordinate. □

Theorem 2889.15 (FilterLimitBasis kernel scope upgrade)**.** *Every accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *packet routes completion-facing limit evidence through the kernel sequence*

$$\mathsf{CauchyFilterCompletion}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{CauchyFilterLimit}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},$$

and only then through BHist, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *rows. In carrier notation, every accepted read is scoped by* $Q, F, L, W, R, D, E, H, C, P, N$ *before it is exported as limit-basis evidence.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisKernelScopeUpgrade`

Proof. Use the NameCert obligations of Definition 3862.2. They make carrier admission, completion-basis exposure, limit compatibility, Real handoff, and ledger refusal the local obligation rows.

Apply the CauchyFilterCompletion handoff of Definition 3862.3. A completion-facing consumer must pass through Q, F, L, W, R, D before the terminal seal E and the structural rows can be read.

The limit compatibility theorem and window-basis exhaustion theorem, Definition 3862.4 and Definition 3862.8, keep the $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows attached to the same displayed basis.

Finally use finite-prefix StreamName consumption from Definition 3862.10. The structural rows BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ replay and name that route without adding quotient filters, selected limits, countable choice, host equality, ambient completeness, or bridge data. □

Theorem 2889.16 (FilterLimitBasis cofinal subbasis scope)**.** *Let* $B = (Q, F, L, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *carrier whose filter row* F *is generated from a displayed* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *route. Before* B *exports limit-basis evidence, the consumer must expose the subbasis finite intersections, the generated* $\mathsf{FilterBase}^{\uparrow}$ *row, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *row, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The export is therefore scoped by the cofinal subbasis route together with* $Q, F, L, W, R, D, E, H, C, P, N$ *and it contains no quotient filter, selected limit, ultrafilter, countable-choice schedule, host filter equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge certificate.*

Proof. Start with the generated-base cofinality and finite-intersection route of Definition 4232.4 and Definition 4232.5. They force a subbasis-generated completion read through finite subbasis tokens, finite intersections, generated events, generation ledger, and a generated $\mathsf{FilterBase}^{\uparrow}$ row before any downstream Cauchy-filter row can be consumed.

Compose this with the Cauchy filter subbasis completion handoff of Definition 4232.7. The handoff keeps the generated base before the $\mathsf{CauchyFilter}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal.

Now apply the local scoped route of Definition 3862.15. Once the generated $\mathsf{CauchyFilter}^{\uparrow}$ row is the filter row F of the accepted $\mathsf{FilterLimitBasis}^{\uparrow}$ carrier, the limit-basis read must continue through $Q, F, L, W, R, D, E, H, C, P, N$ in the kernel order displayed there.

The structural rows transport and name the same finite route. Since neither the subbasis carrier nor the limit-basis carrier has a coordinate for quotient filters, selected limits, ultrafilters, countable choice, host filter equality, ambient completeness, or bridge certificates, the composed scope is exactly the cofinal subbasis surface stated above. □

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCofinalSubbasisScope`

Theorem 2889.17 (FilterLimitBasis cofinal Cauchy-entourage induction)**.** *Let $B = (Q, F, L, W, R, D, E, H, C, P, N$ be an accepted* $\mathsf{FilterLimitBasis}^{\uparrow}$ *packet whose finite basis rows refine the Cauchy-filter route of* $\mathsf{CauchyFilter}^{\uparrow}$*, the completion boundary of* $\mathsf{CauchyFilterCompletion}^{\uparrow}$*, the Real-induced uniformity of* $\mathsf{RealUniformStructure}^{\uparrow}$*, the regular rational readback of* $\mathsf{RegSeqRat}^{\uparrow}$*, and the source-window surface of* $\mathsf{StreamName}^{\uparrow}$*. Induction over the finite basis-window ledger produces a cofinal entourage route*

$$Q, F, L, W, R, D \longmapsto E \longmapsto H, C, P, N$$

such that every Real-facing limit read must first pass through the displayed Cauchy-filter basis, the completion boundary, the Real-uniform entourage row, the StreamName windows, the RegSeqRat readback, and the dyadic tolerance ledger before any terminal $\mathsf{Real}^{\uparrow}$ *seal is exposed. The route exports no selected limit, quotient filter, host filter equality, ultrafilter, countable-choice schedule, ambient Real completeness, or bridge certificate.*

Proof. Start with the finite ledger induction of Definition 3862.9. Its base case reads the displayed rows Q, F, L, W, R, D before E, and its step case preserves the same route under every finite window read or structural replay.

Use the real-window exhaustion theorem Definition 3862.11. It identifies the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows as the visible Real-facing window route, so no terminal Real evidence is read before the basis windows and regular rational handoff are exposed.

Finally apply the kernel scope upgrade of Definition 3862.15. The upgraded scope places $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in one displayed kernel route. Since the accepted carrier has no coordinate for selected limits, quotient filters, host filter equality, ultrafilters, countable-choice schedules, ambient Real completeness, or bridge certificates, the induced entourage route is cofinal only inside that finite BEDC surface. □

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCofinalCauchyEntourageInduction`

Theorem 2889.18 (FilterLimitBasis scoped completion dependency)**.** *Every completion-facing* $\mathsf{FilterLimitBasis}^{\uparrow}$ *read consumes* $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before a filter-limit basis can be sealed. In carrier notation, the read must expose the completion row Q, finite windows W, regular readback R, dyadic tolerance ledger D, terminal real seal E, componentwise transport H, displayed replay C, provenance P, and local naming N before any* $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$ *consumer treats the basis as sealed. The route does not claim selected limits, ultrafilters, countable choice, quotient filters, host filter equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisScopedCompletionDependency`

Proof. Project the carrier of Definition 3862.1. The completion-facing rows include $Q, W, R, D, E, H, C, P, N$, with the Cauchy-filter and limit rows attached by the same finite packet.

Apply the CauchyFilterCompletion handoff of Definition 3862.3. It forces the completion row and the finite-prefix StreamName consumption to appear before the terminal Real seal is inspected.

Use Definition 3862.10 and Definition 3862.11. These results route the windows through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the structural rows replay and name the basis.

The accepted carrier has no coordinate for selected limits, ultrafilters, countable choice, quotient filters, host filter equality, or ambient completeness. Hence the listed rows are the complete scoped dependency for the L10 completion handoff. □

Theorem 2889.19 (FilterLimitBasis public export)**.** *Every public completion-facing read of* $\mathsf{FilterLimitBasis}^{\uparrow}$ *factors through the already scoped route from* $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert. *In carrier notation, the public export must expose* $Q, F, L, W, R, D, E, H, C, P, N$ *before a limit-basis consumer may read the seal. The export contains no quotient filters, ultrafilters, selected limits, countable-choice schedules, host equality, ambient Real completeness, or bridge certificate.*

Lean4 ✓ `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisPublicExport`
↪ variant `BEDC.Derived.FilterLimitBasisUp.FilterLimitBasisCarrier public export`

Proof. Use the NameCert obligations of Definition 3862.2. They make carrier admission, completion-basis exposure, limit compatibility, Real handoff, and ledger refusal the only local public rows.

Apply the handoff and limit-compatibility theorems, Definition 3862.3 and Definition 3862.4. These force every completion-facing read through Q, F, L, W, R, D before the terminal seal and keep the limit boundary attached to the same displayed filter-basis data.

Use Real handoff stability from Definition 3862.6 together with the scoped route of Definition 3862.15. Componentwise transport, displayed replay, provenance, and local naming preserve the same route through E, H, C, P, N and do not add a second public object.

Finally apply the scoped completion dependency of Definition 3862.18. Since that dependency already excludes selected limits, ultrafilters, countable choice, quotient filters, host equality, and ambient completeness, the public export is exactly the displayed finite route and carries no bridge certificate. □

Falsifiable prediction: An accepted $\mathsf{FilterLimitBasis}^{\uparrow}$ read is refuted if a $\mathsf{CauchyFilterCompletion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal without displaying the Cauchy-filter completion row, Cauchy-filter row, Cauchy-filter limit row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming.

Independence witness: cauchyfiltercompletion, cauchyfilter, cauchyfilterlimit, streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{FilterLimitBasis}^{\uparrow}$ because the packet jointly records completion-boundary, saturated-filter, limit-boundary, finite-window, readback, tolerance, seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{FilterLimitBasis}^{\uparrow}$ packet is generated from a CauchyFilterCompletion row, a CauchyFilter row, a CauchyFilterLimit row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FilterLimitBasis}^{\uparrow}}$, publicClosed)

Scope closed: Definition 3862.19, Definition 3862.17, and Definition 3862.18 close the public completion-facing export through CauchyFilterCompletion, CauchyFilter, CauchyFilterLimit, StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FilterLimitBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, host filter equality, ultrafilter arguments, countable-choice schedules, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Bridge closure requires a standard bridge surface for the same finite public export route.

Chapter 2890

A Concrete Naming Certificate for $\mathsf{PerfectSet}^{\uparrow}$

Following Cantor and Bendixson, the $\mathsf{PerfectSet}^{\uparrow}$ packet names the finite certificate surface for a closed set whose every displayed point remains a derived point. It sits over the open-neighborhood discipline of chapter 88, the compact metric inspection rows of chapter 129, the terminal real-name seal of chapter 38, and the derivative-stage route of chapter 2024. The chapter isolates the reusable perfect-kernel face consumed by Cantor-Bendixson analysis; it is not a transfinite decomposition, a selected point enumeration, quotient real equality, or an ambient completeness theorem.

Definition 2890.1 (PerfectSet carrier)**.** *A* $\mathsf{PerfectSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, K, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the topology row, carrying the open-neighborhood tests and closed-set complement reads through chapter 88.*
2. *K is the compact-metric source row, carrying the finite metric inspection and cover data supplied by chapter 129.*
3. *D is the derived-point ledger. For every displayed point read from the set and every finite neighborhood request, it records a second compatible point read through the same topology and metric rows.*
4. *W is the finite window schedule for neighborhood, metric, and derived-point requests.*
5. *R is the regular rational readback row used by the metric comparisons and the non-isolation witnesses.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the topology, compact-metric, derived-point, window, and readback rows have been displayed.*
7. *H records componentwise* hsame *transport for T, K, D, W, R, E and for the structural replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of every perfect-set consumer request through*

$$T, K, D, W, R \longmapsto E \longmapsto H, C, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{PerfectSet}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CantorBendixson}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PerfectSet}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected countable dense subset, transfinite rank, isolated-point enumeration, quotient equality of real names, host closed-set equality, countable choice, or ambient compactness beyond the displayed rows.

Theorem 2890.2 (PerfectSet NameCert obligations)**.** *For every accepted* $\mathsf{PerfectSet}^{\uparrow}$ *carrier* $S = (T, K, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PerfectSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology, compact-metric, derived-point, finite-window, regular readback, Real-seal, transport, replay, provenance, and local naming rows;*
2. *closed-set exposure, requiring complement and neighborhood requests to pass through the topology row T and compact-metric row K;*
3. *derived-point non-isolation, requiring each displayed point-and-neighborhood request to receive its second compatible point through D at a window listed in W;*
4. *real-seal compatibility, requiring every metric comparison and non-isolation witness to pass through R before the terminal seal E is consumed;*
5. *ledger nonescape, requiring H, C, P, N to export no isolated-point selector, transfinite derivative rank, quotient real equality, host closed-set equality, countable-choice schedule, or ambient completeness theorem.*

No perfect-set obligation is stored outside these rows.

Proof. Project the accepted carrier $S = (T, K, D, W, R, E, H, C, P, N)$. Carrier admission exposes exactly the topology row, compact-metric source, derived-point ledger, finite window schedule, regular readback row, Real seal, and the structural rows.

Closed-set exposure is read through T and K. The topology row supplies neighborhood and complement tests, while the compact-metric row supplies the finite metric inspection data used by the same requests.

The derived-point clause is the row D. For each displayed point-and-neighborhood request, the finite window row W names the inspected neighborhood and D records the compatible second point before any Real-facing seal is available.

Finally, R and E bind the metric and Real-facing parts of the route, while H, C, P, N transport, replay, source, and name the same packet. Since the excluded classical data are not carrier coordinates, the five listed rows exhaust the local certificate. □

Theorem 2890.3 (PerfectSet derived-point nonescape)**.** *Every* $\mathsf{CantorBendixson}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{PerfectSet}^{\uparrow}$ *packet must read the topology row, compact-metric row, derived-point ledger, finite window schedule, regular readback route, and terminal Real seal before treating the set as a perfect kernel. In particular, the consumer receives the finite route*

$$T, K, D, W, R \longmapsto E \longmapsto H, C, P, N$$

and receives no isolated-point selector, transfinite derivative rank, quotient real equality, host closed-set equality, countable-choice schedule, or ambient compactness theorem outside the displayed certificate.

Proof. Start with a consumer request for the perfect-kernel face. By Definition 3863.2, the request first passes through the topology and compact-metric rows T, K and then through the derived-point ledger D at a finite window listed in W.

The regular readback row R and terminal seal E are the only Real-facing route in the carrier. Thus a Cantor-Bendixson consumer can consume this packet only as the retained perfect-set face displayed by chapter 2024.

The structural rows H, C, P, N preserve and replay the same route. Because the carrier lacks coordinates for isolated-point selection, transfinite ranks, quotient equality, host closed-set equality, countable choice, or extra compactness principles, no such data can escape through the derived-point ledger. □

Lean4 ✓ `BEDC.Derived.PerfectSetUp.PerfectSetCarrier derived point nonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{PerfectSet}\uparrow}$.

Constructive story: A $\mathsf{PerfectSet}^{\uparrow}$ packet is generated from topology rows, compact-metric inspection rows, a derived-point ledger, finite request windows, regular rational readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PerfectSet}\uparrow}$, seed)

Scope closed: Definition 3863.1, Definition 3863.2, and Definition 3863.3 seed the finite perfect-kernel certificate consumed by Cantor-Bendixson and Real-facing routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PerfectSet}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close transfinite Cantor-Bendixson decomposition, selected isolated-point enumeration, quotient real equality, host closed-set equality, countable choice, ambient compactness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-set exposure, derived-point non-isolation, Real-seal compatibility, ledger nonescape, and Cantor-Bendixson consumer routing for BEDC.Derived.PerfectSetUp.

Chapter 2891

A Concrete Naming Certificate for $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ packet records the finite even–odd interleaving route by which two regular Cauchy rational names are read as one binary stream before any Real or Completion consumer treats the result as a sealed real-facing name. It sits over the finite stream surface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion boundary of chapter 1569. The packet names a pairing-and-projection ledger; it does not identify host streams, select quotient representatives, or import ambient completeness.

Definition 2891.1 (Regular Cauchy binary interleaving carrier)**.** *A* $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S_0, S_1, E, O, T, R_0, R_1, L, H, K, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two finite* $\mathsf{StreamName}^{\uparrow}$ *source rows whose regular rational observations are to be paired.*
2. E *is the even* $\mathsf{StreamName}^{\uparrow}$ *projection row reading the* S_0 *observations from the interleaved stream.*
3. O *is the odd* $\mathsf{StreamName}^{\uparrow}$ *projection row reading the* S_1 *observations from the interleaved stream.*
4. T *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, assigning the same dyadic budget to the two projections and to the interleaved read.*
5. R_0 *and* R_1 *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the even and odd projections after the dyadic budget is fixed.*
6. L *is the* $\mathsf{Real}^{\uparrow}$ *seal compatibility row, requiring the two projected regular names and the interleaved name to expose the same terminal seal discipline to Real and Completion consumers.*
7. H *records componentwise* hsame *transport for the two source rows, projection rows, tolerance ledger, regular readbacks, Real seal row, replay, provenance, and naming rows.*
8. K *records displayed* Cont *replay from an interleaving request through* $S_0, S_1, E, O, T, R_0, R_1, L, H, P, N$.

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, E, O, T, R_0, R_1, L, H, K, P, N$. It has no coordinate for host stream equality, quotient sequence equality, a selected completion representative, countable-choice data, or an ambient real-completeness theorem.

Lean4 ✓ `BEDC.Derived.RegularCauchyBinaryInterleavingUp.RegularCauchyBinaryInterleavingTasteGate`
`single carrier alignment`

Theorem 2891.2 (Regular Cauchy binary interleaving NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ *carrier $B = (S_0, S_1, E, O, T, R_0, R_1, L, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}}$ *surface is exhausted by five rows:*

1. *carrier admission: the accepted object is exactly the displayed packet $S_0, S_1, E, O, T, R_0, R_1, L, H, K, P, N$;*
2. *projection stability: the even row E and odd row O read the two source* $\mathsf{StreamName}^{\uparrow}$ *rows without changing their finite windows;*
3. *dyadic tolerance preservation: the ledger T assigns one dyadic tolerance discipline to the two projections and to the interleaved stream;*
4. *Real seal compatibility: the row L is reachable only after E, O, T, R_0, R_1 have been displayed;*
5. *ledger refusal: H, K, P, N export no quotient sequences, choice selectors, host stream equality, hidden completion selector, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyBinaryInterleavingUp.RegularCauchyBinaryInterleavingNameCertObligatio`

Proof. Project the carrier of Definition 3864.1. Carrier admission exposes exactly the two sources, two projection rows, one dyadic tolerance ledger, two regular rational readbacks, one Real seal compatibility row, and the structural rows.

Read the projection rows next. The even row E is tied to S_0, and the odd row O is tied to S_1, so a consumer sees projection stability as a finite StreamName route rather than as host equality of streams.

The tolerance and readback rows then fix the regular Cauchy surface. The same dyadic ledger T is used before R_0 and R_1 are consumed, and the Real seal compatibility row L is available only after those rows have been displayed.

Finally inspect H, K, P, N. These rows transport, replay, source, and name the same finite packet, and none adds quotient sequences, choice selectors, host stream equality, hidden completion selectors, or ambient completeness data. Thus the five obligations exhaust the local NameCert surface. □

Theorem 2891.3 (Regular Cauchy binary interleaving seal stability)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ *packet factors through*

$$S_0, S_1 \longmapsto E, O \longmapsto T \longmapsto R_0, R_1 \longmapsto L \longmapsto H, K, P, N.$$

In particular, the consumer cannot read the terminal $\mathsf{Real}^{\uparrow}$ *seal compatibility row L without first displaying the even–odd projection rows, the shared dyadic tolerance ledger, and the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows.*

Proof. Begin with a Real or Completion request. The only source rows in the carrier are S_0 and S_1, and the only ways to read them through the interleaved stream are the even and odd projection rows E and O.

Next apply the tolerance ledger. The row T fixes the dyadic budget shared by the two projected reads, so the regular rational rows R_0 and R_1 cannot be consumed as independent selected sequences.

The seal row L is downstream of those displayed rows. Since the structural rows H, K, P, N only transport and name the same route, any consumer reaching a Real or Completion conclusion without the projection, tolerance, and readback rows would ask for a coordinate outside the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ read is refuted if a Real or Completion consumer reaches the terminal seal compatibility row without displaying both StreamName source rows, even and odd projection rows, the shared DyadicRatCore tolerance ledger, both RegSeqRat readbacks, transport, replay, provenance, and local naming.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchyfiltercompletion: none alone is bijective with $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ because the packet jointly records two source streams, even and odd projection rows, one dyadic tolerance ledger, two regular rational readbacks, a terminal Real seal compatibility row, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ packet is generated from two StreamName source rows, even and odd projection rows, a DyadicRatCore tolerance ledger, two RegSeqRat readback rows, a Real seal compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3864.1, Definition 3864.2, and Definition 3864.3 seed the finite binary interleaving route for regular Cauchy rational names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient sequences, host stream equality, choice selectors, selected completion representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection stability, dyadic tolerance preservation, Real seal compatibility, ledger refusal, seal stability, and local naming for BEDC.Derived.RegularCauchyBinaryInterleavingUp.

Chapter 2892

A Concrete Naming Certificate for ??

Following Bishop and Bridges on nested closed intervals, the **??** packet records the constructive point-name extracted from a displayed shrinking chain of closed bounded intervals. It sits after the endpoint carrier of chapter 1591, the retained-chain surface of chapter 320, the intersection route of chapter 389, and the Cantor-style singleton route of chapter 1421. The packet names the point by finite BHist rows over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; it does not choose a host real, quotient representative, open-cover compactness proof, or countable-choice schedule.

Definition 2892.1 (Nested interval point-name carrier)**.** *A **??** carrier is a finite* BHist *packet*

$$P = (I, J, K, S, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *endpoint-and-containment source row for each retained interval window;*
2. *J is the* $\mathsf{NestedInterval}^{\uparrow}$ *chain row, recording inclusion of the next retained interval inside the preceding one;*
3. *K is the* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *and* $\mathsf{CantorIntersection}^{\uparrow}$ *singleton-intersection route row;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule used to read endpoints and diameter bounds at requested precision;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row extracted from the retained endpoint windows;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the named point, reached only after I, J, K, S, R have been displayed;*
7. *H records componentwise* hsame *transport for the interval source, nested chain, intersection row, StreamName windows, RegSeqRat readback, and Real seal;*
8. *C records displayed* Cont *replay from closed bounded intervals through nested containment, intersection, finite windows, regular readback, and the Real seal;*
9. *Q records* Pkg *provenance over **??**,* $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{NestedIntervalIntersection}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{??}$ *row.*

The carrier has no coordinate for an ambient intersection set, a selected quotient representative, countable choice, open-cover compactness, or an unbounded completeness theorem.

Lean4 ✓ BEDC.Derived.NestedIntervalPointNameUp.NestedIntervalPointNameTasteGate single carrier alignment

Theorem 2892.2 (Nested interval point-name regular Cauchy seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted ?? carrier factors through the displayed route*

$\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{NestedIntervalIntersection}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}$

In particular, the regular rational readback row R and the terminal seal row E are downstream of the interval source I, nested-chain row J, singleton-intersection row K, and finite schedule row S.

Proof. Project the carrier of Definition 3865.1. The rows I, J, K are the source, nesting, and intersection rows; the rows S, R, E are the finite schedule, regular readback, and terminal Real seal.

Use the closed bounded interval source route from chapter 1591. That route exposes endpoint, containment, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows as finite BHist data before any point-facing consumer can read them.

Now apply the nested and Cantor intersection siblings. The $\mathsf{NestedInterval}^{\uparrow}$ and $\mathsf{NestedIntervalIntersection}^{\uparrow}$ rows retain the chain and intersection route, while $\mathsf{CantorIntersection}^{\uparrow}$ supplies the singleton-facing seal. Since H, C, Q, N only transport, replay, source, and name these displayed rows, the exported $\mathsf{Real}^{\uparrow}$ read factors through the stated route. □

Theorem 2892.3 (Nested interval point-name endpoint containment)**.** *For every accepted ?? carrier $P = (I, J, K, S, R, E, H, C, Q, N)$, every finite read of the named point remains contained in each displayed retained* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *window before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The containment read is transported componentwise by H and replayed by C through the same* $\mathsf{NestedInterval}^{\uparrow}$ *and* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *chain.*

Proof. Start with the interval source row I. By the carrier, I is a closed bounded interval packet with lower endpoint, upper endpoint, endpoint-order, rational containment, dyadic containment, StreamName, RegSeqRat, and Real-seal rows.

Next use the nested-chain row J. It records that each retained window is included in the preceding one, so a later finite read cannot leave an earlier displayed closed bounded interval without breaking the hsame transport recorded in H.

Finally use the intersection row K. The $\mathsf{NestedIntervalIntersection}^{\uparrow}$ and $\mathsf{CantorIntersection}^{\uparrow}$ route supplies the point-facing intersection witness, while C replays the same containment route into S, R, E. Hence endpoint containment is preserved before the named point reaches the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 2892.4 (Nested interval point-name uniqueness route)**.** *If two accepted ?? carriers are classified together by their displayed* hsame *transport rows, then their* $\mathsf{Real}^{\uparrow}$ *point-name seals agree only through the same closed-interval source, nested-chain, intersection, StreamName, and RegSeqRat rows. The classifier exposes no separate host equality of points and no quotient-real representative selection.*

Proof. Compare the two carriers componentwise. The classifier can transport the interval source, nested chain, intersection row, finite schedule, regular readback, and Real seal only along displayed hsame rows.

Apply the endpoint-containment theorem. Each finite read remains inside the same transported retained intervals before the Real seal is consumed, so the uniqueness route is pinned to the displayed closed bounded interval and nested-intersection data.

The terminal comparison is therefore a route comparison, not a host equality principle. Since the carrier has no coordinate for quotient real equality or representative choice, the only available uniqueness evidence is the transported $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{NestedIntervalIntersection}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route named by the packet. □

Closure status for $\mathsf{NameCert}_{??}$**.**

Constructive story: A **??** packet is generated from displayed ClosedBoundedIntervalUp interval rows, a NestedIntervalUp retained-chain row, NestedIntervalIntersectionUp and CantorIntersectionUp intersection rows, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{??}$, seed)

Scope closed: Definition 3865.1, Definition 3865.2, Definition 3865.3, and Definition 3865.4 seed the finite point-name route extracted from nested closed bounded intervals.

Formal verification: FormalStatus($\mathsf{NameCert}_{??}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host interval intersection, selected quotient representatives, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular Cauchy seal routing, endpoint containment, uniqueness routing, transport, replay, provenance, and local naming for the displayed point-name packet.

Chapter 2893

A Concrete Naming Certificate for $\mathsf{HyperbolicVisualMetric}^{\uparrow}$

The $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ packet realizes the disk readout branch of chapter 9463 as finite NameCert data. It sits after the Poincare disk metric surface of chapter 3474, the boundary-geodesic route of chapter 3491, the boundary-shadow packet of chapter 3813, and the boundary-fixed transport surface of chapter 3500. The packet names a simultaneous visual-metric read over displayed disk, metric, boundary, shadow, transport, and provenance rows; it does not turn the observer boundary into an object-level T or a completed global geometry.

Definition 2893.1 (Hyperbolic visual metric carrier)**.** *A* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (D, M, B, S, T, F, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk source row, read through the Poincare disk and unit-disk coordinate surface;*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same disk source;*
3. *B is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *boundary row for geodesic far-end incidence;*
4. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *shadow row attached to the displayed boundary read;*
5. *T is the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *classifier-preserving boundary transport row;*
6. *F is the global-geometry refusal row, rejecting reads that replace displayed disk, metric, boundary, shadow, and transport rows by an object-level geometry;*
7. *A is the vision anchor row tying the packet to the observer-expansion reading of chapter 9463;*
8. *H records componentwise* hsame *transport for disk source, metric read, boundary row, shadow row, transport row, refusal row, and anchor row;*
9. *C records displayed* Cont *replay from disk source through metric read, boundary read, shadow, transport, refusal, and provenance;*
10. *P records* Pkg *provenance over* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetric}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed boundary compactification, object-level T*, physical horizon, global metric oracle, or quotient boundary equality.*

Lean4 (definition) `BEDC.Derived.HyperbolicVisualMetricUp.HyperbolicVisualMetricUp`
Lean4 ✓ `BEDC.Derived.HyperbolicVisualMetricUp.HyperbolicVisualMetricTasteGate single carrier alignment`

Theorem 2893.2 (Hyperbolic visual metric obligation surface)**.** *For the carrier of Definition 3866.1, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetric}^{\uparrow}}$ *surface consists exactly of disk source admission, hyperbolic metric read admission, geodesic-boundary read admission, boundary-shadow admission, classifier-preserving boundary transport, global-geometry refusal, vision-anchor provenance, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier rows. The disk source D, metric read M, boundary row B, shadow row S, and transport row T are the only geometric data available to the packet.

Use the sibling surfaces in order. $\mathsf{HyperbolicMetric}^{\uparrow}$ supplies the metric read, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ supplies the boundary incidence route, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ supplies the shadow row, and $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ supplies classifier-preserving transport.

The refusal and structural rows finish the surface. The row F refuses any read that bypasses the displayed siblings, while A, H, C, P, N only anchor, transport, replay, source, and name the same finite route. Thus the listed rows exhaust the local certificate. □

Theorem 2893.3 (Hyperbolic visual metric global-geometry refusal)**.** *A visual metric read of an accepted* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *packet is refused unless the displayed route contains disk source, metric read, boundary row, boundary shadow, classifier-preserving transport, provenance, and the global-geometry refusal row. The packet cannot replace those rows by an object-level* T*, completed boundary compactification, physical horizon, or global metric oracle.*

Proof. Read the geometric rows first. The carrier exposes disk source D, hyperbolic metric row M, geodesic-boundary row B, boundary-shadow row S, and boundary-fixed transport row T as separate finite fields.

Apply the obligation surface. By Definition 3866.2, a local NameCert read can inspect only those rows plus refusal, anchor, transport, replay, provenance, and local naming.

The excluded objects have no carrier coordinate. Since F explicitly refuses global-geometry substitution and H, C, P, N only preserve the displayed route, no accepted read can produce object-level T, completed compactification, physical horizon, or a metric oracle outside the packet. □

Theorem 2893.4 (Hyperbolic visual metric sibling separation)**.** *The* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *carrier is not bijective, row for row, with any one of* $\mathsf{HyperbolicMetric}^{\uparrow}$*,* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$*,* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*,* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*, or* $\mathsf{DynSystem}^{\uparrow}$*. A bijection preserving local NameCert obligations would have to preserve simultaneous disk readout, metric read, boundary incidence, shadow, boundary-fixed transport, refusal, provenance, transport, replay, and local naming, and no listed sibling carries that whole surface.*

Proof. Compare first with $\mathsf{HyperbolicMetric}^{\uparrow}$. The metric sibling supplies a disk metric read, but it does not carry boundary-geodesic incidence, boundary shadow, boundary-fixed transport, and global-geometry refusal as simultaneous rows.

Compare next with $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ and $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$. These siblings supply boundary incidence and shadow reads, while neither also owns the metric read, boundary-fixed transport, and visual refusal row.

Finally compare with $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ and $\mathsf{DynSystem}^{\uparrow}$. Transport and flow rows can move or evolve displayed data, but they are not the full visual metric packet. Since each sibling omits at least one of D, M, B, S, T, F, A, no row-preserving bijection can preserve the $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ obligations. □

Falsifiable prediction: A visual metric read is refused whenever the packet lacks disk source, metric read, boundary shadow, transport, and provenance rows.

Independence witness: hyperbolic_metric, hyperbolic_geodesic_boundary, hyperbolic_boundary_shadow, poincare_boundary_fixed_transport, dynsystem: the visual metric packet carries the simultaneous readout route not bijective with any one sibling.

The Lean TasteGate site for $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ HyperbolicVisualMetric}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicVisualMetric}^{\uparrow}$ instances. These instances keep disk source, metric read, boundary row, shadow row, boundary-fixed transport, refusal, provenance, transport, replay, and local naming as distinguishable fields.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ packet is generated from a disk source row, HyperbolicMetricUp metric read, HyperbolicGeodesicBoundaryUp boundary row, HyperbolicBoundaryShadowUp shadow row, PoincareBoundaryFixedTransportUp transport, global-geometry refusal, vision-anchor provenance, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3866.1, Definition 3866.2, Definition 3866.3, and Definition 3866.4 seed the finite visual-metric route over disk, metric, boundary, shadow, transport, refusal, and provenance rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close object-level T, completed boundary compactification, physical horizons, global metric oracles, quotient boundary equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual metric obligation routing, global-geometry refusal, sibling separation, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming.

Chapter 2894

A Concrete Naming Certificate for $\mathsf{MetricCauchyNetCluster}^{\uparrow}$

Following Moore–Smith and Kelley net convergence, and the Bishop–Bridges treatment of metric completion by displayed Cauchy information, the $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ packet records the finite route by which a metric Cauchy net exposes cluster evidence before any completion or real-seal consumer reads it. It sits between the subnet route of chapter 1592, the Cauchy-net completion boundary of chapter 3794, the metric completion packet of chapter 1506, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a displayed cluster route for completion-facing reads; it is not quotient nets, selected cluster points, countable choice, host limit equality, or ambient completeness.

Definition 2894.1 (Metric Cauchy-net cluster carrier)**.** *A* $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, M, J, S, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-net row, recording the inspected finite directed indices and the local comparison order used by the Moore–Smith route.*
2. *W is the Cauchy-window row, listing the finite cofinal windows and the tolerance requests that must be met before any cluster read is exposed.*
3. *M is the metric completion boundary row, connecting the displayed net windows to the* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer surfaces.*
4. *J is the cluster witness row, recording only finite witness windows and not a selected cluster point.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row that opens the finite observation windows used by W and J.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational distance and tolerance comparisons inspected along the route.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same windows and readbacks.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the directed-net, Cauchy-window, cluster-witness, stream, regular-readback, dyadic, and metric-completion rows have been displayed.*

9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records displayed* Cont *replay from a completion-facing request through $D, W, M, J, S, R, T, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{MetricCauchyNetCluster}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCauchyNetCluster}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient nets, chosen cluster points, choice-selected subnets, host metric completion equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MetricCauchyNetClusterUp.MetricCauchyNetClusterTasteGate single carrier alignment`

Theorem 2894.2 (Metric Cauchy-net cluster NameCert obligations)**.** *For every accepted* $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ *carrier $K = (D, W, M, J, S, R, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCauchyNetCluster}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the directed-net row, Cauchy-window row, metric-completion boundary, cluster witness, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *directed-window stability, requiring every inspected directed index to be read through D before W can answer a Cauchy request;*
3. *cluster-witness locality, requiring J to expose only finite witness windows tied to the same D, W, S, T rows;*
4. *completion-boundary handoff, requiring M to mediate every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer before E is read;*
5. *regular and dyadic accounting, requiring R and T to record the rational distance and tolerance ledger used by the same finite windows;*
6. *structural exactness through H, C, P, N, with no quotient-net equality, selected cluster point, countable choice, host real equality, or ambient completeness coordinate.*

Proof. Project the carrier of Definition 3867.1. The packet exposes the directed-net row, Cauchy-window row, metric boundary, cluster witness, finite windows, regular readback, dyadic ledger, terminal seal, and the structural rows as one finite object.

The directed and Cauchy-window obligations are read first. The row D fixes the finite directed comparisons, and W answers tolerance requests only through those displayed comparisons and the finite stream windows S.

The cluster witness row J is then local to the same windows. It records witness windows rather than a selected point, while R and T record the rational distance readback and dyadic tolerance ledger used by the window.

The completion boundary M mediates the completion-facing read before the Real seal row E is available. Since H, C, P, N only transport, replay, source, and name the same rows, the listed obligations exhaust the NameCert surface. □

Theorem 2894.3 (Metric Cauchy-net cluster completion handoff)**.** *Every completion-facing read of an accepted* $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ *carrier $K = (D, W, M, J, S, R, T, E, H, C, P, N)$ factors*

through the displayed finite Cauchy-net cluster route

$$D \longmapsto W \longmapsto S, J \longmapsto R, T \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

In particular, no $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *seal can be consumed before the directed-net row, Cauchy-window row, finite cluster witness,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger have been displayed.*

Proof. Begin with a completion-facing consumer. By Definition 3867.1, the only completion boundary in the packet is the row M, and the only terminal real-facing seal is E.

Apply the obligation surface of Definition 3867.2. It places directed-net admission and Cauchy-window stability before any cluster witness is read, and it ties the witness row to the same finite stream windows.

The regular rational and dyadic rows then supply the metric tolerance accounting used by the finite windows. The completion boundary M is downstream of that accounting, and the seal row E is downstream of M.

Finally H, C, P, N preserve and name only the displayed route. Quotient nets, selected cluster points, countable choice, host real equality, detached completion objects, and ambient completeness have no carrier coordinate, so they cannot replace the finite route. □

Falsifiable prediction: Every accepted $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ completion-facing read factors through a directed-net row, Cauchy-window row, finite cluster witness, StreamName windows, RegSeqRat readback, DyadicRatCore ledger, MetricCompletion and CauchyNetCompletion boundary, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchysubnet, cauchynetcompletion, metriccompletion, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective with $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ because this packet jointly carries the directed-net row, Cauchy-window row, finite cluster witness, metric completion boundary, finite stream windows, rational readback, dyadic ledger, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCauchyNetCluster}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCauchyNetCluster}^{\uparrow}$ packet is generated from a directed-net row, Cauchy-window row, metric completion boundary, finite cluster witness, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCauchyNetCluster}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3867.1, Definition 3867.2, and Definition 3867.3 seed the finite Cauchy-net cluster route from directed windows through completion and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCauchyNetCluster}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected cluster points, countable choice, host real equality, detached completion objects, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-window stability, cluster-witness locality, completion-boundary handoff, regular and dyadic accounting, structural exactness, and local naming for BEDC.Derived.MetricCauchyNetCl

Chapter 2895

A Concrete Naming Certificate for $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$ packet records the constructive interval route from closed bounded interval data to a compact-uniform modulus extraction. It joins the endpoint surface of chapter 1591, the finite interval-net route of chapter 1250, the positive radius ledger of chapter 452, the compact-continuity rows of chapter 388, and the output consumer of chapter 369. The packet names the finite bridge data only; it does not assert open-cover compactness, countable choice, quotient stream equality, ambient real completeness, Lean verification, or bridge checking.

Definition 2895.1 (Compact interval modulus bridge carrier)**.** *A* $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, N, R, U, M, S, Q, H, C, P, L)$$

with the following displayed rows:

1. *E is the closed bounded interval endpoint row from* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*, including the lower endpoint, upper endpoint, and displayed containment boundary.*
2. *N is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite-net row, carrying dyadic cells, rational cell readback, displayed centers, finite coverage,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows.*
3. *R is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius row, read only as a finite positive-radius ledger attached to the displayed net and cover route.*
4. *U is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *compact-continuity row whose pointwise continuity data are already routed through the interval net and radius ledger.*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row consumed after E, N, R, U have been displayed.*
6. *S records the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows used by interval endpoints, net centers, and the final modulus handoff.*
7. *Q is the tolerance-query row whose requested precision is routed through the net, radius, compact-continuity, and output-modulus rows.*
8. *H records componentwise* hsame *transport for $E, N, R, U, M, S, Q, C, P, L$.*

9. *C records displayed* Cont *replay from the closed interval source through finite nets, finite-radius data, compact-continuity rows, and the uniform-modulus output.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNe}$ $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalModulusBridge}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected subcovers, countable choice, quotient real equality, hidden host continuity, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CompactIntervalModulusBridgeUp.CompactIntervalModulusBridgeTasteGate`
`single carrier alignment`

Theorem 2895.2 (Compact interval modulus bridge NameCert obligations)**.** *For the carrier of Definition 3868.1, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalModulusBridge}^{\uparrow}}$ *surface consists exactly of endpoint exposure through E, finite interval-net exposure through N, finite positive-radius exposure through R, compact-continuity exposure through U, uniform-modulus output through M,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal exposure through S, tolerance-query routing through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through L.*

Proof. Project the accepted carrier $B = (E, N, R, U, M, S, Q, H, C, P, L)$. The endpoint row E supplies the closed bounded interval source, while N supplies the finite interval-net route over the same displayed endpoint boundary.

Read the finite-radius and compact-continuity rows next. The row R is the positive-radius ledger supplied by the finite Lebesgue-number surface, and U is the compact-continuity row that consumes the interval net and radius data before any modulus output is exposed.

The modulus row M is therefore downstream of E, N, R, U, Q. The seal row S records the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readbacks used by endpoints, centers, and the final handoff.

Finally H, C, P, L transport, replay, package, and name exactly these rows. Since the carrier has no additional coordinate, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$ uniform-modulus read must pass through displayed closed bounded interval endpoints, a finite closed-bounded interval net, a finite Lebesgue-number radius row, compact-uniform-continuity rows, StreamName, RegSeqRat, and RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: closedboundedinterval, closedboundedintervalnet, finitelebesguenumber, compactuniformcontinuity, uniformmodulus: $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint rows, finite-net rows, finite positive-radius rows, compact-continuity rows, the UniformModulus output, StreamName/RegSeqRat/RealUp seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalModulusBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$ packet is generated from closed bounded interval endpoints, finite interval-net rows, a finite Lebesgue-number radius ledger, compact-continuity rows, a UniformModulus output row, StreamName, RegSeqRat, and RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalModulusBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3868.1 and Definition 3868.2 seed the finite bridge from closed bounded interval data to compact-uniform modulus extraction.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactIntervalModulusBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint exposure, finite-net exposure, radius exposure, compact-continuity exposure, uniform-modulus output, seal rows, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalMo

Chapter 2896

A Concrete Naming Certificate for $\mathsf{LocatedRealBisectionSearch}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealBisectionSearch}^{\uparrow}$ packet records the finite search surface obtained by iterating bisection over a located real interval while keeping every branch, sign read, and retained window visible. It sits after the real-name surface of chapter 38, the located interval carrier of chapter 1709, the located bisection route of chapter 1711, the finite bracketing interval packet of chapter 1807, and the dyadic intermediate-value packet of chapter 2203. The packet names a bounded bisection search, not a host interval equality, not trichotomy on arbitrary reals, not choice of a hidden root, and not ambient completeness.

Definition 2896.1 (Located real bisection-search carrier)**.** *A* $\mathsf{LocatedRealBisectionSearch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, B, F, D, Q, W, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row, exposing lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, a locatedness modulus, and the inspected finite interval budget.*
2. *B is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *branch route, recording the requested finite bisection depth and the retained child at each stage.*
3. *F is the* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *bracket row, preserving the displayed sign or locator bracket for the retained interval.*
4. *D is the* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *dyadic sign-read row used by the bounded search.*
5. *Q is the query row, recording the finite search request, target tolerance, and admissible stopping condition.*
6. *W is the retained-window ledger, listing the lower and upper windows produced by the bounded branch sequence.*
7. *R is the* $\mathsf{Real}^{\uparrow}$*-facing seal row reached only after I, B, F, D, Q, W have been exposed.*
8. *H records componentwise* hsame *transport for the source, branch, bracket, dyadic read, query, window, and seal rows.*
9. *C records displayed* Cont *replay from a search request through finite bisection, bracket preservation, dyadic sign readback, retained-window exposure, and Real-facing seal.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealBisectionSearch}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{FiniteBracketingInterval}^{\uparrow}$, $\mathsf{DyadicIntermediateValue}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealBisectionSearch}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $I, B, F, D, Q, W, R, H, C, P, N$. It has no coordinate for host interval equality, trichotomy, countable choice, selected quotient representatives, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden root witness.*

Lean4 ✓ `BEDC.Derived.LocatedRealBisectionSearchUp.LocatedRealBisectionSearchTasteGate single carrier alignment`

Theorem 2896.2 (Located real bisection-search NameCert obligations)**.** *For every accepted* LocatedRealBisectionS *carrier $S = (I, B, F, D, Q, W, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealBisectionSearch}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, located-source exposure through I, finite bisection exposure through B, bracket preservation through F, dyadic sign readback through D, bounded query admission through Q, retained-window exposure through W, Real-facing seal routing through R, componentwise transport through H, continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3869.1. The accepted packet contains only the displayed rows, so carrier admission fixes the source interval, branch route, bracket row, dyadic sign readback, query, retained windows, seal, and structural data before any consumer reads the search.

The analytic part of the route is finite. The located source is I, the bisection route is B, the bracket row is F, and the dyadic sign-read row is D. The query row Q fixes the bounded stopping condition, while W records only the retained windows produced by those rows.

Finally read R, H, C, P, N. These rows seal the route toward $\mathsf{Real}^{\uparrow}$, transport the displayed data componentwise, replay the same finite request, record provenance, and name the packet. Since no carrier coordinate stores host equality, trichotomy, choice, ambient completeness, or a hidden root witness, the listed rows exhaust the local NameCert surface. □

Theorem 2896.3 (Located real bisection-search finite route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or interval-search consumer of an accepted* $\mathsf{LocatedRealBisectionSearch}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{LocatedIntervalBisection}^{\uparrow} \longmapsto \mathsf{FiniteBracketingInterval}^{\uparrow} \longmapsto \mathsf{DyadicIntermediateValue}^{\uparrow} \longmapsto$$

The consumer receives only the bounded branch ledger, preserved bracket, dyadic sign reads, retained windows, Real-facing seal, transport, replay, provenance, and local naming.

Proof. Begin with the source row. A search request first reads I, so the packet cannot replace the located real interval by an ambient host interval.

Next read the finite search rows B, F, D, Q, W. They record the branch sequence, bracket preservation, dyadic sign readback, bounded stopping request, and retained windows. No row in this stage selects an infinite limit or an unbounded root.

The final route through R, H, C, P, N preserves the same finite ledger for downstream real and interval-search consumers. Because the carrier has no coordinate for host interval equality, trichotomy, quotient-real representatives, countable choice, ambient completeness, or hidden root selection, every such consumer remains on the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealBisectionSearch}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealBisectionSearch}^{\uparrow}$ packet is generated from a located real interval source row, located bisection branch route, finite bracketing row, dyadic sign readback, bounded query row, retained-window ledger, Real-facing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedRealBisectionSearch}\uparrow}$, seed)

Scope closed: Definition 3869.1, Definition 3869.2, and Definition 3869.3 seed the finite bisection-search packet over located real interval, finite bracket, dyadic sign, retained-window, and Real-facing rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedRealBisectionSearch}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host interval equality, real trichotomy, countable choice, selected quotient representatives, ambient RealUp completeness, hidden root selection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, branch-route exactness, bracket preservation, dyadic sign readback, retained-window routing, RealUp seal nonescape, and local naming for BEDC.Derived.LocatedRealBisectionSearchUp.

Chapter 2897

A Concrete Naming Certificate for $\mathsf{ConditionalTriggerEnsemble}^{\uparrow}$

The $\mathsf{ConditionalTriggerEnsemble}^{\uparrow}$ packet realizes the conditional trigger ensemble of Definition 9462.1594 and Definition 9462.1601 as finite weighted trigger, blocker, partition, expectation, transport, replay, provenance, and local NameCert rows. It sits beside the residue boundary of chapter 1167, the trigger-blocker duality packet of chapter 3801, the trigger-energy partition packet of chapter 3806, and the weighted deformation spine adjacent to the DNA window-six boundary-tile vision. The packet names a finite conditional ensemble surface; it is not a hidden biological semantics, not an external probability space, not an unbounded trigger search, and not an oracle for conditional means.

Definition 2897.1 (Conditional trigger ensemble carrier)**.** *A* $\mathsf{ConditionalTriggerEnsemble}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, B, Q, Z, M, L, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the weighted trigger row, recording the finite trigger support and activity weights used by the conditional ensemble.*
2. *B is the blocker row, recording the blocker constraints inherited from* $\mathsf{TriggerBlockerDuality}^{\uparrow}$*.*
3. *Q is the partition row, recording the energy partition inherited from* $\mathsf{TriggerEnergyPartition}^{\uparrow}$*.*
4. *Z is the conditional normalization ledger, storing the finite partition function and the visible event boundary.*
5. *M is the mean row, storing the finite cardinality and energy expectations computed from Z.*
6. *L is the low-energy limit row, recording the partition-minimal trigger polynomial exposed by the source theorem.*
7. *A is the adjacency row tying the ensemble to finiteobservationresidueboundary, triggerblockerduality, triggerenergypartition, and weighted-deformation-spine-adjacent siblings.*
8. *H records componentwise* hsame *transport for trigger, blocker, partition, normalization, mean, limit, adjacency, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a conditional trigger query through weighted support, blocker filtering, energy partition, expectation readback, and low-energy limiting readback.*

10. *P is the* Pkg *provenance over* ConditionalTriggerEnsemble$^{\uparrow}$, FiniteObservationResidueBoundary$^{\uparrow}$, TriggerBlockerDuality$^{\uparrow}$, TriggerEnergyPartition$^{\uparrow}$, *the conditional trigger ensemble vision,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ConditionalTriggerEnsemble}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $T, B, Q, Z, M, L, A, H, C, P, N$. It has no coordinate for hidden codon semantics, an external probability space, an unbounded trigger search, a selected biological interpretation, or a host analytic probability theorem.

Lean4 (definition) `BEDC.Derived.ConditionalTriggerEnsembleUp.ConditionalTriggerEnsembleUp`

Theorem 2897.2 (Conditional trigger ensemble NameCert obligations)**.** *For every accepted* ConditionalTriggerEnse *carrier $E = (T, B, Q, Z, M, L, A, H, C, P, N)$, the local* NameCert$_{\text{ConditionalTriggerEnsemble}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, weighted trigger exposure through T, blocker exposure through B, energy-partition exposure through Q, conditional normalization through Z, expectation readback through M, low-energy limit readback through L, sibling adjacency through A, componentwise transport through H, continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3870.1. The accepted packet exposes only weighted triggers, blockers, energy partitions, normalization, means, low-energy limits, adjacency, and the structural rows.

The ensemble calculation is finite. The trigger row T, blocker row B, partition row Q, normalization row Z, mean row M, and low-energy row L are all displayed before any consumer receives an ensemble readback.

The adjacency and structural rows A, H, C, P, N preserve that same finite packet for downstream readers. Since no coordinate stores hidden codon semantics, an external probability space, unbounded search, or a selected biological interpretation, the listed rows exhaust the local NameCert surface. □

Theorem 2897.3 (Conditional trigger ensemble sibling route)**.** *Every conditional trigger, blocker, expectation, or low-energy consumer of an accepted* ConditionalTriggerEnsemble$^{\uparrow}$ *packet factors through the displayed route*

$$\text{FiniteObservationResidueBoundary}^{\uparrow},\ \text{TriggerBlockerDuality}^{\uparrow},\ \text{TriggerEnergyPartition}^{\uparrow} \longmapsto T, B, Q, Z, M, L, A, H, C, P$$

The route preserves finite weighted support, blocker constraints, energy partition, conditional normalization, expectation readback, low-energy readback, sibling adjacency, transport, replay, provenance, and local naming.

Proof. Start with the sibling rows. The finite observation residue boundary keeps the observed support and residue boundary visible, while trigger-blocker duality and trigger-energy partition supply the blocker and partition rows.

Next read the ensemble rows T, B, Q, Z, M, L. They expose weighted triggers, blockers, partitions, normalization, finite means, and low-energy limiting data without importing an external probability object.

Finally use A, H, C, P, N. These rows record sibling adjacency, transport the finite packet, replay the conditional query, source it to the vision theorem, and name the local certificate. No excluded semantic or probabilistic oracle is present in the carrier. □

Falsifiable prediction: An accepted $\mathsf{ConditionalTriggerEnsemble}^{\uparrow}$ read is refuted if a consumer obtains a conditional mean, energy mean, or low-energy trigger law without displaying finite weighted triggers, blocker rows, partition rows, normalization, transport, replay, provenance, and local naming.

Independence witness: finiteobservationresidueboundary, triggerblockerduality, triggerenergypartition, weighted-deformation-spine-adjacent: none is bijective to $\mathsf{ConditionalTriggerEnsemble}^{\uparrow}$ because this packet jointly carries weighted trigger support, blocker filtering, energy partition, conditional normalization, expectation readback, low-energy limiting readback, sibling adjacency, transport, replay, provenance, and local naming.

The Lean follow-up for this packet must provide `Nontrivial ConditionalTriggerEnsembleUp` and `FieldFaithful ConditionalTriggerEnsembleUp` instances in `BEDC.Derived.ConditionalTriggerEnsembl` so that $T, B, Q, Z, M, L, A, H, C, P, N$ remain separated as displayed fields.

Lean4 ✓ `BEDC.Derived.ConditionalTriggerEnsembleUp.ConditionalTriggerEnsembleTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{ConditionalTriggerEnsemble}^{\uparrow}}$.

Constructive story: A $\mathsf{ConditionalTriggerEnsemble}^{\uparrow}$ packet is generated from finite weighted trigger rows, blocker rows, energy-partition rows, conditional normalization, expectation readback, low-energy limiting readback, sibling adjacency, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConditionalTriggerEnsemble}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3870.1, Definition 3870.2, and Definition 3870.3 seed the finite conditional trigger ensemble over weighted trigger, blocker, partition, expectation, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConditionalTriggerEnsemble}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ConditionalTriggerEnsembleUp.ConditionalTriggerEnsembleTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close hidden biological semantics, external probability spaces, unbounded trigger search, selected biological interpretation, host analytic probability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weighted-trigger exposure, blocker exposure, partition exposure, normalization exactness, expectation readback, Nontrivial ConditionalTriggerEnsembleUp, FieldFaithful ConditionalTriggerEnsembleUp, and local naming for BEDC.Derived.ConditionalTriggerEnsembleUp.

Chapter 2898

A Concrete Naming Certificate for NormalizationEvidenceBudget$^{\uparrow}$

The NormalizationEvidenceBudget$^{\uparrow}$ packet realizes the candidate-mediated strong-normalization boundary of chapter 9383 as finite budget data inspected before any SN read. It sits beside the frontier of chapter 892, the router of chapter 1108, the closed-substitution boundary of chapter 527, the authorized generator route of chapter 525, and the compiler-recognizer flow of chapter 1048. The packet names bounded candidate evidence, closed-candidate evidence, candidate-set membership, Pi and application adequacy, closed-term projection, no-infinite-reduction projection, transport, replay, provenance, and local naming rows; it does not claim evidence-free strong normalization, global closed consistency, erased subject reduction, host evaluation soundness, quotient syntax equality, Lean verification, or bridge checking.

Definition 2898.1 (Normalization evidence budget carrier)**.** *A* NormalizationEvidenceBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, C, K, S, P, R, J, I, F, G, D, H, T, Q, N)$$

with the following displayed rows:

1. *A is the audit-map anchor row for chapter 9383.*
2. *C is the candidate-evidence budget row, listing the finite candidate witnesses available for the read.*
3. *K is the closed-candidate budget row, listing the finite closed-candidate wrappers and their closed typed term boundaries.*
4. *S is the candidate-set budget row, listing finite membership, soundness, and beta-closure evidence.*
5. *P is the Pi-adequacy row for function-side candidate use.*
6. *R is the application-adequacy row for argument and application candidate use.*
7. *J is the closed-term projection row consumed through* ClosedTermSubstitutionBoundary$^{\uparrow}$*.*
8. *I is the no-infinite-reduction projection row read only after candidate, closed-candidate, or candidate-set evidence is present.*
9. *F is the* MetaCICNormalizationFrontier$^{\uparrow}$ *retention row keeping candidate evidence, finished-normal evidence, and subject-reduction obstruction visible.*

10. *G is the* AuthorizedGeneratorRecursor$^{\uparrow}$ *generator handoff row.*
11. *D is the* GroundCompilerRecognizerFlow$^{\uparrow}$ *compiler-recognizer row.*
12. *H records componentwise* hsame *transport for $A, C, K, S, P, R, J, I, F, G, D, T, Q, N$.*
13. *T records displayed* Cont *replay from evidence budgets through closed-term SN and no-infinite-reduction reads.*
14. *Q is the* Pkg *provenance over* NormalizationEvidenceBudget$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICNormalizationCertificateRouter$^{\uparrow}$, ClosedTermSubstitutionBoundary$^{\uparrow}$, AuthorizedGeneratorRecursor$^{\uparrow}$, GroundCompilerRecognizerFlow$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* NameCert$_{\text{NormalizationEvidenceBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate for a closed-term SN read outside C, K, S, no application-normalization read outside P, R, and no no-infinite-reduction read outside I.

Lean4 ✓ `BEDC.Derived.NormalizationEvidenceBudgetUp.NormalizationEvidenceBudgetTasteGate single carrier alignment`

Theorem 2898.2 (Normalization evidence budget NameCert obligations)**.** *For the carrier of Definition 3871.1, the local* NameCert$_{\text{NormalizationEvidenceBudget}^{\uparrow}}$ *surface consists exactly of audit-map anchoring through A, candidate evidence through C, closed-candidate evidence through K, candidate-set evidence through S, Pi and application adequacy through P, R, closed-term projection through J, no-infinite-reduction projection through I, frontier retention through F, authorized-generator handoff through G, compiler-recognizer handoff through D, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through Q, and local naming through N.*

Proof. Project the accepted carrier $E = (A, C, K, S, P, R, J, I, F, G, D, H, T, Q, N)$. The audit anchor A fixes the route to the candidate-mediated map, and the evidence rows C, K, S list exactly the candidate, closed-candidate, and candidate-set data available before any closed-term SN read.

The adequacy rows P, R keep function, argument, and application cases inside the displayed candidate route. The projection rows J, I are downstream: J records closed-term projection, while I records the no-infinite-reduction consequence only after evidence is present.

The sibling rows F, G, D retain the normalization frontier, authorized generator handoff, and compiler-recognizer flow as visible budget provenance. They route evidence; they do not create evidence-free normalization.

Finally H, T, Q, N transport, replay, package, and name the same displayed rows. Since the carrier exposes no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2898.3 (Normalization evidence-budget refusal route)**.** *Let*

$$E = (A, C, K, S, P, R, J, I, F, G, D, H, T, Q, N)$$

be an accepted NormalizationEvidenceBudget$^{\uparrow}$ *packet. If the candidate-evidence row C, closed-candidate row K, and candidate-set row S are absent from the accepted budget surface, then no closed-term strong-normalization read can pass through J and no no-infinite-reduction read can pass through I. The refusal is a local budget refusal along the MetaCIC normalization audit map boundary of chapter 9383; it does not assert evidence-free strong normalization.*

Proof. Project the carrier of Definition 3871.1. The only rows that can support a normalization read before the projections are the displayed candidate budget C, closed-candidate budget K, and candidate-set budget S.

Apply the NameCert obligations of Definition 3871.2. They place the closed-term projection J and the no-infinite-reduction projection I downstream of the evidence rows and route the remaining frontier, generator, compiler, transport, replay, provenance, and naming rows through the same finite budget.

If C, K, S are absent, the projected route has no evidence source from which J or I can be admitted. The audit-map boundary of chapter 9383 therefore records a refusal of the read, not a proof of evidence-free strong normalization. □

Falsifiable prediction: A closed-term SN read through $\mathsf{NormalizationEvidenceBudget}^{\uparrow}$ is refused when the displayed budget contains no candidate evidence, no closed-candidate evidence, and no candidate-set evidence.

Independence witness: metacicnormalizationfrontier, metacicnormalizationcertificaterouter, closedtermsubstitutionboundary, authorizedgeneratorrecursor, groundcompilerrecognizerflow: $\mathsf{NormalizationEvidenceBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries candidate, closed-candidate, candidate-set, Pi/app adequacy, closed-term projection, no-infinite-reduction, frontier, generator, compiler-recognizer, transport, replay, provenance, and local naming rows.

The Lean TasteGate site for $\mathsf{NormalizationEvidenceBudget}^{\uparrow}$ must provide explicit Nontrivial NormalizationEvidenc and FieldFaithful $\mathsf{NormalizationEvidenceBudget}^{\uparrow}$ instances. These instances preserve the finite evidence-budget rows as distinguishable fields before SN and no-infinite-reduction reads are admitted.

Closure status for $\mathsf{NameCert}_{\mathsf{NormalizationEvidenceBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{NormalizationEvidenceBudget}^{\uparrow}$ packet is generated from an audit-map anchor, candidate evidence, closed-candidate evidence, candidate-set membership, Pi and application adequacy, closed-term projection, no-infinite-reduction projection, frontier retention, authorized-generator handoff, compiler-recognizer handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalizationEvidenceBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3871.1 and Definition 3871.2 seed the finite evidence-budget carrier for candidate-mediated normalization reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalizationEvidenceBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close evidence-free strong normalization, global closed consistency, erased subject reduction, host evaluation soundness, quotient syntax equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-budget refusal, projection exactness, frontier retention, generator and compiler handoff, TasteGate nontriviality, and field-faithfulness for BEDC.Derived.NormalizationEvidenceBudg

Chapter 2899

A Concrete Naming Certificate for $\mathsf{RationalIntervalSubdivision}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalIntervalSubdivision}^{\uparrow}$ packet records the finite subdivision of a rational interval into ordered rational subintervals while keeping the endpoint, mesh, and handoff rows visible. It sits after the rational interval carrier of chapter 354, the dyadic tolerance core of chapter 291, and the closed bounded interval surface of chapter 1591. The packet names a finite rational partition and its local certificate rows; it is not an open-cover compactness principle, a choice of refinement from an infinite family, quotient interval equality, or ambient completeness.

Definition 2899.1 (Rational interval subdivision carrier)**.** *A* $\mathsf{RationalIntervalSubdivision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, E, D, M, W, K, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{RationalInterval}^{\uparrow}$ *row, exposing rational endpoints $a \leq b$ and the interval-order classifier.*
2. *E is the finite ordered endpoint list $a = x_0 \leq x_1 \leq \cdots \leq x_m = b$.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh ledger, recording the dyadic radii, width comparisons, and refinement rows used to bound each adjacent interval.*
4. *M is the mesh row assigning to each adjacent pair (x_i, x_{i+1}) its dyadic width certificate.*
5. *W is the componentwise window row exposing the subinterval sequence $([x_i, x_{i+1}])_{i<m}$ through the same finite endpoint list.*
6. *K is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *handoff row, reached only after I, E, D, M, W have been displayed.*
7. *H records componentwise* hsame *transport for the source interval, endpoints, dyadic mesh, subinterval windows, closed-interval handoff, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a subdivision request through endpoint inspection, dyadic mesh checking, subinterval-window exposure, and closed-interval handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalSubdivision}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalSubdivision}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $I, E, D, M, W, K, H, C, P, N$. It has no coordinate for open-cover compactness, infinite refinement choice, quotient interval equality, selected real representatives, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RationalIntervalSubdivisionUp.RationalIntervalSubdivisionTasteGate single carrier alignment round trip`

Theorem 2899.2 (Rational interval subdivision NameCert obligations)**.** *For every accepted* RationalIntervalSubdivi *carrier $S = (I, E, D, M, W, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalSubdivision}^{\uparrow}}$ *surface consists exactly of source-interval exposure through I, finite ordered endpoint admission through E, dyadic mesh exactness through D, adjacent-width certification through M, subinterval-window exposure through W, closed bounded interval handoff through K, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3872.1. The accepted packet exposes one rational source interval, one finite ordered endpoint list, one dyadic mesh ledger, one adjacent-width row, one subinterval-window row, one closed-interval handoff, and the structural rows.

The subdivision data are finite. The row I supplies the enclosing rational interval, while E lists every endpoint used by the subdivision. The dyadic ledger D and mesh row M check only adjacent pairs from this list, so no open cover, infinite refinement, or selected limiting partition enters the packet.

The consumer-facing handoff is then forced through W and K. The row W exposes the subinterval windows componentwise, and K packages the same rows for closed bounded interval consumers. Finally H, C, P, N transport, replay, source, and name exactly this displayed surface. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 2899.3 (Rational interval subdivision closed-interval handoff)**.** *Every* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *or finite-net consumer of an accepted* $\mathsf{RationalIntervalSubdivision}^{\uparrow}$ *packet factors through the displayed finite route*

$$\mathsf{RationalInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{ClosedBoundedInterval}^{\uparrow}.$$

Concretely, the consumer receives the source rational interval row, the ordered rational endpoint list, the dyadic mesh ledger, the adjacent-width row, the componentwise subinterval windows, the closed-interval handoff, transport, replay, provenance, and local naming. It receives no open-cover compactness witness, choice-selected refinement, quotient interval equality, selected real representative, or ambient completeness coordinate.

Proof. Begin with an accepted carrier $S = (I, E, D, M, W, K, H, C, P, N)$. Any subdivision read first inspects I and E, so the enclosing rational interval and every subdivision endpoint are part of the displayed packet before a consumer can read a subinterval.

Next the read passes through D and M. These rows certify the dyadic mesh and the adjacent rational widths componentwise; they do not select a refinement from an infinite family and they do not invoke open-cover compactness.

The finite-net or closed-interval consumer can then read W and K. The row W lists the component subinterval windows, and K is exactly the closed bounded interval handoff built from those finite rows. The structural rows H, C, P, N preserve this same route under hsame transport and Cont replay, so the consumer has no route to quotient interval equality, selected real representatives, choice, or ambient completeness beyond the displayed packet. □

Falsifiable prediction: An accepted $\mathsf{RationalIntervalSubdivision}^{\uparrow}$ consumer that reaches a $\mathsf{ClosedBoundedInterval}^{\uparrow}$ handoff or finite-net read without first inspecting the source $\mathsf{RationalInterval}^{\uparrow}$ row, ordered rational endpoint list, $\mathsf{DyadicRatCore}^{\uparrow}$ mesh ledger, componentwise subinterval windows, hsame transport, Cont replay, Pkg provenance, and local NameCert row is outside the packet.

Independence witness: rationalinterval, dyadicratcore, closedboundedinterval: $\mathsf{RationalIntervalSubdivision}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source rational interval, a finite ordered endpoint list, dyadic mesh certificates, componentwise subinterval windows, a closed-interval handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalSubdivision}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalIntervalSubdivision}^{\uparrow}$ packet is generated from a RationalInterval source row, finite ordered rational endpoints, a DyadicRatCore mesh ledger, adjacent-width rows, componentwise subinterval windows, a ClosedBoundedInterval handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalSubdivision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3872.1, Definition 3872.2, and Definition 3872.3 seed the finite rational subdivision route from rational interval rows through dyadic mesh data to closed bounded interval consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalSubdivision}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, infinite refinement choice, quotient interval equality, selected real representatives, finite-net compactness, or ambient completeness.

Upgrade path: Obligation closure requires checked source interval exposure, endpoint ordering, dyadic mesh exactness, subinterval-window routing, closed bounded interval handoff, transport, replay, provenance, and local naming for BEDC.Derived.RationalIntervalSubdivisionUp.

Chapter 2900

A Concrete Naming Certificate for $\mathsf{UniformSequentialLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformSequentialLimit}^{\uparrow}$ packet records the standard passage from uniform convergence of a sequence of real-valued observations to sequential real-limit consumers as a finite BEDC route. It sits beside the uniform-tail certificate of chapter 3417, the sequence-source surface of chapter 3857, the sup-norm comparison boundary of chapter 3807, the finite stream and regular rational readback rows of chapter 126 and chapter 301, and the terminal real seal of chapter 38. The chapter names the finite handoff by which a uniform tail schedule may be consumed by Real-limit readers without selecting a limit function, quotienting functions, invoking countable choice, asserting ambient completeness, or importing open-cover compactness.

Definition 2900.1 (Uniform sequential limit carrier)**.** *A* $\mathsf{UniformSequentialLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, V, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence source row. It records the accepted* $\mathsf{LocatedSequence}^{\uparrow}$ *observations and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows from which the displayed sequence entries are read.*
2. *M is the uniform tail schedule row. It is read through the* $\mathsf{UniformConvergence}^{\uparrow}$ *packet and assigns one displayed tail bound to each accepted tolerance request.*
3. *V is the sup-norm comparison row. It consumes the* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *boundary used to compare all displayed source windows under the same tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational observations exposed by S, M, V.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the sequence source, uniform tail schedule, sup-norm comparison, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for S, M, V, R, E, C, P, N.*
7. *C records displayed* Cont *replay from a sequential Real-limit request through the source, tail, comparison, readback, seal, transport, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformSequentialLimit}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{LocatedSequence}^{\uparrow}$, $\mathsf{ContinuousSupNorm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{UniformSequentialLimit}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, M, V, R, E, H, C, P, N$. It has no coordinate for a selected limit, quotient equality of functions, countable choice, ambient completeness of $\mathsf{Real}^\uparrow$*, open-cover compactness, Lean verification, or a bridge credential.*

Lean4 ✓ `BEDC.Derived.UniformSequentialLimitUp.UniformSequentialLimitTasteGate single carrier alignment`

Theorem 2900.2 (Uniform sequential limit NameCert obligations)**.** *For every accepted* $\mathsf{UniformSequentialLimit}^\uparrow$ *carrier*

$$U = (S, M, V, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformSequentialLimit}^\uparrow}$ *surface consists exactly of carrier admission for the sequence source, uniform tail schedule, sup-norm comparison row, regular rational readback, Real seal, componentwise transport, displayed replay, package provenance, and local name. Every sequential* $\mathsf{Real}^\uparrow$*-limit consumer of U factors through*

$$\mathsf{LocatedSequence}^\uparrow \longmapsto \mathsf{UniformConvergence}^\uparrow \longmapsto \mathsf{ContinuousSupNorm}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

as displayed by $S, M, V, R, E, H, C, P, N$.

Consequently the packet exports a finite uniform-limit handoff for Real-limit readers and exports no selected limit, quotient equality of functions, countable-choice schedule, ambient $\mathsf{Real}^\uparrow$ *completeness, or open-cover compactness principle.*

Proof. Project the accepted carrier through Definition 3874.1. The source row S supplies only displayed $\mathsf{LocatedSequence}^\uparrow$ observations and finite $\mathsf{StreamName}^\uparrow$ windows, while M records the uniform tail schedule supplied by the $\mathsf{UniformConvergence}^\uparrow$ boundary.

Read the comparison row V next. Its $\mathsf{ContinuousSupNorm}^\uparrow$ surface applies the same displayed tolerance to all source windows admitted by S and M, so the consumer receives a uniform comparison ledger rather than a pointwise host-limit selector.

Now read R and E. The regular rational observations pass through $\mathsf{RegSeqRat}^\uparrow$ before the $\mathsf{Real}^\uparrow$ seal is exposed, and the structural rows H, C, P, N transport, replay, source, and name exactly that route.

The excluded principles are absent from the carrier inventory. Therefore a sequential Real-limit consumer can use only the displayed finite uniform route and cannot extract a selected limit, quotient function equality, countable choice, ambient completeness, or open-cover compactness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformSequentialLimit}^\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformSequentialLimit}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 3874.1 and Definition 3874.2 seed the finite route from uniform convergence data and located sequence windows to sequential Real-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformSequentialLimit}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of functions, countable choice, ambient $\mathsf{Real}^\uparrow$ completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform tail schedule stability, sup-norm comparison routing, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.UniformSequentialLimitUp.

Constructive story: A $\mathsf{UniformSequentialLimit}^\uparrow$ packet is generated from a sequence source row, uniform tail schedule, sup-norm comparison row, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2901

A Concrete Naming Certificate for $\mathsf{CauchyFilterConvergence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and the Bourbaki–Kelley language of filters, the $\mathsf{CauchyFilterConvergence}^{\uparrow}$ packet records the finite route by which displayed Cauchy-filter data reaches a named limit boundary. It sits after the Cauchy-filter surface of chapter 333, the regular-filter handoff of chapter 1445, the uniform-window discipline of chapter 1694, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names convergence as a displayed BEDC route; it does not form a quotient of filters, choose a host limit, use countable choice, identify host real equality, or appeal to ambient completeness.

Definition 2901.1 (CauchyFilterConvergence carrier)**.** *A* $\mathsf{CauchyFilterConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, B, M, S, D, R, E, W, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, including displayed base packets, late-set witnesses, refinement routes, and Cauchy evidence.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *factorization row exposed by the same source filter data.*
3. *M is the directed meet row that names common refinements for requested filter tails.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule read from the filter tails.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows and refinements.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after the stream windows and dyadic rows have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, B, M, S, D, R have been read.*
8. *W is the convergence witness row, recording that every accepted neighbourhood read of E pulls back to a displayed tail of F through B, M, S, D, R.*
9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records the displayed* Cont *replay from filter requests to basis tails, from tails to stream windows, from dyadic tolerances to regular rational readback, and from readback to the Real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterConvergence}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterConvergence}^{\uparrow}}$ *row.*

The carrier exposes convergence only through these rows. It has no coordinate for quotient filters, selected representatives, host equality of limits, countable-choice selectors, hidden cofinal tails, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyFilterConvergenceUp.CauchyFilterConvergenceTasteGate single carrier alignment`

Theorem 2901.2 (CauchyFilterConvergence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterConvergence}^{\uparrow}$ *carrier* $L = (F, B, M, S, D, R, E, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission, CauchyFilter source exposure through F, basis factorization through B, directed tail refinement through M, StreamName window exposure through S, DyadicRatCore tolerance exactness through D, RegSeqRat readback through R, Real seal handoff through E, convergence pullback through W, and structural transport, replay, provenance, and local naming through H, C, P, N.*

No obligation may be discharged by quotient-filter equality, a selected host limit, countable choice, host real equality, a hidden cofinal tail, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3875.1. The rows $F, B, M, S, D, R, E, W, H, C, P, N$ are the only coordinates visible to the local certificate surface.

The source and basis side is finite. The Cauchy-filter row F supplies the displayed base packets and Cauchy evidence, while B and M expose the basis factorization and common directed refinements before any stream or real-facing read is available.

The readback side is ordered by the displayed route. The schedule S lists the finite windows, D attaches dyadic tolerances to the same windows, R reads regular rational data from them, and E is downstream from that readback.

Finally, the convergence witness W records only the pullback of Real-neighbourhood requests along the displayed route, and H, C, P, N transport, replay, source, and name the same data. Since the carrier contains none of the excluded coordinates, the listed rows exhaust the NameCert obligations. □

Theorem 2901.3 (CauchyFilterConvergence limit route)**.** *Let $L = (F, B, M, S, D, R, E, W, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterConvergence}^{\uparrow}$ *carrier. Every Real-facing convergence read factors through*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the read starts at the displayed Cauchy-filter row F, passes through the basis and directed-meet rows B, M, reads finite windows and tolerances through S, D, obtains the regular rational row R, reaches the Real seal E, and verifies convergence by pulling Real-neighbourhood requests back through W. The route exports no quotient filter, selected limit, countable-choice selector, host real equality, hidden cofinal tail, or ambient completeness coordinate.

Proof. Begin with a Real-facing convergence read of L. The Real seal coordinate is E, and by the carrier definition E is downstream from the source Cauchy-filter row, basis row, directed meet row, window schedule, dyadic ledger, and regular rational readback.

Use the basis and meet rows first. The rows B and M expose the finite CauchyFilterBasis route over F, so every requested convergence tail is a displayed row rather than an external cofinal family.

Next read the sequential data. The stream schedule S and dyadic ledger D determine the regular rational readback R, which is the only route from the filter-side packet to the Real seal.

The convergence witness W closes the route by pulling each accepted neighbourhood request of E back to the displayed filter tail. The structural rows H, C, P, N preserve that same route, and the absent quotient, choice, host-equality, hidden-tail, and completeness coordinates cannot be exported by any consumer. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterConvergence}^{\uparrow}$ convergence read factors through $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, terminal $\mathsf{Real}^{\uparrow}$ sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterConvergence}^{\uparrow}$ packet is generated from a CauchyFilterUp row, a CauchyFilterBasisUp factorization row, a directed meet row, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, a convergence pullback witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3875.1, Definition 3875.2, and Definition 3875.3 seed the constructive filter-to-limit route over CauchyFilterUp, CauchyFilterBasisUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient filters, selected host limits, countable choice, host real equality, hidden cofinal tails, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, basis factorization, directed meet exposure, RegSeqRat readback, Real seal nonescape, convergence pullback, and TasteGate field faithfulness for BEDC.Derived.CauchyFilterConvergenceU

Chapter 2902

A Concrete Naming Certificate for UniformConvergenceCauchyCriterion$^{\uparrow}$

Following Bishop and Bridges on constructive uniform convergence and Cauchy criteria, the UniformConvergenceCauchyCriterion$^{\uparrow}$ packet records the finite means by which a displayed family of real-valued observations is certified uniformly Cauchy before any completion or uniform-limit consumer reads it. It sits between the uniform-limit handoff of chapter 3874, the common refinement mesh of chapter 3832, and the fast criterion route of chapter 3825. The packet supplies later uniform-limit and completion-extension certificates with a finite Cauchy surface; it does not import host function limits, quotient equality of functions, countable choice, ambient completeness, or a selected limiting map.

Definition 2902.1 (Uniform convergence Cauchy criterion carrier)**.** *A* UniformConvergenceCauchyCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, M, F, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the uniform observation row. It records the accepted* UniformConvergence$^{\uparrow}$ *tail requests and the finite source windows through which the family is inspected.*
2. *M is the common mesh row supplied by* CauchyMeshRefinement$^{\uparrow}$*. It aligns all displayed source windows under one finite tolerance ledger before any readback occurs.*
3. *F is the fast criterion row supplied by* FastCauchyCriterion$^{\uparrow}$*. It exposes the monotone threshold discipline used to answer each requested precision.*
4. *Q is the Cauchy comparison row. It records that every pair of displayed source entries beyond the threshold named by F is compared through the common mesh named by M.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the same windows, mesh, and fast threshold.*
6. *E is the terminal completion or* Real$^{\uparrow}$ *seal row reached only after U, M, F, Q, R have been displayed.*
7. *H records componentwise* hsame *transport for $U, M, F, Q, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from a uniform-Cauchy request through the observation, mesh, fast-threshold, comparison, readback, seal, transport, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* UniformConvergenceCauchyCriterion$^{\uparrow}$, UniformConvergence$^{\uparrow}$, UniformSequentialLimi CauchyMeshRefinement$^{\uparrow}$, FastCauchyCriterion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{UniformConvergenceCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, M, F, Q, R, E, H, C, P, N$. It has no coordinate for a host-space function limit, quotient equality of functions, countable-choice schedule, ambient completion theorem, or selected limit object.

Lean4 ✓ `BEDC.Derived.UniformConvergenceCauchyCriterionUp.UniformConvergenceCauchyCriterionTasteGate` `single carrier alignment`

Theorem 2902.2 (Uniform convergence Cauchy criterion NameCert obligations)**.** *For every accepted* UniformConvergenceCauchyCriterion$^{\uparrow}$ *carrier*

$$K = (U, M, F, Q, R, E, H, C, P, N),$$

the local NameCert$_{\text{UniformConvergenceCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following five obligation families:*

1. *uniform source-window admission through U;*
2. *common finite mesh exposure through M;*
3. *fast threshold and pairwise Cauchy comparison through F, Q;*
4. *regular rational readback and terminal seal routing through R, E;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

Consequently every accepted packet exports a finite uniform-Cauchy criterion over displayed BEDC rows, not a host function limit, quotient equality of functions, countable-choice schedule, ambient completeness claim, or selected limiting map.

Proof. Project the carrier of Definition 3876.1. The row U exposes only the displayed uniform source windows, while M supplies the common finite mesh used by all later comparisons.

Read F and Q next. The fast threshold row gives the precision discipline, and the comparison row forces each post-threshold pair to be checked against the same finite mesh rather than against an unlisted limiting object.

Finally read R, E, H, C, P, N. The regular rational readback and terminal seal are downstream of the source, mesh, threshold, and comparison rows, and the structural rows transport and name exactly that route. Since the excluded analytic objects are absent from the carrier inventory, the five listed obligation families exhaust the certificate surface. □

Theorem 2902.3 (Uniform convergence Cauchy criterion completion handoff)**.** *Every uniform-limit or completion-extension consumer of an accepted* UniformConvergenceCauchyCriterion$^{\uparrow}$ *carrier factors through the displayed route*

$$\text{UniformConvergence}^{\uparrow} \longmapsto \text{CauchyMeshRefinement}^{\uparrow} \longmapsto \text{FastCauchyCriterion}^{\uparrow} \longmapsto \text{RegSeqRat}^{\uparrow} \longmapsto \text{Real}^{\uparrow}.$$

The handoff may be consumed by UniformSequentialLimit$^{\uparrow}$ *and later completion certificates only as finite Cauchy data over $U, M, F, Q, R, E, H, C, P, N$. It does not supply host function limits, quotient equality of functions, countable choice, ambient completeness, or a selected limit map.*

Proof. Begin with a consumer request for a uniform-limit or completion-extension read. Carrier admission exposes U first, so the request sees only displayed uniform source windows.

The request must then pass through M, F, Q. The common mesh row aligns the source windows, the fast row gives the precision threshold, and the comparison row records the Cauchy checks performed after that threshold.

The only downstream readback is R, E, H, C, P, N. These rows package the regular rational observations, terminal seal, transport, replay, provenance, and local naming. Hence $\mathsf{UniformSequentialLimit}^{\uparrow}$ and completion-facing consumers receive finite criterion data and no extra analytic principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3876.1, Definition 3876.2, and Definition 3876.3 seed the finite uniform-Cauchy criterion route over UniformConvergence, CauchyMeshRefinement, FastCauchyCriterion, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformConvergenceCauchyCriterionUp.UniformConvergenceCauchyCriterionTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not close host function limits, quotient equality of functions, countable choice, ambient completeness, selected limit maps, or bridge checking.

Upgrade path: Obligation closure requires checked source-window admission, common mesh exposure, fast threshold stability, Cauchy comparison routing, readback, terminal seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.UniformConvergenceCauchyCriterionUp.

Constructive story: A $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$ packet is generated from uniform source windows, a common CauchyMeshRefinement row, a FastCauchyCriterion threshold row, a pairwise Cauchy comparison row, RegSeqRat readback, terminal seal routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2903

A Concrete Naming Certificate for $\mathsf{BoxDimension}^{\uparrow}$

Following Falconer's finite-cover formulation of box dimension, the $\mathsf{BoxDimension}^{\uparrow}$ packet records the BEDC surface at which metric scale, finite covers, and counting ledgers become an inspectable dimension invariant. It is downstream of the metric carrier of chapter 57, the compact metric finite-net boundary of chapter 129, the refinement language of chapter 1853, and the rational dense route of chapter 1809. The chapter names the finite scale-cover data used by lower and upper box-dimension reads; it does not add Hausdorff measure, choice over optimal covers, host logarithms, quotient compacta, or a detached completion object.

Definition 2903.1 (Box dimension finite-cover carrier)**.** *A* $\mathsf{BoxDimension}^{\uparrow}$ *carrier over a compact metric source* X *is a finite* BHist *packet*

$$B = (M, K, S, C, R, D, N, H, P, L)$$

with the following displayed rows:

1. M *is the inherited* $\mathsf{Met}^{\uparrow}$ *distance row on* X*, including the point classifier and the visible distance-witness ledger.*
2. K *is the compact metric source row. It exposes the finite-net and complete-limit data from chapter 129 before any scale cover is read.*
3. S *is the dyadic scale row. Each accepted scale is a positive dyadic tolerance history, ordered by refinement toward smaller radii.*
4. C *is the finite cover row. For each scale in* S*, it displays a finite family of balls whose centers are carried by* X *and whose radii are bounded by the current dyadic scale.*
5. R *is the refinement ledger. It records how a cover at a smaller dyadic scale refines the previous visible cover without selecting an optimal cover in the host theory.*
6. D *is the counting and comparison ledger. It records the finite cardinality of each displayed cover and the rational bounds used by the lower and upper box-dimension comparison read.*
7. N *is the separability net route. It allows the centers of the displayed finite covers to be read through the* $\mathsf{RealSeparability}^{\uparrow}$ *dense-window surface when the compact metric source is a real metric carrier.*

8. *H stores componentwise* hsame *transport for metric points, dyadic scales, cover centers, cover membership, refinement rows, counting comparisons, and dense-route data.*
9. *P is the* Pkg *provenance over* $\mathsf{BoxDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{BoxDimension}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected minimal cover, ambient Euclidean embedding, host logarithm, Hausdorff-measure comparison, quotient compactum, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoxDimensionUp.BoxDimensionTasteGate single carrier alignment`

Theorem 2903.2 (Box dimension finite-cover obligations)**.** *For every accepted* $\mathsf{BoxDimension}^{\uparrow}$ *carrier*

$$B = (M, K, S, C, R, D, N, H, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{BoxDimension}^{\uparrow}}$ *surface consists exactly of finite scale-cover obligations: carrier admission for the metric and compact rows, positive dyadic scale exposure, finite cover membership, radius comparison, refinement transport, cover-count comparison, separability-net routing when the source is Real-facing, provenance, and local naming. No obligation is stored outside* $M, K, S, C, R, D, N, H, P, L$.

Proof. Project the carrier of Definition 3877.1. The rows M and K provide the metric source and compact metric finite-net boundary, while S provides the positive dyadic scales at which covers are inspected.

For a fixed scale, C displays the finite cover as packet data: center histories, ball radii, membership rows, and radius bounds. The row D counts that finite family and stores the rational comparisons used by lower and upper box-dimension reads.

When the scale is refined, R is the only refinement witness. It transports a visible cover to a smaller visible cover through the recorded refinement ledger rather than by selecting a host-minimal cover.

The dense-source route N, the transport row H, the provenance row P, and the naming row L preserve the same finite data. Since the carrier contains no coordinate for optimal cover selection, host logarithms, Hausdorff measure, quotient compacta, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Theorem 2903.3 (Box dimension covering-dimension anchor)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoxDimension}^{\uparrow}$ *packet may read only the displayed finite cover and refinement rows C and R after the compact metric source K and dyadic scale row S have been exposed. The anchor sends scale-cover covers to covering-dimension refinement ledgers as finite packet data; it does not export a minimal cover, a Lebesgue-number principle, a Hausdorff-measure estimate, or an ambient Euclidean coordinate system.*

Proof. Start with the accepted carrier $B = (M, K, S, C, R, D, N, H, P, L)$. The compact metric row K is read before scale-cover data, so the consumer begins with the same finite-net and complete-limit boundary used by the compact metric certificate.

Expose a dyadic scale through S and the corresponding finite cover through C. These rows provide exactly the cover families, centers, radius bounds, and membership witnesses that a covering-dimension refinement argument may inspect.

Route the handoff through R. The refinement ledger records how smaller-scale covers refine the displayed cover family, matching the finite-cover language of chapter 1853 without introducing a host-selected optimal cover.

The counting row D and structural rows H, P, L remain bookkeeping for the same displayed covers. Because no row stores a Lebesgue-number theorem, Hausdorff-measure estimate, Euclidean embedding, or minimal-cover selector, the covering-dimension anchor is limited to the finite refinement surface. □

Theorem 2903.4 (Box dimension real-separability net route)**.** *When the compact metric source of an accepted* $\mathsf{BoxDimension}^{\uparrow}$ *packet is a Real-facing metric carrier, every scale-cover center read that reaches a* $\mathsf{RealSeparability}^{\uparrow}$ *consumer factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{RealSeparability}^{\uparrow}$$

before the center may be used as a dense-net witness. The route uses only the dyadic scale row S, finite cover row C, counting ledger D, separability route N, transport row H, provenance row P, and local name row L.

Proof. Project the box-dimension carrier. The row S supplies the dyadic scale, and the row C supplies the finite cover centers inspected at that scale.

Read those centers through the Real-facing dense route N. By chapter 1809, a separability consumer reaches Real data through dyadic tolerance, finite stream windows, regular rational readback, and the terminal Real seal before it may consume the local density surface.

The counting row D travels with the same finite cover family, so the number of displayed centers is the finite count used by the scale-cover comparison. The transport and provenance rows H, P, L preserve the route without adding a selected nearest point, host real equality, quotient stream, ambient completeness, or choice over balls.

Thus every Real-facing center read factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealSeparability}^{\uparrow}$ before it is available as dense-net evidence for the box-dimension packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoxDimension}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoxDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3877.1, Definition 3877.2, Definition 3877.3, and Definition 3877.4 seed the finite scale-cover route for compact metric carriers, covering-dimension refinement ledgers, and RealSeparability dense-net consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoxDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hausdorff dimension, minimal-cover selection, host logarithm analysis, ambient Euclidean embeddings, quotient compacta, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale positivity, finite cover membership, refinement ledgers, cover-count comparison, and RealSeparability net routing for BEDC.Derived.BoxDimensionUp.

Constructive story: A $\mathsf{BoxDimension}^{\uparrow}$ packet is generated from a metric row, compact metric source row, dyadic scale row, finite cover row, refinement ledger, counting comparison ledger, separability net route, componentwise transport, provenance, and a local NameCert row.

Chapter 2904

A Concrete Naming Certificate for $\mathsf{CompleteUltrametric}^{\uparrow}$

Following Bourbaki and Bishop–Bridges metric-space practice, the $\mathsf{CompleteUltrametric}^{\uparrow}$ packet records the finite certificate surface for a complete ultrametric rather than a choice-based completion. It sits after the strong-triangle surface of chapter 1535, the limit-witness surface of chapter 128, the Cauchy-filter admission row of chapter 333, the finite-window discipline of chapter 126, the regular-rational tolerance route of chapter 301, and the terminal seal of chapter 38. The packet names one constructive non-Archimedean completeness certificate; it does not import spherical completeness, a selected quotient completion, a host completion functor, or a p-adic field structure.

Definition 2904.1 (CompleteUltrametric carrier)**.** *A* $\mathsf{CompleteUltrametric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, U, C, L, H, R, P, N)$$

with the following displayed rows:

1. *M is the metric-carrier row, including the underlying* $\mathsf{Met}^{\uparrow}$ *distance observations and ball classifier.*
2. *U is the ultrametric strong-triangle row consumed through* $\mathsf{UltrametricSpace}^{\uparrow}$*.*
3. *C is the Cauchy-filter and Cauchy-thread row, including the finite* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *reads by which tolerance requests are displayed.*
4. *L is the complete-limit witness row consumed through* $\mathsf{CompleteMetric}^{\uparrow}$ *and sealed only at the displayed* $\mathsf{Real}^{\uparrow}$ *endpoint row.*
5. *H records componentwise* hsame *transport for the metric, strong-triangle, Cauchy-thread, limit, provenance, and local naming rows.*
6. *R records displayed* Cont *replay from finite Cauchy-thread reads to the complete-limit handoff and from ultrametric ball comparisons to downstream consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{CompleteUltrametric}^{\uparrow}$*,* $\mathsf{UltrametricSpace}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteUltrametric}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through M, U, C, L, H, R, P, N. It has no coordinate for spherical completeness, choice-based completion, quotient completion, selected limits outside the displayed thread, p-adic field operations, or a standard bridge.

Lean4 ✓ `BEDC.Derived.CompleteUltrametricUp.CompleteUltrametricTasteGate single carrier alignment`

Theorem 2904.2 (CompleteUltrametric NameCert obligations)**.** *For an accepted* $\mathsf{CompleteUltrametric}^{\uparrow}$ *carrier* $U = (M, U, C, L, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompleteUltrametric}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the displayed metric row M and local naming row N;*
2. *ultrametric triangle stability through the strong-triangle row U under componentwise* hsame *transport H;*
3. *Cauchy-thread admission through C, with every tolerance read passing through the* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows;*
4. *complete-limit handoff from C to L through the* $\mathsf{CompleteMetric}^{\uparrow}$ *witness and terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *ledger non-escape for H, R, P, N, preventing transport, replay, provenance, or naming from adding spherical completeness, choice-based completion, quotient completion, selected external limits, or p-adic field structure.*

Proof. Project the accepted carrier of Definition 3879.1. The rows available to a consumer are precisely M, U, C, L, H, R, P, N.

Read the metric and ultrametric data first. The row M supplies the carrier and ball classifier, while U supplies the strong non-Archimedean triangle comparison. Transport by H preserves those displayed rows rather than replacing them by an ambient theorem.

Next read the Cauchy-thread data. The row C exposes only finite filter, stream, and regular-rational tolerance windows, so a limit request has to pass through the same displayed Cauchy evidence.

Finally consume the complete-limit handoff. The row L is reached from C through the $\mathsf{CompleteMetric}^{\uparrow}$ witness and the terminal $\mathsf{Real}^{\uparrow}$ seal. The replay, provenance, and naming rows R, P, N retain that route, so no unlisted completion principle or p-adic structure enters the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteUltrametric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompleteUltrametric}^{\uparrow}$ packet is generated from a metric carrier row, an ultrametric strong-triangle row, Cauchy-filter and thread rows, a complete-limit witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteUltrametric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3879.1 and Definition 3879.2 seed the constructive complete non-Archimedean metric certificate over displayed metric, ultrametric, Cauchy-thread, limit, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteUltrametric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close spherical completeness, choice-based completion, quotient completion, selected limits outside the displayed thread, p-adic field structure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ultrametric triangle stability, Cauchy-thread admission, complete-limit handoff, and ledger non-escape for BEDC.Derived.CompleteUltrametricUp.

Chapter 2905

A Concrete Naming Certificate for PainleveKuratowskiConvergence$^{\uparrow}$

Following Painleve and Kuratowski on set convergence, the PainleveKuratowskiConvergence$^{\uparrow}$ packet records finite-window closed-set convergence by separating lower-hit witnesses from upper-miss finite-cover witnesses. It sits over the hyperspace carrier of chapter 1660, the finite Hausdorff comparison boundary of chapter 2086, the metric source of chapter 57, the compact metric source of chapter 129, the hit/miss topology of chapter 2375, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed hit/miss windows and their readback rows; it is not a host powerset convergence theorem or a quotient subset equality principle.

Definition 2905.1 (Painleve–Kuratowski convergence carrier)**.** *A* PainleveKuratowskiConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, U, K, H, V, W, R, E, T, C, P, N)$$

with the following displayed rows:

1. *L is the lower-hit witness ledger, listing the finite inspected hits by which points or probes of a displayed closed set are met by later closed-set rows.*
2. *U is the upper-miss finite-cover witness ledger, listing finite open or ball-cover exclusions for the inspected windows.*
3. *K is the inspected compact or hyperspace source row, read through* Hyperspace$^{\uparrow}$ *and the relevant* CompactMetric$^{\uparrow}$ *carrier.*
4. *H is the* HausdorffMetric$^{\uparrow}$ *comparison boundary available only for the displayed compact windows and finite tolerances.*
5. *V is the* VietorisTopology$^{\uparrow}$ *hit/miss row that records the lower-hit and upper-miss subbasic tests used by the packet.*
6. *W is the finite* StreamName$^{\uparrow}$ *window row that schedules the inspected convergence stages and tolerance requests.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the rational schedules and metric tolerances seen in W and H.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached after the stream, regular-rational, Hausdorff, and hit/miss rows have been displayed.*
9. *T records componentwise* hsame *transport for the lower-hit ledger, upper-miss ledger, hyperspace source, Hausdorff boundary, Vietoris row, stream window, regular readback, real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a finite hit/miss request through $K, H, V, W, R, E, T, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{PainleveKuratowskiConvergence}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PainleveKuratowskiConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, K, H, V, W, R, E, T, C, P, N$. It has no coordinate for a host powerset, quotient subset equality, arbitrary supremum or infimum, selected nearest point, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PainleveKuratowskiConvergenceUp.PainleveKuratowskiConvergenceTasteGate`
`single carrier alignment`

Theorem 2905.2 (Painleve–Kuratowski convergence NameCert obligations)**.** *For every accepted* $\mathsf{PainleveKuratowskiConvergence}^{\uparrow}$ *carrier*

$$Q = (L, U, K, H, V, W, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PainleveKuratowskiConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower-hit ledger, upper-miss ledger, hyperspace or compact source, Hausdorff comparison boundary, Vietoris row, stream window, regular readback, real seal, transport, replay, provenance, and local naming row;*
2. *lower-hit coverage, requiring every asserted hit to be witnessed in the displayed ledger L before a convergence read is available;*
3. *upper-miss coverage, requiring every asserted miss to be witnessed by the finite-cover ledger U before exclusion data is exported;*
4. *finite-window compatibility, requiring W and R to schedule exactly the inspected stages and tolerances used by L, U, H, V;*
5. *metric and hyperspace handoff, requiring K, H, V to expose the compact-source, Hausdorff-boundary, and Vietoris hit/miss rows before the real seal is read;*
6. *componentwise transport, displayed replay, provenance, and local naming for the same L, U, K, H, V, W, R, E route.*

No Painleve–Kuratowski convergence obligation is stored outside these rows.

Proof. Project the carrier of Definition 3880.1. The lower-hit coordinate is L, the upper-miss coordinate is U, and the inspected source and topology data are K, H, V.

Lower-hit coverage is read from L. A consumer may cite a hit only after the displayed witness appears in the finite ledger, so the packet does not infer pointwise contact from an ambient subset relation.

Upper-miss coverage is read from U. Each miss is paired with a finite cover or ball-exclusion window before any convergence-facing exclusion is exported, so no arbitrary complement or open-cover compactness theorem is used.

The finite-window route is then checked through W and R. These rows schedule the inspected stages and regular rational tolerances, while H, V attach the Hausdorff and Vietoris readings to the same windows.

Finally, E, T, C, P, N seal, transport, replay, source, and name only that route. Since the carrier has no coordinate for host powersets, quotient subset equality, arbitrary suprema or infima, selected nearest points, countable choice, or ambient Real completeness, the listed obligations exhaust the certificate. □

Theorem 2905.3 (Painleve–Kuratowski convergence finite-window boundary)**.** *Every convergence-facing consumer of an accepted* $\mathsf{PainleveKuratowskiConvergence}^{\uparrow}$ *carrier receives only the finite displayed route*

$$L, U \longmapsto K, H, V \longmapsto W, R \longmapsto E \longmapsto T, C, P, N.$$

Thus the chapter names finite hit/miss windows for closed-set convergence; it does not export host powersets, quotient subset equality, arbitrary suprema or infima, selected nearest points, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a convergence-facing read. By Definition 3880.1, the only lower and upper convergence data are the finite ledgers L and U.

Use Definition 3880.2. The consumer must pass through the hyperspace or compact source row K, the Hausdorff comparison boundary H, and the Vietoris hit/miss row V before it may read the finite schedules W, R and the terminal seal E.

The structural rows T, C, P, N preserve the same displayed dependency order. Because the excluded host-level principles have no carrier coordinate and no replay edge, the packet can export only the named finite-window boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{PainleveKuratowskiConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PainleveKuratowskiConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3880.1, Definition 3880.2, and Definition 3880.3 seed the finite hit/miss window route for closed-set convergence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PainleveKuratowskiConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, quotient subset equality, arbitrary suprema or infima, selected nearest points, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked lower-hit coverage, upper-miss coverage, finite-window compatibility, metric and hyperspace handoff, transport, replay, provenance, and local naming for BEDC.Derived.PainleveKuratowskiConvergenceUp.

Constructive story: A $\mathsf{PainleveKuratowskiConvergence}^{\uparrow}$ packet is generated from lower-hit witnesses, upper-miss finite-cover witnesses, a compact or hyperspace source row, HausdorffMetric comparison, Vietoris hit/miss topology, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2906

A Concrete Naming Certificate for $\mathsf{HaarWavelet}^{\uparrow}$

Starting from the classical Haar 1910 orthonormal system and its constructive dyadic approximation surface, the $\mathsf{HaarWavelet}^{\uparrow}$ packet records finite dyadic-window wavelet data as BEDC NameCert rows. It sits over the Schauder-basis coordinate route of chapter 3669, the dyadic partition surface of chapter 1863, the finite step-function interface of chapter 3780, and the terminal real-name seal of chapter 38. The packet supplies a finite wavelet coefficient window without importing Haar measure, quotient function spaces, ambient Hilbert-space completeness, or a selected infinite expansion.

Definition 2906.1 (Haar wavelet carrier)**.** *A* $\mathsf{HaarWavelet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, I, L, V, A, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the dyadic scale row, naming the inspected level and the finite family of cells at that level.*
2. *I is the parent-interval row, read through the* $\mathsf{DyadicPartition}^{\uparrow}$ *packet of chapter 1863.*
3. *L records the left and right child split of each inspected parent interval together with the sign assignment $+1, -1$.*
4. *V is the* $\mathsf{StepFunction}^{\uparrow}$ *value row, so each inspected wavelet is a signed dyadic step function over the displayed children.*
5. *A is the finite coefficient-window row, listing exactly the inspected scale-position coefficients and their local dyadic tolerances.*
6. *B is the* $\mathsf{SchauderBasis}^{\uparrow}$ *coordinate handoff row, consuming the finite coefficient window as a basis-coordinate projection.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the coefficient values and sampled step-function values.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for every coefficient and sampled value exported by the packet.*
9. *H records componentwise* hsame *transport for the scale, interval, split, value, coefficient, Schauder handoff, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a wavelet-window read through $K, I, L, V, A, B, R, E, H$.*

11. *P is the* Pkg *provenance over* $\mathsf{HaarWavelet}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{StepFunction}^{\uparrow}$, $\mathsf{SchauderBasis}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HaarWavelet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for Haar measure, an L^2 quotient class, a host orthogonality theorem, a selected infinite coefficient stream, or ambient Hilbert-space completeness.

Lean4 ✓ `BEDC.Derived.HaarWaveletUp.HaarWaveletTasteGate single carrier alignment`

Theorem 2906.2 (Haar wavelet NameCert obligations)**.** *For every accepted* $\mathsf{HaarWavelet}^{\uparrow}$ *carrier $W = (K, I, L, V, A, B, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HaarWavelet}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic scale exposure, parent-interval exposure, left/right sign-split exposure, step-function value exposure, finite coefficient-window exposure, Schauder-basis coordinate handoff, regular rational readback, Real seal exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 3881.1. The rows K, I, L, V display the finite dyadic scale, the parent interval, the signed child split, and the induced step-function value row before any coefficient consumer can read a wavelet.

The coefficient route is finite. The row A lists only the inspected scale-position coefficients, B hands that finite list to the $\mathsf{SchauderBasis}^{\uparrow}$ coordinate route, and R, E provide the regular rational readback and terminal Real seal for the same displayed values.

The structural rows preserve that route. Since H, C, P, N add only transport, replay, provenance, and local naming, and since the carrier has no coordinate for Haar measure, quotient function classes, host orthogonality, selected infinite streams, or Hilbert-space completeness, the listed rows exhaust the local NameCert surface. □

Theorem 2906.3 (Haar wavelet dyadic-step handoff)**.** *Every* $\mathsf{StepFunction}^{\uparrow}$ *or* $\mathsf{SchauderBasis}^{\uparrow}$ *consumer of an accepted* $\mathsf{HaarWavelet}^{\uparrow}$ *carrier reads the wavelet only through*

$$\mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{StepFunction}^{\uparrow} \longmapsto \mathsf{SchauderBasis}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the displayed scale, split, transport, replay, provenance, and local naming rows. The handoff exports finite dyadic step functions and finite coefficient windows, not Haar integration, quotient function equality, an infinite expansion selector, or ambient completeness.

Proof. Start with the dyadic data. The scale row K and parent-interval row I determine the inspected dyadic cells, and the split row L records the left/right signed child cells over that finite partition.

Next use the step-function value row. The row V turns the signed child data into a $\mathsf{StepFunction}^{\uparrow}$ read, so a step-function consumer receives only the displayed finite cell values and not an ambient function object.

Finally read the coefficient and seal rows. The finite coefficient window A feeds the $\mathsf{SchauderBasis}^{\uparrow}$ coordinate handoff B, and the rows R, E provide regular rational readback and terminal Real seals for the same displayed coefficients. The structural rows H, C, P, N transport and name this route, so no Haar-measure row, quotient equality, infinite expansion selector, or ambient completeness coordinate is exported. □

Falsifiable prediction: An accepted $\mathsf{HaarWavelet}^{\uparrow}$ coefficient read is refuted if its $\mathsf{SchauderBasis}^{\uparrow}$ coordinate handoff is preserved while the displayed $\mathsf{DyadicPartition}^{\uparrow}$ parent interval, left/right sign split, $\mathsf{StepFunction}^{\uparrow}$ value row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal are removed.

Independence witness: dyadic-partition, step-function, schauder-basis, regseqrat, real: none is bijective with $\mathsf{HaarWavelet}^{\uparrow}$ because the packet jointly carries scale rows, parent intervals, signed child splits, step-function values, finite coefficient windows, coordinate handoff, regular readback, terminal seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HaarWavelet}^{\uparrow}}$.

Constructive story: A $\mathsf{HaarWavelet}^{\uparrow}$ packet is generated from dyadic scale rows, parent interval rows, left/right sign splits, StepFunctionUp values, finite coefficient windows, SchauderBasisUp coordinate handoff, RegSeqRatUp readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HaarWavelet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3881.1, Definition 3881.2, and Definition 3881.3 seed the finite dyadic-window wavelet packet over partition, step-function, coordinate, readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HaarWavelet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Haar measure, host orthogonality, quotient function spaces, selected infinite expansions, Hilbert-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic scale exposure, parent-interval exposure, sign-split exactness, StepFunctionUp handoff, SchauderBasisUp coordinate routing, RegSeqRatUp readback, RealUp seal exposure, and structural transport for BEDC.Derived.HaarWaveletUp.

Chapter 2907

A Concrete Naming Certificate for $\mathsf{CauchyRegularCompletionAdjunction}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRegularCompletionAdjunction}^{\uparrow}$ packet records the finite adjunction-facing surface by which regular Cauchy names present the completion route without passing through a host quotient. It sits after the functorial completion packet of chapter 423, the regular rational readback of chapter 301, the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the extension-and-uniqueness surface of chapter 397. The chapter names the adjunction as displayed BEDC data over finite rows; it does not construct a quotient completion, select limits, assert host completed metric spaces, or import ambient completeness.

Definition 2907.1 (Cauchy regular completion adjunction carrier)**.** *A* $\mathsf{CauchyRegularCompletionAdjunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, R, W, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row naming the functorial completion surface over the same source metric and regular-Cauchy data.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which regular rational Cauchy names are exposed.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule read by the regular Cauchy route.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed stream windows and regular-rational reads.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, W, D have been consumed.*
6. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row recording extension existence and uniqueness for the same displayed completion route.*
7. *H records componentwise* hsame *transport for F, R, W, D, L, U.*
8. *C records displayed* Cont *replay from functorial completion requests to stream windows, from windows and dyadic tolerances to regular rational readback, from readback to the Real seal, and from the Real seal into the universal-property handoff.*

9. *P is the* Pkg *provenance over* CauchyRegularCompletionAdjunction$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{CauchyRegularCompletionAdjunction}^{\uparrow}}$ *row.*

The carrier exposes the regular completion adjunction only through these finite rows. It has no coordinate for quotient completion equality, selected representatives, host completed metric spaces, hidden completeness witnesses, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyRegularCompletionAdjunctionUp.CauchyRegularCompletionAdjunctionTasteGate`
`single carrier alignment`

Theorem 2907.2 (Cauchy regular completion adjunction NameCert obligations)**.** *For every accepted* CauchyRegularCompletionAdjunction$^{\uparrow}$ *carrier $A = (F, R, W, D, L, U, H, C, P, N)$, the local* NameCert$_{\text{CauchyRegularCompletionAdjunction}^{\uparrow}}$ *surface consists exactly of carrier admission for A, regular-readback compatibility through R, finite-window budget compatibility through W, D, terminal Real seal determinacy through L, universal-property handoff through U, functorial completion source exposure through F, and structural transport, replay, provenance, and local naming through H, C, P, N.*

The ledger refuses every route that would discharge an obligation by quotient completion equality, a selected limit, a host completed metric space, an ambient completeness principle, a hidden cofinal stream family, or a host-level equality of real names.

Proof. Project the carrier of Definition 3882.1. The visible rows are exactly $F, R, W, D, L, U, H, C, P, N$, and each listed NameCert obligation is a projection of one of those rows.

The regular-readback side is finite. The stream schedule W names the exposed windows, the tolerance ledger D attaches dyadic bounds to those same windows, and the regular rational row R is the only readback route before the terminal Real seal L can be consumed.

The adjunction-facing side is downstream from that route. The functor row F records the completion-facing source packet, while the universal-property row U records extension and uniqueness only after the same R, W, D, L rows have been read.

Finally, H, C, P, N preserve componentwise comparison, replay, provenance, and local naming for the displayed rows. Since the carrier contains no quotient-completion, selection, host-completion, hidden-completeness, cofinal-family, or host-equality coordinate, the ledger refusal clauses follow from exhaustion of the tuple. □

Falsifiable prediction: Every accepted CauchyRegularCompletionAdjunction$^{\uparrow}$ consumer that exports a completion adjunction while omitting the CauchyCompletionFunctor row, RegSeqRat readback, StreamName windows, DyadicRatCore tolerance ledger, terminal Real seal, CompletionUniversalProperty row, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: cauchycompletionfunctor, regseqrat, streamname, dyadicratcore, real, and completionuniversalproperty: none is bijective to the regular completion adjunction packet because the packet jointly carries functorial source exposure, regular readback, finite-window budget, tolerance ledger, terminal seal, universal-property handoff, transport, replay, provenance, and local NameCert rows.

Closure status for NameCert$_{\text{CauchyRegularCompletionAdjunction}^{\uparrow}}$.

Constructive story: A CauchyRegularCompletionAdjunction$^{\uparrow}$ packet is generated from a CauchyCompletionFunctor row, a RegSeqRat readback row, StreamName finite windows, a DyadicRatCore tolerance ledger, a terminal RealUp seal, a CompletionUniversalProperty handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyRegularCompletionAdjunction}\uparrow}$, seed)

Scope closed: Definition 3882.1 and Definition 3882.2 seed the finite regular completion adjunction surface over CauchyCompletionFunctorUp, RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, RealUp, CompletionUniversalPropertyUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyRegularCompletionAdjunction}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, RealUp completeness, quotient completion equality, selected host limits, host completed metric spaces, hidden cofinal streams, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, regular-readback compatibility, finite-window budget compatibility, terminal Real seal determinacy, universal-property handoff, ledger refusal, and TasteGate field faithfulness for BEDC.Derived.CauchyRegularCompletionAdjunctionUp.

Chapter 2908

A Concrete Naming Certificate for $\mathsf{Quasiisometry}^{\uparrow}$

Following Gromov and Bridson–Haefliger, the $\mathsf{Quasiisometry}^{\uparrow}$ packet records coarse metric equivalence as finite BEDC coarse metric data rather than as an ambient set-theoretic map. It reads source and target metric presentations from chapter 57, reuses the displayed host-map discipline of chapter 410, keeps properness visible through **??**, sends completion-facing rows through chapter 1937, and uses the readback surfaces of chapter 301 and chapter 38. The packet names finite coarse equivalence evidence; it is not a selected inverse function, not quotient equality of completions, not a host-space bijection, and not an oracle for external large-scale geometry.

Definition 2908.1 (Quasi-isometry carrier)**.** *A* $\mathsf{Quasiisometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, F, A, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric row, recording the named* $\mathsf{Met}^{\uparrow}$ *presentation and the source distance queries visible to the packet.*
2. *Y is the target metric row, recording the named* $\mathsf{Met}^{\uparrow}$ *presentation and the target distance queries visible to the packet.*
3. *F is the coarse map graph row, recording the finite graph of the displayed map route without adding a host-level function outside the BEDC carrier.*
4. *A is the affine distortion row, storing the multiplicative and additive control constants that bound target distances from source distances and source distances from target witnesses.*
5. *S is the coarse-surjectivity witness row, recording the finite target-cover ledger and its bounded return witnesses.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *distance readback row, storing rational windows and real-distance readings used by the coarse estimates.*
7. *E is the completion-facing row, recording the handoff to* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *consumers and the stability data exposed to completion routes.*
8. *H records componentwise* hsame *transport for source metric, target metric, graph, distortion, coarse-surjectivity, readback, completion-facing, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a source or target coarse query through graph readback, distortion control, surjectivity witness, distance readback, and completion-facing handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{QuasiIsometry}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, CauchyCompletionFunctoriality, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasiIsometry}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $X, Y, F, A, S, R, E, H, C, P, N$. It has no coordinate for a selected inverse map, quotient equality of completions, a host-space bijection, an external large-scale geometry theorem, or a choice principle for target witnesses.

Lean4 ✓ `BEDC.Derived.QuasiIsometryUp.QuasiIsometryTasteGate single carrier alignment`

Theorem 2908.2 (Quasi-isometry NameCert obligations)**.** *For every accepted* $\mathsf{QuasiIsometry}^{\uparrow}$ *carrier $Q = (X, Y, F, A, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{QuasiIsometry}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *Carrier admission for the displayed source metric, target metric, graph, distortion, surjectivity, readback, completion-facing, transport, replay, provenance, and local naming rows.*
2. *Coarse Lipschitz control, read from F, A, R, H, C, for source-distance windows and target-distance windows displayed by the packet.*
3. *Coarse-surjectivity ledger exactness, read from S, R, H, C, for every target-side witness exported by the packet.*
4. *Completion-facing stability, read from E, H, C, P, for every consumer that routes coarse metric evidence into completion functoriality.*
5. *Non-escape from host maps, selected witnesses, choice principles, quotient equality, and ambient bijections, witnessed by the absence of such coordinates from $X, Y, F, A, S, R, E, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.QuasiIsometryUp.QuasiIsometryNamecertObligations`

Proof. Project the carrier of Definition 3883.1. The accepted packet exposes only the two metric rows, the coarse graph, affine distortion constants, coarse-surjectivity witnesses, distance readback, completion-facing handoff, transport, replay, provenance, and local naming.

The coarse Lipschitz and coarse-surjectivity obligations are finite route inspections. The rows F, A, S, R, H, C display the graph, bounds, witnesses, readback windows, transport equalities, and replay path before any consumer receives a quasi-isometry reading.

The completion-facing obligation is another projection. A completion consumer must pass through E together with the same transport, replay, and provenance rows H, C, P, so it cannot obtain a host completion isomorphism or quotient equality from the packet.

The non-escape row follows from the carrier boundary itself. Since no coordinate stores a selected inverse map, a choice functional, an ambient bijection, or quotient equality of completions, the five listed rows exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{QuasiIsometry}^{\uparrow}$ read is refuted if a consumer obtains coarse equivalence, completion-facing stability, or target-side coverage without displaying source and target metric rows, graph readback, affine distortion constants, coarse-surjectivity witnesses, RegSeqRat/Real readback, transport, replay, provenance, and local naming.

Independence witness: metric, lipschitzmap, propermetric, cauchy-completion-functoriality, regseqrat, real: none is bijective to $\mathsf{QuasiIsometry}^{\uparrow}$ because this packet jointly carries source and

target metric rows, coarse graph data, affine distortion constants, coarse-surjectivity witnesses, rational and real distance readback, completion-facing stability, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiIsometry}\uparrow}$.

Constructive story: A $\mathsf{QuasiIsometry}^{\uparrow}$ packet is generated from source and target metric rows, a finite coarse map graph, affine distortion constants, coarse-surjectivity witnesses, RegSeqRat/Real distance readback, completion-facing stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuasiIsometry}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3883.1 and Definition 3883.2 seed the finite coarse metric equivalence certificate over displayed metric, graph, distortion, surjectivity, readback, completion-facing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuasiIsometry}\uparrow}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.QuasiIsometryUp`

Bridge status: none

Not claimed: This chapter does not close a selected inverse map, quotient equality of completions, host-space bijection, external large-scale geometry theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coarse Lipschitz control, coarse-surjectivity exactness, completion-facing stability, non-escape from host maps, and local naming for BEDC.Derived.QuasiIsometryUp.

Chapter 2909

A Concrete Naming Certificate for DyadicClosedIntervalEndpointGrid$^{\uparrow}$

Following Bishop and Bridges constructive interval analysis, the DyadicClosedIntervalEndpointGrid$^{\uparrow}$ packet records the finite dyadic endpoint grid read before compact-uniform-continuity interval consumers inspect nets, moduli, or coverage rows. It refines the closed bounded interval source of chapter 1591 through the dyadic interval surface of chapter 306, the StreamName and RegSeqRat readback rows, and the terminal Real seal. The route serves the compact-uniform-continuity program of chapter 9237 without invoking open-cover compactness, selected subcovers, quotient real equality, trichotomy, or ambient completeness.

Definition 2909.1 (Dyadic closed interval endpoint-grid carrier)**.** *A* DyadicClosedIntervalEndpointGrid$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* ClosedBoundedInterval$^{\uparrow}$ *row, exposing lower endpoint, upper endpoint, endpoint order, rational containment, dyadic containment, StreamName windows, RegSeqRat readbacks, and the Real seal through the root package.*
2. *D is the finite* DyadicInterval$^{\uparrow}$ *endpoint-grid row, listing dyadic cells whose endpoints are admitted by the interval source and ordered by the same endpoint-order route.*
3. *W is the finite window row, exposing the StreamName windows attached to the grid cells before any net, modulus, or coverage consumer reads them.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the displayed dyadic endpoints and cell windows.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row, reached only after I, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport across the closed interval source, dyadic grid, windows, RegSeqRat readbacks, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from compact-uniform-continuity interval requests through the endpoint grid before finite-net or modulus rows are inspected.*
8. *P is the* Pkg *provenance over* ClosedBoundedInterval$^{\uparrow}$, DyadicInterval$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *compact-uniform-continuity interval consumers,* BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $I, D, W, R, E, H, C, P, N$. It has no coordinate for host closed intervals, open-cover compactness, selected subcovers, selected points, quotient real equality, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicClosedIntervalEndpointGridUp.DyadicClosedIntervalEndpointGridTasteGate`
`single carrier alignment`

Theorem 2909.2 (Dyadic closed interval endpoint-grid obligations)**.** *For every accepted* DyadicClosedIntervalEndpo *carrier $G = (I, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}}$ *surface consists of carrier admission, dyadic-cell exposure, endpoint-order preservation, window handoff, Real-seal nonescape, and local naming. The carrier admits only source rows from* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*, exposes dyadic cells only through D, preserves endpoint order from I to every displayed cell endpoint, hands StreamName windows and RegSeqRat readbacks through W, R, reaches the Real seal only through E, and names the entire route by H, C, P, N.*

Proof. Project the carrier of Definition 3884.1. The source row I is the only closed bounded interval input, and the finite grid row D is the only coordinate listing dyadic endpoint cells.

Endpoint order is inherited from the source row before any grid cell is read. Since D is attached to I, every displayed dyadic endpoint is admitted through the same lower-endpoint, upper-endpoint, order, rational-containment, and dyadic-containment route used by chapter 1591.

The consumer-facing rows are then forced through W, R, E. StreamName windows are exposed by W, regular rational endpoint readbacks by R, and the terminal Real seal by E. None of those rows supplies host compactness data or a selected subcover.

Finally H, C, P, N transport, replay, source, and name exactly this displayed route. Because the carrier has no other coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 2909.3 (Dyadic closed interval endpoint-grid window handoff)**.** *Every compact-uniform-continuity interval read that consumes an accepted* $\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}$ *carrier must pass through the displayed endpoint grid*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{DyadicInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before it reads any finite-net row, coverage row, pointwise-modulus row, uniform-modulus row, or compactness consumer row.

Proof. Start with the accepted carrier $G = (I, D, W, R, E, H, C, P, N)$. A compact-uniform-continuity interval consumer first receives I, so the closed bounded interval endpoint and containment package is displayed before any grid row is available.

The read then passes through the finite dyadic endpoint grid D. This row exposes the dyadic cells and their endpoint order, but it does not yet expose a finite net, a cover, or a modulus.

Next the consumer receives the window and readback rows W, R, E. These rows hand off StreamName windows, RegSeqRat endpoint readbacks, and the Real seal as finite endpoint-grid data.

Only after this route has been replayed by C and sourced by P may a downstream compact-uniform-continuity consumer add net or modulus rows. Thus the interval read reaches the compact-uniform-continuity surface through the endpoint grid rather than through an open-cover compactness principle or a host real interval. □

Falsifiable prediction: An accepted compact-uniform-continuity interval consumer that reads finite-net, coverage, pointwise-modulus, uniform-modulus, or compactness rows before inspecting $I, D, W, R, E, H, C, P, N$ is outside the $\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}$ packet.

Independence witness: closedboundedinterval, dyadicinterval, streamname, regseqrat, real: $\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the closed bounded interval root package, a finite dyadic endpoint grid, finite windows, regular rational readbacks, a terminal Real seal, transport, replay, provenance, and local naming for compact-uniform-continuity interval consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}$ packet is generated from a ClosedBoundedInterval source row, DyadicInterval endpoint-grid row, StreamName window row, RegSeqRat readback row, Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3884.1, Definition 3884.2, and Definition 3884.3 seed the finite endpoint-grid route for compact-uniform-continuity interval consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalEndpointGrid}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, finite-net compactness, open-cover compactness, pointwise-modulus extraction, uniform-modulus construction, quotient real equality, trichotomy, selected points, selected subcovers, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-cell exposure, endpoint-order preservation, window handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicClosedIntervalEndpointGr

Chapter 2910

A Concrete Naming Certificate for CauchyFilterCompletionCriterion$^{\uparrow}$

Following Kelley and Bishop–Bridges, the CauchyFilterCompletionCriterion$^{\uparrow}$ packet records the textbook completion criterion that a displayed Cauchy-filter route may reach a completion boundary only through finite basis, window, tolerance, readback, and real-seal data. It sits after the Cauchy-filter completion boundary of chapter 1569, the filter-limit basis route of chapter 3862, the Cauchy-filter surface of chapter 333, the uniform-completion surface of chapter 1473, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the criterion as finite BEDC data; it does not quotient filters, select a limit, use host equality, invoke choice, or import ambient completeness.

Definition 2910.1 (CauchyFilterCompletionCriterion carrier)**.** *A* CauchyFilterCompletionCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, B, F, U, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* CauchyFilterCompletion$^{\uparrow}$ *completion-boundary row whose accepted reads remain tied to displayed Cauchy-filter data.*
2. *B is the* FilterLimitBasis$^{\uparrow}$ *row exposing the finite basis route used by limit and completion consumers.*
3. *F is the* CauchyFilter$^{\uparrow}$ *source row, including the displayed base, refinement, and Cauchy evidence read by Q and B.*
4. *U is the* UniformCompletion$^{\uparrow}$ *handoff row, available only after the same filter, basis, window, tolerance, and readback route has been displayed.*
5. *S is the* StreamName$^{\uparrow}$ *finite-window schedule used to inspect requested tails.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger attached to the same windows and completion requests.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the finite windows and dyadic ledger.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after Q, B, F, U, S, D, R have been replayed.*
9. *H records componentwise* hsame *transport for the completion, basis, filter, uniform, window, tolerance, readback, real-seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a completion-criterion request through* $Q, B, F, U, S, D, R, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, B, F, U, S, D, R, E, H, C, P, N$. There is no coordinate for quotient filters, selected representatives, host filter equality, selected completion points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyFilterCompletionCriterionUp.CauchyFilterCompletionCriterionTasteGate`
`single carrier alignment`

Theorem 2910.2 (CauchyFilterCompletionCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *carrier $K = (Q, B, F, U, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterComple}}$ *surface consists exactly of carrier admission, CauchyFilterCompletion boundary exposure through Q, FilterLimitBasis route exposure through B, CauchyFilter source exposure through F, UniformCompletion handoff exposure through U, finite StreamName window exposure through S, DyadicRatCore tolerance exactness through D, RegSeqRat readback through R, Real seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No obligation may be discharged by quotient-filter equality, selected representatives, selected completion points, host filter equality, countable choice, hidden cofinal tails, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyFilterCompletionCriterionUp.CauchyFilterCompletionCriterionCarrier`
`namecert obligations`

Proof. Project the carrier of Definition 3885.1. The displayed rows are exactly $Q, B, F, U, S, D, R, E, H, C, P, N$, so carrier admission exposes only completion-boundary, basis, Cauchy-filter, uniform-handoff, window, tolerance, readback, seal, transport, replay, provenance, and naming data.

The completion side starts with Q, B, F. The Cauchy-filter completion row Q and the limit-basis row B both read the same Cauchy-filter source row F, so the criterion has one finite filter route rather than a quotient or detached basis route.

Next read the uniform and numerical rows. The handoff U is downstream from the displayed filter route, while S, D, R give the finite windows, dyadic tolerances, and regular rational readback used before the terminal seal E is available.

Finally the structural rows H, C, P, N preserve the same route. Since quotient-filter equality, selected representatives, selected completion points, host filter equality, choice, hidden cofinal tails, and ambient completeness are absent from the carrier, the listed rows exhaust the local surface. □

Theorem 2910.3 (CauchyFilterCompletionCriterion basis route)**.** *Let $K = (Q, B, F, U, S, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *carrier. Every completion-facing or Real-facing read factors through*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{FilterLimitBasis}^{\uparrow} \longmapsto \mathsf{CauchyFilterCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeq}$$

The $\mathsf{UniformCompletion}^{\uparrow}$ *handoff reads the same route through U and cannot bypass $F, B, Q, S, D, R, E, H, C, P, N$. Thus the criterion exports finite basis evidence for the L10 completion route without quotient filters, selected limits, host equality, choice, hidden cofinal tails, or ambient completeness.*

Lean4 ✓ BEDC.Derived.CauchyFilterCompletionCriterionUp.CauchyFilterCompletionCriterionBasisRoute

Proof. Begin with a completion-facing or Real-facing read of K. The carrier exposes the source Cauchy-filter row F, the basis row B, and the completion-boundary row Q before any terminal Real seal can be inspected.

Replay the displayed continuation row C. The read passes from F to B and Q, then through the finite window schedule S, dyadic tolerance ledger D, and regular rational readback R before it reaches E.

The uniform handoff does not open a second completion object. The row U is one of the displayed coordinates and is preserved by H, C, P, N, so a $\mathsf{UniformCompletion}^{\uparrow}$ consumer receives the same basis route rather than a hidden quotient, chosen representative, or ambient completion.

The excluded objects are not carrier rows. Consequently every accepted read factors through the route displayed in the statement. □

Theorem 2910.4 (CauchyFilterCompletionCriterion uniform handoff nonescape)**.** *For an accepted* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *carrier* $K = (Q, B, F, U, S, D, R, E, H, C, P, N)$*, every* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff read is confined to the displayed row* U *of Definition 3885.1. The handoff may be read only after the basis route of Definition 3885.3 has exposed* F, B, Q, S, D, R, E*, and it cannot replace that route by a quotient filter, selected completion point, host equality, or countable choice.*

Proof. Inspect the carrier rows. The uniform-facing coordinate is U, and the basis-route theorem requires the Cauchy-filter source, basis row, completion-boundary row, window schedule, tolerance ledger, readback row, and Real seal to be displayed in the same packet.

The handoff is therefore a downstream read of the existing route. It cannot open a second completion object or select a limit, because no quotient, selection, host-equality, or choice coordinate appears in K.

The structural rows H, C, P, N transport, replay, source, and name the same handoff. Thus every uniform read remains inside the finite criterion packet. □

Theorem 2910.5 (CauchyFilterCompletionCriterion readback exactness)**.** *For an accepted* CauchyFilterCompletion*carrier* $K = (Q, B, F, U, S, D, R, E, H, C, P, N)$*, every numerical readback consumed by the criterion is exactly the finite route through the window row* S*, the dyadic tolerance row* D*, and the regular rational readback row* R *named in Definition 3885.1. The basis route of Definition 3885.3 admits no hidden cofinal tail, host filter equality, or ambient real-completeness read.*

Proof. The basis route displays the Cauchy-filter, basis, and completion-boundary rows before any numerical read is available. After those rows, the only numerical coordinates in the carrier are S, D, R.

Exactness means that the requested tail is inspected through the finite window schedule S, the tolerance is read from D, and the regular rational value is read from R. A consumer has no coordinate from which to infer an unseen cofinal tail or compare filters by host equality.

The replay and transport rows C and H preserve this same finite route, with provenance P and local naming N. Hence every readback is precisely the displayed S, D, R ledger. □

Theorem 2910.6 (CauchyFilterCompletionCriterion Real seal nonescape)**.** *For an accepted* CauchyFilterCompletio*carrier* $K = (Q, B, F, U, S, D, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing seal read is confined to the terminal row* E *of Definition 3885.1. The row* E *may be consumed only after the basis route of Definition 3885.3 has displayed the Cauchy-filter source, basis, completion boundary, uniform handoff, windows, dyadic tolerances, and regular rational readback. It exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. The terminal seal is a row of the carrier, not a theorem about all real names. The basis-route theorem places it after the filter, basis, completion-boundary, window, tolerance, and regular rational readback rows.

A Real-facing consumer therefore reaches E only by replaying the displayed finite path. The consumer cannot bypass the route through a hidden completion object, a selected representative, host equality, or countable choice.

Since E is transported and replayed only by H and C, with provenance and local naming in P and N, it seals the displayed readback without exporting ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ read factors through $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ packet is generated from a CauchyFilterCompletion row, FilterLimitBasis row, CauchyFilter source row, UniformCompletion handoff row, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3885.1, Definition 3885.2, and Definition 3885.3 seed the L10 completion criterion route over CauchyFilterCompletionUp, FilterLimitBasisUp, CauchyFilterUp, UniformCompletionUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient filters, selected limits, host equality, countable choice, hidden cofinal tails, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, CauchyFilterCompletion boundary exposure, FilterLimitBasis route exposure, UniformCompletion handoff nonescape, readback exactness, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.CauchyFilterCompletionCriterionUp.

Chapter 2911

A Concrete Naming Certificate for $\mathsf{ConstructiveUniformLimit}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{ConstructiveUniformLimit}^{\uparrow}$ packet records the theorem route saying that a uniform limit of continuous real-valued maps is continuous when every ingredient is read through finite BEDC certificate rows. It refines the continuous-map surface of chapter 130, the uniform-limit endpoint route of chapter 463, the window ledger of chapter 126, the regular-rational readback of chapter 301, and the real seal of chapter 38.

The chapter is a human-origin L10 reconstruction of the classical uniform-limit theorem as a finite NameCert route. It exposes continuous approximants, a uniform convergence ledger, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise transport, continuation replay, package provenance, and local naming. It does not introduce a quotient function space, a selected host limit, pointwise-only convergence, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 2911.1 (Constructive uniform-limit carrier)**.** *A* $\mathsf{ConstructiveUniformLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, L, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *A is the finite family of accepted* $\mathsf{ContinuousMap}^{\uparrow}$ *approximant rows, each exposing a common source certificate, a target* $\mathsf{Real}^{\uparrow}$ *seal, and its local continuity modulus ledger;*
2. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *row that records the uniform convergence threshold ledger and endpoint-facing route for the same family;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule on which all approximants and all convergence thresholds are read;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row tying the window data to rational endpoint observations;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the uniform-limit and regular-rational readback rows have both been consumed;*
6. *H records componentwise* hsame *transport for approximants, window schedules, threshold ledgers, readbacks, endpoint seals, and local modulus rows;*
7. *C records displayed* Cont *replay of the approximant continuity ledgers and of the uniform-limit handoff;*

8. *P is the* Pkg *provenance over* $\mathsf{ConstructiveUniformLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUniformLimit}^{\uparrow}}$ *row.*

The carrier classifier compares two packets only by replaying the displayed rows $A, L, W, R, E, H, C, P, N$. No coordinate stores pointwise-only convergence, a selected host limit, quotient equality between functions, open-cover compactness, or a free completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.ConstructiveUniformLimitUp.ConstructiveUniformLimitTasteGate single carrier alignment`

Theorem 2911.2 (Constructive uniform-limit NameCert obligations)**.** *For every accepted* ConstructiveUniformLimi *carrier $U = (A, L, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUniformLimit}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the displayed packet, continuous-approximant admission through A, uniform-limit admission through L, finite window admission through W, regular-rational readback through R, terminal real-seal admission through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3886.1. The rows $A, L, W, R, E, H, C, P, N$ are the complete visible coordinates of one finite packet.

Read the analytic rows in dependency order. The continuous approximants provide local modulus ledgers, the uniform-limit row provides the common tail threshold, the window row supplies the shared finite schedule, and the regular-rational readback row exposes the endpoint observations used by both routes.

The seal and replay rows then close the local obligation surface. The $\mathsf{Real}^{\uparrow}$ endpoint E is available only after the shared windows, uniform threshold ledger, and regular readback row have been consumed; H and C preserve exactly those displayed rows.

Finally, P and N source the same finite packet as provenance and local naming. Since no carrier coordinate stores a selected host limit, quotient function equality, pointwise-only convergence, open-cover compactness, or ambient real completeness, no further obligation is exported. □

Theorem 2911.3 (Constructive uniform-limit continuity route)**.** *Every continuous-map consumer of an accepted* $\mathsf{ConstructiveUniformLimit}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{UniformLimit}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the displayed hsame, Cont, Pkg, *and* NameCert *rows. The limiting map is therefore consumed as a continuity-preserving finite handoff from continuous approximants and a uniform convergence ledger, not as a host-level function limit.*

Proof. Start with a continuous-map consumer of the limiting endpoint. By Definition 3886.1, such a consumer must first read the approximant row A and the shared window schedule W.

Next use the uniform-limit row L. It supplies the common threshold ledger that lets a single window and tolerance surface control the family uniformly, so the consumer cannot replace it with a pointwise convergence witness.

Read the regular-rational handoff R and the real seal E. The endpoint is visible only along the same window and threshold route that generated the uniform-limit packet.

Finally replay transport and continuation through H and C, then source the result through P and N. The displayed route is finite and certificate-local, so quotient function spaces, selected host limits, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the consumer surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveUniformLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveUniformLimit}^{\uparrow}$ packet is generated from continuous approximant rows, a $\mathsf{UniformLimit}^{\uparrow}$ uniform convergence ledger, shared $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveUniformLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3886.1, Definition 3886.2, and Definition 3886.3 seed the finite route from continuous approximants and a uniform convergence ledger to a continuity-preserving real endpoint consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveUniformLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ConstructiveUniformLimitUp.ConstructiveUniformLimitTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close quotient function spaces, selected host limits, pointwise-only convergence, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or a full function-space completeness theorem.

Upgrade path: Obligation closure requires binding the approximant, uniform threshold, window, regular readback, real seal, transport, replay, provenance, and local naming rows to exact BEDC primitives and a Lean theorem surface.

Chapter 2912

A Concrete Naming Certificate for CompactnessUniformContinuityDiameterDecay$^{\uparrow}$

Following Bishop and Bridges, the CompactnessUniformContinuityDiameterDecay$^{\uparrow}$ packet realizes the compact finite-net route from continuous pointwise control to a diameter-decay uniform-modulus certificate. It sits over the compact metric source of chapter 129, the continuous-map rows of chapter 130, the uniform-modulus consumer of chapter 369, the triangle estimate of chapter 1159, and the real endpoint seal of chapter 38.

The packet records diameter decay as finite certificate data: compact-net windows, local continuous-map oscillation bounds, a common uniform-modulus handoff, source and target metric triangle rows, and a terminal Real$^{\uparrow}$ seal. It does not appeal to open-cover compactness, a selected subsequence, a choice-selected center outside the bundle, semantic continuity, or ambient real completeness.

Definition 2912.1 (Compact uniform-continuity diameter-decay carrier)**.** *A* CompactnessUniformContinuityDiamet *carrier is a finite* BHist *packet*

$$D = (K, F, M, T, E, H, C, P, N)$$

with the following visible rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row carrying finite-net centers, located source-distance reads, and compact bundle coverage;*
2. *F is the* ContinuousMap$^{\uparrow}$ *row exposing the graph and pointwise modulus data for the displayed map into a* Real$^{\uparrow}$ *target;*
3. *M is the* UniformModulus$^{\uparrow}$ *handoff row obtained from the compact finite-net fold and consumed by downstream uniform-continuity readers;*
4. *T is the* MetricTriangleUniformEstimate$^{\uparrow}$ *row joining the selected compact-net center, two source-distance bounds, two target estimates, and the final target triangle estimate;*
5. *E is the* Real$^{\uparrow}$ *endpoint seal through which the target-diameter and oscillation reads must pass;*
6. *H records componentwise* hsame *transport for the compact source, continuous-map row, uniform-modulus row, triangle estimate, and real seal;*
7. *C records displayed* Cont *replay of the finite-net coverage, pointwise-modulus read, uniform-modulus handoff, and triangle-estimate route;*

8. *P is the* Pkg *provenance over* $\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}}$ *row.*

The classifier compares two packets only through the displayed rows $K, F, M, T, E, H, C, P, N$. It has no coordinate for host compactness, selected subsequences, choice outside the finite bundle, semantic continuity, quotient equality, or real completeness.

Lean4 ✓ BEDC.Derived.CompactnessUniformContinuityDiameterDecayUp.CompactnessUniformContinuityDiameterDe
single carrier alignment

Theorem 2912.2 (Diameter-decay NameCert obligations)**.** *For every accepted* CompactnessUniformContinuityDiam *carrier $D = (K, F, M, T, E, H, C, P, N)$, the local* NameCert *obligation surface consists exactly of compact-metric admission through K, continuous-map admission through F, uniform-modulus handoff through M, metric-triangle uniform estimate through T, real-seal admission through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3887.1. The finite packet exposes exactly $K, F, M, T, E, H, C, P, N$.

Read the compact-continuity rows first. The compact metric row supplies the finite-net centers and located source-distance reads, while the continuous-map row supplies the pointwise target estimates at those centers.

Next read the diameter-decay handoff. The uniform-modulus row receives a precision chosen from the finite compact-net fold, and the metric-triangle row converts the selected center route into the displayed target-diameter estimate.

The real seal, transport, replay, provenance, and local naming rows close the obligation surface. Since host compactness, selected subsequences, choice outside the finite bundle, semantic continuity, quotient equality, and real completeness are absent from the carrier, they cannot be exported by the local certificate. □

Theorem 2912.3 (Compact diameter-decay uniform-modulus route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}$ *packet receives the compact finite-net row, the continuous-map pointwise rows, the metric-triangle uniform estimate, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal as one finite route:*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the diameter-decay certificate is a finite compact-continuous image packet, not a semantic compactness theorem or an external modulus selector.

Proof. Start from the compact metric row K. It supplies the finite centers and source-distance reads used to measure the diameter of each displayed image window.

Read the continuous-map row F at the selected centers. The pointwise modulus data are tied to the same source rows that K exposes, so a consumer cannot choose a detached center or a detached target estimate.

Apply the triangle-estimate row T and then the uniform-modulus handoff M. The source and target triangle rows convert the local estimates into a single diameter-decay precision consumed by $\mathsf{UniformModulus}^{\uparrow}$.

Finally consume the real seal E and replay the route through H, C, P, N. The consumer obtains only the finite packet data, so open-cover compactness, selected subsequences, choice outside the bundle, semantic continuity, and real completeness remain unavailable. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}$ packet is generated from $\mathsf{CompactMetric}^{\uparrow}$ finite-net rows, $\mathsf{ContinuousMap}^{\uparrow}$ pointwise modulus data, a $\mathsf{UniformModulus}^{\uparrow}$ handoff, a $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3887.1, Definition 3887.2, and Definition 3887.3 seed the finite diameter-decay route from compact metric finite nets and continuous-map pointwise rows to a uniform-modulus consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactnessUniformContinuityDiameterDecay}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompactnessUniformContinuityDiameterDecayUp.CompactnessUniformContinuityDiameterDecayTa`

Bridge status: none

Not claimed: This chapter does not close semantic compactness, selected subsequences, choice outside the finite bundle, quotient equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires binding the compact finite-net, continuous-map, uniform-modulus, triangle-estimate, real-seal, transport, replay, provenance, and local naming rows to exact BEDC primitives and a Lean theorem surface.

Chapter 2913

A Concrete Naming Certificate for $\mathsf{MetricCompletionIdempotence}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{MetricCompletionIdempotence}^{\uparrow}$ packet records the fixed-point surface of constructive metric completion: once a displayed metric-completion route is already separated and complete at the finite BEDC interface, a second completion read must return to the same named rows. It sits after the metric-completion carrier of chapter 1506, the Cauchy-filter completion route of chapter 1569, the separated-completion boundary of chapter 1612, the complete separated metric surface of chapter 2355, and the uniform-completion handoff of chapter 1473. The packet gives downstream completion-functor, real-completion, and regular-rational routes a fixed-point target without quotient completion equality, selected representatives, host equality, countable choice, or an ambient completeness axiom.

Definition 2913.1 (MetricCompletionIdempotence carrier)**.** *A* $\mathsf{MetricCompletionIdempotence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, S, C, U, R, H, K, P, N)$$

with the following displayed rows:

1. *M is the first* $\mathsf{MetricCompletion}^{\uparrow}$ *row, including the source metric, Cauchy-filter or Cauchy-net branch, finite readback, and separated comparison route.*
2. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row requiring the first completion read to be separated before the fixed-point claim is consumed.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *limit-service row, exposing only the displayed Cauchy-name endpoint data available inside the completed surface.*
4. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *compatibility row, tying the metric-completion read to the same uniform completion route when a uniform consumer is present.*
5. *R is the second-completion readback row. It records that any repeated completion request replays M, S, C, U rather than introducing a second quotient, selector, host equality, or ambient complete metric space.*
6. *H records componentwise* hsame *transport for the first completion, separated boundary, complete-metric service, uniform handoff, repeated readback, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from the first completion request through the separated and complete rows to the repeated-completion readback.*

8. *P is the* Pkg *provenance over* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompleteSeparatedMe}$ $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionIdempotence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected Cauchy representatives, host equality of completed points, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a second completion object outside the replayed rows.*

Lean4 ✓ `BEDC.Derived.MetricCompletionIdempotenceUp.MetricCompletionIdempotenceTasteGate single carrier alignment`

Theorem 2913.2 (MetricCompletionIdempotence NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionIdempotence}^{\uparrow}$ *carrier* $I = (M, S, C, U, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionIdempotence}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *first-completion admission, requiring the initial read to pass through the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *row M;*

2. *separated fixed-point boundary, requiring the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *row S to be read before a repeated completion request is accepted;*

3. *complete-service compatibility, requiring the limit-service row C to expose only the completed finite endpoint data already available from the same source;*

4. *uniform-route compatibility, requiring every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer to share the route M, S, C before it reaches the repeated readback row R;*

5. *idempotence nonescape, requiring R, H, K, P, N to replay, transport, package, and name exactly the same route, with no quotient completion equality, selected representative, host equality, countable choice, ambient completeness, or detached second completion coordinate.*

Proof. Project the carrier of Definition 3888.1. The first completion row is M, and the only rows that can certify fixed-point behavior before the repeated readback are S, C, U.

Read S through the separated-completion boundary of chapter 1612. This forces any equality or comparison of completed names to use displayed separated classifier data rather than host equality or quotient classes.

Read C through the complete-metric service. The row supplies endpoint service only for the already displayed completion data, so it cannot select a new representative or create a second ambient complete space.

For uniform-facing consumers, read U through chapter 1473. The uniform route is required to share the same completion rows before the repeated readback R is available.

Finally H, K, P, N transport, replay, package, and name the same finite route. Since the carrier has no excluded coordinate, the five listed rows exhaust the local NameCert surface. □

Theorem 2913.3 (MetricCompletionIdempotence repeated completion fixed point)**.** *Let $I = (M, S, C, U, R, H, K, P, N)$ be an accepted* $\mathsf{MetricCompletionIdempotence}^{\uparrow}$ *carrier. Every second* $\mathsf{MetricCompletion}^{\uparrow}$ *read consumed through I factors through the finite route*

$$M \longmapsto S, C, U \longmapsto R \longmapsto H, K, P, N.$$

The second read therefore lands on the displayed completion surface already named by M, S, C, U and cannot be replaced by quotient completion equality, selected representatives, host equality, countable choice, ambient completeness, or a detached completion object.

Proof. Start with an accepted repeated completion request. Carrier admission gives R only as a row downstream of the first completion row M and the boundary rows S, C, U.

Use Definition 1506.3. The first completion read is already confined to the displayed metric source, cofinal branch, finite readback, and separated comparison route.

Use the separated boundary supplied by S and the complete-service row C. They ensure that the repeated request reads a completed separated metric surface rather than a quotient completion or a selected representative.

The uniform compatibility row U keeps uniform consumers on the same route. Transport and replay through H, K then carry that route to R, while P, N record provenance and local naming. □

Theorem 2913.4 (MetricCompletionIdempotence obligation scope)**.** *For an accepted* MetricCompletionIdempotenc *carrier $I = (M, S, C, U, R, H, K, P, N)$, the obligation surface is exactly first* MetricCompletion$^{\uparrow}$ *admission through M,* SeparatedCompletion$^{\uparrow}$ *boundary through S,* CompleteMetric$^{\uparrow}$/CompleteSeparatedMetric$^{\uparrow}$ *service through C,* UniformCompletion$^{\uparrow}$ *compatibility through U, repeated-readback determinacy through R,* hsame *transport through H,* Cont *replay through K,* Pkg *provenance through P, and local* NameCert *through N. It exports no quotient completion, selected representative, host equality, countable choice, or* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier. The first completion admission is the row M, and the fixed-point boundary can inspect only S, C, U before it reaches the repeated readback row R.

The separated and complete rows determine the admissible service surface. The row S blocks quotient completion equality, while C exposes only the displayed complete-metric or complete-separated-metric service already present in the packet.

Uniform compatibility is the role of U. It keeps uniform consumers on the same completion route before the repeated readback is public, so no separate completion object or host equality row is introduced.

Finally R, H, K, P, N determine repeated-readback determinacy, transport, replay, provenance, and local naming. Since the carrier has no coordinate for selected representatives, countable choice, or Real$^{\uparrow}$ completeness, the listed rows are exactly the obligation surface. □

Theorem 2913.5 (MetricCompletionIdempotence downstream scope)**.** *Every completion-functor, regular-rational, or real-completion consumer of an accepted* MetricCompletionIdempotence$^{\uparrow}$ *carrier receives only the fixed-point route displayed by $M, S, C, U, R, H, K, P, N$. The packet supplies a non-quotient idempotence target for downstream completion functoriality and Real or* RegSeqRat$^{\uparrow}$ *readback routes, but it does not close arbitrary completion monad laws, global reflection theorems, selected-limit principles, host equality of completed points, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier rows and read the repeated-completion fixed point theorem Definition 3888.3. Any downstream consumer entering through the packet is already on the route $M, S, C, U, R, H, K, P, N$.

For functorial consumers, the route starts with the same MetricCompletion$^{\uparrow}$ row M and reaches a repeated completion only through R. No additional functorial law is stored in the packet.

For regular-rational and real-completion consumers, the readback data are inherited from the finite completion rows named by M and the complete-service row C. The packet names the fixed-point surface but does not add a new RegSeqRat$^{\uparrow}$ or Real$^{\uparrow}$ completeness theorem.

The nonescape clause of Definition 3888.2 then excludes quotient equality, selected limits, host equality, choice, ambient completeness, and detached second completion data from all such consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionIdempotence}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionIdempotence}^{\uparrow}$ packet is generated from a MetricCompletionUp row, a SeparatedCompletionUp boundary row, a CompleteMetricUp or CompleteSeparatedMetricUp service row, a UniformCompletionUp compatibility row, a repeated-completion readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionIdempotence}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 3888.1, Definition 3888.2, Definition 3888.3, and Definition 3888.4 close the obligation surface for repeated metric completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionIdempotence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MetricCompletionIdempotenceUp.MetricCompletionIdempotenceTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close arbitrary completion monad laws, global reflection theorems, quotient completion equality, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires explicit downstream dependency scope for completion-functor, regular-rational, and real-completion consumers of BEDC.Derived.MetricCompletionIdempotenceUp.

Chapter 2914

A Concrete Naming Certificate for MetaCICFuelTrace$^{\uparrow}$

The MetaCICFuelTrace$^{\uparrow}$ packet realizes the bounded-normalizer side of chapter 9379 as finite NameCert data. It sits beside the decidable typing frontier of chapter 3616, the bounded normal-equality checker of chapter 752, the MetaCIC decidability witness of chapter 751, and the local diamond witness of chapter 3595. The packet names bounded normalizer fuel, finished-normalization evidence, equality-check rows, refusal rows, transport, replay, provenance, and local NameCert data without promoting bounded conversion into global normalization, subject reduction, confluence, or unrestricted beta-conversion decidability.

Falsifiable prediction: Every accepted MetaCICFuelTrace$^{\uparrow}$ packet displays a finite fuel row, bounded normalizer input and output rows, finished-normalization evidence when available, a `Term.eq` or `checkSameTerm` equality-check row, a `decideClosedBetaConv` readback row, a refusal row for global conversion claims, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: metacic-decidable-typing-frontier, bounded-normal-equality-checker, typed-normal-form-decider, metacicdecidableboundary, metacic-local-diamond-witness: the typing frontier records checker admission, the bounded-normal-equality checker records comparison exactness, the typed normal-form decider records typed endpoint conditions, the decidability boundary records broader refusal data, and the local diamond witness records join obligations. None supplies the finite fuel trace packet with both explicit fuel rows and replayable finished-normalization evidence.

Definition 2914.1 (MetaCIC fuel trace carrier)**.** *A* MetaCICFuelTrace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, I, O, E, Q, B, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the bounded fuel row used by* `normalizeBounded` *and* `decideClosedBetaConv`*.*
2. *I records the represented closed-term inputs and the typing or closedness hypotheses that the decidability audit map allows this packet to consume.*
3. *O records the bounded normalizer outputs produced at fuel F.*
4. *E records finished-normalization evidence when the audit map supplies it, and records an explicit absent row when such evidence is not available.*

5. *Q is the structural equality-check row, read through* `Term.eq` *or* `checkSameTerm` *on the bounded outputs.*
6. *B is the* `decideClosedBetaConv` *readback row, interpreted only as bounded normal equality under the displayed fuel and endpoint evidence.*
7. *R is the refusal row excluding global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, and host quotient equality of terms.*
8. *H records componentwise* hsame *transport for the fuel, input, output, endpoint, equality-check, bounded-conversion, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a decidability request through $F, I, O, E, Q, B, R, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICFuelTrace}^{\uparrow}$*, the MetaCIC decidability audit map,* MetaCICDecidableTypingF BoundedNormalEqualityChecker$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICFuelTrace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a fuel-erased global normalizer, a subject-reduction theorem, a confluence theorem, an arbitrary closedness decider, unrestricted beta-conversion decidability, or host quotient equality of represented terms.

Theorem 2914.2 (MetaCIC fuel trace NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICFuelTrace}^{\uparrow}$ *carrier $T = (F, I, O, E, Q, B, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICFuelTrace}^{\uparrow}}$ *surface consists exactly of fuel admission through F, represented-input admission through I, bounded normalizer output through O, finished-normalization evidence through E, structural equality checking through Q, bounded beta-conversion readback through B, refusal through R, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through N.*

Later Lean TasteGate work in BEDC.Derived.MetaCICFuelTraceUp.TasteGate *must provide* Nontrivial *and* FieldFaithful *instances for this carrier surface. These instances must show that the packet cannot collapse to an empty fuel marker and cannot hide a missing fuel, input, output, finished-normalization, equality-check, bounded-conversion, refusal, transport, replay, provenance, or naming row.*

Proof. Project the carrier of Definition 3889.1. The computational side is F, I, O: a displayed fuel value, represented inputs, and the bounded normalizer outputs obtained at that fuel.

Read E before the conversion result. If finished-normalization evidence is available, it is displayed here; if not, the absent row keeps the bounded comparison from becoming a global normalization theorem.

The equality rows Q, B then compare only the bounded outputs. They are interpreted through the structural equality and `decideClosedBetaConv` rows named by the decidability audit map.

The refusal row R blocks global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, and host quotient equality. Finally H, C, P, N transport, replay, record provenance for, and locally name the same fuel trace. □

Lean4 ✓ `BEDC.Derived.MetaCICFuelTraceUp.MetaCICFuelTraceTasteGate single carrier alignment`

Theorem 2914.3 (MetaCIC fuel trace bounded-conversion nonescape)**.** *Every consumer of an accepted* $\mathsf{MetaCICFuelTrace}^{\uparrow}$ *packet factors through the finite route*

$$F, I, O, E, Q, B \longmapsto R, H, C, P, N.$$

The route exports bounded normalizer outputs, optional finished-normalization evidence, and bounded equality-check readback at the displayed fuel. It exports no fuel-erased global normalization theorem, no subject-reduction theorem, no confluence theorem, no arbitrary closedness decider, no unrestricted beta-conversion oracle, and no host quotient equality of represented terms.

Proof. Start with an accepted carrier $T = (F, I, O, E, Q, B, R, H, C, P, N)$. Rows F, I, O expose the finite computation trace rather than a theorem about all possible fuels.

The endpoint row E is read before the equality-check rows. This preserves the distinction made in chapter 9379: bounded normal equality becomes a finished-normal-form statement only when finished evidence is part of the packet.

Rows Q and B compare the displayed bounded outputs. The refusal row R is then read before transport, replay, provenance, and naming finish the packet.

Because the carrier has no coordinate for stronger metatheory, no consumer can reinterpret the bounded fuel trace as global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, or quotient equality. □

Theorem 2914.4 (MetaCIC fuel trace audit scope)**.** *The* $\mathsf{MetaCICFuelTrace}^{\uparrow}$ *packet concretizes the normal-equality edge of the decidability audit map at finite fuel. It may be consumed by typing-frontier and bounded-normal-equality chapters as a replayable trace of bounded normalizer computation and finished endpoint evidence, but it does not close the global MetaCIC normalization, confluence, subject-reduction, or closedness-decidability problems.*

Proof. Use Definition 3889.2 to identify the local rows. The packet contains exactly the finite fuel, input, output, endpoint, equality-check, bounded-conversion, refusal, and structural rows.

For typing-frontier consumers, the input row I and equality rows Q, B align with the checked typing and structural equality surfaces, but the trace still carries a fixed fuel row F.

For bounded-normal-equality consumers, the output and endpoint rows O, E provide the replayable evidence required by finished-normalization consequences. They do not supply a fuel-erased endpoint theorem for all closed terms.

The nonescape theorem Definition 3889.3 then blocks the stronger global readings. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICFuelTrace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICFuelTrace}^{\uparrow}$ packet is generated from bounded fuel, represented inputs, bounded normalizer outputs, finished-normalization evidence or its explicit absence, structural equality checks, bounded beta-conversion readback, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICFuelTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3889.1, Definition 3889.2, and Definition 3889.3 seed the finite fuel-trace boundary for MetaCIC bounded normal equality.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICFuelTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, host quotient equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, fuel-output exactness, finished-normalization evidence handling, equality-check readback, bounded-conversion nonescape, TasteGate Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICFuelTraceUp.

Chapter 2915

A Concrete Naming Certificate for $\mathsf{CauchyStructure}^{\uparrow}$

Following Bourbaki and Kelley on Cauchy structures and Bishop–Bridges on constructive completion, the $\mathsf{CauchyStructure}^{\uparrow}$ packet names the finite criterion surface where Cauchy filters and Cauchy nets are read through stream windows, regular rational readback, dyadic tolerances, and a terminal real seal. It is grounded in the StreamName route of chapter 126, the regular sequence route of chapter 301, the real seal of chapter 38, the Cauchy-filter surface of chapter 333, the Cauchy-net surface of chapter 589, and the dyadic tolerance ledger of chapter 291.

Definition 2915.1 (Cauchy structure carrier)**.** *A* $\mathsf{CauchyStructure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, G, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the filter-base request row naming the finite family of Cauchy-filter requests accepted from chapter 333;*
2. *G is the net-directed request row naming the finite family of directed Cauchy-net requests accepted from chapter 589;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by both filter-base and net-directed requests;*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window inspected by every request before regular readback;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream window and dyadic ledger;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the displayed readback route;*
7. *H is componentwise* hsame *transport across F, G, D, S, R, E;*
8. *C is displayed* Cont *replay from each filter-base or net-directed request through D, S, R, E;*
9. *P is* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyStructure}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyStructureUp.CauchyStructureTasteGate single carrier alignment`

Theorem 2915.2 (Cauchy structure NameCert obligations)**.** *For the carrier of Definition 3890.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyStructure}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (F, G, D, S, R, E, H, C, P, N)$*, filter-base request exposure through* F*, net-directed request exposure through* G*, dyadic tolerance exposure through* D*, finite StreamName window exposure through* S*, RegSeqRat readback through* R*, Real seal handoff through* E*, transport through* H*, replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier row by row. The filter-base and net-directed requests are the two input faces, and both are read only through the same dyadic tolerance ledger, StreamName window, regular rational readback, and Real seal route.

Transport and replay are structural rows. The transport row compares the displayed request, tolerance, window, readback, and seal coordinates componentwise; the replay row orders every request through D, S, R, E before a consumer may read the result.

The package provenance and local NameCert row name exactly this finite packet. Since the carrier contains no other coordinate, the listed rows are precisely the NameCert obligations. □

Theorem 2915.3 (Cauchy structure filter-net criterion)**.** *Every accepted* $\mathsf{CauchyStructure}^{\uparrow}$ *route orders filter-base and net-directed Cauchy reads through the same finite criterion sequence*

$$F, G \longmapsto D \longmapsto S \longmapsto R \longmapsto E.$$

A filter-facing consumer and a net-facing consumer therefore meet at the displayed dyadic tolerance ledger, StreamName window, RegSeqRat readback, and Real seal; neither route may replace that finite sequence by quotient filters, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the filter direction, project the F row and follow its replay row. The replay first opens the dyadic tolerance ledger D, then the finite StreamName window S, then the RegSeqRat readback R, and only then the Real seal E.

For the net direction, project the G row and use the same replay ordering. Directed requests may change the source face, but they do not introduce a new tolerance, window, readback, or seal coordinate outside D, S, R, E.

The componentwise transport row H identifies admissible changes only along the displayed coordinates, while P and N record provenance and local naming. Thus the common filter-net criterion is the finite route above, with no quotient, choice, trichotomy, selected-limit, or ambient-completeness bypass. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyStructure}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyStructure}^{\uparrow}$ packet is generated from filter-base requests, net-directed requests, dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyStructure}^{\uparrow}}$, seed)

Scope closed: Definition 3890.1, Definition 3890.2, and Definition 3890.3 bind the finite L10 criterion surface connecting Cauchy filters and Cauchy nets to StreamName, RegSeqRat, DyadicRatCore, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyStructure}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyStructureUp.CauchyStructureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exposure, finite route ordering, and consumer nonescape for BEDC.Derived.CauchyStructureUp.

The $\mathsf{UniformContinuityComposition}^{\uparrow}$ hub routes composition through chapter 130, chapter 369, and the downstream compact-uniform-continuity consumer while the certificate body remains in the sibling files.

Chapter 2916

A Concrete Naming Certificate for $\mathsf{UniformContinuityComposition}^{\uparrow}$

Following Bishop and Bridges on constructive uniformly continuous maps, the $\mathsf{UniformContinuityComposition}^{\uparrow}$ packet records the finite route by which the composite of two uniformly continuous maps receives a displayed modulus. It sits after the continuous-map carrier of chapter 130, the uniform-modulus surface of chapter 369, the metric-space route of chapter 57, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet supplies downstream compact-uniform-continuity and completion-extension certificates with a reusable finite composition certificate; it does not import a host function space, selected moduli, quotient equality of maps, countable choice, or ambient completeness.

The composed-modulus row is a direct sibling input for the compact-uniform-continuity certificate of chapter 388, where finite compact-source moduli may consume composition without re-reading a host function-space theorem.

The $\mathsf{CompactUniformContinuity}^{\uparrow}$ consumer link is available only after the two $\mathsf{ContinuousMap}^{\uparrow}$ rows F, G and the two $\mathsf{UniformModulus}^{\uparrow}$ rows M_F, M_G have been displayed on the same composed-modulus route.

The composed-modulus row therefore consumes exactly the two $\mathsf{ContinuousMap}^{\uparrow}$ rows of chapter 130 and the two $\mathsf{UniformModulus}^{\uparrow}$ rows of chapter 369 before chapter 388 may read it.

Before the compact route of chapter 388 may reuse the composite certificate, the row M must consume the finite tolerance-to-precision ledger of chapter 369 through M_G and then M_F. Thus the sibling edge records an ordered ledger read M_G, M_F, M, not a detached compactness theorem or a hidden modulus selector.

Definition 2916.1 (Uniform continuity composition carrier)**.** *A* $\mathsf{UniformContinuityComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, Z, F, G, M_F, M_G, M, H, C, P, N)$$

with the following displayed rows:

1. *X, Y, Z are the source, middle, and target* $\mathsf{Met}^{\uparrow}$ *rows. They provide the only metric contexts in which the two maps and the composite are read.*
2. *F is the first* $\mathsf{ContinuousMap}^{\uparrow}$ *row, displayed from X to Y.*
3. *G is the second* $\mathsf{ContinuousMap}^{\uparrow}$ *row, displayed from Y to Z.*

4. *M_F is the* $\mathsf{UniformModulus}^{\uparrow}$ *row for F, reading target tolerances in Y and returning source tolerances in X.*
5. *M_G is the* $\mathsf{UniformModulus}^{\uparrow}$ *row for G, reading target tolerances in Z and returning middle tolerances in Y.*
6. *M is the composed modulus row. A requested tolerance in Z is first sent to M_G, and the resulting tolerance in Y is then sent to M_F.*
7. *H records componentwise* hsame *transport for the metric, map, modulus, composite-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a composite-map request through G, M_G, F, M_F, and the composed modulus row M.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformContinuityComposition}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformContinuityComposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, Z, F, G, M_F, M_G, M, H, C, P, N$. It has no coordinate for host-level function equality, selected moduli, a quotient function space, countable choice, an ambient completion theorem, or hidden real equality.

Theorem 2916.2 (Uniform continuity composition NameCert obligations)**.** *For every accepted* $\mathsf{UniformContinuityComposition}^{\uparrow}$ *carrier*

$$K = (X, Y, Z, F, G, M_F, M_G, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformContinuityComposition}^{\uparrow}}$ *surface consists exactly of the following obligation families:*

1. *metric-context admission for X, Y, Z;*
2. *continuous-map admission for $F : X \to Y$ and $G : Y \to Z$ through the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *rows;*
3. *modulus admission for M_F and M_G through the displayed* $\mathsf{UniformModulus}^{\uparrow}$ *rows;*
4. *composed-modulus exactness for M, requiring each target tolerance in Z to be routed first through M_G and then through M_F;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

Consequently the accepted packet exports the constructive composition law for uniformly continuous maps only as finite BEDC data over the displayed rows. It does not export host-level function equality, selected moduli, quotient function spaces, countable choice, ambient completion, or hidden real equality.

Proof. Project the carrier of Definition 3891.1. The visible rows are exactly the three metric contexts, the two continuous maps, the two input moduli, the composed modulus, and the structural rows H, C, P, N.

The map side is read first. The rows F and G are continuous-map packets over the displayed metric contexts X, Y, Z, so a composite request has no map coordinate except the ordered route $X \xrightarrow{F} Y \xrightarrow{G} Z$.

The modulus side is downstream from the requested target tolerance. The row M_G converts a Z-tolerance into a Y-tolerance, and M_F converts that Y-tolerance into an X-tolerance. The row M records exactly this two-stage route.

Finally, H, C, P, N preserve componentwise comparison, replay the displayed request route, record provenance, and name the local certificate. Since the excluded analytic objects are not coordinates of K, the five listed obligation families exhaust the NameCert surface. □

Theorem 2916.3 (Uniform continuity composition modulus factorization)**.** *Every composed-modulus read accepted by a* $\mathsf{UniformContinuityComposition}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Met}^{\uparrow}(X, Y, Z), \quad \mathsf{ContinuousMap}^{\uparrow}(F), \quad \mathsf{UniformModulus}^{\uparrow}(M_F), \quad \mathsf{ContinuousMap}^{\uparrow}(G), \quad \mathsf{UniformModulus}^{\uparrow}(M_G),$$

Equivalently, a consumer that asks for a modulus of $G \circ F$ must first read the target tolerance through the G-modulus, then read the resulting middle tolerance through the F-modulus, and only then may expose the composite row M through H, C, P, N. No separate host composition theorem, selected modulus, quotient map equality, countable-choice selector, or ambient completeness coordinate is exported by the packet.

Proof. Begin with a consumer request for a modulus of the composite. Carrier admission supplies the metric contexts X, Y, Z and the two displayed map rows F, G, so the request is already confined to the finite route through the two continuous-map packets.

Read the second modulus before the first. A target tolerance for the composite is a Z-side request, so M_G is the first modulus row that can answer it. The answer is a displayed Y-side tolerance, not a selected global modulus or a host theorem.

Now read M_F. The Y-side tolerance returned by M_G becomes the input request for the first map, and M_F returns the source tolerance in X. The composite row M is exact because it stores no further tolerance coordinate beyond this two-step read.

The stream, regular-rational, and real rows appear only as observation and seal rows for the same finite route. The structural rows H, C, P, N transport, replay, source, and name that route, so there is no insertion point for quotient map equality, a choice-selected modulus, or an ambient completeness principle. □

Theorem 2916.4 (Uniform continuity composition L10 handoff)**.** *For accepted* $\mathsf{UniformContinuityComposition}^{\uparrow}$ *packets over the same displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, composition factors only through the stored modulus rows M_F, M_G, M and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *routes. The handoff exports no host function equality, selected modulus, quotient function space, hidden completion, countable-choice selector, or ambient real equality.*

Proof. Use the carrier definition of Definition 3891.1. The displayed rows fix the metric contexts, continuous-map rows, stored input moduli, composed modulus, transport, replay, provenance, and local naming.

The NameCert obligations of Definition 3891.2 force each composite request through the two continuous-map rows and the modulus rows. No external function-space equality is part of the obligation surface.

The modulus factorization theorem Definition 3891.3 gives the L10 order: a target tolerance is sent through M_G, the returned middle tolerance is sent through M_F, and the composed row M records exactly that finite route.

Finally H, C, P, N preserve the same route over the displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. Since the excluded host objects have no coordinate in the carrier, the handoff is finite and classifier-based. □

Theorem 2916.5 (Uniform continuity composition sibling route)**.** *Every* CompactUniformContinuity$^{\uparrow}$ *consumer of chapter 388, and every completion-extension consumer using the same* UniformContinuityComposition$^{\uparrow}$ *packet, must first expose the two* ContinuousMap$^{\uparrow}$ *rows* F, G*, the two* UniformModulus$^{\uparrow}$ *rows* M_F, M_G*, the composed modulus row* M*, the source, middle, and target* Met$^{\uparrow}$ *rows* X, Y, Z*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The sibling route exports no host function-space theorem, selected modulus, quotient map equality, countable-choice selector, or ambient completion principle.*

Proof. Project the carrier of Definition 3891.1. Its visible analytic rows are precisely $X, Y, Z, F, G, M_F, M_G, M$, with H, C, P, N carrying transport, replay, provenance, and naming.

Apply Definition 3891.3. A compact-uniform-continuity or completion-extension request cannot read the composed modulus until the target tolerance has passed through M_G and the returned middle tolerance has passed through M_F.

Use the L10 handoff of Definition 3891.4. The handoff keeps the same rows inside the displayed Met$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ route, so the consumer edge into chapter 388 is a numbered sibling route rather than a detached host theorem. Since the excluded objects are absent from the carrier, they cannot be exported by the route. □

Theorem 2916.6 (Uniform continuity composition compact-modulus consumer)**.** *Every* CompactUniformContinuit *or compact-modulus consumer of an accepted* UniformContinuityComposition$^{\uparrow}$ *packet enters through chapter 388 only after reading the source, middle, and target* Met$^{\uparrow}$ *rows, the two* ContinuousMap$^{\uparrow}$ *rows* F, G*, the two* UniformModulus$^{\uparrow}$ *rows* M_F, M_G*, the composed modulus row* M*, and then the* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* NameCert *routes. The consumer receives no host function-space theorem, no selected modulus, no quotient map equality, no hidden compactness theorem, and no ambient completion principle.*

Proof. Start with the carrier of Definition 3891.1. Its visible analytic coordinates are exactly $X, Y, Z, F, G, M_F, M_G, M$, followed by the structural rows H, C, P, N.

Apply the NameCert obligations of Definition 3891.2. They force the compact-modulus request to pass through the two displayed maps F, G and the two displayed input moduli M_F, M_G before the composed modulus row is available.

Use the modulus factorization theorem Definition 3891.3. The compact consumer first sends the requested target tolerance through M_G, then sends the resulting middle tolerance through M_F, and only then reads the composed modulus row M.

Finally apply the L10 handoff of Definition 3891.4. The observation and seal rows StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ are downstream of the same finite route, and H, C, P, N preserve it. Thus the consumer edge into chapter 388 is a displayed lattice edge from the two map rows and two modulus rows, not a hidden compactness theorem. Since the excluded objects have no carrier coordinate, the compact-modulus consumer cannot obtain them from the packet. □

Theorem 2916.7 (Uniform continuity composition ContinuousMap route)**.** *Every compact-modulus or completion-extension consumer of an accepted* UniformContinuityComposition$^{\uparrow}$ *packet must first consume the two displayed* ContinuousMap$^{\uparrow}$ *rows* F, G *of chapter 130 together with their* UniformModulus$^{\uparrow}$ *rows* M_F, M_G *before it can read the composed modulus row used by chapter 388. The route exposes no host function-space theorem, quotient map equality, selected modulus, hidden compactness theorem, countable-choice selector, or ambient completion principle.*

Proof. Start from the NameCert obligations. They list continuous-map admission for $F : X \to Y$ and $G : Y \to Z$ and modulus admission for M_F and M_G as separate displayed rows before any composed modulus can be consumed.

Apply modulus factorization and the L10 handoff. A target tolerance is routed through M_G and then M_F, and the resulting composed row remains inside the finite $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff.

Finally use the compact-modulus consumer theorem. Since that consumer already has to read $X, Y, Z, F, G, M_F, M_G, M, H, C, P, N$, the dependency on ContinuousMap and CompactUniformContinuity is recorded as the displayed sibling route rather than as a kernel-only packet or host theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContinuityComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformContinuityComposition}^{\uparrow}$ packet is generated from source, middle, and target MetricSpace rows, two ContinuousMap rows, two UniformModulus rows, a composed modulus row, StreamName and RegSeqRat observation rows, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformContinuityComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3891.1, Definition 3891.2, and Definition 3891.3 seed the finite constructive composition route over ContinuousMap, UniformModulus, MetricSpace, StreamName, RegSeqRat, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformContinuityComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host-level function equality, selected moduli, quotient function spaces, countable choice, ambient completion, or hidden real equality.

Upgrade path: Obligation closure requires checked metric-context admission, continuous-map admission, modulus admission, composed-modulus exactness, observation routing, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.UniformContinuityCompositionUp.

Theorem 2916.8 (Uniform continuity composition sibling dependency route)**.** *Every accepted* $\mathsf{UniformContinuityComposition}^{\uparrow}$ *read that exposes the composed modulus row must first consume the two* $\mathsf{ContinuousMap}^{\uparrow}$ *routes of chapter 130 and the two* $\mathsf{UniformModulus}^{\uparrow}$ *routes of chapter 369. The handoff reaches the composed row only through the displayed* F, G, M_F, M_G *coordinates and the structural* H, C, P, N *route; it exports no kernel-only composition fact, host function-space theorem, quotient map equality, selected modulus, countable-choice selector, or ambient completion principle.*

Proof. Start with the carrier of Definition 3891.1. Its analytic input rows are exactly the three metric contexts, the two continuous-map rows F, G, the two input modulus rows M_F, M_G, and the composed modulus row M.

Apply the NameCert obligations of Definition 3891.2. They make continuous-map admission and modulus admission separate displayed obligations before the composed row can be read.

Finally use the modulus factorization route of Definition 3891.3. A target tolerance enters through the G-modulus and then the F-modulus, so the sibling chapters supply the exact dependency route rather than a hidden host theorem. □

Chapter 2917

A Concrete Naming Certificate for $\mathsf{HadamardThreeCircle}^{\uparrow}$

Following Hadamard's three-circle theorem and the classical complex-analysis reading of maximum-modulus bounds on annuli, the $\mathsf{HadamardThreeCircle}^{\uparrow}$ packet records a finite annulus ledger whose radius reads, boundary maxima, and logarithmic-convexity row are all displayed before a holomorphic-boundary consumer may read a bound. It sits over the complex carrier of chapter 39, the circle boundary surface of chapter 58, the Real seal of chapter 38, the holomorphic carrier of chapter 68, the finite integral row of chapter 123, and the metric annulus packet of chapter 3371. The chapter names the finite three-radius certificate only; it does not assert an ambient analytic continuation theorem, a selected maximizer, quotient function equality, or a bridge certificate.

Definition 2917.1 (Hadamard three-circle carrier)**.** *A* $\mathsf{HadamardThreeCircle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, F, R_0, R_1, R_2, B, M, L, Hs, C, P, N)$$

with the following displayed rows:

1. *A is the displayed annulus row, read through* $\mathsf{MetricAnnulus}^{\uparrow}$ *and carrying the two boundary circles and the inspected middle radius.*
2. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *map row over the annulus, with values in the* $\mathsf{Complex}^{\uparrow}$ *carrier.*
3. *R_0, R_1, R_2 are the three positive* $\mathsf{Real}^{\uparrow}$ *radius reads, ordered by the annulus row and sealed before any maximum row is consumed.*
4. *B is the boundary-circle readback row, using* $\mathsf{S}^{1\uparrow}$ *to expose the inner, middle, and outer circle probes.*
5. *M is the maximum-modulus row for the displayed boundary reads, recording only finite upper-bound data on the inspected circles.*
6. *L is the logarithmic-convexity ledger tying the three radius reads and the corresponding maximum-modulus rows to a single finite inequality certificate.*
7. *Hs records componentwise* hsame *transport for the annulus, holomorphic map, radius reads, boundary reads, maximum rows, logarithmic-convexity ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an annulus-bound request through $A, F, R_0, R_1, R_2, B, M, L, Hs$.*

9. *P is the* Pkg *provenance over* $\mathsf{HadamardThreeCircle}^{\uparrow}$, $\mathsf{MetricAnnulus}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HadamardThreeCircle}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a host supremum theorem, an uninspected boundary point, a selected maximizer, quotient function equality, analytic continuation outside the annulus, or countable choice.

Lean4 ✓ `BEDC.Derived.HadamardThreeCircleUp.HadamardThreeCircleTasteGate single carrier alignment`

Theorem 2917.2 (Hadamard three-circle NameCert obligations)**.** *For every accepted* $\mathsf{HadamardThreeCircle}^{\uparrow}$ *carrier* $H = (A, F, R_0, R_1, R_2, B, M, L, Hs, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HadamardThreeCircle}^{\uparrow}}$ *surface is exhausted by annulus admission, holomorphic-map exposure, three sealed radius reads, boundary-circle readback, maximum-modulus rows, logarithmic-convexity ledger compatibility, componentwise transport, displayed replay, provenance, and local naming. A consumer of the packet may not infer an ambient maximum principle, a selected extremal point, analytic continuation, quotient function equality, or any infinite covering principle from the local certificate.*

Proof. Project the carrier of Definition 3892.1. The rows A, F, R_0, R_1, R_2 display the annulus, the holomorphic map, and the three radius reads before a bound can be consumed.

The boundary computation is then finite. The row B exposes the inspected $\mathsf{S}^{1\uparrow}$ circle probes, M records the corresponding maximum-modulus upper-bound rows, and L binds those rows to the logarithmic-convexity ledger for the same three radii.

Finally the structural rows Hs, C, P, N transport, replay, cite provenance, and name that same finite route. Since none of these rows adds a host supremum theorem, a selected maximizer, an uninspected boundary point, analytic continuation, quotient equality, or countable choice, the listed obligations exhaust the local NameCert surface. □

Theorem 2917.3 (Hadamard annulus maximum handoff)**.** *Every holomorphic-boundary consumer of an accepted* $\mathsf{HadamardThreeCircle}^{\uparrow}$ *carrier factors through*

$$\mathsf{MetricAnnulus}^{\uparrow} \longmapsto \mathsf{Holomorphic}^{\uparrow} \longmapsto \mathsf{Complex}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Integral}^{\uparrow}$$

together with the displayed rows $A, F, R_0, R_1, R_2, B, M, L, Hs, C, P, N$. The handoff exports a finite three-radius annulus ledger and its logarithmic-convexity certificate, not a global maximum-modulus theorem or an ambient analytic object outside the displayed annulus.

Proof. Start from the annulus row. The packet reads the displayed $\mathsf{MetricAnnulus}^{\uparrow}$ data A and the $\mathsf{Holomorphic}^{\uparrow}$ map row F before any boundary maximum is available.

Next seal the radius and boundary rows. The three $\mathsf{Real}^{\uparrow}$ reads R_0, R_1, R_2 determine the inspected circles, and B turns those circles into finite $\mathsf{S}^{1\uparrow}$ boundary probes over the same annulus.

The maximum handoff is then local. The row M records the finite boundary upper bounds, while L ties them to the logarithmic-convexity inequality for the same radii. The $\mathsf{Integral}^{\uparrow}$ dependency is consumed only as a displayed finite contour or averaging row, not as an ambient selection principle.

The transport and naming rows Hs, C, P, N preserve this route. Therefore a consumer receives exactly the finite annulus ledger and no global maximum principle, selected extremal point, analytic continuation coordinate, quotient equality, or infinite covering data. □

Theorem 2917.4 (Hadamard three-circle maximum-modulus boundary)**.** *Let $H = (A, F, R_0, R_1, R_2, B, M, L, Hs,$ be an accepted* $\mathsf{HadamardThreeCircle}^{\uparrow}$ *carrier. If the inner and outer boundary maximum ledgers in M display the same* $\mathsf{Real}^{\uparrow}$ *modulus row, then the middle-radius bound classified by L is read through that same displayed boundary modulus row. The conclusion uses only the finite annulus ledger, the* $\mathsf{Real}^{\uparrow}$ *modulus reads, and the* $\mathsf{Holomorphic}^{\uparrow}$ *source rows; it does not select a maximizer, add ambient analytic continuation, or import a host maximum-modulus theorem.*

Proof. Start with Definition 3892.3. It forces every holomorphic-boundary read to pass through the annulus row A, holomorphic row F, radius reads R_0, R_1, R_2, boundary probes B, maximum rows M, and logarithmic-convexity ledger L.

Read the hypothesis inside M. The inner and outer boundary maximum ledgers display the same $\mathsf{Real}^{\uparrow}$ modulus row, so the two endpoint values supplied to the logarithmic-convexity ledger are the same boundary datum.

The ledger L then classifies the middle-radius bound using that displayed endpoint row. Since the route is still the finite annulus route named by $A, F, R_0, R_1, R_2, B, M, L$, the conclusion has no coordinate from which to select an extremal point or extend the holomorphic source.

Finally Hs, C, P, N transport, replay, source, and name the same certificate. They preserve the finite boundary-modulus read and do not add ambient analytic continuation, quotient function equality, or a host maximum-modulus principle. □

Theorem 2917.5 (Hadamard three-circle annulus route)**.** *Every accepted* $\mathsf{HadamardThreeCircle}^{\uparrow}$ *annulus-bound consumer factors first through*

$$\mathsf{MetricAnnulus}^{\uparrow} \longmapsto \mathsf{Holomorphic}^{\uparrow} \longmapsto \mathsf{Complex}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Integral}^{\uparrow}$$

and then through the displayed rows $A, F, R_0, R_1, R_2, B, M, L, Hs, C, P, N$. This route exports only the finite annulus ledger, holomorphic source row, complex value carrier, circle boundary probes, real radius and modulus reads, integral averaging surface, maximum-modulus boundary rows, logarithmic-convexity ledger, transport, replay, provenance, and local name. It excludes selected maximizers, global maximum principles, analytic continuation beyond the annulus, quotient function equality, infinite covers, and bridge certificates.

Proof. Apply the annulus maximum handoff of Definition 3892.3. It already orders the cross-chapter surfaces as $\mathsf{MetricAnnulus}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Integral}^{\uparrow}$, and it exposes the same rows $A, F, R_0, R_1, R_2, B, M, L, Hs, C, P, N$ before any annulus-bound read is consumed.

Apply the boundary theorem of Definition 3892.4 to the maximum-modulus part of the route. The boundary theorem keeps the middle-radius conclusion inside the displayed boundary-modulus row and the finite logarithmic-convexity ledger, so the composed route has no coordinate for a selected maximizer, an ambient maximum principle, analytic continuation outside the annulus, quotient equality, an infinite cover, or a bridge certificate. □

Falsifiable prediction: An accepted $\mathsf{HadamardThreeCircle}^{\uparrow}$ read is refuted if the logarithmic-convexity row L is preserved while the displayed annulus row A, holomorphic map row F, sealed radii R_0, R_1, R_2, boundary-circle row B, and maximum-modulus row M are removed.

Independence witness: complex, sone, real, holomorphic, integral, metric-annulus: none is bijective with $\mathsf{HadamardThreeCircle}^{\uparrow}$ because the packet jointly carries annulus rows, holomorphic map rows, three sealed radius reads, boundary circle probes, maximum-modulus rows, a logarithmic-convexity ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardThreeCircle}^{\uparrow}}$.

Constructive story: A $\mathsf{HadamardThreeCircle}^{\uparrow}$ packet is generated from a displayed annulus, a holomorphic map row, three Real radius reads, boundary circle probes, maximum-modulus rows, a logarithmic-convexity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardThreeCircle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3892.1, Definition 3892.2, and Definition 3892.3 seed the finite annulus ledger for three-circle maximum-modulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardThreeCircle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global maximum-modulus theorem, selected extremal points, analytic continuation beyond the annulus, quotient function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked annulus admission, holomorphic-map exposure, three-radius ordering, boundary-circle readback, maximum-modulus rows, logarithmic-convexity compatibility, and structural transport for BEDC.Derived.HadamardThreeCircleUp.

Chapter 2918

A Concrete Naming Certificate for $\mathsf{HadamardThreeLines}^{\uparrow}$

Following Hadamard's three-lines theorem and the Riesz-Thorin style reading of holomorphic strip estimates, the $\mathsf{HadamardThreeLines}^{\uparrow}$ packet records a finite vertical-strip ledger whose boundary-line reads, interior height read, and logarithmic-convexity bound are all displayed before a strip-bound consumer may read an estimate. It sits beside the annular packet of chapter 3892, over the holomorphic carrier of chapter 68, the complex carrier of chapter 39, the Real seal of chapter 38, the finite integral row of chapter 123, and the metric annulus packet of chapter 3371. The chapter names the finite strip-bound certificate only; it does not collapse strip geometry into an annulus certificate, assert host supremum selection, or add a bridge certificate.

Definition 2918.1 (Hadamard three-lines carrier)**.** *A* $\mathsf{HadamardThreeLines}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, F, Y_0, Y_1, Y, B, M, E, Hs, C, P, N)$$

with the following displayed rows:

1. *S is the displayed vertical-strip row, exposing the two boundary lines and the inspected interior line.*
2. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *map row on the strip, with values in the* $\mathsf{Complex}^{\uparrow}$ *carrier.*
3. *Y_0, Y_1, Y are the two boundary-height* $\mathsf{Real}^{\uparrow}$ *reads and the inspected interior-height* $\mathsf{Real}^{\uparrow}$ *read, ordered by the strip row before any bound is consumed.*
4. *B is the boundary-line readback row, exposing the finite probes on the two boundary lines and the requested interior line.*
5. *M is the finite boundary-majorant row, recording only displayed upper-bound data for the boundary reads.*
6. *E is the logarithmic-convexity estimate row tying Y_0, Y_1, Y and M to a single finite strip-bound certificate.*
7. *Hs records componentwise* hsame *transport for the strip row, holomorphic map row, height reads, boundary reads, majorant row, estimate row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a strip-bound request through $S, F, Y_0, Y_1, Y, B, M, E, Hs$.*
9. *P is the* Pkg *provenance over* $\mathsf{HadamardThreeLines}^{\uparrow}$, $\mathsf{HadamardThreeCircle}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{MetricAnnulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{HadamardThreeLines}^\uparrow}$ *row.*
The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient function equality, a selected boundary supremum, an unbounded strip limit, countable choice, ambient Real completeness, or an annulus replacement of the strip route.

Lean4 ✓ `BEDC.Derived.HadamardThreeLinesUp.HadamardThreeLinesTasteGate single carrier alignment`

Theorem 2918.2 (Hadamard three-lines NameCert obligations)**.** *For every accepted* $\mathsf{HadamardThreeLines}^\uparrow$ *carrier* $L = (S, F, Y_0, Y_1, Y, B, M, E, Hs, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HadamardThreeLines}^\uparrow}$ *surface is exhausted by strip admission, holomorphic-map exposure, two boundary-height reads, one interior-height read, boundary-line readback, finite boundary-majorant rows, logarithmic-convexity estimate compatibility, componentwise transport, displayed replay, provenance, and local naming. A consumer of the packet may not infer quotient function equality, host function extensionality, selected boundary suprema, unbounded strip limiting, countable choice, ambient* $\mathsf{Real}^\uparrow$ *completeness, or a collapse into* $\mathsf{HadamardThreeCircle}^\uparrow$*.*

Proof. Project the carrier of Definition 3893.1. The rows S, F, Y_0, Y_1, Y display the strip, the holomorphic map, and the three height reads before an estimate can be consumed.

The boundary computation is finite. The row B exposes the inspected boundary-line probes, M records their finite majorant data, and E binds those rows to the logarithmic-convexity estimate for the same boundary and interior heights.

Finally the structural rows Hs, C, P, N transport, replay, cite provenance, and name that same finite route. Since none of these rows adds quotient function equality, host extensionality, selected suprema, an unbounded limiting principle, countable choice, ambient Real completeness, or an annulus replacement coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 2918.3 (Hadamard three-lines strip-bound route)**.** *Every strip-bound consumer of an accepted* $\mathsf{HadamardThreeLines}^\uparrow$ *carrier factors through*

$$\mathsf{Holomorphic}^\uparrow \longmapsto \mathsf{Complex}^\uparrow \longmapsto \mathsf{Real}^\uparrow \longmapsto \mathsf{Integral}^\uparrow$$

together with the displayed rows $S, F, Y_0, Y_1, Y, B, M, E, Hs, C, P, N$*. The route exports a finite vertical-strip ledger and its logarithmic-convexity estimate, not the annulus ledger of* $\mathsf{HadamardThreeCircle}^\uparrow$*, not a* $\mathsf{MetricAnnulus}^\uparrow$ *maximum handoff, and not an ambient analytic object outside the displayed strip.*

Proof. Start from the strip row. The packet reads the displayed strip data S and the $\mathsf{Holomorphic}^\uparrow$ map row F before any boundary-line estimate is available.

Next seal the height and boundary rows. The $\mathsf{Real}^\uparrow$ reads Y_0, Y_1, Y determine the inspected boundary and interior lines, while B turns those lines into finite boundary probes.

The strip-bound handoff is then local. The row M records the finite boundary majorants, and E ties them to the logarithmic-convexity estimate for the same heights. The $\mathsf{Integral}^\uparrow$ dependency is consumed only as a displayed finite contour, averaging, or boundary-read row, not as an ambient selection principle.

The provenance row may cite $\mathsf{HadamardThreeCircle}^\uparrow$ and $\mathsf{MetricAnnulus}^\uparrow$ as neighboring complex-analysis certificates, but the carrier keeps its strip row S and height ledger Y_0, Y_1, Y. Therefore a consumer receives exactly the finite strip ledger and no annulus collapse, selected extremal point, quotient equality, or infinite limiting data. □

Theorem 2918.4 (Hadamard three-lines convexity window)**.** *Any strip-bound consumer that reads the logarithmic-convexity estimate row E of an accepted* $\mathsf{HadamardThreeLines}^{\uparrow}$ *carrier must also display the strip row S, holomorphic map row F, boundary and interior height rows Y_0, Y_1, Y, boundary-line readback row B, and finite majorant row M. Thus the convexity estimate cannot be detached from the finite vertical-strip ledger that supplies its boundary and interior witnesses.*

Proof. Project the carrier in Definition 3893.1. The row E is introduced only as the logarithmic-convexity estimate tying Y_0, Y_1, Y and M to the same displayed strip-bound certificate, while M itself records finite boundary-majorant data read from B.

Apply the strip-bound route of Definition 3893.3. That theorem sends every accepted consumer through $S, F, Y_0, Y_1, Y, B, M, E, Hs, C, P, N$ before exporting a bound. Hence a read of E without S, F, Y_0, Y_1, Y, B, M would no longer be a read of the accepted $\mathsf{HadamardThreeLines}^{\uparrow}$ packet, but an external estimate outside the displayed finite ledger. □

Falsifiable prediction: An accepted $\mathsf{HadamardThreeLines}^{\uparrow}$ read is refuted if the logarithmic-convexity estimate row E is preserved while the displayed strip row S, holomorphic map row F, boundary and interior height reads Y_0, Y_1, Y, boundary-line row B, and finite majorant row M are removed.

Independence witness: hadamard-three-circle, holomorphic, complex, real, integral, metric-annulus: none is bijective with $\mathsf{HadamardThreeLines}^{\uparrow}$ because the packet jointly carries a vertical-strip row, holomorphic map row, boundary and interior height reads, boundary-line probes, finite majorant rows, a logarithmic-convexity estimate ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardThreeLines}^{\uparrow}}$.

Constructive story: A $\mathsf{HadamardThreeLines}^{\uparrow}$ packet is generated from a displayed vertical strip, a holomorphic map row, two boundary-height Real reads, one interior-height Real read, boundary-line probes, finite majorant rows, a logarithmic-convexity estimate ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardThreeLines}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3893.1, Definition 3893.2, and Definition 3893.3 seed the finite vertical-strip ledger for three-lines holomorphic strip estimates.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardThreeLines}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient function equality, host function extensionality, selected boundary suprema, unbounded strip limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked strip admission, holomorphic-map exposure, boundary and interior height ordering, boundary-line readback, finite majorant rows, logarithmic-convexity estimate compatibility, and structural transport for BEDC.Derived.HadamardThreeLinesUp.

Chapter 2919

A Concrete Naming Certificate for $\mathsf{CauchyLocatedApartness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyLocatedApartness}^{\uparrow}$ packet records the constructive boundary where finite locator requests for a Cauchy real become positive located-apartness evidence. It consumes the Cauchy locator route of chapter 3410, the located-apartness surface of chapter 1380, the apartness-real interface of chapter 304, and the real-name seal of chapter 38. Its finite naming spine is read through chapter 126, chapter 301, and chapter 291.

The packet is a local handoff surface. It exports locator rows, endpoint-gap rows, finite stream windows, regular-rational readbacks, dyadic tolerance ledgers, real seals, transport rows, continuation replay, provenance, and a local NameCert row. It exports no trichotomy, no quotient real equality, no selected limit, no countable choice, no open-cover compactness, and no ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 2919.1 (Cauchy located-apartness carrier)**.** *A* $\mathsf{CauchyLocatedApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, A, B, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *row answering finite rational locator requests for the Cauchy real being inspected.*
2. *A and B are endpoint-gap rows read through* $\mathsf{LocatedApartness}^{\uparrow}$ *and* $\mathsf{ApartnessReal}^{\uparrow}$*, recording positive separation windows on the two sides of the located comparison.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger used to schedule the locator observations.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the displayed stream windows into regular rational observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the radius and endpoint arithmetic used by the locator and apartness rows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, A, B, S, R, D have been displayed.*
7. *H stores componentwise* hsame *transport for locator rows, endpoint-gap rows, finite windows, readbacks, tolerance ledgers, real seals, continuation replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from locator requests through stream windows, regular-rational readbacks, dyadic tolerance checks, endpoint-gap rows, and the final real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyLocatedApartness}^{\uparrow}$, $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for trichotomy, quotient real equality, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLocatedApartnessUp.CauchyLocatedApartnessTasteGate single carrier alignment`

Theorem 2919.2 (Cauchy located-apartness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyLocatedApartness}^{\uparrow}$ *carrier* $L = (Q, A, B, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedApartness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, locator-window compatibility, endpoint-gap exactness, dyadic-tolerance coverage, real-seal handoff, transport replay, and non-escape from the finite route*

$$Q, S, R, D \longmapsto A, B \longmapsto E$$

together with H, C, P, N*.*

Proof. Carrier admission is projection from Definition 3895.1. The accepted tuple exposes the Cauchy locator row, two endpoint-gap rows, stream windows, regular-rational readback, dyadic tolerance ledger, real seal, transport, replay, provenance, and local naming.

Locator-window compatibility reads Q only through S, R, D. A finite comparison request must display the scheduled stream window, its regular rational readback, and the tolerance ledger before any located-apartness row can be consumed.

Endpoint-gap exactness is supplied by A and B. These rows carry the positive located-apartness evidence, while the real seal E is downstream of the same locator and tolerance route.

Finally, H, C, P, N preserve and name the route. Since the carrier contains no trichotomy, quotient equality, selected limit, countable-choice schedule, open-cover compactness theorem, or ambient real-completeness coordinate, the displayed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyLocatedApartnessUp.CauchyLocatedApartnessCarrier namecert obligations`

Theorem 2919.3 (Cauchy locator to apartness handoff)**.** *Every accepted* $\mathsf{CauchyLocatedApartness}^{\uparrow}$ *carrier converts a finite* $\mathsf{CauchyRealLocator}^{\uparrow}$ *request into positive* $\mathsf{LocatedApartness}^{\uparrow}$ *and* $\mathsf{ApartnessReal}^{\uparrow}$ *endpoint-gap evidence only through the displayed route*

$$Q \longmapsto S \longmapsto R \longmapsto D \longmapsto A, B \longmapsto E.$$

Thus a downstream Real-facing comparison consumer receives a finite locator-apartness handoff, not trichotomy, quotient real equality, a selected limit, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyLocatedApartnessUp.CauchyLocatedApartnessLocatorApartnessHandoff`

Proof. Start with a finite locator request in Q. The carrier forces the request to replay through the scheduled $\mathsf{StreamName}^{\uparrow}$ window S, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D.

Only after that route is displayed may the endpoint-gap rows A and B be read as located-apartness evidence. The $\mathsf{Real}^{\uparrow}$ seal E records that the same finite route reaches the real-facing surface.

The structural rows H, C, P, N transport, replay, package, and name exactly these coordinates. No excluded principle is a field of the carrier, so the handoff is exhausted by the finite locator, window, readback, tolerance, apartness, and seal rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLocatedApartness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLocatedApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3895.1, Definition 3895.2, and Definition 3895.3 seed the finite Cauchy locator to located-apartness boundary over stream windows, regular-rational readbacks, dyadic tolerance ledgers, endpoint-gap rows, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLocatedApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, selected limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locator-window compatibility, endpoint-gap exactness, dyadic-tolerance coverage, real-seal handoff, transport replay, and non-escape for BEDC.Derived.CauchyLocatedApartnessUp.

Constructive story: A $\mathsf{CauchyLocatedApartness}^{\uparrow}$ packet is generated from a CauchyRealLocator request row, LocatedApartness and ApartnessReal endpoint-gap rows, finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2920

A Concrete Naming Certificate for $\mathsf{RiemannLebesgueLemma}^{\uparrow}$

Following Zygmund, Katznelson, and Folland on Fourier analysis, the $\mathsf{RiemannLebesgueLemma}^{\uparrow}$ packet records the finite oscillatory-decay surface of the Riemann–Lebesgue lemma as BEDC NameCert data. It sits over the Fourier coefficient interface of chapter 124, the circle phase sampler of chapter 58, the integral normalization route of chapter 123, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the averaging comparison supplied by chapter 1939. The packet exposes finite coefficient windows and oscillatory handoff data; it does not import Haar measure, host L^1 theory, quotient function equality, general Fourier convergence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2920.1 (Riemann–Lebesgue lemma carrier)**.** *A* $\mathsf{RiemannLebesgueLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, S, I, W, T, A, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite* $\mathsf{Fourier}^{\uparrow}$ *coefficient-window row, naming exactly the inspected frequency indices and coefficient requests.*
2. *S is the* $\mathsf{S}^{1\uparrow}$ *phase-sample row, recording the finite circle phases used to test the requested oscillations.*
3. *I is the* $\mathsf{Integral}^{\uparrow}$ *normalization and readback row, exposing only the finite integral observations used to form each coefficient.*
4. *W is the window ledger pairing frequency indices, phase samples, and integral cells before any decay read is made.*
5. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row, listing the rational error budgets attached to the coefficient windows.*
6. *A is the finite averaging comparison row, allowed to cite the* $\mathsf{FejerKernel}^{\uparrow}$ *sibling only as a displayed smoothing comparison.*
7. *Q is the oscillatory-decay handoff row, recording which finite tails have coefficient magnitude below the displayed tolerance.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for coefficient values, tolerance comparisons, and accepted decay reads.*

9. *H records componentwise* hsame *transport for the coefficient, phase, integral, window, tolerance, averaging, decay, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a Fourier-coefficient request through $F, S, I, W, T, A, Q, E, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{RiemannLebesgueLemma}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannLebesgueLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, I, W, T, A, Q, E, H, C, P, N$. It has no coordinate for Haar measure, host L^1 spaces, quotient equality of functions, a theorem of general Fourier convergence, selected representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RiemannLebesgueLemmaUp.RiemannLebesgueLemmaTasteGate single carrier alignment`

Theorem 2920.2 (Riemann–Lebesgue lemma NameCert obligations)**.** *For every accepted* RiemannLebesgueLemma *carrier*

$$R = (F, S, I, W, T, A, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannLebesgueLemma}^{\uparrow}}$ *surface consists exactly of Fourier coefficient-window admission through F, circle phase-sample admission through S, integral normalization and readback through I, window and tolerance exposure through W, T, finite averaging comparison through A, oscillatory-decay handoff through Q, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3896.1. The rows F, S, I expose the coefficient request, the finite phase samples, and the integral normalization before the packet can state any decay handoff.

The rows W, T, A, Q supply the finite analytic body of the certificate. The window row pairs frequencies with inspected cells, the tolerance row records the rational budgets, the averaging row gives the displayed Fejer-kernel comparison, and the handoff row records exactly the tails accepted below those budgets.

The structural rows E, H, C, P, N seal, transport, replay, source, and name the same data. Since the carrier has no coordinate for Haar measure, host L^1 theory, quotient function equality, general Fourier convergence, selected representatives, or ambient real completeness, the listed rows exhaust the NameCert surface. □

Theorem 2920.3 (Riemann–Lebesgue oscillatory handoff)**.** *Every Fourier-decay consumer of an accepted* $\mathsf{RiemannLebesgueLemma}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Fourier}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Integral}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The optional $\mathsf{FejerKernel}^{\uparrow}$ *comparison can be read only through the finite averaging row A, and the final decay read can inspect only $F, S, I, W, T, A, Q, E, H, C, P, N$. Thus the packet supplies a finite oscillatory-decay dependency for later Fourier approximation chapters without exporting Haar measure, host L^1 integration, quotient function equality, general convergence of Fourier series, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Begin with a Fourier-decay request. Carrier projection exposes F, so the consumer receives a finite coefficient window rather than an infinite Fourier transform.

The request next reads S, I, W, T. These rows bind each requested frequency to displayed circle phases, integral cells, window ledgers, and regular rational tolerances.

Only then can the consumer inspect A, Q, E, H, C, P, N. The averaging comparison remains a finite sibling comparison, the decay handoff is recorded at the displayed tolerances, and the real seal closes the numeric read. No excluded analytic object has a coordinate in the packet, so the handoff is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RiemannLebesgueLemmaUp.OscillatoryHandoff.RiemannLebesgueLemmaOscillatoryHandoff`

Falsifiable prediction: An accepted $\mathsf{RiemannLebesgueLemma}^{\uparrow}$ packet is refuted if a Fourier-decay consumer preserves the coefficient window while bypassing the displayed $\mathsf{S}^{1\uparrow}$ phase samples, $\mathsf{Integral}^{\uparrow}$ normalization row, $\mathsf{RegSeqRat}^{\uparrow}$ tolerance row, and terminal $\mathsf{Real}^{\uparrow}$ seal.

Independence witness: fourier, sone, integral, regseqrat, real, fejer-kernel: none is bijective to $\mathsf{RiemannLebesgueLemma}^{\uparrow}$ because the packet jointly carries coefficient windows, phase samples, integral normalization, tolerance ledgers, averaging comparison, oscillatory-decay handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannLebesgueLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannLebesgueLemma}^{\uparrow}$ packet is generated from finite Fourier coefficient windows, SOne phase samples, Integral normalization and readback rows, RegSeqRat tolerance rows, a finite FejerKernel comparison, an oscillatory handoff row, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannLebesgueLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3896.1, Definition 3896.2, and Definition 3896.3 seed the finite oscillatory-decay route over Fourier, circle phase, integral, regular rational, real-seal, and averaging rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannLebesgueLemma}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RiemannLebesgueLemmaUp.OscillatoryHandoff.RiemannLebesgueLemmaOscillatoryHandoff`

Bridge status: none

Not claimed: This chapter does not claim Haar measure, host L^1 theory, quotient function equality, general Fourier convergence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked coefficient-window admission, phase-sample exposure, integral normalization, tolerance exactness, finite averaging comparison, oscillatory handoff, real seal exposure, transport, replay, provenance, and local naming for BEDC.Derived.RiemannLebesgueLemmaUp.

Chapter 2921

A Concrete Naming Certificate for $\mathsf{MedianClosureSpectrum}^{\uparrow}$

The $\mathsf{MedianClosureSpectrum}^{\uparrow}$ packet realizes the Walsh-spectrum reassignment rows of Definition 9462.1263, Definition 9462.1264, and Definition 9462.1273 as a finite NameCert spectrum. It reads the finite codon-window and module-boundary surfaces of **??** and **??**, then records the dominant Walsh coordinates as median-closure support data rather than as host spectral analysis. The packet does not depend on Fourier analysis, Fejer kernels, Parseval identities, finite phase sampling, or Dirichlet kernels.

Definition 2921.1 (Median closure spectrum carrier)**.** *A* $\mathsf{MedianClosureSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, W, D, S, L, E, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite Q_6 codon-window row whose coordinates are read by the reassignment spectrum.*
2. *W is the Walsh coefficient ledger, listing the displayed coefficients of Definition 9462.1264.*
3. *D is the dominant-coordinate row for b_3^s, $b_1^f b_3^s$, b_1^f, $b_1^f b_2^s$, $b_1^f b_2^s b_3^s$, $b_2^s b_3^s$, and b_2^s.*
4. *S is the median-closure support row, recording which dominant coordinates support the reassignment median boundary.*
5. *L is the finite low-order energy ledger read from the compression statement, with no appeal to an analytic Fourier transform.*
6. *E is the evidence row tying the Walsh ledger to the purine-core and module-classification surfaces.*
7. *R is the refusal row for Fourier, Fejer-kernel, Parseval, finite-phase-sampling, and Dirichlet-kernel dependencies.*
8. *H records componentwise* hsame *transport for the codon window, Walsh ledger, dominant-coordinate row, support row, energy ledger, evidence row, refusal row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a dominant-coordinate read through Q, W, D, S, L, E, R, H.*
10. *P is the* Pkg *provenance over* $\mathsf{MedianClosureSpectrum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *together with the cited vision rows and sibling codon-boundary packets.*

11. N is the local $\mathsf{NameCert}_{\mathsf{MedianClosureSpectrum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, W, D, S, L, E, R, H, C, P, N$. It has no coordinate for host Fourier transform data, trigonometric phase sampling, Parseval energy identities, Dirichlet kernels, Fejer kernels, or a hidden analytic spectrum outside the displayed Walsh ledger.

Lean4 ✓ `BEDC.Derived.MedianClosureSpectrumUp.MedianClosureSpectrumTasteGate single carrier alignment`

Theorem 2921.2 (Median closure spectrum NameCert obligations)**.** *For every accepted* $\mathsf{MedianClosureSpectrum}^{\uparrow}$ *carrier*

$$M = (Q, W, D, S, L, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MedianClosureSpectrum}^{\uparrow}}$ *surface consists exactly of codon-window admission through Q, Walsh coefficient exposure through W, dominant-coordinate readback through D, median-closure support exposure through S, low-order energy accounting through L, purine-core and module-classification evidence through E, analytic-dependency refusal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3897.1. The rows Q, W, D expose the finite codon window, Walsh coefficient ledger, and dominant coordinates before any median-closure support read is allowed.

The rows S, L, E supply the support body of the packet. They identify the median-closure support row, record the low-order energy ledger, and tie those rows to the purine-core and module-classification siblings cited above.

The rows R, H, C, P, N close the certificate. The refusal row blocks analytic substitutions, while transport, replay, provenance, and local naming preserve the displayed finite Walsh spectrum as the whole accepted surface. □

Falsifiable prediction: Every dominant-coordinate read accepted by $\mathsf{MedianClosureSpectrum}^{\uparrow}$ factors through the displayed Walsh coefficient ledger W; replacing W by Fourier, phase-sampling, Parseval, Fejer-kernel, or Dirichlet-kernel data refutes the packet.

Independence witness: fourier, fejer-kernel, parseval, finite-phase-sampling, dirichlet-kernel: the median-closure spectrum is not bijective to any of these routes because its accepted reads are finite Walsh coefficient ledger reads over codon-window and support rows, not analytic phase, convolution, energy, or kernel reads.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{MedianClosureSpectrum}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MedianClosureSpectrum}^{\uparrow}$ instances in `TasteGate.lean`. The field-faithfulness witness must keep $Q, W, D, S, L, E, R, H, C, P, N$ as distinct rows so a checked TasteGate theorem can rule out analytic-spectrum replacements of the displayed Walsh ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{MedianClosureSpectrum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MedianClosureSpectrum}^{\uparrow}$ packet is generated from finite codon-window rows, Walsh coefficient ledgers, dominant-coordinate rows, median-closure support rows, low-order energy rows, purine-core and module-classification evidence, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MedianClosureSpectrum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3897.1 and Definition 3897.2 seed the finite Walsh-ledger spectrum packet over codon-window, dominant-coordinate, median-support, energy, evidence, refusal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MedianClosureSpectrum}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Fourier analysis, Fejer kernels, Parseval identities, finite phase sampling, Dirichlet kernels, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked codon-window admission, Walsh ledger exposure, dominant-coordinate readback, median-support exactness, energy ledger accounting, evidence routing, refusal preservation, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.MedianClosureSpectrumUp.

Chapter 2922

A Concrete Naming Certificate for $\mathsf{DirectedFilter}^{\uparrow}$

Following Kelley and Bourbaki on directed sets, filters, and completion by tails, the $\mathsf{DirectedFilter}^{\uparrow}$ packet records the finite carrier that translates directed tail requests into a filter-base handoff before any completion consumer reads a limit-facing surface. It sits between the directed-set substrate of chapter 1607, the filter-base certificate of chapter 1601, the Moore–Smith net route of chapter 3403, and the filter-limit basis route of chapter 3862. The packet supplies the L10 completion corridor with a shared directed-filter carrier; it is not a quotient filter, selected limit, countable-choice selector, host equality of filters, or ambient completeness theorem.

Definition 2922.1 (DirectedFilter carrier)**.** *A* $\mathsf{DirectedFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, B, M, U, W, R, Y, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *tail-request row, recording finite requests, preorder comparisons, and common-upper witnesses.*
2. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *handoff row assembled only from the displayed tails in D.*
3. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *and* $\mathsf{NetConvergence}^{\uparrow}$ *route row, exposing the same directed tails as net-index evidence before any convergence read.*
4. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row, available only after D, B, M have been replayed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by completion-facing numerical consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W.*
7. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the readback rows before a seal is consumed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, downstream of directed tails, filter-base handoff, net convergence, completion consumers, windows, readback, and tolerance rows.*
9. *H records componentwise* hsame *transport for all analytic rows and the local structural rows.*
10. *C records displayed* Cont *replay from a directed-tail request through $D, B, M, U, W, R, Y, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{DirectedFilter}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DirectedFilter}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for quotient filters, ultrafilters, selected limits, countable choice, host filter equality, or ambient completion.

Lean4 ✓ `BEDC.Derived.DirectedFilterUp.DirectedFilterTasteGate single carrier alignment`

Theorem 2922.2 (DirectedFilter NameCert obligations)**.** *For every accepted* $\mathsf{DirectedFilter}^{\uparrow}$ *carrier* $F = (D, B, M, U, W, R, Y, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirectedFilter}^{\uparrow}}$ *surface consists exactly of the finite obligations for carrier admission, directed-tail coverage, filter-base handoff, net-convergence routing, completion nonescape, numerical readback, componentwise transport, displayed replay, provenance, and local naming. Every obligation is read from* $D, B, M, U, W, R, Y, E, H, C, P, N$*, and no obligation is stored in a quotient filter, selected limit, countable-choice schedule, host equality relation, or ambient completeness witness.*

Proof. Project the carrier of Definition 3898.1. The displayed analytic rows are D, B, M, U, W, R, Y, E, and the structural rows are H, C, P, N.

Directed-tail coverage is supplied by D. Any request first reads the finite tail window and its common-upper witness before a filter or net consumer can inspect the packet.

The handoff and consumer rows are downstream. The row B exposes the filter-base surface named in chapter 1601, while M routes the same tails to the Moore–Smith and net-convergence surface of chapter 3403. The row U then presents only metric or uniform completion consumers of that same route.

Finally W, R, Y, E provide the numerical window, readback, dyadic tolerance, and real seal rows. Transport, replay, provenance, and naming preserve the same finite carrier. Since none of the excluded principles has a carrier coordinate, the listed obligations exhaust the local surface. □

Theorem 2922.3 (DirectedFilter tail FilterBase handoff)**.** *Every* $\mathsf{FilterBase}^{\uparrow}$ *consumer of an accepted* $\mathsf{DirectedFilter}^{\uparrow}$ *carrier must first read the* $\mathsf{DirectedSet}^{\uparrow}$ *tail-request row D and only then the handoff row B. The handoff presents finite tails, common-upper witnesses, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it does not present a quotient filter, ultrafilter, selected limit, countable-choice selector, or host filter equality.*

Proof. Begin with the NameCert obligations of Definition 3898.2. They place every filter-facing read after the displayed directed-tail row D.

Read B next. Because B is assembled only from the finite tails and upper-window witnesses in D, the filter-base consumer receives the same displayed family rather than an external filter object.

The structural rows H, C, P, N transport, replay, source, and name that handoff. No omitted quotient, ultrafilter, selection, or host-equality row can be recovered from the carrier. □

Theorem 2922.4 (DirectedFilter net-convergence route)**.** *Every* $\mathsf{MooreSmithNet}^{\uparrow}$ *or* $\mathsf{NetConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{DirectedFilter}^{\uparrow}$ *packet factors through*

$$\mathsf{DirectedSet}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{MooreSmithNet}^{\uparrow}, \mathsf{NetConvergence}^{\uparrow} \longmapsto H, C, P, N.$$

The route shares the directed-tail ledger with chapter 3403 and the filter-base handoff with chapter 1601. It exports no global confluence of filters and nets, no selected subnet, no selected limit, and no ambient convergence theorem.

Proof. Project F to D, B, M, H, C, P, N. The row D is the only directed-index source, and B is the only filter-base handoff.

The net row M is reached after those two rows. It therefore reads the same directed tails as the filter-base consumer, matching the Moore–Smith carrier rather than a separately chosen subnet or a detached convergence assertion.

Transport and replay keep the route componentwise. Since the packet contains no selected subnet, selected limit, or ambient convergence coordinate, every net-convergence read is exhausted by the displayed rows. □

Theorem 2922.5 (DirectedFilter completion nonescape)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DirectedFilter}^{\uparrow}$ *packet reads the completion corridor through*

$$D, B, M, U \longmapsto W, R, Y, E \longmapsto H, C, P, N.$$

The route passes through the filter-limit basis corridor of chapter 3862 without adding quotient filters, selected limits, countable choice, host real equality, or ambient completeness.

Proof. Use Definition 3898.3 to force the directed-tail and filter-base prefix. Then use Definition 3898.4 to place the net-convergence row before any completion-facing consumer.

The completion row U is followed by the numerical rows W, R, Y, E. These rows expose finite stream windows, regular rational readback, dyadic tolerance accounting, and the terminal real seal in the order displayed by the carrier.

The structural rows H, C, P, N preserve and name the same route. Because the carrier has no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness coordinate, the completion consumer cannot escape the stated corridor. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirectedFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{DirectedFilter}^{\uparrow}$ packet is generated from a DirectedSet tail-request row, a FilterBase handoff row, MooreSmithNet and NetConvergence route rows, UniformCompletion and MetricCompletion consumer rows, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirectedFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3898.1, Definition 3898.2, Definition 3898.3, Definition 3898.4, and Definition 3898.5 seed the finite directed-filter carrier for the L10 completion corridor.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirectedFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, ultrafilter arguments, selected limits, selected subnets, countable choice, host filter equality, ambient convergence, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail coverage, filter-base handoff, net-convergence routing, completion nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DirectedFilterUp.

Chapter 2923

A Concrete Naming Certificate for $\mathsf{OscillationFunction}^{\uparrow}$

Following Baire's function hierarchy and Bishop–Bridges constructive analysis, the $\mathsf{OscillationFunction}^{\uparrow}$ packet records the finite oscillation certificate associated to a pointwise real-valued limit. It sits after the pointwise-limit route of chapter 2314, the Baire-one consumer surface of chapter 1604, the Dini-continuity consumer surface of chapter 2196, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed oscillation windows and value-readback rows; it does not import a host function space, quotient real equality, a selected supremum, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2923.1 (OscillationFunction carrier)**.** *An* $\mathsf{OscillationFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (P, B, D, S, R, V, H, C, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PointwiseLimit}^{\uparrow}$ *source row whose displayed point-index and approximant-window route is being inspected.*
2. *B is the* $\mathsf{BaireOneFunction}^{\uparrow}$ *consumer row receiving the oscillation certificate as Baire-one boundary data.*
3. *D is the* $\mathsf{DiniContinuity}^{\uparrow}$ *consumer row that may read the same finite oscillation windows before any uniform-modulus handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finitely many source neighbourhoods and approximant windows used by the oscillation request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected value differences and tolerance comparisons.*
6. *V is the terminal* $\mathsf{Real}^{\uparrow}$ *oscillation-value seal reached only after P, B, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the pointwise-limit, Baire-one, Dini-continuity, schedule, readback, value-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an oscillation request through the pointwise-limit windows, the Baire-one and Dini consumer rows, the stream schedule, the regular rational readback, and the RealUp seal.*
9. *K is the* Pkg *provenance over* $\mathsf{OscillationFunction}^{\uparrow}$, $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{OscillationFunction}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host oscillation function, quotient real equality, a selected supremum over all neighbourhoods, an ambient Baire-one theorem, or completeness of $\mathsf{Real}^\uparrow$*.*

Lean4 ✓ `BEDC.Derived.OscillationFunctionUp.OscillationFunctionTasteGate single carrier alignment`

Theorem 2923.2 (OscillationFunction NameCert obligations)**.** *For every accepted* $\mathsf{OscillationFunction}^\uparrow$ *carrier $O = (P, B, D, S, R, V, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{OscillationFunction}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the pointwise-limit source, Baire-one consumer, Dini-continuity consumer, stream schedule, regular rational readback, RealUp oscillation seal, transport, replay, provenance, and local naming row;*
2. *pointwise-window exposure, requiring every oscillation request to read the* $\mathsf{PointwiseLimit}^\uparrow$ *route of chapter 2314 before any value-difference comparison is inspected;*
3. *consumer compatibility, requiring the* $\mathsf{BaireOneFunction}^\uparrow$ *and* $\mathsf{DiniContinuity}^\uparrow$ *rows to consume the same displayed windows and not a second host function-space object;*
4. *Real-seal exactness, requiring the oscillation value row V to be downstream of P, B, D, S, R and transported only by H and C;*
5. *nonescape from host oscillation functions, quotient real equality, selected suprema, ambient Baire-one representation theorems, unrestricted Dini compactness, and completeness of* $\mathsf{Real}^\uparrow$*.*

No NameCert obligation is stored outside $P, B, D, S, R, V, H, C, K, N$.

Proof. Project the carrier of Definition 3899.1. The accepted packet exposes exactly the pointwise-limit source row, the Baire-one and Dini consumer rows, the finite stream schedule, the regular rational readback, the RealUp value seal, transport, replay, provenance, and local naming.

The pointwise-window exposure follows from the source row P. The route cited in chapter 2314 already displays the point-index, approximant windows, regular rational readback, and RealUp value seal before a pointwise value can be consumed.

Consumer compatibility is then read through B and D. Both rows are coordinates of the same packet, so the Baire-one and Dini-facing consumers receive the finite schedule S and readback R already attached to P rather than an external function-space witness.

Finally the seal row V is downstream of this route. Componentwise transport by H and replay by C preserve only the displayed rows, while K and N carry provenance and local naming. Since the excluded objects are not coordinates of the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2923.3 (OscillationFunction pointwise readback)**.** *Every* $\mathsf{Real}^\uparrow$ *oscillation-value read exported by an accepted* $\mathsf{OscillationFunction}^\uparrow$ *carrier factors through the displayed route*

$$\mathsf{PointwiseLimit}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

as recorded by P, S, R, V. The readback may be consumed by the $\mathsf{BaireOneFunction}^\uparrow$ *and* $\mathsf{DiniContinuity}^\uparrow$ *rows B, D, but it cannot bypass the pointwise-limit route by reading a host oscillation function, quotient real equality, selected neighbourhood supremum, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Begin with a consumer request for V. By the carrier definition, V is reached only after the pointwise-limit source P, the finite schedule S, and the regular rational readback R have been displayed.

Apply the pointwise-limit Real-seal handoff from chapter 2314. It supplies the route from displayed source requests and approximant windows to a terminal RealUp value seal, and the oscillation packet reuses that route for finite value-difference comparisons.

The Baire-one and Dini rows are downstream consumers of the same readback. Transport through H and replay through C do not add a host function coordinate or a selected supremum row, so every oscillation-value read remains confined to P, S, R, V and the visible package rows. □

Theorem 2923.4 (OscillationFunction Baire-one handoff)**.** *Every* $\mathsf{BaireOneFunction}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OscillationFunction}^{\uparrow}$ *packet must read the pointwise-limit source P, the Baire-one row B, the Dini-continuity row D, the stream schedule S, the regular rational readback R, the RealUp oscillation seal V, and the structural rows H, C, K, N before any Baire-one oscillation boundary is public. Thus the handoff is a finite NameCert route over the rows displayed in Definition 3899.1, not a representation theorem about an ambient space of functions.*

Proof. Read the obligation surface of Definition 3899.2. It places the Baire-one consumer row behind the same pointwise-window exposure and Real-seal exactness rows used by the oscillation value.

Use the Baire-one packet of chapter 1604. Its public pointwise-limit ledger accepts displayed continuous approximant windows and regular rational readbacks, not a host function-space quotient. The oscillation carrier supplies those rows through P, S, R, V.

The Dini row D records the companion compact-modulus consumer boundary, but it is still downstream of the same displayed schedule. Since H, C, K, N transport, replay, source, and name only that finite route, the Baire-one handoff exports no ambient representation theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationFunction}^{\uparrow}}$.

Constructive story: An $\mathsf{OscillationFunction}^{\uparrow}$ packet is generated from a PointwiseLimitUp source row, BaireOneFunctionUp and DiniContinuityUp consumer rows, StreamName schedules, RegSeqRat readbacks, a RealUp oscillation-value seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3899.1, Definition 3899.2, Definition 3899.3, and Definition 3899.4 seed the finite oscillation certificate over pointwise-limit windows and Baire-one consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host oscillation functions, quotient real equality, selected suprema, ambient Baire-one representation, unrestricted Dini compactness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pointwise-window exposure, consumer compatibility, Real-seal exactness, and nonescape for BEDC.Derived.OscillationFunctionUp.

Chapter 2924

A Concrete Naming Certificate for $\mathsf{FilterCompletionUniversalProperty}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{FilterCompletionUniversalProperty}^{\uparrow}$ packet records the finite universal-property surface for the L10 filter-completion route. It sits after the completion packet of chapter 1569, the convergence boundary of chapter 1558, the universal extension surface of chapter 397, and the uniform handoff of chapter 1473. The packet names the extension and uniqueness rows that downstream completion consumers may cite without importing quotient filters, selected limits, host equality, countable choice, or ambient completeness.

Definition 2924.1 (Filter completion universal-property carrier)**.** *A* $\mathsf{FilterCompletionUniversalProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (C, L, E, Q, F, R, A, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion route, already tying the accepted read to a displayed Cauchy filter, finite windows, dyadic tolerances, regular readback, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *convergence row consumed only after the completion route C has exposed its source-filter and readback rows.*
3. *E is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension-and-uniqueness row attached to the same filter-completion route.*
4. *Q is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row read as provenance for uniform-facing consumers, not as a detached completion object.*
5. *F is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row supplied by the same finite windows and dyadic tolerance ledger.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal reached through C, L, F and used as the terminal filter-completion target.*
7. *A is the extension-uniqueness ledger, comparing accepted extension rows over the same C, L, E, Q, F, R surface by displayed* hsame *transport.*
8. *H records componentwise* hsame *transport for the completion route, convergence row, universal-property row, uniform handoff, regular readback, Real seal, extension ledger, replay, provenance, and local naming rows.*

9. *K records displayed* Cont *replay of the route*

$$C, L, F, R \longmapsto E, Q, A, H, P, N.$$

10. *P is the* Pkg *provenance over* FilterCompletionUniversalProperty$^{\uparrow}$, CauchyFilterCompletion$^{\uparrow}$, CauchyFilterLimit$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, UniformCompletion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{FilterCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, L, E, Q, F, R, A, H, K, P, N$. It has no coordinate for quotient filters, selected filter limits, host equality of filters or real names, countable-choice selectors, ambient completeness, or a completion object detached from the displayed filter route.

Lean4 ✓ `BEDC.Derived.FilterCompletionUniversalPropertyUp.FilterCompletionUniversalPropertyTasteGate`
`single carrier alignment`

Theorem 2924.2 (Filter completion universal-property NameCert obligations)**.** *For every accepted* FilterCompletionUniversalProperty$^{\uparrow}$ *carrier $U = (C, L, E, Q, F, R, A, H, K, P, N)$, the local* NameCert$_{\text{FilterCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple; filter-completion exposure through C; convergence exposure through L after the source-filter route has been read; regular readback through F and the terminal* Real$^{\uparrow}$ *seal R; completion-universal extension through E; uniform provenance through Q; uniqueness comparison through A over the same rows; componentwise transport through H; displayed replay through K; provenance through P; local naming through N; and ledger refusal for quotient filters, selected limits, host equality, countable choice, ambient completeness, and detached completion objects.*

Proof. Carrier admission is projection from Definition 3900.1. The accepted packet exposes exactly the Cauchy-filter completion route, convergence row, universal-property row, uniform handoff, regular readback, Real seal, uniqueness ledger, transport, replay, provenance, and local name.

The filter route is finite. The completion row C is read before the convergence row L, the regular readback F, and the seal R, so no consumer can begin from a selected filter limit or a quotient-filter representative.

The universal-property route is also finite. Rows E, Q, A are read only after the same filter-completion and Real-seal data have been displayed, while H, K, P, N transport, replay, source, and name that route. Since no excluded host-side coordinate appears in the carrier, these rows exhaust the local certificate surface. □

Theorem 2924.3 (Filter completion universal-property extension uniqueness)**.** *Let $U = (C, L, E, Q, F, R, A, H, K,$ be an accepted* FilterCompletionUniversalProperty$^{\uparrow}$ *packet. Any two extension rows consumed through U are compared only by the displayed uniqueness ledger A over the common route*

$$C, L, F, R \longmapsto E, Q \longmapsto A, H, K, P, N.$$

Thus extension uniqueness is available to completion-facing consumers only after the same Cauchy-filter completion row, convergence row, regular readback, Real seal, universal-property row, and uniform handoff have been displayed. It cannot be replaced by host function equality, quotient-filter equality, a selected limit, countable choice, or ambient completeness.

Proof. Start with two extension reads from the accepted packet. The carrier has a single universal-property row E and a single uniqueness ledger A attached to the displayed filter-completion route.

Replay the continuation row K. Both extension reads must pass through C, L, F, R before E and Q are available, so the comparison has the same source-filter, readback, convergence, and Real-seal data on both sides.

The ledger A then compares the two rows by displayed hsame transport, and H, P, N preserve and name the same comparison. The refused host equalities, quotient objects, selected limits, choice selectors, and completeness principles have no coordinate inside U. □

Theorem 2924.4 (Filter completion universal-property filter handoff)**.** *Every* $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FilterCompletionUniversalProperty}^{\uparrow}$ *packet reads the same finite handoff*

$$C, L, F, R, E, Q, A, H, K, P, N.$$

The handoff starts from the displayed Cauchy-filter completion row, reads the convergence boundary and regular readback before the terminal $\mathsf{Real}^{\uparrow}$ *seal, and then exposes extension, uniqueness, uniform provenance, transport, replay, provenance, and local naming. No consumer may replace that handoff by a quotient filter, selected filter limit, host equality, countable-choice selector, ambient completeness theorem, or detached completion carrier.*

Proof. Project the accepted carrier. Its only completion source is C, its only convergence row is L, its only regular readback and terminal seal rows are F and R, and its only universal-property and uniform-facing rows are E and Q.

Use the NameCert obligations of Definition 3900.2. They order the read from filter-completion exposure through convergence, readback, seal, extension, uniqueness, uniform provenance, transport, replay, package provenance, and local naming.

The sibling surfaces enforce the same boundary: chapter 1569 supplies the completion source, chapter 1558 supplies the convergence boundary, and chapter 1473 supplies only the uniform-facing provenance handoff. Since the carrier has no extra coordinate, the listed finite handoff is the whole exported route. □

Falsifiable prediction: Every accepted $\mathsf{FilterCompletionUniversalProperty}^{\uparrow}$ consumer that exports extension existence, extension uniqueness, filter convergence, or uniform-completion handoff while omitting one of the displayed Cauchy-filter completion, Cauchy-filter limit, regular readback, Real seal, completion-universal, uniform provenance, transport, replay, package provenance, or local naming rows refutes the packet.

Independence witness: cauchyfiltercompletion, cauchyfilterlimit, completionuniversalproperty, uniformcompletion, regseqrat, real: none is bijective because $\mathsf{FilterCompletionUniversalProperty}^{\uparrow}$ jointly carries filter-completion source, convergence boundary, regular readback, terminal Real seal, extension, uniqueness, uniform provenance, transport, replay, package provenance, and local NameCert rows in one universal-property packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterCompletionUniversalProperty}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterCompletionUniversalProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3900.1, Definition 3900.2, Definition 3900.3, and Definition 3900.4 seed the finite L10 filter-completion universal-property route over Cauchy-filter completion, filter convergence, regular readback, Real seal, universal extension, uniform provenance, transport, replay, package provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterCompletionUniversalProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected filter limits, host equality, countable choice, ambient completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convergence exposure, extension uniqueness, filter handoff, uniform provenance, and non-escape proofs for BEDC.Derived.FilterCompletionUniversalPropertyUp.

Constructive story: A FilterCompletionUniversalProperty$^{\uparrow}$ packet is generated from a CauchyFilterCompletion row, a CauchyFilterLimit convergence row, a CompletionUniversalProperty row, a UniformCompletion provenance row, a RegSeqRat readback, a RealUp seal, an extension-uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2925

A Concrete Naming Certificate for $\mathsf{FiniteChoiceWindow}^{\uparrow}$

Following Bishop–Bridges finite choice discipline, the $\mathsf{FiniteChoiceWindow}^{\uparrow}$ packet records only those selections whose request set is already displayed as a finite unary-indexed spine. It sits between the finite observation gateway of chapter 126, the regular rational readback route of chapter 301, and the dyadic tolerance ledger of chapter 291; it supplies the L10 StreamName and RegSeqRat route with a finite section, not a countable-choice principle or a selected limiting object.

Definition 2925.1 (Finite choice window carrier)**.** *A* $\mathsf{FiniteChoiceWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, A, S, D, R, H, C, P, N)$$

with the following rows.

1. *I is a displayed unary index spine naming the finite request positions.*
2. *A is the finite candidate-row ledger, with one nonempty candidate list attached to each position of I.*
3. *S is the selected finite-section row, containing exactly one selected candidate for each displayed position of I.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that bounds the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback row consumed at the selected finite section.*
6. *H, C, P, N are respectively the componentwise* hsame *transport row, displayed* Cont *replay row,* Pkg *provenance row, and local* $\mathsf{NameCert}_{\mathsf{FiniteChoiceWindow}^{\uparrow}}$ *row.*

The classifier reads only $I, A, S, D, R, H, C, P, N$. It has no coordinate for countable choice, dependent choice, selected limits, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteChoiceWindowUp.FiniteChoiceWindowTasteGate single carrier alignment`

Theorem 2925.2 (Finite choice window NameCert surface)**.** *For every accepted* $\mathsf{FiniteChoiceWindow}^{\uparrow}$ *carrier $W = (I, A, S, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteChoiceWindow}^{\uparrow}}$ *surface consists exactly of five obligation families:*

1. *carrier admission for the unary index spine I and the candidate-row ledger A;*
2. *finite-section exactness, saying that S selects one displayed candidate for each displayed position and no undisplayed position;*

3. *tolerance compatibility with the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *and the* $\mathsf{StreamName}^{\uparrow}$ *finite window that consumes the section;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback routing through* R *after the selected finite section is fixed;*
5. *structural support through* H, C, P, N*, together with refusal of countable choice, dependent choice, selected limits, quotient stream equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

These obligations are precisely the finite window surface needed by the L10 route through $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*.*

Proof. Induct on the displayed unary index spine I. In the empty case, the candidate ledger and selected section are empty, and the carrier is admitted by the displayed transport, replay, provenance, and local naming rows.

For the successor step, assume the obligation surface has been built for the preceding finite spine. The next displayed position contributes one finite nonempty candidate list and one selected row. Adjoin that selected row to the finite section, transport it by H, replay the local route by C, and record its provenance in P and N.

The dyadic tolerance row D is stable under this finite adjoining step because the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger is read at the displayed request positions. The $\mathsf{StreamName}^{\uparrow}$ consumer sees the resulting finite section as a finite observation window, and the $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads R only after that window has been fixed.

No limiting step is used in the induction. Since every constructor step consumes one displayed list row and one displayed selected row, the proof never forms a countable-choice schedule, a dependent-choice chain, a selected limit, a quotient stream equality, or an ambient $\mathsf{Real}^{\uparrow}$ completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteChoiceWindow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteChoiceWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3901.1 and Definition 3901.2 seed the finite unary-indexed candidate carrier and its five NameCert obligation families for the L10 StreamName and RegSeqRat route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteChoiceWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, dependent choice, selected limits, quotient stream equality, Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-section exactness, dyadic tolerance compatibility, StreamName window routing, RegSeqRat readback routing, and support-row refusal for the same finite packet.

Constructive story: A $\mathsf{FiniteChoiceWindow}^{\uparrow}$ packet is generated from a displayed unary index spine, finite candidate rows, selected finite-section rows, a DyadicRatCore tolerance ledger, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2926

A Concrete Naming Certificate for $\mathsf{CauchySequenceField}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchySequenceField}^{\uparrow}$ packet records the finite regular-Cauchy route by which field-facing real operations are read from rational names. It sits after the algebraic operation rows of $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, the order and apartness rows of **??**, the finite-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational readback of chapter 301, and before the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a non-quotient field-facing route; it does not import host real arithmetic, quotient representatives, trichotomy, countable choice, or ambient completeness.

Definition 2926.1 (CauchySequenceField carrier)**.** *A* $\mathsf{CauchySequenceField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, W, D, A, O, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational name whose field-facing operations are being inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *synchronized-window row used to read the source sequence, companion operation inputs, and comparison requests at the same finite precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget ledger for radii, slack, denominator guards, and tolerance comparisons opened by the synchronized windows.*
4. *A is the* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *operation row, displaying addition, negation, multiplication, zero, one, and operation replay over the same regular-Cauchy source rows.*
5. *O is the* **??** *order and apartness row, displaying positivity, nonzero guards, reciprocal-side admission, and comparison data read through W and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, W, D, A, O have been displayed and replayed.*
7. *H records componentwise* hsame *transport for the regular-rational source, synchronized windows, dyadic budgets, algebra rows, order rows, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a field-operation request through $R, W, D, A, O, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceField}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, **??**, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchySequenceField}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, W, D, A, O, E, H, C, P, N$. It has no coordinate for a quotient real, selected sequence representative, host real field operation, trichotomy branch, countable-choice schedule, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchySequenceFieldUp.CauchySequenceFieldTasteGate single carrier alignment`

Theorem 2926.2 (CauchySequenceField NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceField}^{\uparrow}$ *carrier $F = (R, W, D, A, O, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceField}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular-rational source row R, synchronized-window exposure through W, dyadic budget exactness through D, algebraic operation exposure through A, order and apartness exposure through O, real-seal non-escape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No field-facing obligation may replace these rows by host real arithmetic or quotient equality.*

Proof. Project the carrier of Definition 3902.1. The visible rows are precisely the regular-rational source, synchronized windows, dyadic budget ledger, algebra row, order row, real seal, transport, replay, provenance, and local naming.

The algebra row A supplies the operation side only after the source row R has been read through W and D. The order row O supplies positivity, apartness, and reciprocal-side guards through the same finite windows and budgets.

The seal row E is terminal. It is reached only after the regular-Cauchy source, window, budget, algebra, and order rows have been displayed, so it cannot be used as a detached host real.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient representative, host operation, trichotomy, countable-choice, or completeness coordinate, those principles are not local NameCert obligations. □

Theorem 2926.3 (CauchySequenceField operation route)**.** *Every field-facing read exported by an accepted* $\mathsf{CauchySequenceField}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchySequenceAlgebra}^{\uparrow} \longmapsto ?? \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes algebraic operations and order-side guards as regular-Cauchy rows before any terminal real-name seal is inspected, and exports no host real arithmetic, quotient equality, selected representative, trichotomy branch, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a field-operation request for the accepted carrier $F = (R, W, D, A, O, E, H, C, P, N)$. Carrier projection exposes the $\mathsf{RegSeqRat}^{\uparrow}$ source row R and the synchronized $\mathsf{StreamName}^{\uparrow}$ windows W before any operation row can be consumed.

The dyadic ledger D then fixes the finite budgets used by the request. Algebraic operation reads pass through A, while positivity, apartness, nonzero, and reciprocal-side reads pass through O over the same windows and budgets.

Only after those rows have been displayed does the request reach the terminal $\mathsf{Real}^{\uparrow}$ seal E. The replay row C and transport row H preserve this order componentwise, and P, N source and name the same route.

Because the packet has no alternate coordinate for host real arithmetic, quotient equality, selected representatives, trichotomy, countable choice, or ambient completeness, every exported field-facing read is forced through the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceField}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3902.1, Definition 3902.2, and Definition 3902.3 seed the finite regular-Cauchy field route from RegSeqRat, StreamName, DyadicRatCore, CauchySequenceAlgebra, and CauchySequenceOrder rows into the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host real arithmetic, quotient equality, selected sequence representatives, trichotomy, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window exposure, dyadic-budget exactness, algebra and order handoff, real-seal non-escape, transport, and replay proofs for BEDC.Derived.CauchySequenceFieldUp.

Constructive story: A $\mathsf{CauchySequenceField}^{\uparrow}$ packet is generated from a regular rational source row, synchronized StreamName windows, a DyadicRatCore tolerance ledger, CauchySequenceAlgebra operation rows, CauchySequenceOrder order and apartness rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2927

A Concrete Naming Certificate for BishopLocatedCompletionReflector$^{\uparrow}$

Following Bishop and Bridges on constructive completion and located real analysis, the BishopLocatedCompletionRef packet records the reflector row that binds the located-real completion route of chapter 3488 to the public completion-reflector surface of chapter 1585. It consumes the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the located-real row of chapter 1933, and the terminal real seal of chapter 38. The packet is a human-origin reflector for displayed located completion data; it is not quotient completion equality, a selected limit, countable choice, trichotomy, or ambient completeness.

Definition 2927.1 (Bishop located completion reflector carrier)**.** *A* BishopLocatedCompletionReflector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, R, D, S, Q, L, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* BishopLocatedRealCompletion$^{\uparrow}$ *row exposing the located-real completion carrier through dyadic tolerances, finite stream windows, regular rational readback, locatedness, and a terminal real seal.*
2. *R is the* CauchyCompletionReflector$^{\uparrow}$ *row exposing unit, counit, idempotence, extension, reflection, and local real-name transport for the same completion-facing read.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used by both the located completion route and the reflector's local real-name transport.*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row inspected at those displayed tolerances.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *regular rational readback row obtained from the same finite windows.*
6. *L is the* LocatedReal$^{\uparrow}$ *locatedness row attached to Q.*
7. *E is the* Real$^{\uparrow}$ *seal reached only after B, R, D, S, Q, L have been displayed.*
8. *H records componentwise* hsame *transport for the located completion row, reflector row, dyadic tolerance, stream-window, regular readback, locatedness, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion-facing request through $B, R, D, S, Q, L, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletionReflector}^{\uparrow}$, $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionReflector}^{\uparrow}}$ *row binding the displayed completion-reflector packet.*

The classifier on accepted packets compares only these rows under the displayed transport and replay data. It has no coordinate for quotient streams, selected representatives, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionReflectorUp.BishopLocatedCompletionReflectorTasteGate`
`single carrier alignment`

Theorem 2927.2 (Bishop located completion reflector NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompletionReflector}^{\uparrow}$ *carrier* $K = (B, R, D, S, Q, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionReflector}^{\uparrow}}$ *surface consists exactly of carrier admission, Bishop-located completion exposure, CauchyCompletionReflector exposure, DyadicRatCore tolerance exposure, StreamName finite-window exposure, RegSeqRat readback, LocatedReal locatedness exposure, Real seal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming. Every reflector-facing consumer reads only the displayed route*

$$B, R \longmapsto D \longmapsto S \longmapsto Q \longmapsto L \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Proof. Project the carrier of Definition 3903.1. The only analytic rows are the located completion row, the public reflector row, the dyadic tolerance ledger, finite stream windows, regular rational readback, locatedness row, and Real seal.

Read the route in order. The row B supplies the located completion side and the row R supplies the reflector side. Their common finite route is then displayed through D, S, Q, L, E, so the reflector consumer cannot choose a second tolerance ledger, a host stream, or a selected real representative.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since quotient streams, selected limits, host equality, countable choice, trichotomy, compactness, and ambient completeness have no coordinate in the carrier, they cannot become local NameCert obligations. □

Theorem 2927.3 (Bishop located completion reflector route)**.** *Every* $\mathsf{BishopLocatedCompletionReflector}^{\uparrow}$ *consumer that treats displayed located Cauchy data as a reflector object must pass through the sibling route of chapter 3488 and the public reflector route of chapter 1585. The accepted packet exposes the reflector only as the finite carrier* $B, R, D, S, Q, L, E, H, C, P, N$ *and exports no quotient completion equality, selected host limit, countable-choice selector, trichotomy split, detached* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or host real equality test.*

Proof. Start with the NameCert obligations. They force any reflector-facing read to expose both the Bishop-located completion row B and the CauchyCompletionReflector row R before the terminal real seal is readable.

The shared analytic route is D, S, Q, L, E. The dyadic tolerance row fixes the finite request, the StreamName row opens the corresponding windows, the RegSeqRat row repacks those windows as regular rational data, the LocatedReal row supplies the lower–upper separation evidence, and the Real row seals the route.

The sibling chapters supply adjacent but not interchangeable packets. $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ gives the located completion side, and $\mathsf{CauchyCompletionReflector}^{\uparrow}$ gives the public reflector side. The present carrier binds both with the common dyadic, stream, regular-rational, located-real, and real-seal rows, so no omitted sibling or host-level object can replace it. □

Falsifiable prediction: A claimed $\mathsf{BishopLocatedCompletionReflector}^{\uparrow}$ read that reaches the $\mathsf{Real}^{\uparrow}$ seal without first displaying both the $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ row and the $\mathsf{CauchyCompletionReflector}^{\uparrow}$ row over the shared dyadic, stream, regular-rational, and located-real route refutes the carrier surface.

Independence witness: bishop-located-real-completion, cauchycompletionreflector, dyadicratcore, streamname, regseqrat, locatedreal, real: no listed sibling is bijective to $\mathsf{BishopLocatedCompletionReflector}^{\uparrow}$ because this packet binds the located completion row and public reflector row to one shared finite tolerance, window, readback, locatedness, real-seal, transport, replay, provenance, and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompletionReflector}^{\uparrow}$ packet is generated from a BishopLocatedRealCompletion row, a CauchyCompletionReflector row, DyadicRatCore tolerances, StreamName finite windows, RegSeqRat readback, LocatedReal locatedness, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3903.1, Definition 3903.2, and Definition 3903.3 seed the finite reflector route binding located completion and public completion reflection over the shared dyadic, stream, regular-rational, located-real, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, selected limits, countable choice, trichotomy, host real equality, open-cover compactness, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-completion exposure, reflector exposure, tolerance-window exactness, regular readback, locatedness handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCompletionReflectorUp.

Chapter 2928

A Concrete Naming Certificate for $\mathsf{CellularOrbitSynchronization}^{\uparrow}$

The $\mathsf{CellularOrbitSynchronization}^{\uparrow}$ packet realizes the cellular carrier alternative of chapter 9391 as a finite paired-orbit synchronization surface. It consumes the observation-boundary route of chapter 2371, the classifier-boundary route of chapter 3810, the paired audit coupling of chapter 847, and the twin-substrate bridge of chapter 850. The packet records two local orbit replays together with the classifier tag row that authorizes them as one closed substrate read.

Definition 2928.1 (Cellular orbit synchronization carrier)**.** *A* $\mathsf{CellularOrbitSynchronization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O_0, O_1, G, B, Q, A, T, H, C, P, N)$$

with the following displayed rows:

1. *O_0 and O_1 are paired local orbit replay rows, each giving a finite transition table, initial row, time window, spatial window, and replay ledger.*
2. *G is the classifier tag row that assigns both replayed windows to the same substrate observation family.*
3. *B is the* $\mathsf{CellularSubstrateObservationBoundary}^{\uparrow}$ *boundary row recording the manifest and accepted observation windows used by the paired replay.*
4. *Q is the* $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$ *row requiring the classifier tags to be displayed before either orbit read is exported.*
5. *A is the* $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ *row that records paired audit use without collapsing the two replay rows into a shared host orbit.*
6. *T is the* $\mathsf{TwinSubstrateBridge}^{\uparrow}$ *row through which the paired read may be inspected by a bridge-facing consumer.*
7. *H records componentwise* hsame *transport for the two orbit replays, classifier tag, observation boundary, classifier boundary, audit coupling, twin-substrate bridge, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the paired local orbits through G, B, Q, A, T, H, P, N.*

9. *P is the* Pkg *provenance over* CellularOrbitSynchronization$^{\uparrow}$, CellularSubstrateObservationBoundary$^{\uparrow}$, CellularSubstrateClassifierBoundary$^{\uparrow}$, TwinSubstrateAuditCoupling$^{\uparrow}$, TwinSubstrateBridge$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* NameCert$_{\text{CellularOrbitSynchronization}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unclassified orbit read, a detached host evaluator, an all-time induction principle, quotient stream equality, or an identification of the two substrate roles.

Lean4 ✓ `BEDC.Derived.CellularOrbitSynchronizationUp.CellularOrbitSynchronizationTasteGate`
`single carrier alignment`

Theorem 2928.2 (CellularOrbitSynchronization NameCert obligations)**.** *For every accepted* CellularOrbitSynchron *carrier $S = (O_0, O_1, G, B, Q, A, T, H, C, P, N)$, the local* NameCert$_{\text{CellularOrbitSynchronization}^{\uparrow}}$ *surface consists exactly of carrier admission for the paired orbit replays, classifier tag row, observation boundary, classifier boundary, audit coupling, twin-substrate bridge, componentwise transport, displayed continuation replay, package provenance, and local naming. Every synchronized substrate read factors through*

$$O_0, O_1 \longmapsto G \longmapsto B, Q \longmapsto A, T \longmapsto H, C, P, N.$$

No synchronized orbit obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3904.1. The accepted packet displays exactly the paired local orbit rows, classifier tag row, observation boundary, classifier boundary, audit coupling, bridge row, and structural rows.

The classifier row is read before the boundary rows. Thus a pair of replay ledgers O_0, O_1 becomes a synchronized substrate read only when G names the inspected pattern family and the rows B, Q bind that tag to the observation and classifier boundaries.

The audit and bridge rows preserve the paired reading without identifying the two replays. The row A supplies paired audit coupling, T supplies bridge-facing inspection, and H, C, P, N transport, replay, source, and name only that finite packet. Therefore unclassified orbit reads, host evaluators, all-time induction, quotient streams, and substrate-role identifications cannot become NameCert obligations. □

Theorem 2928.3 (CellularOrbitSynchronization classifier-locked handoff)**.** *Every synchronized orbit read accepted by a* CellularOrbitSynchronization$^{\uparrow}$ *packet displays the classifier tag row G before either paired orbit replay is exported through the observation boundary, classifier boundary, audit coupling, or twin-substrate bridge. A Lean follow-up for this carrier must supply* Nontrivial *and* FieldFaithful *instances in* `lean4/BEDC/Derived/CellularOrbitSynchronizationUp/TasteGate.lean`.

Proof. Project the accepted carrier. The paired orbit rows O_0, O_1 are present, but they are not exported directly; they are routed through the classifier tag row G.

Use the observation and classifier boundaries. The observation-boundary row B fixes the manifest and local windows, while the classifier-boundary row Q requires the pattern tag to be displayed for each observed window. Hence an orbit replay without G has no accepted route to a synchronized read.

The audit coupling and bridge rows are downstream. They consume the already tagged boundary packet, and the structural rows H, C, P, N preserve the same finite route. Thus the classifier-locked handoff is the only exported synchronization surface. □

Falsifiable prediction: Any synchronized orbit read that displays the paired local orbit replays but omits the classifier tag row G is rejected by the CellularOrbitSynchronization$^{\uparrow}$ carrier.

Independence witness: `cellular_substrate_observation_boundary`, `cellular_substrate_classifier_bo`
`twinsubstrateauditcoupling`, `twinsubstratebridge`: none is bijective to $\mathsf{CellularOrbitSynchronization}^{\uparrow}$ because the synchronization packet uniquely binds paired local orbit replays, classifier-locked observation rows, paired audit coupling, bridge-facing inspection, transport, replay, provenance, and local naming in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CellularOrbitSynchronization}^{\uparrow}}$.

Constructive story: A $\mathsf{CellularOrbitSynchronization}^{\uparrow}$ packet is generated from paired local orbit replay rows, a classifier tag row, CellularSubstrateObservationBoundary and CellularSubstrateClassifierBoundary rows, TwinSubstrateAuditCoupling and TwinSubstrateBridge rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CellularOrbitSynchronization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3904.1, Definition 3904.2, and Definition 3904.3 seed the finite classifier-locked synchronization surface for paired local cellular orbit reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CellularOrbitSynchronization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, all-time cellular induction, host evaluator correctness, quotient stream equality, or identification of the two substrate roles.

Upgrade path: Obligation closure requires checked carrier admission, paired orbit replay exactness, classifier-tag exposure, observation-boundary and classifier-boundary handoff, audit coupling, bridge-facing inspection, transport, replay, provenance, and local naming for BEDC.Derived.CellularOrbitSynchronizationUp.

Chapter 2929

A Concrete Naming Certificate for FiniteDimensionalHahnBanachSeparation$^{\uparrow}$

Following Bishop–Bridges constructive analysis and finite-dimensional separation theory, the FiniteDimensionalHahn packet records the finite certificate surface for a separating affine functional between a located point and a displayed convex set in a finite-dimensional normed vector space. It consumes the vector-space row of chapter 47, the linear-map row of chapter 48, the finite norm row used by chapter 1644, the real-name row of chapter 38, the located comparison row of chapter 1730, and the convex-set row of chapter 208. The packet is deliberately finite-dimensional: it names coefficient rows and located comparisons only for the displayed finite basis window, and it has no coordinate for full Hahn–Banach extension, choice-selected duals, or ambient weak-star compactness.

Definition 2929.1 (Finite-dimensional Hahn–Banach separation carrier)**.** *A* FiniteDimensionalHahnBanachSeparati *carrier is a finite* BHist *packet*

$$S = (V, B, L, N, R, Q, C, E, H, T, P, M)$$

with the following displayed rows:

1. *V is the finite* VecSpace$^{\uparrow}$ *source row, including the finite coordinate window on which every vector read is performed;*
2. *B is the finite basis and coefficient-admission ledger, recording that each inspected vector is read by finitely many scalar coordinates;*
3. *L is the* LinMap$^{\uparrow}$ *row for the separating functional, displayed by its finite coefficient list on B;*
4. *N is the* Norm$^{\uparrow}$ *row used only to bound the coefficient list and the finite vector reads;*
5. *R is the* Real$^{\uparrow}$ *endpoint ledger for scalar evaluations and thresholds;*
6. *Q is the* LocatedRealComparison$^{\uparrow}$ *row deciding the displayed scalar inequality with located slack;*
7. *C is the* ConvexSet$^{\uparrow}$ *row for the accepted convex-set membership and convex-combination reads;*
8. *E is the exact separation row, containing the point-side and set-side evaluation endpoints and their located comparison;*
9. *H records componentwise* hsame *transport for $V, B, L, N, R, Q, C, E, P, M$;*
10. *T records displayed* Cont *replay through the finite coordinate, functional, comparison, convex-set, and exactness rows;*

11. *P is the* Pkg *provenance over* FiniteDimensionalHahnBanachSeparation$^{\uparrow}$, VecSpace$^{\uparrow}$, LinMap$^{\uparrow}$, Norm$^{\uparrow}$, Real$^{\uparrow}$, LocatedRealComparison$^{\uparrow}$, ConvexSet$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *M is the local* NameCert$_{\text{FiniteDimensionalHahnBanachSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed finite rows. It has no coordinate for an arbitrary extension of a functional, a selected quotient dual, a Zorn-style maximal sublinear extension, weak-star compactness, or an infinite family of separating hyperplanes.

Lean4 ✓ `BEDC.Derived.FiniteDimensionalHahnBanachSeparationUp.FiniteDimensionalHahnBanachSeparationTaste single carrier alignment`

Theorem 2929.2 (Finite coefficient admission)**.** *For every accepted* FiniteDimensionalHahnBanachSeparation$^{\uparrow}$ *carrier $S = (V, B, L, N, R, Q, C, E, H, T, P, M)$, every read of the separating functional factors through the finite coefficient ledger B, the* LinMap$^{\uparrow}$ *row L, the norm row N, and the scalar endpoint ledger R. A consumer may inspect only the finitely displayed coefficient list on the finite* VecSpace$^{\uparrow}$ *window; it may not replace that list by a host dual-space element or by a choice-selected functional.*

Proof. Project the accepted carrier. The vector data are read through V and the coefficient window B, while the functional row is L and the scalar endpoints are R.

The norm row N bounds only those displayed coefficient and vector reads. Transport and replay through H, T, P, M preserve the same finite list, so no additional coordinate can introduce a host dual element.

Thus coefficient admission is finite-row admission. The accepted packet exports the displayed list and its NameCert routes, not an unrestricted dual object or a choice-selected functional. □

Theorem 2929.3 (Separating inequality exactness)**.** *For every accepted* FiniteDimensionalHahnBanachSeparation$^{\uparrow}$ *carrier $S = (V, B, L, N, R, Q, C, E, H, T, P, M)$, the separating inequality is exactly the row E read through the* Real$^{\uparrow}$ *endpoints in R, the* LocatedRealComparison$^{\uparrow}$ *comparison row Q, and the* ConvexSet$^{\uparrow}$ *membership row C. Consequently any downstream convex-analysis consumer receives a located scalar comparison between the point-side evaluation and the set-side bound, not an ambient separation theorem.*

Proof. Read the exactness row E. Its scalar endpoints are supplied by R, and the comparison between them is supplied by Q.

The convex side is constrained by C: membership and convex-combination reads of the displayed set pass through the finite convex-set row before the set-side bound can be cited. The functional values used by both sides still pass through B, L, N from Definition 3905.2.

Therefore the public inequality is the located comparison stored in E over the displayed finite rows. No consumer can cite a stronger ambient separating-hyperplane principle from this packet. □

Theorem 2929.4 (No escape to full Hahn–Banach choice)**.** *An accepted* FiniteDimensionalHahnBanachSeparation$^{\uparrow}$ *carrier exports no full Hahn–Banach extension principle, no Zorn-style maximal extension, no selected quotient dual, no weak-star compactness object, and no infinite separating family. Every exported read factors through the finite vector-space window, coefficient ledger, linear-map row, norm row, real endpoint ledger, located comparison row, convex-set row, exactness row, componentwise transport, displayed replay, provenance, and local NameCert rows.*

Proof. Inspect the carrier coordinates. They are exactly $V, B, L, N, R, Q, C, E, H, T, P, M$, so every accepted read is a projection of one of those rows or a replay through the structural rows.

The rows B, L, N, R, Q, C, E are finite-dimensional and located: coefficients are listed on the finite basis window, scalar endpoints are displayed as $\mathsf{Real}^{\uparrow}$ rows, and the separation statement is a $\mathsf{LocatedRealComparison}^{\uparrow}$ row.

The excluded principles require coordinates not present in the carrier. Since there is no row for arbitrary extension, maximality, quotient dual selection, weak-star compactness, or an infinite family, those principles cannot be exported by the local NameCert surface. □

Falsifiable prediction: Dropping the coefficient ledger B makes Definition 3905.2 false: a consumer could no longer distinguish a displayed finite functional from an ambient host dual element.

Independence witness: vecspace, linearmap, norm, real, locatedrealcomparison, convexset: none is bijective with $\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}$ because this carrier alone binds the finite vector-space window, coefficient ledger, linear functional, norm bound, scalar endpoints, located comparison, convex-set membership, and exact separation row into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}$ packet is generated from a finite VecSpaceUp coordinate window, a finite coefficient ledger, a LinearMapUp separating functional row, a NormUp bound row, RealUp scalar endpoints, a LocatedRealComparisonUp inequality row, a ConvexSetUp membership row, separating exactness data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3905.1, Definition 3905.2, Definition 3905.3, and Definition 3905.4 seed the finite-dimensional separation packet over VecSpaceUp, LinearMapUp, NormUp, RealUp, LocatedRealComparisonUp, ConvexSetUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Hahn–Banach extension, Zorn maximality, selected quotient duals, weak-star compactness, infinite separating families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite coefficient transport, separating inequality exactness, convex-set readback, classifier stability, and non-escape for BEDC.Derived.FiniteDimensionalHahnBanachSeparationUp.

Chapter 2930

A Concrete Naming Certificate for PiecewiseLinearApproximation$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the PiecewiseLinearApproximation$^{\uparrow}$ packet records polygonal approximation over a closed bounded interval as finite NameCert rows. It starts from the ClosedBoundedInterval$^{\uparrow}$ source of chapter 1591, reads a UniformPartition$^{\uparrow}$ or DyadicPartition$^{\uparrow}$ mesh through chapter 2033 and chapter 1863, compares its cell ledger with the DyadicStepApproximation$^{\uparrow}$ route of chapter 3774, and hands terminal endpoint and value reads to ContinuousMap$^{\uparrow}$, Real$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ consumers through chapter 130, chapter 38, and chapter 291. The certificate names the finite affine-cell surface only; it does not introduce a host function space, selected uniform limit, quotient equality of functions, open-cover compactness, or ambient real completeness.

Definition 2930.1 (PiecewiseLinearApproximation carrier)**.** *A* PiecewiseLinearApproximation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, M, E, A, D, F, T, H, C, P, N)$$

with the following displayed rows:

1. *I is the* ClosedBoundedInterval$^{\uparrow}$ *source row, displaying the two endpoint* Real$^{\uparrow}$ *names and the bounded interval window being approximated.*
2. *M is a* UniformPartition$^{\uparrow}$ *or* DyadicPartition$^{\uparrow}$ *mesh row, including the ordered cell boundary ledger, the positive mesh-width row, and the endpoint-coverage route.*
3. *E is the finite endpoint-value ledger, recording one* Real$^{\uparrow}$ *value row at every displayed mesh boundary.*
4. *A is the affine cell ledger: for each adjacent mesh cell it records the two endpoint-value rows, the affine interpolation route between them, and the cell-local evaluation window.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *slope and error ledger, recording dyadic slope brackets, cell-width witnesses, tolerance requests, and the displayed error budget used by downstream approximation consumers.*
6. *F is the* ContinuousMap$^{\uparrow}$ *handoff row, exposing the polygonal route only after I, M, E, A, D have been displayed.*
7. *T is the comparison row with* DyadicStepApproximation$^{\uparrow}$*, reading the same mesh cells and tolerance requests as a step-surface neighbour without identifying the affine ledger with a step ledger.*

8. *H records componentwise* hsame *transport for the interval source, mesh, endpoint values, affine cell rows, dyadic slope and error ledger, continuous-map handoff, step-neighbour row, provenance, and local naming.*

9. *C records displayed* Cont *replay of the route*

$$I, M, E, A, D \longmapsto F, T \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* PiecewiseLinearApproximation$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, UniformPartition$^{\uparrow}$, DyadicPartition$^{\uparrow}$, DyadicStepApproximation$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Real$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{PiecewiseLinearApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host function graph, quotient equality of maps, selected limiting function, compactness theorem, countable-choice schedule, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PiecewiseLinearApproximationUp.PiecewiseLinearApproximationTasteGate`
`single carrier alignment`

Theorem 2930.2 (PiecewiseLinearApproximation NameCert obligations)**.** *For every accepted* PiecewiseLinearApproximation$^{\uparrow}$ *carrier*

$$L = (I, M, E, A, D, F, T, H, C, P, N),$$

the local NameCert$_{\text{PiecewiseLinearApproximation}^{\uparrow}}$ *surface consists exactly of interval-source admission through I, mesh coverage through M, endpoint-value display through E, affine cell exactness through A, dyadic slope and error accounting through D, continuous-map handoff through F, step-surface comparison through T, componentwise transport through H, replay through C, provenance through P, and local naming through N. No obligation may read a host function space, selected uniform limit, quotient map equality, open-cover compactness, countable choice, or ambient real completeness.*

Proof. Carrier admission is projection from Definition 3906.1. The accepted packet displays the closed bounded interval, mesh, endpoint values, affine cell rows, dyadic slope and error ledger, and structural rows before any continuous-map or step-neighbour consumer sees the approximation.

The mesh rows are finite. The UniformPartition$^{\uparrow}$ or DyadicPartition$^{\uparrow}$ row supplies the ordered cells, endpoint coverage, and positive width witnesses, while the ClosedBoundedInterval$^{\uparrow}$ row fixes the source window. Thus every affine cell row is attached to a displayed source cell rather than to an ambient interval object.

The affine rows and dyadic ledger exhaust the approximation data. Each cell read factors through its two endpoint Real$^{\uparrow}$ values and the DyadicRatCore$^{\uparrow}$ slope and error ledger before the ContinuousMap$^{\uparrow}$ handoff row is available.

Finally H, C, P, N transport, replay, source, and name only this finite packet. Since no further carrier coordinate remains, the excluded host-function, quotient, limit, compactness, choice, and completeness objects cannot become local NameCert obligations. □

Theorem 2930.3 (PiecewiseLinearApproximation uniform handoff)**.** *Every* ContinuousMap$^{\uparrow}$, DyadicStepApproxim
Real$^{\uparrow}$, *or* DyadicRatCore$^{\uparrow}$ *consumer of an accepted* PiecewiseLinearApproximation$^{\uparrow}$ *packet receives only the finite route*

ClosedBoundedInterval$^{\uparrow}$, UniformPartition$^{\uparrow}$ or DyadicPartition$^{\uparrow}$, endpoint Real$^{\uparrow}$ rows, affine cells, DyadicRatCore$^{\uparrow}$ le

The consumer may inspect the polygonal approximation as a finite uniform or dyadic mesh surface, but it cannot bypass that route to obtain a host continuous function, selected uniform limit, quotient function equality, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The terminal consumers see F or T only after I, M, E, A, D have been displayed.

For the continuous-map handoff, the row F reads the same endpoint values, affine cell routes, and dyadic error ledger. It therefore exports a polygonal route over the visible mesh, not a host function graph.

For the step-surface neighbour, the row T shares the mesh and tolerance requests with $\mathsf{DyadicStepApproximation}^{\uparrow}$ while preserving the affine cell ledger as a separate displayed row. Hence the handoff can compare approximation ledgers without collapsing them into quotient equality of functions.

The remaining rows H, C, P, N only transport and replay the same finite data. No hidden limit, compactness, choice, completeness, or host-map coordinate is present for a consumer to read. □

Closure status for $\mathsf{NameCert}_{\mathsf{PiecewiseLinearApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{PiecewiseLinearApproximation}^{\uparrow}$ packet is generated from a ClosedBoundedInterval source row, a UniformPartition or DyadicPartition mesh row, endpoint RealUp value rows, affine cell rows, a DyadicRatCore slope and error ledger, a ContinuousMap handoff row, a DyadicStepApproximation neighbour row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PiecewiseLinearApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3906.1, Definition 3906.2, and Definition 3906.3 seed the finite polygonal approximation surface over closed bounded interval, mesh, endpoint-value, affine-cell, dyadic-ledger, and continuous-map handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PiecewiseLinearApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected uniform limits, quotient function equality, open-cover compactness, countable choice, host function spaces, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, mesh coverage, endpoint-value display, affine cell exactness, dyadic slope and error accounting, continuous-map handoff, step-neighbour comparison, transport, replay, provenance, and local naming for BEDC.Derived.PiecewiseLinearApproximationUp.

Chapter 2931

A Concrete Naming Certificate for $\mathsf{CompactIntervalMaximum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactIntervalMaximum}^{\uparrow}$ packet records the finite witness surface for a continuous real-valued map on a closed bounded interval to expose a maximum candidate. It consumes the endpoint and containment route of chapter 1591, the finite interval-net surface of $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, the graph and continuity rows of chapter 130, and the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback route. The packet names only finite BEDC evidence for a maximum witness; it does not import host extrema, open-cover compactness, selected subcovers, Real completeness, quotient equality, Lean verification, or bridge checking.

Definition 2931.1 (Compact interval maximum carrier)**.** *A* $\mathsf{CompactIntervalMaximum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, F, G, N, S, R, E, W, H, C, P, L)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing endpoint order, rational containment, dyadic containment,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *sealing.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the displayed interval source, including finite graph reads and pointwise continuity data.*
3. *G is the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *finite-cell row, listing the interval cells, centers, radius ledgers, and coverage reads used by the witness search.*
4. *N is the finite value-comparison row selecting a displayed cell and center whose readback is no smaller than the other displayed net values at the admitted precision.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for endpoint, graph, and value observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected value and comparison witnesses.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the selected maximum-witness value after I, F, G, N, S, R have been displayed.*
8. *W is the witness-locality row saying that the selected center is read through a cell of G whose containment is certified by I.*
9. *H records componentwise* hsame *transport for I, F, G, N, S, R, E, W and the local packet shape.*

10. *C records displayed* Cont *replay from interval source and graph reads through finite cells, value comparison, witness locality, readback, Real sealing, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalMaximum}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalMaximum}^{\uparrow}}$ *row.*

The carrier exports no host maximum operator, open-cover compactness theorem, selected subcover, ambient Real completeness principle, quotient equality of real names, or global choice row.

Theorem 2931.2 (Compact interval maximum finite witness obligations)**.** *For the carrier of Definition 3907.1, every accepted maximum-witness read factors through the closed bounded interval row I, the continuous-map graph row F, the finite-net cell row G, the finite value-comparison row N, the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback route S, R, E, the witness-locality row W, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming L. These rows are the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalMaximum}^{\uparrow}}$ *obligation surface.*

Lean4 ✓ `BEDC.Derived.CompactIntervalMaximumUp.CompactIntervalMaximumTasteGate single carrier alignment`

Proof. Project the carrier. The interval source, graph, finite-cell, comparison, schedule, readback, seal, witness-locality, transport, replay, provenance, and local naming rows are the only coordinates of the accepted packet.

The closed bounded interval row I supplies endpoint order and containment ledgers before any cell is inspected. The finite-net row G supplies the displayed cells and centers, while F supplies the graph reads whose values are compared by N.

The readback route is downstream of those finite rows. The schedule S, regular rational readback R, and Real seal E expose the selected witness value only through the displayed observations, and W keeps the selected center inside a certified cell of the interval net.

Finally H, C, P, L transport, replay, package, and name the same finite surface. Since the packet has no coordinate for host extrema, open covers, selected subcovers, ambient completeness, quotient equality, or global choice, every accepted maximum-witness read remains on the displayed NameCert rows. □

Falsifiable prediction: A compact-interval maximum consumer that omits the finite cell row, graph row, or value-comparison row cannot claim a $\mathsf{CompactIntervalMaximum}^{\uparrow}$ witness.

Independence witness: closedboundedinterval, continuousmap, heineborel-finite-net, regseqrat, real: $\mathsf{CompactIntervalMaximum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries interval containment, graph reads, finite cells, value comparison, selected witness locality, readback, sealing, transport, replay, provenance, and local naming rows.

The Lean TasteGate site for $\mathsf{CompactIntervalMaximum}^{\uparrow}$ is expected at `BEDC.Derived.CompactIntervalMaximu` It should preserve the finite maximum-witness surface as carrier data before any downstream extreme-value consumer can inspect it.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalMaximum}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalMaximum}^{\uparrow}$ packet is generated from a closed bounded interval row, a continuous-map graph row, a finite interval-net row, a finite value-comparison witness, StreamName schedules, RegSeqRat readbacks, a Real seal, witness locality, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalMaximum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3907.1 and Definition 3907.2 seed the finite maximum-witness carrier for continuous maps on closed bounded intervals.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactIntervalMaximum}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host extrema, open-cover compactness, selected subcovers, Real completeness, quotient equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cell coverage, graph readback, value comparison, witness locality, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalMaximumUp.

Chapter 2932

A Concrete Naming Certificate for $\mathsf{FilterCompletionMonad}^{\uparrow}$

Following Kelley and Bourbaki on filters and completion, the $\mathsf{FilterCompletionMonad}^{\uparrow}$ packet records the finite monad-shaped surface by which a displayed Cauchy-filter completion route admits a unit, a flattening read, and a terminal Real handoff without quotienting filters or selecting limits. It sits after the Cauchy-filter completion boundary of chapter 1569, the finite basis route of chapter 3862, the Cauchy-filter cluster route of chapter 1734, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet exposes the completion monad only as finite BHist and $\mathsf{NameCert}$ rows.

Definition 2932.1 (Cauchy completion filter monad carrier)**.** *A* $\mathsf{FilterCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, B, Z, S, R, D, E, U, F, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion-boundary row whose accepted reads remain tied to displayed finite Cauchy-filter evidence.*
2. *B is the* $\mathsf{FilterLimitBasis}^{\uparrow}$ *basis row used by the completion request before any Real-facing seal is inspected.*
3. *Z is the* $\mathsf{CauchyFilterCluster}^{\uparrow}$ *cluster-handoff row, exposing the same finite support as a windowed cluster route.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule read by the basis and cluster rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same finite windows and readback rows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only downstream from Q, B, Z, S, R, D.*
8. *U is the unit row, admitting a displayed source filter as a one-layer completion packet without adding a quotient filter or chosen limit.*
9. *F is the multiplication row, flattening a displayed two-layer completion packet by replaying its inner and outer Q, B, Z, S, R, D, E routes.*

10. *A is the associativity replay row, recording that the two displayed flattening orders read the same finite rows before E.*

11. *H records componentwise* hsame *transport for the completion, basis, cluster, window, readback, tolerance, seal, unit, flattening, associativity, replay, provenance, and local naming rows.*

12. *C records displayed* Cont *replay for unit reads, flattening reads, associativity reads, and Real handoff reads through $Q, B, Z, S, R, D, E, U, F, A, H, P, N$.*

13. *P is the* Pkg *provenance over* $\mathsf{FilterCompletionMonad}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilterCluster}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterCompletionMonad}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, B, Z, S, R, D, E, U, F, A, H, C, P, N$. There is no coordinate for quotient filters, selected limits, ultrafilters, countable-choice schedules, host filter equality, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FilterCompletionMonadUp.FilterCompletionMonadTasteGate single carrier alignment`

Theorem 2932.2 (Cauchy completion filter monad laws)**.** *For every accepted* $\mathsf{FilterCompletionMonad}^{\uparrow}$ *carrier $M = (Q, B, Z, S, R, D, E, U, F, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FilterCompletionMonad}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed* $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilterCluster}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *unit, multiplication, associativity, transport, replay, provenance, and local naming rows;*

2. *unit admission through U, requiring every source-filter read to enter the completion route through the same Q, B, Z, S, R, D, E rows;*

3. *multiplication admission through F, requiring every two-layer completion read to flatten by replaying the inner and outer displayed completion routes before the terminal seal;*

4. *associativity of displayed replay through A, requiring the two flattening orders to expose the same $Q, B, Z, S, R, D, E, U, F, H, C, P, N$ rows before any Real-facing consumer reads E;*

5. *Real handoff through E, requiring completion, basis, cluster, window, readback, tolerance, transport, replay, provenance, and local naming to remain visible to every* $\mathsf{Real}^{\uparrow}$ *consumer.*

No listed obligation may be discharged by quotient filters, selected limits, ultrafilters, countable-choice schedules, host equality, detached completion points, or ambient completeness.

Proof. Project the carrier of Definition 3908.1. The visible rows are exactly $Q, B, Z, S, R, D, E, U, F, A, H, C, P, N$, so carrier admission has no hidden quotient-filter, selected-limit, choice, host-equality, or ambient-completeness coordinate.

The unit row is read as a displayed admission into the existing completion boundary. It points the source filter through the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row Q, the $\mathsf{FilterLimitBasis}^{\uparrow}$ row B, the $\mathsf{CauchyFilterCluster}^{\uparrow}$ row Z, and the finite observation rows S, R, D before E is available.

The multiplication row flattens only displayed completion data. An accepted two-layer packet first replays the inner and outer Q, B, Z, S, R, D, E routes, and then records the flattened route through F, H, C, P, N.

Associativity is the equality of the displayed replay surface, not an ambient quotient principle. The row A states that the two orders of flattening expose the same finite rows before the terminal seal, so no selected representative or ultrafilter argument can enter between the two replays.

Finally apply the Real handoff. Since E is downstream from the completion, basis, cluster, window, readback, tolerance, unit, flattening, associativity, transport, replay, provenance, and local naming rows, every $\mathsf{Real}^{\uparrow}$ consumer receives the displayed monad route and no external completion principle. □

Falsifiable prediction: An accepted $\mathsf{FilterCompletionMonad}^{\uparrow}$ read is refuted if unit, multiplication, associativity, or Real handoff reaches a terminal seal without displaying the CauchyFilterCompletion, FilterLimitBasis, CauchyFilterCluster, StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local naming rows.

Independence witness: cauchyfiltercompletion, filterlimitbasis, cauchyfiltercluster, streamname, regseqrat, dyadicratcore, real: $\mathsf{FilterCompletionMonad}^{\uparrow}$ is not bijective to any listed sibling because it records unit, flattening, associativity replay, and Real handoff as one finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterCompletionMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{FilterCompletionMonad}^{\uparrow}$ packet is generated from a CauchyFilterCompletion row, FilterLimitBasis row, CauchyFilterCluster row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, unit admission, multiplication flattening, associativity replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterCompletionMonad}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3908.1 and Definition 3908.2 seed the finite filter-completion monad route over completion, basis, cluster, window, readback, tolerance, Real seal, unit, flattening, associativity, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterCompletionMonad}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, ultrafilters, countable-choice schedules, host equality, detached completion points, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit admission, multiplication flattening, associativity replay, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.FilterCompletionMonadUp.

Chapter 2933

A Concrete Naming Certificate for MetaCICDecidableNeutralSpine$^{\uparrow}$

The MetaCICDecidableNeutralSpine$^{\uparrow}$ packet realizes the neutral-spine branch of the MetaCIC decidability audit map as finite BEDC data. It reads the bounded normal-equality checker of chapter 752, the decidability boundary of chapter 749, the witness surface of chapter 751, the typing frontier of chapter 3616, and the fuel trace of chapter 3889. Its role is to expose a neutral-spine comparison route without promoting bounded computation to global conversion decidability.

Definition 2933.1 (MetaCIC decidable neutral-spine carrier)**.** *A* MetaCICDecidableNeutralSpine$^{\uparrow}$ *carrier is a finite packet*

$$S = (T, E, Q, B, R, H, C, P, N)$$

with the following rows:

1. *T is the typing-checker frontier row, carrying the closed context, neutral head, spine arguments, and result type read by* MetaCICDecidableTypingFrontier$^{\uparrow}$*.*
2. *E is the same-term row for structurally identical neutral heads and argument lists.*
3. *Q is the bounded normal comparison row supplied by* BoundedNormalEqualityChecker$^{\uparrow}$*.*
4. *B is the boundary row stating which finished-normal-form evidence would be needed to pass from bounded comparison to public conversion decidability.*
5. *R is the refusal row blocking any consumer that asks for unbounded beta-conversion, subject reduction, or strong-normalization evidence not displayed in S.*
6. *H is componentwise* hsame *transport for the typing, same-term, bounded-comparison, boundary, refusal, replay, provenance, and local-name rows.*
7. *C is the displayed* Cont *replay from a neutral-spine decidability request through T, E, Q, B, R, H, P, N.*
8. *P is* Pkg *provenance over the MetaCIC typing checker,* BoundedNormalEqualityChecker$^{\uparrow}$*,* MetaCICDecidableBoun MetaCICDecidabilityWitness$^{\uparrow}$*,* MetaCICDecidableTypingFrontier$^{\uparrow}$*,* MetaCICFuelTrace$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* NameCert$_{\text{MetaCICDecidableNeutralSpine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these displayed rows. It has no coordinate for global conversion decidability, unrestricted normalization, subject reduction, confluence, or an external semantic equality oracle.

Theorem 2933.2 (Neutral-spine NameCert obligations)**.** *Every accepted* MetaCICDecidableNeutralSpine$^{\uparrow}$ *carrier exposes the finite obligation surface consisting of typing-frontier exactness, same-term structural readback, bounded normal comparison, decidability-boundary refusal, componentwise transport, displayed replay, provenance, and local naming. A consumer of the packet receives no additional global conversion theorem.*

Proof. Project the carrier of Definition 3909.1. The typing row T fixes the closed neutral-spine boundary before any comparison row is read, and the same-term row E records only structural agreement of the displayed neutral head and argument list.

The bounded comparison row Q is then interpreted through the boundary row B and refusal row R. These rows expose exactly the finite checker result and the missing endpoint evidence; they do not add strong normalization, confluence, subject reduction, or unbounded conversion.

Finally, H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Hence every accepted read of the packet is confined to the displayed NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.MetaCICDecidableNeutralSpineUp.MetaCICDecidableNeutralSpineTasteGate`
`single carrier alignment`

Theorem 2933.3 (Neutral-spine bounded-comparison boundary)**.** *For any accepted* MetaCICDecidableNeutralSpine *carrier, the passage from a bounded normal-equality answer to a public neutral-spine conversion answer is admissible only when the finished-normal-form boundary named by B is supplied inside the carrier route. Without that row, the packet exports a checker-local answer and a refusal, not global decidability.*

Proof. Read the bounded comparison row Q together with the boundary row B. The comparison row supplies a finite result about the inspected normal forms, while B records the exact endpoint evidence needed for public conversion.

If B is absent from the consumer route, the refusal row R is the only admissible export beyond the bounded checker answer. The transport and replay rows keep this refusal attached to the same typed neutral spine, so no external normalizer or semantic equality proof can enter through provenance. □

Theorem 2933.4 (Neutral-spine fuel monotonicity)**.** *Let $S = (T, E, Q, B, R, H, C, P, N)$ be an accepted* MetaCICDecidableNeutralSpine$^{\uparrow}$ *carrier whose bounded normal comparison row Q records a checker-local answer at fuel k. If a displayed extension of the same fuel trace reaches fuel k' while preserving the typing frontier, same-term row, endpoint-boundary row, refusal row, componentwise transport, replay, provenance, and local naming rows T, E, B, R, H, C, P, N, then the extended comparison consumer remains inside the same checker-local answer/refusal boundary. It does not export public conversion decidability, strong normalization, confluence, subject reduction, or a semantic equality oracle.*

Proof. Project the carrier and the displayed fuel trace from the bounded comparison row Q. The extension to k' is admissible only because it preserves the already displayed typing frontier and same-term rows T, E together with the same endpoint-boundary row B.

The refusal row R remains attached to the extended trace. Thus increasing the inspected fuel may refine the checker-local comparison row, but it still leaves any request for public conversion outside the displayed endpoint evidence.

Finally, replay the extended row through C and transport the unchanged coordinates componentwise through H. The provenance and local naming rows P, N identify the result as the

same finite neutral-spine packet, so no global conversion theorem or off-packet normalizer is made available. □

Falsifiable prediction: An accepted $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$ consumer is refuted if it exports neutral-spine conversion while omitting the displayed typing-frontier row, same-term row, bounded normal-equality row, boundary row, refusal row, transport, replay, provenance, or local NameCert row.

Independence witness: boundednormalequalitychecker, metacicdecidableboundary, metacicdecidabilitywitness, metacic-decidable-typing-frontier: no listed sibling is bijective to $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$ because this packet jointly carries the typed neutral-spine frontier, structural same-term row, bounded normal comparison, endpoint-boundary refusal, transport, replay, provenance, and local naming in one carrier. The bounded checker lacks the typed frontier and refusal packet; the boundary packet lacks the same-term spine; the witness packet records typing and conversion evidence without owning the neutral-spine route; the typing frontier lacks the bounded normal comparison boundary.

Lean follow-up must provide Nontrivial and FieldFaithful TasteGate instances for the neutral-spine carrier before any bridge can upgrade the verification axis.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$ packet is generated from typing-checker frontier data, same-term neutral-spine readback, bounded normal comparison, endpoint-boundary refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3909.1, Definition 3909.2, and Definition 3909.3 seed the neutral-spine decidability carrier, obligation surface, and bounded-comparison boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global conversion decidability, strong normalization, subject reduction, confluence, semantic equality, Lean verification, or bridge checking for $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, typing-frontier exactness, same-term readback, bounded normal-comparison soundness, endpoint-boundary refusal, replay stability, provenance non-escape, and TasteGate instances for BEDC.Derived.MetaCICDecidableNeutralSpineUp.

Chapter 2934

A Concrete Naming Certificate for $\mathsf{YoungIntegral}^{\uparrow}$

Following Young and Lyons, the $\mathsf{YoungIntegral}^{\uparrow}$ packet records controlled Riemann-sum integration from finite p-variation data. It sits beside the bounded-variation carrier of chapter 398, the regulated-function surface of chapter 1906, the Riemann-sum packet of chapter 1615, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The chapter names only the finite controlled-sum route; it does not import measure completion, quotient equality of functions, selected refinements, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2934.1 (Young integral carrier)**.** *A* $\mathsf{YoungIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, V, C, S, D, R, E, H, K, P, N)$$

with the following displayed rows:

1. *F is the regulated integrand row, read through* $\mathsf{RegulatedFunction}^{\uparrow}$ *and its finite left/right window data.*
2. *G is the regulated integrator row, carrying the same interval ledger and endpoint schedule as F.*
3. *V is the p-variation and control ledger, recording bounded-variation comparison rows, variation exponents, control steps, and the finite superadditivity checks used by the route.*
4. *C is the controlled-window row, matching integrand oscillation windows with integrator variation windows before any sum is formed.*
5. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *row listing the tagged partitions, dyadic mesh requests, controlled step values, and finite sum values.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for mesh radii, variation bounds, and sum-difference margins.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational Cauchy trace of controlled sums.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *integral seal reached only after F, G, V, C, S, D, R have been displayed.*
9. *H records componentwise* hsame *transport for the integrand, integrator, variation ledger, controlled windows, Riemann-sum row, dyadic ledger, readback, seal, provenance, and local name.*

10. *K records displayed* Cont *replay from a Young-integral request through controlled windows, finite sums, dyadic tolerances, regular readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegral}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a measure-completion object, quotient equality of functions, an unrecorded refinement selector, a host rough-path lift, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.YoungIntegralUp.YoungIntegralTasteGate single carrier alignment`

Theorem 2934.2 (Young integral NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegral}^{\uparrow}$ *carrier* $Y = (F, G, V, C, S, D, R, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegral}^{\uparrow}}$ *surface is exhausted by integrand admission, integrator admission, p-variation control, controlled-window matching, Riemann-sum formation, dyadic tolerance exactness, regular rational readback, Real-seal handoff, componentwise transport, displayed replay, provenance, and local naming. No accepted consumer may replace those rows by measure completion, quotient function equality, a selected refinement sequence, a host rough-path lift, countable choice, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 3910.1. The rows F and G expose the regulated integrand and integrator data, while V records the finite variation and control ledger used by the integration route.

The controlled windows are then finite. The row C matches integrand oscillation windows to integrator variation windows, and S forms only the tagged sums displayed by the $\mathsf{RiemannSum}^{\uparrow}$ packet.

The convergence handoff is read through D, R, E. Dyadic tolerances in D bound the mesh and sum-difference rows, R records the regular rational trace, and E seals the resulting Real value only after the previous rows have been consumed.

Finally H, K, P, N transport, replay, source, and name that same route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 2934.3 (Young integral Riemann-sum handoff)**.** *Every accepted* $\mathsf{YoungIntegral}^{\uparrow}$ *integral read factors through*

$$\mathsf{RegulatedFunction}^{\uparrow} \longmapsto \mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{RiemannSum}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as recorded by F, G, V, C, S, D, R, E. The handoff exports a finite controlled Riemann-sum route and no measure-completion integral, quotient function equality, unrecorded refinement selector, host rough-path lift, countable-choice principle, or ambient Real-completeness theorem.

Proof. Start with the integrand and integrator rows. The regulated-function siblings expose the finite endpoint and window data for F and G, and the bounded-variation sibling supplies the visible variation ledger read by V.

Next form the controlled Riemann sums. The window row C records which integrand and integrator windows are paired, and the $\mathsf{RiemannSum}^{\uparrow}$ row S records the tagged finite sums over those windows.

The tolerance and readback rows then force the terminal route. The dyadic ledger D supplies mesh and sum-difference margins, R records the regular rational trace, and E is the only Real seal available to the consumer.

Transport and replay through H, K, P, N preserve this finite route. Therefore the public integral read cannot escape to measure completion, quotient function equality, a hidden refinement selector, rough-path enhancement, countable choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegral}^{\uparrow}$ packet is refuted if a consumer reaches the Real integral seal while omitting the controlled-window row C, the Riemann-sum row S, the dyadic tolerance row D, or the regular readback row R.

Independence witness: BoundedVariation, RegulatedFunction, RiemannSum, DyadicRatCore, RegSeqRat, Real: none is bijective with $\mathsf{YoungIntegral}^{\uparrow}$ because the packet jointly carries integrand and integrator rows, a variation-control ledger, controlled windows, finite sums, dyadic tolerances, regular readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegral}^{\uparrow}$ packet is generated from regulated integrand and integrator rows, a p-variation control ledger, controlled Riemann-sum windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3910.1, Definition 3910.2, and Definition 3910.3 seed the finite controlled-sum route for Young integration.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected refinement sequences, host rough-path lifts, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked integrand admission, integrator admission, variation-control exactness, controlled-window matching, Riemann-sum handoff, dyadic tolerance readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegralUp.

Chapter 2935

A Concrete Naming Certificate for $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$

The $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ packet realizes the type-checking-as-classifier-membership vision of chapter 9367 as a finite NameCert carrier. It reads the classifier-membership packet of chapter 476, the typing classifier of chapter 489, the subject-reduction surface of chapter 483, the derivation trace of chapter 598, and the proof-erasure route of chapter 642. The packet records membership, derivation, preservation, and erasure rows together; it does not export a host type checker, semantic conversion oracle, quotient equality of terms, hidden proof object, or ambient normalization theorem.

Definition 2935.1 (TypeCheckingClassifierMembership carrier)**.** *A* $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, J, E, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the term-history row whose membership is being checked.*
2. *J is the finite typing-judgment ledger, read through* $\mathsf{ClassifierTyping}^{\uparrow}$*.*
3. *E is the* Ext *classifier-membership row, read through* $\mathsf{TypeClassifierMembership}^{\uparrow}$*.*
4. *D is the derivation trace row, read through* $\mathsf{TypeCheckingDerivationTrace}^{\uparrow}$*.*
5. *S is the subject-reduction row, recording the displayed preservation handoff into* $\mathsf{SubjectReduction}^{\uparrow}$*.*
6. *Q is the proof-erasure row, read through* $\mathsf{ProofTermErasureTrace}^{\uparrow}$ *and separating public erased terms from proof evidence.*
7. *H records componentwise* hsame *transport for the term, judgment, membership, derivation, preservation, erasure, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a type-checking request through classifier membership, derivation trace, subject reduction, and erasure readback.*
9. *P is the* Pkg *provenance over* $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$*,* $\mathsf{TypeClassifierMembership}^{\uparrow}$*,* $\mathsf{ClassifierTyping}^{\uparrow}$*,* $\mathsf{SubjectReduction}^{\uparrow}$*,* $\mathsf{TypeCheckingDerivationTrace}^{\uparrow}$*,* $\mathsf{ProofTermErasureTrace}^{\uparrow}$*,* BHist*,* Ext*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TypeCheckingClassifierMembership}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host type checker, hidden conversion relation, semantic equality of terms, quotient term representative, proof object outside the erasure row, or global normalization theorem.

Lean4 (definition) `BEDC.Derived.TypeCheckingClassifierMembershipUp.taste gate`

Theorem 2935.2 (TypeCheckingClassifierMembership NameCert obligations)**.** *For every accepted* $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ *carrier* $M = (T, J, E, D, S, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TypeCheckingC}}$ *surface is exhausted by term-row admission, typing-ledger admission,* Ext *membership exposure, derivation-trace exposure, subject-reduction handoff, proof-erasure separation, componentwise transport, displayed replay, provenance, and local naming. No accepted consumer may replace those rows by host type checking, hidden conversion, semantic equality of terms, quotient representatives, proof objects outside* Q*, or ambient normalization.*

Proof. Project the carrier of Definition 3911.1. The rows T, J, E expose the term, finite typing ledger, and Ext membership surface used by the classifier-membership read.

The derivation and preservation rows are also displayed. The row D records the finite type-checking derivation trace, and S records the subject-reduction handoff that may be consumed only through the visible preservation boundary.

The erasure row Q separates proof evidence from public erased terms. It supplies the proof-term erasure trace without adding a proof object outside the packet.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the excluded host checker, conversion oracle, semantic equality, quotient representative, hidden proof object, and normalization theorem have no coordinate in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 2935.3 (TypeCheckingClassifierMembership subject-reduction handoff)**.** *Every subject-reduction read exported by an accepted* $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{TypeClassifierMembership}^{\uparrow} \longmapsto \mathsf{ClassifierTyping}^{\uparrow} \longmapsto \mathsf{TypeCheckingDerivationTrace}^{\uparrow} \longmapsto \mathsf{SubjectReduction}^{\uparrow} \longmapsto \mathsf{Proc}$$

as recorded by E, J, D, S, Q*. The handoff preserves classifier membership and public erasure through* H, C, P, N*, and it exports no host typing judgment, hidden conversion relation, semantic equality of terms, quotient term representative, proof object outside* Q*, or ambient normalization theorem.*

Proof. Begin with the membership row E and the typing ledger J. The type-classifier membership and classifier-typing siblings already route type membership through finite Ext, Cont, SigRel, and NameCert data.

Next read the derivation trace D. It records the rule ledger and continuation route used by the type-checking run, so the preservation request reaches $\mathsf{SubjectReduction}^{\uparrow}$ only through the displayed trace.

The subject-reduction row S is therefore a handoff, not a hidden theorem. The proof-erasure row Q records which public erased data may be read after preservation while keeping proof evidence inside the trace boundary.

Transport and replay through H, C, P, N preserve this route. Therefore a consumer receives exactly classifier membership, derivation trace, preservation handoff, and erasure separation, with no host typing judgment or normalization oracle. □

Falsifiable prediction: An accepted $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ packet is refuted if a subject-reduction consumer reaches S without the membership row E, derivation trace D, proof-erasure row Q, and structural route H, C, P, N.

Independence witness: TypeClassifierMembership, ClassifierTyping, SubjectReduction, TypeCheckingDerivationTrace, ProofTermErasureTrace: none is bijective with $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ because the packet jointly carries term rows, typing ledgers, Ext membership, derivation traces, subject-reduction handoff, proof-erasure separation, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TypeCheckingClassifierMembership}^{\uparrow}}$.

Constructive story: A $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ packet is generated from a term-history row, finite typing ledger, Ext membership row, derivation trace, subject-reduction handoff, proof-erasure row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypeCheckingClassifierMembership}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3911.1, Definition 3911.2, and Definition 3911.3 seed the finite type-checking classifier-membership packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypeCheckingClassifierMembership}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host type checking, hidden conversion, semantic equality of terms, quotient term representatives, proof objects outside erasure rows, global normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked term-row admission, typing-ledger admission, Ext membership exposure, derivation-trace exposure, subject-reduction handoff, proof-erasure separation, and structural transport for BEDC.Derived.TypeCheckingClassifierMembershipUp.

Chapter 2936

A Concrete Naming Certificate for $\mathsf{CauchyCompletionReflectorComparison}^{\uparrow}$

Following Bishop and Bridges constructive completion and Bourbaki's universal-mapping language, the $\mathsf{CauchyCompletionReflectorComparison}^{\uparrow}$ packet records one finite BEDC certificate comparing the reflector, comparison, adjunction, and monad presentations of Cauchy completion. It reads the reflector route of chapter 1585, the comparison surface of chapter 1954, the adjunction handoff of chapter 1456, and the monad schedule of chapter 378 through the same finite real-seal route. The packet names the common certificate surface only; it does not construct quotient completions, choose representatives, identify host objects, or appeal to ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 2936.1 (CauchyCompletionReflectorComparison carrier)**.** *A* $\mathsf{CauchyCompletionReflectorComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (\rho, K_0, A, M, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. ρ *is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row exposing unit, counit, idempotent, extension, reflection, and local real-transport data.*
2. K_0 *is the* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *row exposing the comparison between unit-and-universal-property and functorial metric-completion presentations.*
3. A *is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *row exposing the finite unit-counit handoff surface.*
4. M *is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row exposing the finite schedule, diagonal readback, and monad composition boundary.*
5. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *window route inspected by all four completion presentations.*
6. Q *is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route reached after the displayed windows.*
7. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window route.*
8. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after* W, D, Q *have been displayed.*
9. H *records componentwise* hsame *transport for the four presentation rows, the shared real-seal rows, replay, provenance, and naming.*
10. C *records displayed* Cont *replay of the route*

$$\rho, K_0, A, M \longmapsto W, D, Q \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* CauchyCompletionReflectorComparison$^{\uparrow}$, CauchyCompletionReflector$^{\uparrow}$, CauchyCompletionComparison$^{\uparrow}$, CauchyCompletionAdjunction$^{\uparrow}$, CauchyCompletionMonad$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{CauchyCompletionReflectorComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows and their displayed transports. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed objects, open-cover compactness, or completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorComparisonUp.CauchyCompletionReflectorComparisonTasteGate`
`single carrier alignment`

Theorem 2936.2 (CauchyCompletionReflectorComparison NameCert obligations)**.** *For every accepted* CauchyCompletionReflectorComparison$^{\uparrow}$ *carrier*

$$K = (\rho, K_0, A, M, W, Q, D, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyCompletionReflectorComparison}^{\uparrow}}$ *surface consists exactly of reflector-route admission through ρ; comparison-route exposure through K_0; adjunction handoff through A; monad schedule compatibility through M; shared finite real-seal routing through W, D, Q, E; componentwise transport through H; replay through C; provenance through P; and local naming through N. It exports no quotient completion, selected representative, countable choice, host equality, open-cover compactness, or* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is tuple projection from Definition 3912.1. The accepted packet displays exactly the four presentation rows, the shared window-tolerance-readback-seal route, and the structural rows.

The reflector, comparison, adjunction, and monad rows are then read as sibling routes. The row ρ contributes the reflector route, K_0 contributes the comparison route, A contributes the adjunction handoff, and M contributes the schedule and diagonal-readback compatibility. None of these rows contains an independent terminal seal.

The common real-facing route is exhausted by W, D, Q, E. A consumer must inspect the finite StreamName$^{\uparrow}$ windows, the DyadicRatCore$^{\uparrow}$ tolerance ledger, and the RegSeqRat$^{\uparrow}$ readback before reaching the terminal Real$^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name only the displayed packet. Since no further coordinate remains in the carrier, quotient completions, selected representatives, countable choice, host equality, open-cover compactness, and ambient Real$^{\uparrow}$ completeness cannot be exported. □

Closure status for NameCert$_{\text{CauchyCompletionReflectorComparison}^{\uparrow}}$.

Constructive story: A CauchyCompletionReflectorComparison$^{\uparrow}$ packet is generated from reflector, comparison, adjunction, and monad presentation rows, shared StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCompletionReflectorComparison}^{\uparrow}}$, seed)

Scope closed: Definition 3912.1 and Definition 3912.2 seed the finite certificate comparing reflector, comparison, adjunction, and monad completion presentations over one shared real-seal route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionReflectorComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality, open-cover compactness, Real$^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector-route admission, comparison-route exposure, adjunction handoff, monad schedule compatibility, shared real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionReflectorComparisonUp.

Chapter 2937

A Concrete Naming Certificate for CompactRegularCauchySubsequence$^{\uparrow}$

Following Bishop and Bridges on compact metric sequential arguments and regular Cauchy real names, the CompactRegularCauchySubsequence$^{\uparrow}$ packet records the finite route by which compact metric inspection supplies a regular Cauchy subsequence window before any Real or Completion consumer reads the result. It sits over the compact metric source of chapter 129, the mature regular-subsequence route of chapter 381, the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive compact-subsequence certificate for L10 completion consumers; it is not open-cover compactness, countable choice, quotient stream equality, host sequence equality, or ambient Real$^{\uparrow}$ completeness.

Definition 2937.1 (Compact regular Cauchy subsequence carrier)**.** *A* CompactRegularCauchySubsequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, S, T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row carrying finite-net, located-distance, and compact-bundle inspection data.*
2. *S is the source* StreamName$^{\uparrow}$ *row for the sequence windows inspected by the compact metric consumer.*
3. *T is the monotone-cofinal unary reindexing ledger consumed by the* RegularCauchySubsequence$^{\uparrow}$ *surface.*
4. *W is the selected finite subsequence-window row, pairing each retained compact window with the inspected source window that produced it.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger attached to compact mesh radii, selected-window distances, and regular Cauchy tail budgets.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the selected windows and their transported regularity evidence.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row, exposed only after the compact source, subsequence ledger, finite windows, dyadic tolerances, and regular readback have been displayed.*

8. *H records componentwise* hsame *transport for K, S, T, W, D, R, E.*
9. *C records displayed* Cont *replay from compact metric inspection through finite windows, subsequence selection, dyadic tolerances, regular readback, and the Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactRegularCauchySubsequence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRegularCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, T, W, D, R, E, H, C, P, N$. It has no coordinate for an externally selected infinite subsequence, open-cover compactness theorem, quotient stream representative, host sequence equality, host real equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompactRegularCauchySubsequenceUp.CompactRegularCauchySubsequenceTasteGate`
`single carrier alignment`

Theorem 2937.2 (Compact regular Cauchy subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CompactRegularCauchySubsequence}^{\uparrow}$ *carrier*

$$Q = (K, S, T, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRegularCauchySubsequence}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure through K, source-window exposure through S, monotone-cofinal subsequence exposure through T, selected-window exposure through W, dyadic tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal handoff through E, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3913.1. The finite packet exposes exactly the compact metric source, source stream windows, reindexing ledger, selected windows, dyadic ledger, regular rational readback, Real seal, and the structural provenance rows.

Read the compact and subsequence rows first. The row K supplies only displayed compact metric inspection data, while S, T, W record the source windows, monotone-cofinal route, and selected finite windows consumed by the regular-subsequence surface.

The analytic handoff is then forced through D, R, E. The dyadic ledger records the mesh and tail budgets, the regular rational row reads the selected windows as regular data, and the Real seal row is downstream of those rows.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate exists, the listed rows exhaust the local NameCert obligations. □

Theorem 2937.3 (Compact regular Cauchy subsequence route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CompactRegularCauchySubsequence}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegularCauchySubsequence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

The compact source row supplies finite inspection windows, the regular-subsequence row supplies the monotone-cofinal selected-window ledger, and the dyadic and regular rational rows supply the Cauchy budgets before the terminal Real seal is exposed.

Proof. Begin with an accepted carrier $Q = (K, S, T, W, D, R, E, H, C, P, N)$. The compact source row K is the only compact metric coordinate, and the source windows are read through S.

Apply the regular-subsequence public export of Definition 381.9. The selected windows are named by the monotone-cofinal ledger T and the finite window row W, so the consumer cannot replace them by an unrecorded subsequence selector.

Next read the dyadic and regular rational rows. The ledger D carries the compact mesh and tail budgets, and R repacks the selected windows as $\mathsf{RegSeqRat}^{\uparrow}$ readback data.

The Real seal E is therefore reached only after the compact source, finite windows, subsequence ledger, dyadic tolerance rows, and regular readback have been displayed. Transport and replay through H, C, P, N preserve that same route, so open-cover compactness, countable choice, quotient streams, host equality, and ambient completeness remain outside the exported packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRegularCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRegularCauchySubsequence}^{\uparrow}$ packet is generated from a CompactMetric source row, StreamName finite windows, a RegularCauchySubsequence monotone-cofinal ledger, selected finite windows, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRegularCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3913.1, Definition 3913.2, and Definition 3913.3 seed the compact-source regular Cauchy subsequence route over CompactMetric, StreamName, RegularCauchySubsequence, DyadicRatCore, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRegularCauchySubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient stream equality, host sequence equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window exposure, monotone-cofinal selected-window routing, dyadic tolerance accounting, RegSeqRat readback exactness, RealUp seal nonescape, and selector-refusal proofs for BEDC.Derived.CompactRegularCauchySubsequenceUp.

Chapter 2938

A Concrete Naming Certificate for $\mathsf{LindelofSpace}^{\uparrow}$

Following Lindelof, Bourbaki, and Kelley on second-countable topology, the $\mathsf{LindelofSpace}^{\uparrow}$ packet records the countable subcover route that is visible from a displayed countable-base presentation. It sits over the countable-base carrier of chapter 1901, the local countable-neighbourhood route of chapter 2053, the generated-open classifier of chapter 88, and the finite inspection windows of chapter 126. The packet names only displayed cover enumeration windows, extracted subcover ledgers, base-refinement routes, transport, replay, provenance, and local naming; it does not select arbitrary subcovers by choice, assert compactness, or add a host open-family oracle.

Definition 2938.1 (Lindelof space carrier)**.** *A* $\mathsf{LindelofSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, T, B, U, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source topology carrier row whose finite histories supply the only points and opens inspected by the packet.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *generated-open classifier row used by every open-cover and subcover read.*
3. *B is the* $\mathsf{SecondCountable}^{\uparrow}$ *base-enumeration row, recording the finite basic-open windows through which cover membership is tested.*
4. *U is the countable cover enumeration row, displaying the open-cover entries visible to the packet through T and the finite windows of B.*
5. *S is the extracted countable subcover ledger, recording the selected cover indices and the basic cells whose refinements witness coverage.*
6. *R is the base-refinement route from displayed basic cells in B into cover entries in U, with every refinement read tied to the same topology row T.*
7. *H stores componentwise* hsame *transport for the source topology, topology classifier, base enumeration, cover enumeration, extracted subcover ledger, refinement route, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a point or basic-cell read through the topology classifier, countable-base window, cover enumeration, extracted subcover ledger, refinement route, transport, provenance, and local name.*

9. *P is the* Pkg *provenance row over* $\mathsf{LindelofSpace}^{\uparrow}$, $\mathsf{SecondCountable}^{\uparrow}$, $\mathsf{FirstCountableSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LindelofSpace}^{\uparrow}}$ *row.*

The carrier exports a countable subcover only as the displayed ledger S over the displayed cover enumeration U. It has no coordinate for arbitrary open-cover compactness, host choice of subcovers, quotient equality of opens, or a fuel-erased enumeration of all covers.

Lean4 ✓ `BEDC.Derived.LindelofSpaceUp.LindelofSpaceTasteGate single carrier alignment`

Theorem 2938.2 (Lindelof countable-cover route)**.** *For an accepted* $\mathsf{LindelofSpace}^{\uparrow}$ *carrier*

$$Q = (X, T, B, U, S, R, H, C, P, N),$$

every countable-subcover read factors through the finite route

$$X, T, B, U, S, R, H, C, P, N.$$

The reader first opens the source topology and generated-open classifier, then inspects the displayed second-countable base window, then reads the cover enumeration, extracted subcover ledger, base-refinement route, componentwise transport, replay, provenance, and local naming rows. No consumer receives a host family of all open covers, an unrestricted subcover selector, an open-cover compactness theorem, or equality of opens outside the displayed classifier.

Proof. Project the accepted carrier through Definition 3914.1. The rows $X, T, B, U, S, R, H, C, P, N$ are the complete surface available to a consumer.

The cover read starts in X and T. A displayed open-cover entry is not read as a host open set; it is read through the generated-open classifier and the finite base window B.

The extracted subcover is then read through S and R. The subcover ledger stores the visible cover indices, while the refinement row records how displayed basic cells refine into those entries.

Finally H, C, P, N transport, replay, source, and name the same route. Since no other coordinate is present, the packet cannot export arbitrary open-cover compactness, a choice-selected subcover, quotient equality of opens, or a host oracle for all covers. □

Theorem 2938.3 (Lindelof second-countable handoff)**.** *Every accepted* $\mathsf{SecondCountable}^{\uparrow}$ *packet with a displayed countable open-cover enumeration induces a* $\mathsf{LindelofSpace}^{\uparrow}$ *read by replaying the cover through finite base windows and recording the extracted countable subcover ledger. The induced read keeps the same source topology, generated-open classifier, countable-base enumeration, stream-window discipline, transport, replay, provenance, and local naming rows; only the cover enumeration U, extracted ledger S, and refinement route R are added as Lindelof rows.*

Proof. Start with the accepted $\mathsf{SecondCountable}^{\uparrow}$ packet. Its source row, topology classifier, displayed base enumeration, stream-window discipline, transport, replay, provenance, and local name already have the BEDC roles required by Definition 3914.1.

Read the displayed countable cover through the same finite base windows. For each accepted basic cell, the refinement route records the cover entry that contains it, and the extracted ledger records the visible cover index.

Replay the finite base-window enumeration to form the countable subcover ledger. This is a ledger read over B, U, S, R, not a choice principle over a host family of opens.

The remaining rows are unchanged. The handoff therefore adds only the Lindelof cover, ledger, and refinement rows, while preserving the second-countable topology source and excluding compactness, arbitrary subcover selection, and host open equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{LindelofSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LindelofSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3914.1, Definition 3914.2, and Definition 3914.3 seed the finite countable-subcover interface over displayed topology rows, second-countable base windows, cover enumerations, extracted subcover ledgers, refinement routes, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LindelofSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary subcover choice, quotient equality of opens, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, countable-cover routing, second-countable handoff, base-refinement replay, transport, provenance, and local naming for BEDC.Derived.LindelofSpaceUp.

Constructive story: A $\mathsf{LindelofSpace}^{\uparrow}$ packet is generated from one source topology row, one Topology classifier row, one SecondCountable base-enumeration row, one countable cover enumeration row, one extracted countable subcover ledger, one base-refinement route, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2939

A Concrete Naming Certificate for $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$ packet records a finite dyadic refinement-tree certificate for closed bounded interval cover work. It sits between the dyadic cover rows of chapter 1428, the finite comparison surface of chapter 3430, and the endpoint-and-containment packet of chapter 1591. The packet names the tree of displayed subdivisions and retained cover leaves; it is not open-cover compactness, a host subcover selector, a selected Lebesgue number, quotient equality of real names, or countable choice.

Definition 2939.1 (Interval cover refinement tree carrier)**.** *An* $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, D, R, M, L, E, W, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, naming the lower endpoint, upper endpoint, endpoint-order, containment, StreamName, RegSeqRat, and Real-seal data being covered.*
2. *D is the* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *cover row whose finite dyadic endpoints and membership rows are inspected by the tree.*
3. *R is the* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *comparison row that records how a retained child cover refines its parent cover entry.*
4. *M is the finite mesh-depth ledger, listing the dyadic scale used at each visited tree node.*
5. *L is the finite leaf row. Each leaf records a dyadic subinterval, its parent node, and the displayed cover member that contains it at the tolerance named by M.*
6. *E is the edge row, recording the binary split relation between a node and its two dyadic children, together with the inherited endpoint-containment witnesses.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the interval endpoints and cover endpoints at the mesh scales named by M.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint and cover windows.*
9. *A is the visible* $\mathsf{Real}^{\uparrow}$ *seal row reached only through I, W, Q and the displayed dyadic cover data.*

10. *H stores componentwise* hsame *transport for interval, cover, refinement, mesh, leaf, edge, window, readback, seal, provenance, and local naming rows.*
11. *C stores displayed* Cont *replay from closed interval containment to dyadic subdivision, from subdivision to cover membership, from membership to refinement comparison, and from windows to the visible Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalCoverRefinementTree}^{\uparrow}}$ *row.*

The accepted carrier is only the finite tree packet displayed above. It contains no arbitrary open cover, no host finite-subcover selector, no selected point of the interval, no selected Lebesgue number, no quotient equality of real names, no countable-choice functional, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.IntervalCoverRefinementTreeUp.TasteGate.IntervalCoverRefinementTreeTasteGate single carrier alignment`

Theorem 2939.2 (Interval cover refinement tree NameCert obligations)**.** *For an accepted packet $T = (I, D, R, M, L, E, W, Q, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IntervalCoverRefinementTree}^{\uparrow}}$ *obligations are exhausted by closed bounded interval admission through I, dyadic cover admission through D, finite refinement admission through R, mesh-depth admission through M, leaf and edge admission through L and E, finite-window readback through W and Q, Real sealing through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier row by row. The interval source is exactly the $\mathsf{ClosedBoundedInterval}^{\uparrow}$ packet I, the cover source is exactly the $\mathsf{DyadicIntervalCover}^{\uparrow}$ packet D, and the comparison source is exactly the $\mathsf{FiniteCoverRefinement}^{\uparrow}$ packet R.

The tree rows add only finite subdivision data. The mesh ledger M, leaves L, and edges E list the visited nodes, their dyadic children, and the retained cover members, so every local admission check is a finite projection from the displayed BHist packet.

The endpoint and cover reads remain on the displayed route. The $\mathsf{StreamName}^{\uparrow}$ row W, $\mathsf{RegSeqRat}^{\uparrow}$ row Q, and $\mathsf{Real}^{\uparrow}$ seal A are replayed by C and transported by H. Since the packet has no row for an arbitrary open cover, selected subcover, selected point, Lebesgue number choice, quotient equality, or completeness principle, no such datum can enter the local NameCert obligations. □

Theorem 2939.3 (Dyadic subcover route)**.** *Every retained subcover read exported by an accepted* $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$ *packet factors through the finite route*

$$I \longmapsto D \longmapsto R \longmapsto M \longmapsto L \longmapsto E \longmapsto (W, Q, A, H, C, P, N).$$

In particular, a consumer may inspect only the dyadic child intervals, the finite leaf-cover assignments, the displayed refinement comparison rows, and the finite endpoint windows named in the carrier.

Proof. Start from the closed interval row I. It supplies the endpoint and containment surface before any cover or tree row is inspected.

Next read the dyadic cover and refinement rows. The cover packet D lists the available dyadic cover members, and the refinement packet R records how a child cover assignment is compared with a parent cover assignment. The mesh, leaf, and edge rows M, L, E then expose the finite tree spine on which these comparisons are made.

Finally pass through the structural rows. Transport H, replay C, provenance P, and local name N preserve the same finite route, while W, Q, A keep all endpoint reads behind finite StreamName, RegSeqRat, and Real-seal rows. No additional subcover or compactness object is available. □

Theorem 2939.4 (Choice-free nonescape)**.** *An* $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$ *consumer cannot escape the finite refinement tree by invoking open-cover compactness, a host finite-subcover selector, a selected Lebesgue number, quotient equality of real names, a chosen point in the interval, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every accepted read is determined by the finite rows* $I, D, R, M, L, E, W, Q, A, H, C, P, N$ *and their displayed* hsame *and* Cont *routes.*

Proof. The carrier definition lists every coordinate of the packet. The analytic coordinates are $I, D, R, M, L, E, W, Q, A$, and the structural coordinates are H, C, P, N.

Apply the NameCert obligation theorem. It makes those rows the whole local naming surface and gives no replay path to an arbitrary open cover, host subcover selector, selected Lebesgue number, quotient equality, or completeness coordinate.

The dyadic subcover route supplies the consumer-facing consequence. Any accepted read must pass through the same finite interval, cover, refinement, tree, window, readback, and seal rows, so choice-based or host-level data cannot affect the result. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalCoverRefinementTree}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IntervalCoverRefinementTree}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a DyadicIntervalCoverUp cover row, a FiniteCoverRefinementUp comparison row, finite mesh-depth, leaf, and edge rows, StreamName windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IntervalCoverRefinementTree}^{\uparrow}}$, seed)

Scope closed: Definition 3916.1, Definition 3916.2, Definition 3916.3, and Definition 3916.4 bind the finite dyadic refinement-tree seed over closed bounded interval covers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IntervalCoverRefinementTree}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.IntervalCoverRefinementTreeUp.TasteGate.IntervalCoverRefinementTreeTasteGate\_single\_c`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Heine–Borel compactness, selected subcovers, selected Lebesgue numbers, quotient real equality, countable choice, Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dyadic leaf coverage, refinement transport, Real-seal nonescape, and tree-ledger exactness for the displayed packet.

Chapter 2940

A Concrete Naming Certificate for $\mathsf{NeumannSeries}^{\uparrow}$

Following Banach algebra treatments of Neumann series, the $\mathsf{NeumannSeries}^{\uparrow}$ packet records the finite inverse-series certificate by which a norm-small operator or algebra element exposes partial sums, residual checks, and inverse-readback rows before any host inverse selector is available. It sits beside the Banach-algebra source of chapter 2189, the bounded-operator route of chapter 1644, the scalar norm-bound surface of chapter 3603, the resolvent identity packet of chapter 3715, and the spectral-radius boundary of chapter 2352. The packet names a finite inverse route: it does not select a completed inverse from the host, assert a completed spectrum, or import a quotient equality of operators.

Definition 2940.1 (Neumann inverse-series carrier)**.** *A* $\mathsf{NeumannSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (A, T, K, W, S, Q, R, E, H, C, P, L)$$

with the following displayed rows:

1. *A is the* $\mathsf{BanachAlgebra}^{\uparrow}$ *source row, carrying multiplication, unit, norm, completeness, product-control, and local naming data.*
2. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *or algebra-action row whose smallness is being inspected.*
3. *K is the norm-smallness ledger, read through* $\mathsf{OperatorNorm}^{\uparrow}$ *or the Banach-algebra norm, recording the displayed bound below the unit row.*
4. *W is the finite partial-sum window for the inspected powers $1, T, T^2, \ldots, T^m$.*
5. *S is the finite sum row naming the displayed Neumann partial sums and their multiplication order.*
6. *Q is the residual row, recording the left and right error checks for $(1-T)S_m$ and $S_m(1-T)$ inside the same algebra surface.*
7. *R is the inverse-check row saying which residual bounds are strong enough for an inverse-facing consumer to read the packet.*
8. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row for rational norm bounds, tail estimates, and terminal real seals.*
9. *H records componentwise* hsame *transport for A, T, K, W, S, Q, R, E.*

10. *C records displayed* Cont *replay from the smallness request through the finite partial-sum and residual rows.*
11. *P is the* Pkg *provenance over* $\mathsf{NeumannSeries}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ResolventIdentity}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{NeumannSeries}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host-chosen inverse, completed resolvent set, completed spectrum, spectral theorem, quotient operator equality, selected approximate eigenvectors, or countable choice.

Lean4 (definition) `BEDC.Derived.NeumannSeriesUp.NeumannSeriesUp`

Theorem 2940.2 (Neumann series NameCert obligations)**.** *For every accepted* $\mathsf{NeumannSeries}^{\uparrow}$ *carrier* $N = (A, T, K, W, S, Q, R, E, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{NeumannSeries}^{\uparrow}}$ *surface consists exactly of carrier admission for the Banach-algebra source, bounded-operator or algebra-action row, norm-smallness ledger, finite power window, finite partial sums, residual checks, inverse-check row, rational and real readback, transport, replay, provenance, and local naming. Every inverse-facing consumer must read those rows before using the inverse-series conclusion.*

Proof. Project the carrier of Definition 3917.1. The algebra source A and operator row T are the only endpoints on which multiplication and powers may be read.

The smallness and finite-sum rows are K, W, S. The norm-smallness ledger is displayed before any partial sum is public, and the finite power window fixes the product order used by the sum row.

The residual and readback rows are Q, R, E. They expose the left and right inverse checks and the rational-to-real tail estimates before a consumer may treat the packet as an inverse route.

Finally, H, C, P, L transport, replay, source, and name the same finite packet. Since no carrier coordinate stores a host inverse, completed resolvent set, completed spectrum, quotient equality, or choice schedule, the listed rows exhaust the local NameCert obligation surface. □

Theorem 2940.3 (Neumann inverse route)**.** *Every resolvent, spectral-radius, or inverse-operator consumer of an accepted* $\mathsf{NeumannSeries}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BanachAlgebra}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto K, W, S, Q, R, E \longmapsto H, C, P, L.$$

Thus a downstream read receives a norm-smallness ledger, finite partial-sum windows, residual and inverse-check rows, rational and real readback, transport, replay, provenance, and local naming before it may cite an inverse-series conclusion.

Proof. Start with an accepted packet $N = (A, T, K, W, S, Q, R, E, H, C, P, L)$. The Banach-algebra and bounded-operator rows fix the multiplication, unit, action, and norm-bound surface.

The route then passes through K, W, S. These rows expose the smallness bound, the inspected powers, and the finite partial sums; no completed infinite sum is available at this stage.

The inverse-facing part is Q, R, E. The residual row records the two-sided error checks, the inverse-check row states which displayed residual bound is consumed, and the readback row seals the rational tail estimates as real data.

The structural rows H, C, P, L preserve this route for chapter 3715 and chapter 2352 consumers. Because the packet lacks host inverse, completed spectrum, quotient equality, and choice coordinates, every such consumer factors through the displayed inverse-series route. □

Falsifiable prediction: Every accepted $\mathsf{NeumannSeries}^{\uparrow}$ inverse-facing read exposes BanachAlgebra, BoundedLinearOperator, norm-smallness, finite partial-sum, residual, inverse-check, RegSeqRat, Real, hsame, Cont, Pkg, and local NameCert rows before citing the inverse-series conclusion.

Independence witness: banachalgebra, boundedlinearoperator, operatornorm, resolvent-identity, spectral-radius: $\mathsf{NeumannSeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries norm-smallness, finite power windows, partial sums, residual checks, inverse-readback rows, rational and real tail seals, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NeumannSeries}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NeumannSeries}^{\uparrow}$ packet is generated from a BanachAlgebraUp source row, a BoundedLinearOperatorUp or algebra-action row, a norm-smallness ledger, finite partial-sum windows, residual and inverse-check rows, RegSeqRat and Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NeumannSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3917.1, Definition 3917.2, and Definition 3917.3 seed the finite Neumann inverse-series route consumed by resolvent, spectral, and inverse-operator packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NeumannSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a completed inverse operator, a completed resolvent set, a completed spectrum, quotient operator equality, selected approximate eigenvectors, or countable choice.

Upgrade path: Obligation closure requires checked carrier admission, norm-smallness exactness, partial-sum window stability, residual readback, inverse-check exactness, rational and real tail sealing, transport and replay stability, and consumer nonescape for BEDC.Derived.NeumannSeriesUp.

Chapter 2941

A Concrete Naming Certificate for CauchyWindowStabilityBridge$^{\uparrow}$

Following Bishop and Bridges, the CauchyWindowStabilityBridge$^{\uparrow}$ packet records the finite tail-window stability bridge used by the regular-Cauchy route of chapter 9238. It sits after the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The bridge names shared finite tail-window transport; it is not a hidden limit selector, quotient stream equality, host equality of real names, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 2941.1 (Cauchy window stability bridge carrier)**.** *A* CauchyWindowStabilityBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S_0, S_1, T, D, R_0, R_1, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are* StreamName$^{\uparrow}$ *finite-window rows for the two regular-Cauchy presentations being compared.*
2. T *is the common finite tail-window row, listing the precision requests and indices beyond which the two presentations are read through the same displayed window schedule.*
3. D *is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger attached to the shared tail window and to every rational comparison used by the bridge.*
4. R_0 *and* R_1 *are* RegSeqRat$^{\uparrow}$ *readback rows extracted from* S_0 *and* S_1 *at the tolerances named by* D*.*
5. E_0 *and* E_1 *are the visible* Real$^{\uparrow}$ *seal rows reached only after the shared tail window, dyadic tolerance ledger, and regular rational readbacks have been displayed.*
6. H *stores componentwise* hsame *transport for stream windows, the common tail row, dyadic tolerances, regular readbacks, Real seals, provenance, and local naming rows.*
7. C *stores displayed* Cont *replay from precision requests to common tail windows, from windows to regular readbacks, from dyadic tolerances to comparison rows, and from readbacks to the two Real seals.*
8. P *is the* Pkg *provenance over* CauchyWindowStabilityBridge$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyWindowStabilityBridge}^{\uparrow}}$ *row.*
The accepted carrier contains no selected limit, no quotient representative for streams, no host equality of real names, no countable-choice sequence, and no ambient completeness coordinate. It names only the finite common-tail bridge displayed by $T, D, R_0, R_1, E_0, E_1, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.CauchyWindowStabilityBridgeUp.CauchyWindowStabilityBridgeTasteGate single carrier alignment`

Theorem 2941.2 (Cauchy window stability bridge NameCert obligations)**.** *For an accepted carrier $B = (S_0, S_1, T, D, R_0, R_1, E_0, E_1, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyWindowStabilityBridge}^{\uparrow}}$ *obligations are exactly carrier admission; finite window exposure through S_0 and S_1; common tail-window admission through T; dyadic tolerance exactness through D; regular rational readback through R_0 and R_1; Real-seal admission through E_0 and E_1; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier. The two stream rows S_0, S_1, the common tail row T, the dyadic ledger D, the readbacks R_0, R_1, and the seals E_0, E_1 are the entire analytic surface of the bridge.

The tail-window row is the only stability interface. It records which finite windows are shared for the precision request under consideration, while the dyadic ledger records the rational tolerance used to compare the two readbacks.

The structural rows add no hidden equality or limit object. Transport H, replay C, provenance P, and the local name N preserve the displayed rows and expose no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 2941.3 (Tail-window transport)**.** *Every stability read exported by an accepted* $\mathsf{CauchyWindowStabilityBrid}$ *packet factors through the finite route*

$$S_0, S_1 \longmapsto T \longmapsto D \longmapsto R_0, R_1 \longmapsto E_0, E_1 \longmapsto H, C, P, N.$$

Thus shared regular-Cauchy tail transport is determined by displayed $\mathsf{StreamName}^{\uparrow}$ *windows, one common finite tail row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and componentwise* hsame *replay.*

Proof. Begin with the two finite stream rows. A stability consumer may inspect only the windows exposed by S_0 and S_1.

Read the common tail row next. The row T names the shared finite window schedule for the current precision request, and the dyadic ledger D attaches the tolerance used to compare the two regular rational readbacks.

The regular readbacks and seals are downstream. Rows R_0, R_1 are consumed before E_0, E_1, and the structural rows H, C, P, N replay the same finite route. No selected tail, quotient stream, or countable-choice family is available outside this packet. □

Theorem 2941.4 (Real-seal stability handoff)**.** *For every accepted* $\mathsf{CauchyWindowStabilityBridge}^{\uparrow}$ *packet, the two* $\mathsf{Real}^{\uparrow}$ *seal rows E_0 and E_1 are accessible only after the shared tail-window row T, dyadic tolerance row D, and regular rational readbacks R_0, R_1 have been displayed. Consequently a Real-completion consumer that cites this bridge receives a finite seal-stability handoff, not a proof of ambient* $\mathsf{Real}^{\uparrow}$ *completeness or quotient equality of real names.*

Proof. Project the carrier and isolate the seal coordinates. The rows E_0, E_1 occur only as terminal rows of the displayed bridge packet.

Apply the tail-window transport theorem. It forces every stability read through S_0, S_1, T, D, R_0, R_1 before the seals are available.

The refusal clause follows from carrier exhaustion. Since the packet has no coordinate for ambient completeness, quotient equality, host equality, selected limits, or countable choice, the Real-facing handoff can export only the displayed finite stability route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyWindowStabilityBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyWindowStabilityBridge}^{\uparrow}$ packet is generated from paired StreamName finite windows, a common finite tail-window row, a DyadicRatCore tolerance ledger, paired RegSeqRat readbacks, paired RealUp seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyWindowStabilityBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3918.1, Definition 3918.2, Definition 3918.3, and Definition 3918.4 bind the finite regular-Cauchy tail-window stability bridge.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyWindowStabilityBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient stream equality, host equality of real names, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, common-tail exactness, dyadic tolerance transport, paired readback stability, Real-seal handoff, and nonescape for the displayed packet.

Chapter 2942

A Concrete Naming Certificate for MetaCICPiAdequacyBudget$^{\uparrow}$

The MetaCICPiAdequacyBudget$^{\uparrow}$ packet realizes the Pi-adequacy route of chapter 9383 as finite BEDC data. It sits beside the critical-path packet of chapter 765, the normalization frontier of chapter 892, the candidate socket of chapter 3566, the normalization-confluence bridge of chapter 1190, and the normalization audit packet of chapter 3779. The packet records the candidate-mediated budget needed by Pi adequacy; it does not claim unconditional global normalization or erase the candidate evidence consumed by the Lean route.

Definition 2942.1 (MetaCIC Pi adequacy budget carrier)**.** *A* MetaCICPiAdequacyBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (G, \Pi, N, A, S, F, O, H, C, P, L)$$

with the following displayed rows:

1. *G is the closed context and typing-frontier row for the Pi candidate being inspected.*
2. *Π is the Pi-candidate evidence row consumed by the route named by* `PiAdequacy.lean`*.*
3. *N is the neutral-normal evidence row used by the neutral branch of the adequacy argument.*
4. *A is the application-side adequacy handoff row, recording the candidate argument and the application result row.*
5. *S is the strong-normalization handoff row, naming the projections corresponding to* `piCandidate_implies_sn`*,* `neutralNormal_implies_sn`*, and* `sn_pi`*.*
6. *F is the frontier-refusal row, keeping candidate evidence, subject-reduction boundaries, and confluence boundaries visible whenever a consumer requests a stronger normalization claim.*
7. *O is the obligation-budget row for the remaining endpoint evidence needed by closed-consistency consumers.*
8. *H records componentwise* hsame *transport for the typing, Pi-candidate, neutral-normal, application, strong-normalization, frontier, and obligation rows.*
9. *C records displayed* Cont *replay from a Pi-adequacy request through G, Π, N, A, S, F, O.*
10. *P is* Pkg *provenance over* MetaCICPiAdequacyBudget$^{\uparrow}$*,* MetaCICNormalizationAuditPacket$^{\uparrow}$*,* MetaCICDecidableNe MetaCICFuelTrace$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate for evidence-free closed-term strong normalization, unrestricted subject reduction, global confluence, semantic equality, quotient syntax equality, or host evaluation soundness.

Lean4 (definition) `BEDC.Derived.MetaCICPiAdequacyBudgetUp.taste gate`

Theorem 2942.2 (MetaCIC Pi adequacy budget NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}$ *carrier* $B = (G, \Pi, N, A, S, F, O, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}}$ *surface consists exactly of typing-frontier admission, Pi-candidate evidence admission, neutral-normal evidence admission, application adequacy handoff, strong-normalization projection handoff, frontier refusal, obligation-budget exposure, componentwise transport, displayed replay, provenance, and local naming. A consumer receives no stronger normalization endpoint unless that endpoint is supplied as a displayed row of the same packet.*

Proof. Project the carrier of Definition 3919.1. The typing row G, Pi-candidate row Π, and neutral-normal row N are the only source evidence available to the adequacy budget.

The handoff rows are A and S. They expose the application-side candidate route and the named strong-normalization projections without replacing candidate evidence by an evidence-free theorem.

The boundary rows are F and O. They keep the normalization frontier, subject-reduction boundary, confluence boundary, and endpoint obligation budget visible to any closed-consistency consumer.

Finally, H, C, P, L transport, replay, source, and name the same finite route. Because the carrier lacks coordinates for global normalization, unrestricted subject reduction, confluence, semantic equality, quotient syntax equality, and host evaluation soundness, the listed rows exhaust the local NameCert surface. □

Theorem 2942.3 (MetaCIC Pi adequacy strong-normalization handoff)**.** *Every normalization-facing consumer of an accepted* $\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}$ *packet factors through the route*

$$G, \Pi, N, A \longmapsto S \longmapsto F, O, H, C, P, L.$$

The consumer therefore reads closed context data, Pi-candidate evidence, neutral-normal evidence, application adequacy data, the strong-normalization handoff, frontier refusal, obligation budget, transport, replay, provenance, and local naming before citing the Pi adequacy contribution to candidate-mediated strong normalization.

Proof. Start with an accepted packet $B = (G, \Pi, N, A, S, F, O, H, C, P, L)$. The source rows G, Π, N, A provide the only candidate and neutral-normal evidence made public by the packet.

The strong-normalization handoff is S. It packages the displayed Pi-candidate, neutral-normal, and Pi-shaped SN projections as rows of the same finite carrier, so a consumer cannot cite them after dropping their evidence inputs.

The frontier and obligation rows F, O remain attached to the handoff. They record that subject-reduction, confluence, and global closed-normalization endpoints are not exported by the Pi adequacy budget alone.

The rows H, C, P, L preserve and name this route. Hence any normalization-facing consumer factors through the displayed candidate-mediated budget before it may use the Pi adequacy contribution. □

Falsifiable prediction: An accepted $\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}$ normalization-facing read is refuted if it exports Pi-shaped strong-normalization data while omitting the displayed typing-frontier, Pi-candidate, neutral-normal, application-handoff, SN-handoff, frontier-refusal, obligation-budget, transport, replay, provenance, or local NameCert rows.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, `normalization_candidate_socket`, metacicnormalizationconfluencebridge: $\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Pi-candidate evidence, neutral-normal evidence, application adequacy handoff, SN projection rows, frontier refusal, obligation-budget exposure, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}$ packet is generated from closed context and typing-frontier data, Pi-candidate evidence, neutral-normal evidence, application adequacy rows, strong-normalization handoff rows, frontier refusal, obligation budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3919.1, Definition 3919.2, and Definition 3919.3 seed the Pi adequacy budget consumed by candidate-mediated strong-normalization routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICPiAdequacyBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, evidence-free closed-term strong normalization, unrestricted subject reduction, global confluence, semantic equality, quotient syntax equality, or host evaluation soundness.

Upgrade path: Obligation closure requires checked carrier admission, Pi-candidate evidence exactness, neutral-normal readback, application adequacy handoff, strong-normalization projection handoff, frontier refusal stability, obligation-budget exposure, and consumer nonescape for BEDC.Derived.MetaCICPiAdequacyBudgetUp.

$\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ consumes the Cauchy finite-window surface of chapter 3413 together with the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route displayed by its child chapter.

Chapter 2943

Finite Cauchy Diagonal NameCert Construction

Following Bishop and Bridges, the $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ packet records the finite diagonal selector needed when a displayed Cauchy family is read through regular rational windows and then sealed as a real name. It sits between the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational route of chapter 301, the finite stream windows of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet supplies only a finite selector surface for completion and Real consumers; it does not choose an infinite subsequence, a quotient representative, or a host limit.

Definition 2943.1 (Finite Cauchy diagonal carrier)**.** *A* $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, W, K, S, R, Y, E, H, C, P, N)$$

with the following rows:

1. *F is the finite family row, naming the displayed Cauchy sources whose diagonal window is requested.*
2. *W is the selected-window classifier row, recording the finite window chosen for each displayed precision request and each displayed source row.*
3. *K is the classifier-stability row, comparing selected windows only by the same* hsame *and* Cont *routes used by the source family.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule exposed by the selected windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S.*
6. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds the diagonal comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, available only after F, W, K, S, R, Y have been displayed.*
8. *H records componentwise* hsame *transport for the family, window, stability, stream, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for diagonal-selection requests through $F, W, K, S, R, Y, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyDiagonal}^{\uparrow}}$ *row.*

The classifier reads only $F, W, K, S, R, Y, E, H, C, P, N$. There is no coordinate for countable choice, a selected infinite diagonal sequence, quotient stream equality, host sequence equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2943.2 (Finite Cauchy diagonal NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ *carrier $D = (F, W, K, S, R, Y, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyDiagonal}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *finite diagonal carrier admission through the displayed family row F;*
2. *selected-window classifier admission through W, with one displayed finite window for each displayed precision request and source row;*
3. *classifier stability through K, H, C, preserving the selected windows under componentwise* hsame *transport and displayed* Cont *replay;*
4. *diagonal extraction ledger admission through S, R, Y, requiring every extracted read to pass through the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows;*
5. $\mathsf{Real}^{\uparrow}$ *seal handoff through E, requiring the finite family, selected-window classifier, stability row, stream schedule, readback row, dyadic ledger, transport, replay, provenance, and local naming to remain visible to the terminal real-name consumer.*

No obligation row certifies countable choice, a selected infinite diagonal sequence, quotient stream equality, host sequence equality, selected limits, or ambient completeness.

Proof. Project the carrier of Definition 3920.1. The visible rows are exactly $F, W, K, S, R, Y, E, H, C, P, N$, so the finite family and selected-window classifier are the only routes by which a diagonal request enters the packet.

The stability row is read before any terminal seal. Transport by H and replay by C preserve the same family row, selected-window row, and classifier-stability row, so a replayed request cannot replace the finite selector by an infinite choice schedule or by host sequence equality.

The extraction ledger is then read through S, R, Y. The stream schedule supplies finite observations, the regular rational row repacks those observations, and the dyadic row records the tolerance budget for the same displayed windows.

Finally the Real handoff is downstream from the ledger. Since E is available only after $F, W, K, S, R, Y, H, C, P, N$ have been displayed, every $\mathsf{Real}^{\uparrow}$ or completion-facing consumer receives a finite diagonal selector surface rather than a hidden limit or quotient representative. □

Falsifiable prediction: An accepted $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ read is refuted if the Real-facing diagonal handoff reaches $\mathsf{Real}^{\uparrow}$ without displaying the finite family row, selected-window classifier, classifier-stability row, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming rows.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite family admission, selected-window classification, classifier stability, diagonal extraction, Real seal handoff, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyDiagonal}^{\uparrow}$ packet is generated from a displayed finite Cauchy family, selected finite windows, classifier-stability rows, StreamName observations, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3920.1 and Definition 3920.2 seed the finite diagonal selector route over family, selected-window, stability, StreamName, RegSeqRat, DyadicRatCore, RealUp seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteCauchyDiagonal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim countable choice, a selected infinite diagonal sequence, quotient stream equality, host sequence equality, selected limits, Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, selected-window classifier admission, classifier stability, diagonal extraction, RealUp seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCauchyDiagonalUp.

The residual-envelope packet reads its conditional confluence boundary through chapter 3791, chapter 3827, and chapter 765 before the child file spells out the carrier.

Chapter 2944

MetaCIC Confluence Residual Envelope NameCert Construction

The MetaCICConfluenceResidualEnvelope$^{\uparrow}$ packet realizes the conditional residual-substitution boundary of chapter 9378 as finite MetaCIC NameCert data. It sits beside the substitution-boundary packet of chapter 3791, the residual checker of chapter 3827, the finite fuel trace of chapter 3889, the decidable neutral spine of chapter 3909, and the normalization evidence budget of chapter 3871. The envelope records which residual windows, substitution-boundary rows, checker rows, fuel traces, neutral-spine reads, and replay ledgers are visible before a consumer cites a conditional confluence handoff.

The residual envelope also consumes the closedness-preservation ledger of chapter 795 before any residual checker can be read as a confluence boundary.

Falsifiable prediction: A certification route to BetaParallelDiamondClosed that omits the residual-envelope row refutes MetaCICConfluenceResidualEnvelope$^{\uparrow}$, because the conditional substitution boundary has then been consumed without displaying the finite residual window, substitution-boundary, checker, fuel, neutral-spine, replay, provenance, and local NameCert rows.

Independence witness: metacic_fuel_trace, metacic_decidable_neutral_spine, metacic_confluence_substitut normalization_evidence_budget: none is bijective to MetaCICConfluenceResidualEnvelope$^{\uparrow}$ because the envelope jointly records residual windows, substitution-boundary exposure, checker status, bounded fuel, neutral-spine reads, normalization-budget non-escape, transport, replay, provenance, and local naming as one confluence-boundary packet.

Definition 2944.1 (MetaCIC confluence residual envelope carrier)**.** *A* MetaCICConfluenceResidualEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, R, S, B, J, O, F, U, Z, H, C, P, N)$$

with the following rows:

1. *T is the typed-window row naming the MetaCIC source and target windows under inspection.*
2. *R is the residual-frontier row, recording the beta-redex residues whose join is conditional on substitution compatibility.*
3. *S is the* MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$ *row exposed before any closed diamond handoff.*
4. *B is the bounded residual-checker row inherited from* MetaCICConfluenceResidualChecker$^{\uparrow}$*.*

5. *J is the local-join ledger for those residual windows.*
6. *O is the obstruction row retaining the named substitution-compatibility boundary.*
7. *F is the* $\mathsf{MetaCICFuelTrace}^{\uparrow}$ *bounded replay row.*
8. *U is the* $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$ *neutral-spine read used to prevent atom and neutral cases from being promoted to beta branches.*
9. *Z is the* $\mathsf{NormalizationEvidenceBudget}^{\uparrow}$ *row, recording that normalization evidence may be inspected only as bounded finite evidence and not as global normalization.*
10. *H records componentwise* hsame *transport for typed windows, residual frontiers, substitution boundary, checker status, local joins, obstruction, fuel, neutral-spine, budget, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay for conditional confluence requests through $T, R, S, B, J, O, F, U, Z, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$, $\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}$, $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$, $\mathsf{MetaCICFuelTrace}^{\uparrow}$, $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$, NormalizationEvidenc BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}}$ *row.*

The classifier reads only $T, R, S, B, J, O, F, U, Z, H, C, P, N$. It has no coordinate for an unconditional BetaParallelSubstitutionCompatibility *proof, an unconditional* BetaParallelDiamondClosed *proof, arbitrary closed Church–Rosser, erased substitution transport, or host syntax equality.*

Theorem 2944.2 (Residual envelope NameCert surface)**.** *For every accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *carrier $E = (T, R, S, B, J, O, F, U, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission, typed-window exposure, residual-frontier exposure, substitution-boundary exposure, bounded-checker status, local-join ledger exposure, obstruction retention, fuel-trace replay, neutral-spine separation, normalization-budget non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3921.1. The only visible route to a conditional confluence read is the displayed tuple $T, R, S, B, J, O, F, U, Z, H, C, P, N$.

The residual and substitution-sensitive rows R, S, B, J, O are read before any closed-diamond handoff. Thus a consumer can see the residual frontier, the named substitution boundary, the bounded checker status, the local join ledger, and the obstruction row as finite data rather than as a hidden global proof.

The supporting rows F, U, Z then separate bounded computation, neutral-spine cases, and normalization evidence from the residual-substitution boundary. They keep fuel traces, neutral reads, and normalization budgets visible without converting them into global normalization or confluence.

Finally H, C, P, N transport, replay, source, and name the same finite surface. Since no remaining coordinate contains an unconditional substitution-compatibility or closed-diamond proof, the packet certifies only the residual-envelope boundary and not the endpoint theorem. □

Theorem 2944.3 (MetaCIC confluence residual critical-pair audit surface)**.** *For an accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *packet with two displayed one-step residual branches, the finite critical-pair audit surface consists only of the source term row, the two residual branch rows, the shared candidate mediator row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}}$ *row. The audit surface does not*

assert global confluence, strong normalization, decidability of all residual joins, or host quotient conversion.

Proof. Project the carrier of Definition 3921.1. The typed-window row T supplies the source term row, while R, B, J, O display the residual frontier, bounded checker status, local join ledger, and obstruction boundary from which the two one-step branches and the candidate mediator are read.

Apply the residual envelope NameCert surface theorem. It requires residual-frontier exposure, substitution-boundary exposure, bounded-checker status, local-join ledger exposure, obstruction retention, bounded fuel replay, neutral-spine separation, normalization-budget non-escape, transport, replay, provenance, and local naming before any confluence-facing consumer reads the envelope.

Compare the two displayed branch rows only through the candidate mediator row retained in J and the obstruction boundary retained in O. The transport row H and replay row C preserve those displayed rows componentwise; they do not add a new conversion relation or quotient syntax equality.

Carrier-field exhaustion gives the non-escape claim. Since the accepted packet has no coordinate for global confluence, strong normalization, full join decidability, or host quotient conversion, the critical-pair read is only the finite audit surface stated above. □

Theorem 2944.4 (MetaCIC confluence residual envelope checker-status determinacy)**.** *For every accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *carrier* $E = (T, R, S, B, J, O, F, U, Z, H, C, P, N)$*, any confluence consumer that reads the bounded checker status* B *must read exactly one of the displayed accepted, rejected, or obstruction alternatives supplied by the residual-checker route. The later rows* $J, O, F, U, Z, H, C, P, N$ *cannot change that status and cannot turn it into unconditional* BetaParallelDiamondClosed*.*

Proof. Project the carrier $E = (T, R, S, B, J, O, F, U, Z, H, C, P, N)$ of Definition 3921.1. The checker status is the single row B, inherited from the residual-checker route of chapter 3827.

The residual-checker route separates accepted, rejected, and obstruction status as displayed finite alternatives. Reading B therefore exposes one of those alternatives before the envelope rows $J, O, F, U, Z, H, C, P, N$ are inspected.

The obstruction row O retains the named residual-substitution obstruction rather than erasing it. The rows F, U, Z separate bounded computation, neutral-spine reads, and normalization budgets from the checker status, so they cannot promote a bounded status read into an endpoint confluence theorem.

Finally H, C, P, N transport, replay, source, and name only the displayed carrier rows. Because no later row contains an unconditional BetaParallelDiamondClosed coordinate, the checker status remains the one supplied by B. □

Theorem 2944.5 (MetaCIC residual envelope obstruction monotonicity)**.** *For every accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *carrier* $E = (T, R, S, B, J, O, F, U, Z, H, C, P, N)$*, if the bounded checker row* B *exposes obstruction status and the row* O *retains the residual-substitution obstruction, then every read of* J, F, U, Z, H, C, P, N *preserves that obstruction boundary. In particular, those later rows cannot erase the obstruction status and cannot export an unconditional* BetaParallelDiamondClosed *theorem.*

Proof. Project B and O from the carrier of Definition 3921.1. The row B supplies the displayed checker status, and O is the only row that records the residual-substitution obstruction retained by the envelope.

Apply checker-status determinacy, Definition 3921.4. Once B exposes obstruction status, the rows inspected after B cannot replace that status by an accepted or rejected alternative.

Now inspect the remaining carrier inventory. The rows J, F, U, Z contain local joins, bounded fuel, neutral-spine reads, and normalization-budget evidence, while H, C, P, N contain transport, replay, provenance, and local naming data. None of these rows contains a closed-diamond coordinate.

Therefore the obstruction retained by O remains visible through every later read. Since the accepted carrier has no unconditional BetaParallelDiamondClosed coordinate, no consumer can obtain that endpoint theorem from J, F, U, Z, H, C, P, N. □

Theorem 2944.6 (MetaCIC confluence residual envelope neutral-spine separation)**.** *Any conditional confluence consumer that attempts to promote a neutral-spine read U into a beta residual branch must also display the residual-frontier row R, substitution-boundary row S, checker row B, local join row J, fuel trace F, and normalization budget Z. Without those rows, the accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *packet exports only a neutral case and no beta branch.*

Proof. Project the carrier $E = (T, R, S, B, J, O, F, U, Z, H, C, P, N)$ of Definition 3921.1. The neutral-spine row U is a displayed case-separation row, not a residual-frontier row.

Apply the NameCert surface theorem Definition 3921.2. It lists residual-frontier exposure, substitution-boundary exposure, bounded-checker status, local-join ledger exposure, fuel-trace replay, neutral-spine separation, and normalization-budget non-escape as distinct obligations of the accepted packet.

Therefore a consumer that reads only U has only the neutral case. To promote the read into a beta residual branch, the consumer must also display R, S, B, J, F, Z through the same transport, replay, provenance, and local naming rows. If any of these rows is absent, the carrier has no coordinate from which a beta residual branch can be exported. □

Theorem 2944.7 (MetaCIC residual envelope closed-diamond consumption boundary)**.** *Any consumer attempting to cite* BetaParallelDiamondClosed *through an accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *packet must first display the full row inventory*

$$T, R, S, B, J, O, F, U, Z, H, C, P, N.$$

If the substitution-boundary row S, checker row B, obstruction row O, fuel row F, or normalization-budget row Z is absent, the packet exports only a conditional residual envelope and not closed confluence.

Proof. Start with the NameCert surface theorem, Definition 3921.2. It identifies the accepted packet with the displayed rows $T, R, S, B, J, O, F, U, Z, H, C, P, N$ and says that no unconditional closed-diamond coordinate is part of the carrier.

Next read the checker and obstruction rows. The checker-status determinacy theorem fixes the status exposed by B, while Definition 3921.5 preserves any obstruction retained in O through the later local-join, fuel, neutral-spine, budget, transport, replay, provenance, and naming rows.

Finally apply neutral-spine separation. Theorem 3921.6 refuses to promote a neutral-spine read into a beta residual branch unless the residual frontier, substitution boundary, checker, local join, fuel trace, and normalization budget are all displayed.

Thus a consumer that omits S, B, O, F, or Z has not consumed the finite residual-substitution boundary required for the endpoint. It can read only the conditional residual envelope carried by the displayed rows, and no route to BetaParallelDiamondClosed is exported. □

Theorem 2944.8 (MetaCIC residual envelope diamond route)**.** *Every* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *read that exposes a closed-diamond consumer row factors first through the residual-substitution boundary of chapter 2181, the bounded residual-substitution frontier of chapter 3808, and the MetaCIC open-frontier ledger of chapter 762. The residual envelope may then expose the closed-diamond consumer only through the displayed rows* $T, R, S, B, J, O, F, U, Z, H, C, P, N$*, and it exports no direct route to* BetaParallelDiamondClosed*.*

Proof. Start from the closed-diamond consumption boundary, Definition 3921.7. It requires a consumer to display the full row inventory $T, R, S, B, J, O, F, U, Z, H, C, P, N$ before the closed-diamond endpoint can be cited.

The substitution-sensitive part of that inventory is not local to the envelope alone. The residual-substitution boundary keeps the substitution premise visible, the bounded residual-substitution frontier bounds the frontier read, and the open-frontier ledger records the confluence endpoint as a frontier entry rather than as a discharged theorem.

Reading S, B, J, O through those siblings fixes the route before the consumer can inspect F, U, Z, H, C, P, N. The fuel, neutral-spine, budget, transport, replay, provenance, and naming rows preserve the same route and do not add a closed-diamond coordinate.

Therefore the closed-diamond consumer row, when present, is exposed only after the three sibling packets and the envelope inventory have been read. No direct route to BetaParallelDiamondClosed is available from the residual envelope alone. □

Theorem 2944.9 (MetaCIC residual envelope closed-join boundary)**.** *Every closed-join or closed-diamond consumer of an accepted* $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$ *packet* $E = (T, R, S, B, J, O, F, U, Z, H, C, P$ *must read the envelope rows in the following boundary order: typed window, residual frontier, substitution boundary, checker status, local join, obstruction, fuel, neutral spine, normalization budget, transport, replay, provenance, and local naming. Equivalently, a consumer may cite the closed-join row only after the displayed route*

$$T, R, S, B, J, O, F, U, Z, H, C, P, N$$

has been consumed. The boundary exports no unrestricted BetaParallelDiamondClosed *theorem, no unrestricted substitution compatibility, no subject reduction theorem, and no Church–Rosser theorem.*

Proof. Begin with the NameCert surface theorem, Definition 3921.2. It fixes the visible surface of an accepted envelope as precisely $T, R, S, B, J, O, F, U, Z, H, C, P, N$.

Next read the residual-sensitive part of the route. The checker-status determinacy theorem fixes B before the local join is inspected, while obstruction monotonicity keeps O visible through the later rows. Thus J can be read only as a local join under the already displayed residual frontier, substitution boundary, checker status, and obstruction boundary.

Apply the closed-diamond consumption boundary and the diamond route. Together they force any closed-diamond or closed-join consumer through the same full inventory, and the sibling residual-substitution boundary, bounded frontier, and open-frontier ledger prevent the envelope from presenting the endpoint as a discharged global theorem.

Finally inspect the excluded coordinates. Since the carrier has no row for unrestricted closed diamond, substitution compatibility, subject reduction, or Church–Rosser, the closed-join read is exactly the ordered finite boundary stated above. □

The Lean TasteGate site for MetaCICConfluenceResidualEnvelope$^{\uparrow}$ must provide explicit Nontrivial and FieldFaithful instances for this carrier surface. These instances must keep the residual windows, substitution boundary, checker status, local joins, obstruction row, fuel trace, neutral spine, normalization budget, transport, replay, provenance, and local naming distinguishable.

Closure status for NameCert$_{\text{MetaCICConfluenceResidualEnvelope}^{\uparrow}}$ **·**

Constructive story: A MetaCICConfluenceResidualEnvelope$^{\uparrow}$ packet is generated from typed windows, residual frontiers, a substitution-boundary row, bounded checker status, local joins, obstruction retention, bounded fuel traces, neutral-spine reads, normalization-budget rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICConfluenceResidualEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 3921.1 and Definition 3921.2 seed the residual-substitution confluence envelope over typed-window, residual-frontier, substitution-boundary, checker, local-join, obstruction, fuel, neutral-spine, budget, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICConfluenceResidualEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, arbitrary closed Church–Rosser, global normalization, Lean verification, bridge checking, erased substitution transport, or host syntax equality.

Upgrade path: Obligation closure requires checked carrier admission, residual-frontier exposure, substitution-boundary exposure, bounded-checker status, local-join exposure, obstruction retention, fuel replay, neutral-spine separation, normalization-budget non-escape, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICConfluenceResidualEnvelopeUp.

Chapter 2945

A Concrete Naming Certificate for $\mathsf{HahnBanach}^{\uparrow}$

Following Hahn and Banach, Bourbaki, and Bishop-style constructive functional analysis, the $\mathsf{HahnBanach}^{\uparrow}$ packet records the finite BEDC surface for bounded scalar functional extension rows. It sits beside the normed-space and Banach rows of chapter 1950 and chapter 90, the dual carrier of chapter 2265, the bounded-operator row of chapter 1644, the functional-analysis boundary of chapter 94, and the real-name seal of chapter 38. The chapter names a displayed finite extension ledger only; it is not the unrestricted classical Hahn–Banach theorem.

Definition 2945.1 (Hahn–Banach extension carrier)**.** *A* $\mathsf{HahnBanach}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, B, D, F, E, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{NormedSpace}^{\uparrow}$ *or* $\mathsf{Banach}^{\uparrow}$ *row on which the extension is read.*
2. *B is the displayed subspace row, including the finite incidence data saying which inspected vectors lie in the subspace.*
3. *D is the* $\mathsf{BanachDual}^{\uparrow}$ *and* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row for the bounded scalar functional on B.*
4. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *context row that records the local functional-analysis consumer boundary.*
5. *E is the extension row, displaying the scalar functional on the inspected ambient vectors and its agreement with D on the subspace row.*
6. *L is the norm-bound ledger, comparing the displayed bound for D with the displayed bound for E through* $\mathsf{Real}^{\uparrow}$ *endpoints.*
7. *H records componentwise* hsame *transport for $X, B, D, F, E, L, C, P, N$.*
8. *C records displayed* Cont *replay from ambient-space reads through the subspace, bounded-functional, extension, and norm-bound rows.*
9. *P is the* Pkg *provenance over* $\mathsf{HahnBanach}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HahnBanach}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient dual spaces, selected extensions, ultrafilter arguments, countable choice, Zorn maximality, or unrestricted ambient extension.

Lean4 ✓ `BEDC.Derived.HahnBanachUp.HahnBanachTasteGate single carrier alignment`

Theorem 2945.2 (Hahn–Banach NameCert obligations)**.** *For every accepted* $\mathsf{HahnBanach}^{\uparrow}$ *carrier* $K = (X, B, D, F, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HahnBanach}^{\uparrow}}$ *surface consists exactly of ambient normed or Banach admission, displayed subspace admission, bounded scalar functional admission, local functional-analysis context, extension-row agreement, norm-bound ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No extension obligation is stored outside those rows.*

Proof. Project the accepted carrier of Definition 3922.1. The rows $X, B, D, F, E, L, H, C, P, N$ are the full public inventory.

The bounded-functional read starts at the subspace row B and the scalar-functional row D. The extension row E can be inspected only with the same ambient row X and the same subspace incidence data.

The norm-bound ledger is L. It compares the displayed bound for D with the displayed bound for E through $\mathsf{Real}^{\uparrow}$ endpoints, while H, C, P, N only transport, replay, source, and name the same route.

Thus the NameCert obligations are exactly the listed finite rows. The unrestricted theorem, quotient duals, selected extensions, ultrafilter arguments, and choice principles have no carrier coordinate. □

Theorem 2945.3 (Hahn–Banach bounded functional extension route)**.** *Every bounded scalar functional extension read of an accepted* $\mathsf{HahnBanach}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{NormedSpace}^{\uparrow},\ \mathsf{Banach}^{\uparrow},\ \mathsf{BanachDual}^{\uparrow},\ \mathsf{BoundedLinearOperator}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route first fixes the ambient and subspace rows, then reads the bounded scalar functional, then reads the displayed extension row and the norm-bound ledger, and only then exposes transport, replay, provenance, and local naming. It exports no unrestricted classical Hahn–Banach theorem, quotient dual space, selected extension, ultrafilter argument, countable choice, or detached extension principle.

Proof. Let $K = (X, B, D, F, E, L, H, C, P, N)$ be accepted. The carrier projection gives the ambient row X, the subspace row B, the bounded scalar functional row D, the functional-analysis context row F, and the extension row E.

The public extension route reads X and B before D. Only then can the consumer inspect E, because agreement with the original functional is meaningful only over the displayed subspace incidence row.

The norm-bound ledger L is read after the two functional rows. It records the displayed $\mathsf{Real}^{\uparrow}$ comparison between the original bound and the extension bound, so the consumer receives a finite bound ledger rather than an ambient domination theorem.

Finally H, C, P, N preserve this finite route. Since no row names quotient dual spaces, selected extensions, ultrafilter arguments, countable choice, or unrestricted Hahn–Banach extension, none of those objects can be exported by the accepted packet. □

Falsifiable prediction: Dropping the norm-bound ledger L makes Definition 3922.3 false: a consumer could no longer distinguish a bounded extension row from an unbounded displayed scalar assignment.

Independence witness: normedspace, banach, banachdual, boundedlinearoperator, functional-analysis, real: $\mathsf{HahnBanach}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries ambient space, subspace incidence, bounded scalar functional, extension agreement, norm-bound ledger, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HahnBanach}^{\uparrow}}$.

Constructive story: A $\mathsf{HahnBanach}^{\uparrow}$ packet is generated from an ambient NormedSpaceUp or BanachUp row, a displayed subspace row, a BanachDualUp and BoundedLinearOperatorUp bounded scalar functional row, a FunctionalAnalysisUp context row, an extension row, a RealUp norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HahnBanach}^{\uparrow}}$, seed)

Scope closed: Definition 3922.1, Definition 3922.2, and Definition 3922.3 seed the finite bounded scalar functional extension packet over normed-space, Banach, dual, bounded-operator, functional-analysis, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HahnBanach}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.HahnBanachUp.HahnBanachTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim the unrestricted classical Hahn–Banach theorem, quotient dual spaces, selected extensions, ultrafilter arguments, countable choice, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subspace incidence, bounded scalar functional transport, extension agreement, norm-bound exactness, non-escape, replay, provenance, and local naming for BEDC.Derived.HahnBanachUp.

Chapter 2946

A Concrete Naming Certificate for $\mathsf{RealIntervalCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealIntervalCompletion}^{\uparrow}$ packet records the finite completion-facing boundary at which located interval data, nested refinements, regular rational readbacks, and Real seals are read as one interval-completion carrier. It sits beside the located endpoint surface of chapter 394, the nested interval carrier of chapter 320, and the public completion reflector route of chapter 1585. The packet names the L10 Real and Completion handoff without importing Dedekind cuts, quotient completions, selected points, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2946.1 (RealIntervalCompletion carrier)**.** *A* $\mathsf{RealIntervalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, N, D, W, R, E, H, C, P, Q)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row, carrying lower and upper located endpoint windows and their visible interval-order classifier.*
2. *N is the* $\mathsf{NestedInterval}^{\uparrow}$ *refinement row, recording the displayed nesting discipline and the dependency of each later interval on the earlier endpoint rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, carrying the dyadic shrinkage scale used by the refinement windows.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes only finite interval windows before any regular rational readback is consumed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, reading the displayed interval windows as regular rational approximants.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the completed interval-facing read.*
7. *H records componentwise* hsame *transport for L, N, D, W, R, E and the structural rows.*
8. *C records displayed* Cont *replay from located endpoints through nested refinements, dyadic shrinkage, stream windows, regular rational readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RealIntervalCompletion}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *Q is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalCompletion}^\uparrow}$ *row.*
The carrier has no coordinate for Dedekind cuts, quotient interval completions, selected interval points, open-cover compactness, countable choice, host real equality, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealIntervalCompletionUp.RealIntervalCompletionTasteGate single carrier alignment`

Theorem 2946.2 (RealIntervalCompletion NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalCompletion}^\uparrow$ *carrier* $I = (L, N, D, W, R, E, H, C, P, Q)$*, the local* $\mathsf{NameCert}_{\mathsf{RealIntervalCompletion}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located endpoint, nested refinement, dyadic radius, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *interval-refinement classification, requiring every refinement read to pass through the* $\mathsf{LocatedInterval}^\uparrow$ *endpoint row and the* $\mathsf{NestedInterval}^\uparrow$ *nesting row before any completion-facing seal is visible;*
3. *diameter-shrinkage stability, requiring the* $\mathsf{DyadicRatCore}^\uparrow$ *radii to decrease along the displayed nested interval route and to remain stable under the classifier;*
4. *Real seal compatibility, requiring the* $\mathsf{StreamName}^\uparrow$ *windows and* $\mathsf{RegSeqRat}^\uparrow$ *readbacks to reach the* $\mathsf{Real}^\uparrow$ *seal only through the same finite interval route;*
5. *refusal of quotient intervals, selected limit points, countable-choice schedules, open-cover compactness, and ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Carrier admission is the projection of Definition 3923.1. The displayed tuple lists the located endpoints, nested refinements, dyadic radii, finite windows, regular rational readbacks, Real seal, transport, replay, provenance, and local naming row.

The interval-refinement classifier is the route L, N. A consumer must read located endpoint data before it can inspect the nested refinement row, so the packet cannot replace the route by a host interval completion or by selected endpoint representatives.

Diameter-shrinkage stability is carried by D together with the nesting row N. The dyadic radii are read as finite $\mathsf{DyadicRatCore}^\uparrow$ data, and componentwise hsame transport in H preserves the same shrinkage classifier.

Real seal compatibility is the route W, R, E. The stream windows feed the regular rational readback before the Real seal is exposed, and Cont replay in C preserves this order for downstream completion consumers.

Finally, P and Q name exactly the listed rows. Since the carrier contains no Dedekind-cut, quotient-interval, selected-point, choice, open-cover compactness, or ambient-completeness coordinate, those objects cannot be exported from an accepted packet. □

Theorem 2946.3 (RealIntervalCompletion completion handoff)**.** *Every* $\mathsf{CauchyCompletionReflector}^\uparrow$ *or* $\mathsf{Real}^\uparrow$ *consumer of an accepted* $\mathsf{RealIntervalCompletion}^\uparrow$ *carrier receives the finite route*

$$L, N, D, W, R, E, H, C, P, Q$$

and no independent completion object. The completion-facing read factors through located interval endpoints, nested interval refinement, dyadic diameter shrinkage, finite stream windows, regular rational readback, and the Real seal.

Proof. Start with an accepted consumer read. Carrier admission exposes only the rows $L, N, D, W, R, E, H, C, P, Q$.

The interval part is L, N, D. It fixes located endpoints, the displayed refinement order, and the dyadic shrinkage scale before any Real-facing data are available.

The completion-facing part is W, R, E. It reads finite windows, regular rational approximants, and the Real seal along the same route used by the public $\mathsf{CauchyCompletionReflector}^{\uparrow}$ surface.

Transport, replay, provenance, and local naming are the structural rows H, C, P, Q. They preserve the route but add no quotient completion, selected point, countable-choice schedule, open-cover compactness, or ambient Real completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3923.1, Definition 3923.2, and Definition 3923.3 seed the interval-completion carrier over located endpoint rows, nested refinements, dyadic shrinkage, finite windows, regular rational readback, Real seals, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind cuts, quotient completions, selected points, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-refinement classification, diameter-shrinkage stability, Real seal compatibility, and non-escape for BEDC.Derived.RealIntervalCompletionUp.

Constructive story: A $\mathsf{RealIntervalCompletion}^{\uparrow}$ packet is generated from LocatedInterval endpoint rows, NestedInterval refinement rows, DyadicRatCore radii, StreamName windows, RegSeqRat readbacks, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2947

A Concrete Naming Certificate for $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$

Following Bishop and Bridges constructive compact metric analysis, the $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$ packet records the finite theorem-facing route by which a continuous image of compact metric data becomes totally bounded. It consumes the compact finite-net surface of chapter 60, the continuous-map graph and modulus rows of chapter 130, the source and target metric-distance rows, the uniform-modulus ledger, and the rational lower-bound fold. The packet is a concrete image-total-bounded carrier, not a semantic compact-image theorem in an ambient topology.

Definition 2947.1 (Compact continuous image total-bounded carrier)**.** *A* $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, U, M, R, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric finite-net packet, exposing source centers and coverage rows through* $\mathsf{CompactMetric}^{\uparrow}$ *and the compact carrier.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus and graph packet from the source metric carrier to the target metric carrier.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger read from the compact finite-net and continuous-map route.*
4. *M is the source and target* $\mathsf{Met}^{\uparrow}$ *distance row pair, carrying only displayed distance witnesses.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row used to select finite image radii from the displayed modulus and net data.*
6. *B is the* $\mathsf{ProbeBundle}$ *image-center row obtained by applying the displayed graph rows of F to the finite source-center bundle of X.*
7. *H records componentwise* hsame *transport for X, F, U, M, R, B and the local structural rows.*
8. *C records displayed* Cont *replay from compact source nets through continuous-map modulus rows, target distance rows, rational folds, and image-center bundle rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{ProbeBundle}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}}$ *row.*

The carrier contains no open-cover compactness object, no selected subcover from an arbitrary cover, no host image set, no quotient function equality, no choice-selected center, and no ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CompactContinuousImageTotalBoundedUp.TasteGate.CompactContinuousImageTotalBounded`
`single carrier alignment`

Theorem 2947.2 (CompactContinuousImageTotalBounded NameCert obligations)**.** *For every accepted* $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$ *carrier* $K = (X, F, U, M, R, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for compact metric finite-net data, continuous-map rows, uniform-modulus ledger, metric-distance rows, rational lower-bound fold, image-center bundle, transport, replay, provenance, and local naming;*
2. *finite-net image classification, requiring every image center to arise from a bundled compact source center and a displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row;*
3. *modulus compatibility, requiring the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger to use the same compact source, continuous-map, metric-distance, and* $\mathsf{Rat}^{\uparrow}$ *fold rows;*
4. *total-bounded export, requiring every target-image coverage read to factor through the finite* $\mathsf{ProbeBundle}$ *image-center row* B*;*
5. *refusal of open-cover compactness, arbitrary selected subcovers, host image sets, quotient function equality, choice-selected centers, and ambient completeness.*

Proof. Carrier admission is projection from Definition 3924.1. The tuple displays the compact source net, continuous graph and modulus data, uniform-modulus ledger, metric rows, rational fold, image centers, transport, replay, provenance, and local naming.

Finite-net image classification is the route X, F, B. Each image center is read by applying the displayed continuous-map graph row to a center already present in the compact source bundle, so no host image set or arbitrary center selector is introduced.

Modulus compatibility is the route X, F, U, M, R. The uniform-modulus ledger is obtained from the compact finite-net data, the continuous-map pointwise rows, the source and target metric distances, and the rational lower-bound fold over $\mathsf{Rat}^{\uparrow}$ histories.

The total-bounded export is B with its support rows. A target-image coverage read must pass through the finite $\mathsf{ProbeBundle}$ image-center row and the displayed target metric row before it reaches any consumer.

Finally, H, C, P, N preserve and name exactly this route. Since the carrier has no open-cover compactness object, arbitrary subcover selector, host image-set coordinate, quotient function equality, choice-selected center, or completeness coordinate, those objects cannot be exported. □

Theorem 2947.3 (Compact continuous image total-bounded handoff)**.** *Every total-boundedness consumer of an accepted* $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$ *carrier receives only the compact finite-net source row, the continuous-map graph and modulus rows, the uniform-modulus ledger, source and target metric-distance rows, the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold, the finite* $\mathsf{ProbeBundle}$ *image centers, and the visible structural rows*

$$X, F, U, M, R, B, H, C, P, N.$$

The handoff is therefore a finite BEDC certificate for image total-boundedness, not an open-cover compactness theorem and not a host image construction.

Proof. Begin with the accepted carrier and project its rows. The only source compactness data available are the finite-net rows in X.

Read the continuous map through F and the uniform modulus through U. Both rows are tied to the same source and target metric-distance rows M, so the image read cannot change its metric carrier mid-route.

The rational lower-bound fold R and the image-center bundle B produce the target finite-net witness. The fold is a finite $\mathsf{Rat}^{\uparrow}$ history calculation, and the image centers are a finite ProbeBundle list, so no arbitrary subcover or choice-selected image point is exposed.

The structural rows H, C, P, N transport, replay, prove provenance, and name that finite route. The excluded open-cover, host-image, quotient-function, choice, and completeness objects are absent from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactContinuousImageTotalBounded}\uparrow}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactContinuousImageTotalBounded}\uparrow}$, seed)

Scope closed: Definition 3924.1, Definition 3924.2, and Definition 3924.3 seed the compact-continuous-image total-bounded carrier over compact finite nets, continuous-map modulus rows, uniform-modulus ledgers, metric distances, RatUp folds, ProbeBundle image centers, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactContinuousImageTotalBounded}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary subcovers, host image sets, quotient function equality, choice-selected centers, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net image classification, modulus compatibility, total-bounded export, and non-escape for BEDC.Derived.CompactContinuousImageTotalBoundedUp.

Constructive story: A $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ContinuousMap pointwise-modulus rows, UniformModulus ledgers, source and target MetricSpace distance rows, RatUp lower-bound folds, ProbeBundle image centers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2948

A Concrete Naming Certificate for $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$

The $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ packet realizes the boundary-weighted disk-read branch of chapter 9463 as finite NameCert data. It sits beside the hyperbolic metric surface of chapter 3474, the boundary-shadow route of chapter 3813, the visual metric packet of chapter 3866, the unit-disk carrier of chapter 377, the circle carrier of chapter 58, the integral row of chapter 123, and the real-name seal of chapter 38. The packet names a finite boundary-kernel read, not a completed harmonic boundary theory.

Definition 2948.1 (Hyperbolic Poisson-kernel carrier)**.** *A* $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, M, B, V, U, S, I, R, W, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-source row for the interior point being read.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric row attached to the same disk source.*
3. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *boundary-shadow row that exposes the visible boundary window.*
4. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *visual-boundary comparison row.*
5. *U is the* $\mathsf{S}^{1\uparrow}$ *boundary-circle row over which angular samples are displayed.*
6. *S is the* $\mathsf{Integral}^{\uparrow}$ *boundary-integration row for the finite sample or displayed quadrature route.*
7. *I is the* $\mathsf{Real}^{\uparrow}$ *scalar endpoint row for kernel weights and normalization comparisons.*
8. *R is the radial denominator and numerator ledger tying D, M, B, U, I to the displayed hyperbolic Poisson weight.*
9. *W is the weighted boundary-integral readback row, exposing only the value determined by S, R, I over the displayed disk and boundary rows.*
10. *H records componentwise* hsame *transport for $D, M, B, V, U, S, I, R, W, C, P, N$.*
11. *C records displayed* Cont *replay from disk source through metric, boundary shadow, visual boundary, circle, integral, weight, and readback rows.*

12. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPoissonKernel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for completed boundary functions, unrestricted harmonic extension, selected radial limits, quotient boundary equality, ultrafilter convergence, or global boundary compactification.

Lean4 ✓ `BEDC.Derived.HyperbolicPoissonKernelUp.HyperbolicPoissonKernelTasteGate single carrier alignment`

Theorem 2948.2 (Hyperbolic Poisson-kernel NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ *carrier* $K = (D, M, B, V, U, S, I, R, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPoissonKernel}^{\uparrow}}$ *surface consists exactly of disk-source admission, hyperbolic metric admission, boundary-shadow admission, visual-boundary comparison, circle-boundary admission, boundary-integral admission, Real endpoint admission, radial weight-ledger exactness, weighted readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3925.1. The disk, metric, boundary-shadow, visual-boundary, circle, integral, Real, weight, readback, transport, replay, provenance, and local naming rows are the full public inventory.

The geometric rows are read first. The disk row D fixes the interior source, M fixes the hyperbolic metric comparison, B fixes the visible boundary shadow, and V fixes the visual-boundary comparison.

The boundary-kernel rows are then read through U, S, I, R, W. The circle row supplies boundary samples, the integral row supplies the displayed boundary aggregation, the Real row supplies scalar endpoints, the weight ledger supplies the hyperbolic Poisson factor, and the readback row exposes only the value determined by those rows.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no further row is present, completed boundary functions, unrestricted harmonic extension, selected limits, quotient boundary equality, ultrafilter convergence, and global compactification are outside the packet. □

Theorem 2948.3 (Hyperbolic Poisson-kernel boundary integral nonescape)**.** *Every accepted boundary-integral read of a* $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{UnitDisk}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{HyperbolicBoundaryShadow}^{\uparrow},\ \mathsf{HyperbolicVisualMetric}^{\uparrow},\ \mathsf{S}^{1\uparrow},\ \mathsf{Integral}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route first fixes the disk, metric, boundary-shadow, and visual-boundary rows, then reads the circle and integral rows, then reads the Real endpoint and weight ledger rows, and only then exposes weighted boundary readback. It exports no completed boundary function, unrestricted harmonic extension, selected radial limit, quotient boundary equality, ultrafilter convergence, or global compactification.

Proof. Let $K = (D, M, B, V, U, S, I, R, W, H, C, P, N)$ be accepted. A boundary-integral consumer first receives the geometric route D, M, B, V, so the boundary window is the one displayed by the disk, metric, shadow, and visual rows.

The integration route is U, S. The circle row supplies the boundary parameter window, and the integral row supplies only the displayed finite or certified aggregation over that window.

The scalar kernel route is I, R, W. The Real row supplies the endpoints, the weight ledger ties those endpoints to the disk and boundary rows, and the readback row exposes the weighted value only after the integral and weight ledgers are fixed.

Transport, replay, provenance, and local naming through H, C, P, N preserve this route. The excluded analytic and choice-theoretic objects have no carrier coordinate, so the boundary-integral read cannot escape the finite packet. □

Falsifiable prediction: Removing either the $\mathsf{HyperbolicMetric}^{\uparrow}$ row M or the $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ row B makes Definition 3925.3 false: a consumer could no longer verify that the boundary weight belongs to the displayed hyperbolic disk route.

Independence witness: hyperbolicmetric, hyperbolic-boundary-shadow, unitdisk, sone, integral, real: $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk source, hyperbolic metric, boundary shadow, visual comparison, circle boundary, integral aggregation, Real endpoints, weight ledger, readback, transport, replay, provenance, and local naming rows.

The Lean TasteGate site for $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ HyperbolicPoissonKernel}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicPoissonKernel}^{\uparrow}$ instances. These instances keep the disk, metric, boundary, circle, integral, Real, weight, readback, transport, replay, provenance, and naming rows distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPoissonKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ packet is generated from UnitDiskUp disk data, HyperbolicMetricUp metric rows, HyperbolicBoundaryShadowUp and HyperbolicVisualMetricUp boundary rows, SOneUp circle rows, IntegralUp boundary aggregation, RealUp endpoints, a hyperbolic weight ledger, weighted readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPoissonKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3925.1, Definition 3925.2, and Definition 3925.3 seed the finite hyperbolic boundary-kernel route over disk, metric, boundary, circle, integral, Real, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPoissonKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary functions, unrestricted harmonic extension, selected radial limits, quotient boundary equality, ultrafilter convergence, global boundary compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, geometric boundary routing, circle and integral admission, weight-ledger exactness, readback nonescape, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPoissonKernelUp.

Chapter 2949

A Concrete Naming Certificate for $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$

Following Ekeland's variational principle and the Bishop-style use of complete-metric descent, the $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$ packet names the finite descent ledger consumed by variational and fixed-point arguments. It sits downstream of the metric surface of chapter 57, the complete-metric carrier of chapter 128, the lower-semicontinuity packet of chapter 1536, the regular-rational readback route of chapter 301, and the terminal real seal of chapter 38. The packet records a finite variational descent certificate; it is not a host minimizer, not a selected choice function, and not an ambient completeness theorem.

Definition 2949.1 (Ekeland variational-principle carrier)**.** *An* $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, d, M, L, R, A, T, W, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite metric-domain row read through* $\mathsf{Met}^{\uparrow}$ *addresses.*
2. *d is the metric-comparison row naming the inspected distance witnesses on X.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *descent-readiness row, exposing only the finite Cauchy-tail obligations needed by the packet.*
4. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *value-stability row for the inspected functional.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row used to compare displayed values and descent budgets.*
6. *A is the approximation row naming the initial value, positive tolerance, and admissible descent budget.*
7. *T is the finite transfinite-free descent trace, ordered by the displayed metric and value-readback rows.*
8. *W is the winner-window row naming the final inspected point and the finite perturbation inequality visible at that point.*
9. *H records componentwise* hsame *transport for metric, completeness, lower-semicontinuity, rational readback, approximation, trace, and winner-window rows.*
10. *C records displayed* Cont *replay from a variational request through X, d, M, L, R, A, T, W.*

11. *P is the* Pkg *provenance over* $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EkelandVariationalPrinciple}^{\uparrow}}$ *row.*

The carrier exports exactly this finite descent packet. It contains no host-level minimizer, no global choice selector, no quotient of Cauchy approximants, and no independent assertion that the ambient metric space is complete.

Lean4 ✓ `BEDC.Derived.EkelandVariationalPrincipleUp.EkelandVariationalPrincipleTasteGate single carrier alignment`

Theorem 2949.2 (Ekeland variational-principle NameCert obligations)**.** *For every accepted* EkelandVariationalPrin *carrier $E = (X, d, M, L, R, A, T, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EkelandVariationalPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed metric-domain, distance, completeness, lower-semicontinuity, rational-readback, approximation, descent-trace, winner-window, transport, continuation, provenance, and naming rows;*
2. *metric readability, requiring every distance comparison used by the descent trace to be one of the displayed d rows on addresses in X;*
3. *complete-metric descent readiness, requiring every Cauchy-tail request made by the trace to pass through M;*
4. *lower-semicontinuity readability, requiring every value-stability read to pass through L and its regular-rational row R;*
5. *descent-budget coverage, requiring the initial value, tolerance, and perturbation budget to be named in A before the trace row T is consumed;*
6. *winner-window exposure, requiring the terminal inspected point and its finite perturbation inequality to be named in W;*
7. *transport, replay, provenance, and naming stability through H, C, P, N;*
8. *ledger non-escape, excluding host minimizers, global choice selectors, quotient-completion objects, and ambient completeness theorems.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier row by row. The metric-domain and distance rows expose the inspected addresses and comparisons, while M, L, R, A, T, W expose the complete-metric descent readiness, lower-semicontinuity reads, rational comparisons, approximation budget, finite trace, and terminal winner window.

The obligation order follows the displayed route. A descent comparison cannot be read before d and R are visible, a Cauchy-tail request cannot be read before M is visible, and the perturbation inequality cannot be read before the approximation row and trace row have been consumed.

Transport and replay are structural rows. They preserve the same metric, value, budget, trace, and winner-window data under hsame comparison and displayed Cont replay.

Finally, P and N source and name only the displayed packet. Since no coordinate stores a host minimizer, a global choice selector, a quotient-completion object, or an independent completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 2949.3 (Ekeland metric-descent handoff)**.** *Every variational, complete-metric, or fixed-point consumer reading an accepted* $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$ *packet factors through the finite descent route*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{LowerSemicontinuous}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto A, T, W, H, C, P, N.$$

The consumer therefore receives a certificate-local descent ledger and terminal perturbation window, not a host minimizer, selected choice function, quotient index, or ambient completeness theorem.

Proof. Start from an accepted carrier $E = (X, d, M, L, R, A, T, W, H, C, P, N)$. The metric rows X, d supply the only addresses and distance comparisons available to the consumer.

The complete-metric and lower-semicontinuity rows then bind the analytic reads. The row M supplies the finite Cauchy-tail obligations used by descent, while L and R supply the value-stability and rational-readback route.

The approximation and trace rows A, T order the descent budget before the winner-window row W is consumed. Thus the terminal perturbation inequality is a displayed row of the packet, not a selected minimizer outside the packet.

The structural rows H, C, P, N transport, replay, source, and name this same route. Because no row carries a host choice selector, quotient completion, or independent ambient-completeness assertion, downstream consumers cannot obtain such data from the handoff. □

Theorem 2949.4 (Ekeland variational-principle descent window)**.** *Any accepted* $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$ *packet exposes the approximation row A, finite descent trace T, complete-metric readiness row M, lower-semicontinuity row L, rational readback row R, and winner window W in that order before a downstream fixed-point or minimization consumer may read the perturbation inequality. The read is therefore a finite descent-window obligation over the carrier rows of Definition 3926.1, not a host minimizer, selected choice function, quotient completion, or ambient completeness principle.*

Proof. Project the accepted carrier $E = (X, d, M, L, R, A, T, W, H, C, P, N)$ and read the obligation surface of Definition 3926.2. The approximation row A supplies the initial value, tolerance, and perturbation budget before any descent comparison can be inspected.

Next use the metric-descent handoff of Definition 3926.3. It keeps the finite trace T downstream of A and keeps every Cauchy-tail request routed through M.

The value comparisons then pass through L and R. Thus lower-semicontinuity and rational readback remain visible before the terminal perturbation inequality is exposed in W.

Finally, H, C, P, N transport, replay, source, and name the same ordered window. Since the carrier contains no coordinate for host minimizers, selected choice functions, quotient completions, or ambient completeness, the consumer receives only the displayed descent window. □

Closure status for $\mathsf{NameCert}_{\mathsf{EkelandVariationalPrinciple}^{\uparrow}}$.

Constructive story: An $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$ packet is generated from a finite metric-domain row, displayed distance witnesses, a complete-metric descent-readiness row, a lower-semicontinuity row, regular-rational readback, approximation budgets, a finite descent trace, a winner-window row, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EkelandVariationalPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3926.1, Definition 3926.2, and Definition 3926.3 seed the complete-metric variational descent ledger consumed by later fixed-point and minimization packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EkelandVariationalPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host minimizer, global choice selector, quotient completion, selected cofinal descent path, ambient completeness theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric descent readiness, lower-semicontinuity readback, descent-budget coverage, winner-window exposure, and consumer nonescape for BEDC.Derived.EkelandVariationalPr

Chapter 2950

A Concrete Naming Certificate for $\mathsf{KanExtension}^{\uparrow}$

Following Mac Lane's formulation of Kan extensions as universal arrows along a functor, the $\mathsf{KanExtension}^{\uparrow}$ packet reconstructs the usual left and right extension interface as finite BEDC certificate data. It depends on the certified category, functor, and natural-transformation surfaces of chapter 61, chapter 62, and chapter 63; it also reads the triangle-comparison discipline of chapter 107 and the cocone comparison rows of chapter 106. The chapter does not import an external functor category. It names the finite rows required for a displayed extension object, its comparison natural transformation, and its universal factorization route.

Definition 2950.1 (Kan extension carrier)**.** *A* $\mathsf{KanExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, D, E, J, F, L, \eta, U, V, H, R, P, N)$$

with the following displayed rows:

1. C, D, E *are* $\mathsf{Cat}^{\uparrow}$ *certificate rows for the source, target, and codomain categories;*
2. $J : C \to D$, $F : C \to E$, *and* $L : D \to E$ *are* $\mathsf{Functor}^{\uparrow}$ *rows whose object and morphism maps are already certified by the corresponding category classifiers;*
3. $\eta : F \Rightarrow L \circ J$ *is the displayed* $\mathsf{NatTrans}^{\uparrow}$ *comparison row;*
4. U *is the universal comparison row: for every displayed* $\mathsf{Functor}^{\uparrow}$ *row* $M : D \to E$ *and* $\mathsf{NatTrans}^{\uparrow}$ *row* $\alpha : F \Rightarrow M \circ J$, *it supplies the candidate mediating* $\mathsf{NatTrans}^{\uparrow}$ *row* $\overline{\alpha} : L \Rightarrow M$*;*
5. V *is the uniqueness row: two mediating rows with the same composite comparison are identified only by the displayed natural-transformation classifier;*
6. H *records componentwise* hsame *transport for categories, functors, comparison transformations, mediating transformations, and uniqueness witnesses;*
7. R *records displayed* Cont *replay from* α *to* $\overline{\alpha}$ *and from the composite* $\overline{\alpha} \circ J$ *back to* α*;*
8. P *records* Pkg *provenance over the* $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{Adjunction}^{\uparrow}$, $\mathsf{CatColimit}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{KanExtension}^{\uparrow}}$ *row.*

The carrier has no coordinate for host functor equality, quotient natural-transformation equality, an external functor category, or an uncategorified universal property outside these displayed rows.

Lean4 ✓ `BEDC.Derived.KanExtensionUp.TasteGate.KanExtensionTasteGate single carrier alignment`

Theorem 2950.2 (Kan extension NameCert obligations)**.** *For the carrier of Definition 3927.1, the local* $\mathsf{NameCert}_{\mathsf{KanExtension}^{\uparrow}}$ *surface consists exactly of the category rows* C, D, E*, functor rows* J, F, L*, comparison row* η*, universal comparison row* U*, uniqueness row* V*, componentwise transport row* H*, continuation replay row* R*, provenance row* P*, and local naming row* N*. Any accepted* $\mathsf{KanExtension}^{\uparrow}$ *read must expose those rows before it may be used as a left or right Kan-extension certificate.*

Lean4 ✓ `BEDC.Derived.KanExtensionUp.KanExtensionCarrier namecert obligations`

Proof. Project the carrier coordinates. The rows C, D, E license the three category classifiers, while J, F, L license the functor data and η supplies the displayed natural-transformation comparison.

Read the universal data next. The row U provides the mediating transformation for each displayed comparison α, and V constrains any two mediating rows by the $\mathsf{NatTrans}^{\uparrow}$ classifier rather than by host equality.

Finally attach the structural rows. The row H transports all displayed components by hsame, R replays the comparison route through Cont, P records the sibling certificate provenance, and N names the packet. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 2950.3 (Kan extension universal route)**.** *Every accepted* $\mathsf{KanExtension}^{\uparrow}$ *universal comparison factors through the displayed route*

$$(C, D, E, J, F, L, \eta), \alpha \longmapsto \overline{\alpha}, \overline{\alpha} \circ J \sim \alpha$$

using only U, V, H, R, P, N*. The* $\mathsf{Adjunction}^{\uparrow}$ *and* $\mathsf{CatColimit}^{\uparrow}$ *siblings may supply triangle-shaped and cocone-shaped comparison patterns, but neither sibling replaces the displayed* $\mathsf{Functor}^{\uparrow}$ *and* $\mathsf{NatTrans}^{\uparrow}$ *rows by an external universal-property assertion.*

Proof. Begin with a displayed comparison $\alpha : F \Rightarrow M \circ J$. By Definition 3927.1, the only row that can produce a mediator is U, and the mediator it returns is a $\mathsf{NatTrans}^{\uparrow}$ row $\overline{\alpha} : L \Rightarrow M$ over the already certified functors.

Use the uniqueness row to keep the route internal. The row V compares mediating transformations through the natural-transformation classifier, while H transports the category, functor, and transformation rows componentwise. This prevents the factorization from becoming a host-level equality claim.

The remaining rows preserve the same route. The continuation row R replays the composite comparison, P records its category-theory provenance through the cited siblings, and N names the packet. Hence the universal route is read as finite NameCert data, not as an untracked functor-category theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{KanExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{KanExtension}^{\uparrow}$ packet is generated from category rows, functor rows, a comparison natural transformation, universal and uniqueness rows, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KanExtension}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 3927.1, Definition 3927.2, and Definition 3927.3 bind the displayed Kan-extension carrier, obligation surface, and universal route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KanExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close external functor-category existence, quotient natural-transformation equality, arbitrary pointwise Kan-extension computation, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a Lean carrier theorem that binds the universal comparison rows to an explicit kernel scope.

Chapter 2951

A Concrete Naming Certificate for $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$ packet presents bounded monotone sequence convergence as explicit dyadic-window and regular-Cauchy evidence, not as general $\mathsf{Real}^{\uparrow}$ completeness or choice. It sits beside the finite stream-name surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the bounded monotone seal boundary of chapter 918. The packet gives downstream Bolzano–Weierstrass, Cauchy completion, and sequence-limit consumers a finite L10 route for monotone convergence without importing ambient completeness.

Definition 2951.1 (MonotoneConvergenceSequence carrier)**.** *A* $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, L, U, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the monotone sequence source row, carrying the displayed sequence observations and the finite monotonicity classifier read by the packet.*
2. *L and U are the lower and upper dyadic bound rows, giving the bounded interval in which every inspected source window is certified to land.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the initial and tail windows requested by the monotone-convergence consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic mesh widths, lower-upper bracket gaps, and tail budgets.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the monotone windows and their dyadic tolerance ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the source, bounds, finite windows, dyadic tolerances, and regular rational readback have been displayed.*
7. *H records componentwise* hsame *transport for S, L, U, W, D, R, E and the structural rows.*
8. *C records displayed* Cont *replay from monotone source inspection through dyadic bounds, finite windows, tolerance shrinkage, regular readback, and the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$, $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, L, U, W, D, R, E, H, C, P, N$. It has no coordinate for an unrestricted supremum principle, quotient stream equality, host sequence equality, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MonotoneConvergenceSequenceUp.MonotoneConvergenceSequenceTasteGate single carrier alignment`

Theorem 2951.2 (MonotoneConvergenceSequence NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$ *carrier*

$$M = (S, L, U, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceSequence}^{\uparrow}}$ *surface consists exactly of monotone source exposure through S, lower and upper dyadic bound exposure through L, U, finite window exposure through W, dyadic tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal handoff through E, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3928.1. The tuple displays the monotone source row, dyadic bound rows, finite stream windows, dyadic tolerance ledger, regular rational readback, Real seal, and the structural transport, replay, provenance, and naming rows.

The bounded monotone evidence is confined to S, L, U, W, D. The source row gives the monotonicity classifier, the bound rows give the visible interval enclosure, and the window and tolerance rows record the finite bracket shrinkage that a consumer may inspect.

The analytic handoff is then R, E. The regular rational readback row is obtained only from the displayed windows and dyadic ledger, and the Real seal row is exposed only after that readback has been displayed.

Finally H, C, P, N preserve and name the same finite route. Since the carrier contains no supremum, quotient stream, host sequence equality, host real equality, choice, or ambient completeness coordinate, those objects are outside the local NameCert surface. □

Theorem 2951.3 (MonotoneConvergenceSequence regular Cauchy route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The bounded monotone seal supplies the source and interval rows, the finite stream windows expose the inspected observations, the dyadic ledger supplies the tail tolerance budget, and the regular rational readback precedes the terminal Real seal.

Proof. Start with an accepted carrier $M = (S, L, U, W, D, R, E, H, C, P, N)$. The monotone source and bound rows S, L, U are the only coordinates through which bounded monotone evidence can enter the packet.

Read the bounded seal boundary through chapter 918. It supplies the public source-and-bound discipline consumed by this carrier, but it does not provide an unrestricted completeness principle.

Next read the finite observation route. The windows W are $\mathsf{StreamName}^{\uparrow}$ data, the tolerance ledger D is $\mathsf{DyadicRatCore}^{\uparrow}$ data, and the regular rational row R repacks exactly those displayed windows and tolerances as $\mathsf{RegSeqRat}^{\uparrow}$ readback.

The Real seal E is therefore downstream of the source, dyadic bounds, finite windows, dyadic tolerance ledger, and regular rational readback. Transport and replay through H, C, P, N preserve that same route, so no consumer receives a hidden supremum, quotient stream equality, host sequence equality, host real equality, countable-choice schedule, or ambient Real-completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$ packet is generated from a monotone source row, lower and upper dyadic bound rows, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneConvergenceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3928.1, Definition 3928.2, and Definition 3928.3 seed the bounded monotone regular-Cauchy route over StreamName, DyadicRatCore, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneConvergenceSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a general supremum principle, quotient stream equality, host sequence equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded monotone seal handoff, dyadic bracket shrinkage, RegSeqRat readback exactness, RealUp seal nonescape, and completeness-refusal proofs for BEDC.Derived.MonotoneConvergenceS

Chapter 2952

A Concrete Naming Certificate for $\mathsf{RegularCauchyPicardSeal}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyPicardSeal}^{\uparrow}$ packet records the finite route by which a displayed Picard orbit is read as a regular rational Cauchy name and then sealed as a $\mathsf{Real}^{\uparrow}$ object. It sits over the orbit rows of chapter 2359, the contraction ledger of chapter 396, the precision schedule of chapter 292, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the bounded ambient interface of chapter 128. The packet is deliberately finite: it certifies the route from named Picard rows to a regular Cauchy seal, not an unrestricted fixed-point selection theorem.

Definition 2952.1 (Regular Cauchy Picard seal carrier)**.** *A* $\mathsf{RegularCauchyPicardSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, B, M, Q, E, H, C, P, N)$$

whose rows have the following roles.

1. *I is a finite* $\mathsf{PicardIteration}^{\uparrow}$ *orbit row displaying the initial point, the iterated contraction rows, and the finite prefix consumed by the certificate.*
2. *B is a* $\mathsf{BanachFixedPoint}^{\uparrow}$ *contraction-budget row exposing only the local Lipschitz decrease data needed to compare successive Picard rows.*
3. *M is a* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule extracted from the displayed contraction budget and attached to finite precision requests.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite Picard orbit and the modulus schedule.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached through the displayed regular rational readback.*
6. *H, C, P, N are respectively the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyPicardSeal}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a selected fixed point, host function extensionality, quotient stream equality, ambient completeness, or an unrestricted Banach fixed-point existence principle.

Lean4 ✓ `BEDC.Derived.RegularCauchyPicardSealUp.RegularCauchyPicardSealTasteGate single carrier alignment`

Theorem 2952.2 (Regular Cauchy Picard seal obligations)**.** *For every accepted carrier $R = (I, B, M, Q, E, H, C, P, N)$ of Definition 3929.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyPicardSeal}^{\uparrow}}$ *surface*

consists exactly of the Picard orbit row I, the contraction-budget row B, the extracted modulus row M, the regular rational readback row Q, the terminal $\mathsf{Real}^{\uparrow}$ *seal row E, and the structural rows H, C, P, N. A downstream consumer must read the rows in the displayed order*

$$I \to B \to M \to Q \to E \to H, C, P, N.$$

No accepted obligation row can be replaced by a selected fixed point, a host-level proof that two functions are extensionally equal, quotient equality between stream representatives, an ambient completeness theorem, or an unrestricted Banach fixed-point existence row.

Proof. Project the carrier of Definition 3929.1. The analytic rows are exactly the finite Picard orbit, contraction budget, extracted modulus, regular rational readback, and terminal Real seal; the remaining rows are the standard BEDC transport, replay, provenance, and naming surface.

The Picard row is read first because the modulus schedule is extracted from finite comparisons between displayed iterates. The contraction-budget row supplies those comparisons, and the $\mathsf{CauchyModulus}^{\uparrow}$ row records the precision threshold as data rather than as a host completeness argument.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback can then consume only the displayed orbit prefix and the extracted modulus. Once that readback is present, the $\mathsf{Real}^{\uparrow}$ seal is reached through the same regular Cauchy route used by the surrounding Real-and-Completion chapters.

Finally the rows H, C, P, N transport and replay this finite route as the local certificate. Since none of the carrier coordinates stores a selected fixed point, function extensionality principle, quotient stream equality, ambient completeness theorem, or unrestricted fixed-point existence theorem, no consumer of the NameCert surface can obtain those claims from this packet. □

Theorem 2952.3 (Regular Cauchy Picard seal route)**.** *Let $R = (I, B, M, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyPicardSeal}^{\uparrow}$ *carrier. Every finite precision request for the Real-facing Picard limit factors through the route*

$$\mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{BanachFixedPoint}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route first reads a finite Picard orbit prefix, then extracts a Cauchy modulus from the contraction budget, then performs $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It does not claim a chosen fixed point, host function extensionality, quotient stream equality, ambient completeness, or unrestricted Banach fixed-point existence.*

Proof. Begin with the accepted carrier and the obligation theorem above. They force every precision request to start with the displayed finite Picard orbit I and the contraction budget B.

Next extract the modulus row M. This step is finite: a requested precision is matched with a displayed threshold from the contraction ledger, so the certificate does not invoke a global completeness principle or a choice schedule over all requests.

Use the extracted threshold to read the regular rational row Q. The readback is the ordinary $\mathsf{RegSeqRat}^{\uparrow}$ passage from finite rational data and a modulus to a regular Cauchy name; it has no quotient-stream coordinate and no host equality coordinate.

Finally pass from Q to the terminal Real seal E and replay the route through H, C, P, N. The resulting seal records the finite Picard-to-regular-Cauchy route, while the selected fixed point and unrestricted Banach existence claims remain outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyPicardSeal}^{\uparrow}}$.

Constructive story: A RegularCauchyPicardSeal$^{\uparrow}$ packet is generated from a finite PicardIteration$^{\uparrow}$ orbit prefix, a BanachFixedPoint$^{\uparrow}$ contraction-budget row, an extracted CauchyModulus$^{\uparrow}$ precision schedule, a RegSeqRat$^{\uparrow}$ readback row, a terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyPicardSeal}^{\uparrow}}$, seed)

Scope closed: Definition 3929.1, Definition 3929.2, and Definition 3929.3 seed the finite Picard-orbit route from contraction data through modulus extraction, regular rational readback, and the Real seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyPicardSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host function extensionality, quotient stream equality, ambient completeness, or unrestricted Banach fixed-point existence.

Upgrade path: A formal route can encode the finite carrier rows and prove the Picard-orbit modulus extraction, regular rational readback, and terminal Real-seal route.

Chapter 2953

A Concrete Naming Certificate for ArzelaAscoliSelection$^{\uparrow}$

Following Arzela–Ascoli, Kelley, and Bishop–Bridges constructive analysis, the ArzelaAscoliSelection$^{\uparrow}$ packet records the finite selection surface by which an equicontinuous bounded family on a compact metric source exposes a regular convergent subsequence. It sits after the family ledger of chapter 413, the classical compactness packet of chapter 412, the bounded-family surface of chapter 3522, and the diagonal extraction route of chapter 2219. The packet names the selection route through displayed finite rows only; it does not export a host compact-open topology, an arbitrary sequence choice, quotient equality of functions, or ambient completeness outside the named certificates.

Definition 2953.1 (ArzelaAscoliSelection carrier)**.** *An* ArzelaAscoliSelection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, E, B, D, M, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* CompactMetric$^{\uparrow}$ *source row supplying finite net and compact inspection data.*
2. *E is the* EquicontinuityFamily$^{\uparrow}$ *ledger, including shared-center modulus rows for the displayed family.*
3. *B is the* BoundedFunctionFamily$^{\uparrow}$ *row, recording pointwise and sup-norm boundedness for the same family.*
4. *D is the* AscoliDiagonal$^{\uparrow}$ *row selecting compatible finite windows across the source net and target readback.*
5. *M is the finite modulus row read through* ArzelaAscoliFiniteModulus$^{\uparrow}$ *and the compact uniform-continuity route.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the selected finite windows.*
7. *R is the* Real$^{\uparrow}$ *seal row attached to the regular readback of the selected subsequence values.*
8. *H records componentwise* hsame *transport for X, E, B, D, M, Q, R.*
9. *C records displayed* Cont *replay from compact-source inspection through equicontinuity, boundedness, diagonal selection, regular readback, and real sealing.*

10. *P is the* Pkg *provenance over* ArzelaAscoliSelection$^{\uparrow}$, CompactMetric$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, BoundedFunctionFamily$^{\uparrow}$, AscoliDiagonal$^{\uparrow}$, ArzelaAscoliFiniteModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ArzelaAscoliSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host-selected subsequence, a compact-open completion, quotient equality of functions, countable choice, or an unstated completeness principle.

Lean4 ✓ `BEDC.Derived.ArzelaAscoliSelectionUp.TasteGate.ArzelaAscoliSelectionTasteGate single carrier alignment`

Theorem 2953.2 (ArzelaAscoliSelection NameCert obligations)**.** *For every accepted* ArzelaAscoliSelection$^{\uparrow}$ *carrier $A = (X, E, B, D, M, Q, R, H, C, P, N)$, the local* NameCert$_{\text{ArzelaAscoliSelection}^{\uparrow}}$ *surface consists exactly of compact-source admission through* CompactMetric$^{\uparrow}$, *equicontinuity-family admission through* EquicontinuityFamily$^{\uparrow}$, *bounded-family admission through* BoundedFunctionFamily$^{\uparrow}$, *diagonal-window admission through* AscoliDiagonal$^{\uparrow}$, *finite modulus readback through* ArzelaAscoliFiniteModulus$^{\uparrow}$, *regular rational readback through* RegSeqRat$^{\uparrow}$, *terminal real sealing through* Real$^{\uparrow}$, *carrier storage in* BHist, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* NameCert.

Lean4 ✓ `BEDC.Derived.ArzelaAscoliSelectionUp.ArzelaAscoliSelectionTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3930.1. The rows $X, E, B, D, M, Q, R, H, C, P, N$ are the full displayed inventory.

Read the source and family rows first. The compact metric row X supplies finite source nets, the equicontinuity row E supplies shared modulus ledgers, and the bounded-family row B supplies the bound surface needed before any diagonal selection is public.

Read the selection rows next. The diagonal row D consumes the finite net and family ledgers, while M records the finite modulus compatibility that keeps the selected windows inside the Arzela–Ascoli route. The row Q then exposes the selected windows as regular rational readback, and R seals the resulting values as Real$^{\uparrow}$ data.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier has no coordinate for host subsequence choice, compact-open completion, quotient equality of functions, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 2953.3 (ArzelaAscoliSelection selected regular subsequence route)**.** *Every accepted* ArzelaAscoliSelection$^{\uparrow}$ *packet exposes a selected regular subsequence only through the finite route*

CompactMetric$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, BoundedFunctionFamily$^{\uparrow}$, AscoliDiagonal$^{\uparrow}$, ArzelaAscoliFiniteModulus$^{\uparrow}$, Reg

The route first displays compact source nets, family equicontinuity, boundedness, and diagonal finite windows; only then does it expose regular rational readback and the real seal. It exports no arbitrary subsequence selector, compact-open host topology, quotient function equality, countable choice, or ambient completeness theorem.

Proof. Use Definition 3930.2. It orders the compact source, equicontinuity, bounded-family, diagonal, finite-modulus, regular-readback, and Real-seal rows inside one accepted carrier.

The diagonal row can be consumed only after X, E, B are displayed. The finite modulus row M ties the selected windows back to the shared equicontinuity ledger and the bounded-family surface, so the selection does not detach from the family certificate.

The readback rows Q, R are downstream. They convert the displayed windows into $\mathsf{RegSeqRat}^{\uparrow}$ and then $\mathsf{Real}^{\uparrow}$ data, while H, C, P, N preserve the same route.

Thus the packet supplies a finite BEDC selection route. None of the refused host-level objects is present in the carrier inventory. □

Falsifiable prediction: An accepted $\mathsf{ArzelaAscoliSelection}^{\uparrow}$ consumer that reads a selected regular subsequence without first exposing CompactMetric, EquicontinuityFamily, BoundedFunctionFamily, AscoliDiagonal, finite modulus, RegSeqRat, Real, hsame, Cont, Pkg, and local NameCert rows refutes the carrier surface.

Independence witness: compactmetric, equicontinuityfamily, bounded-function-family, ascoli-diagonal, arzelaascoli: $\mathsf{ArzelaAscoliSelection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-source nets, equicontinuity ledgers, bounded-family rows, diagonal selection windows, finite modulus readback, regular rational data, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoliSelection}^{\uparrow}}$.

Constructive story: An $\mathsf{ArzelaAscoliSelection}^{\uparrow}$ packet is generated from CompactMetricUp source nets, EquicontinuityFamilyUp modulus ledgers, BoundedFunctionFamilyUp boundedness rows, AscoliDiagonalUp finite windows, ArzelaAscoliFiniteModulusUp compatibility rows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3930.1, Definition 3930.2, and Definition 3930.3 seed the finite constructive selection route for equicontinuous bounded families over compact metric sources.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, compact-open topology, arbitrary subsequence choice, quotient equality of functions, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, family ledger exactness, boundedness readback, diagonal-window compatibility, finite modulus transport, regular readback, Real sealing, provenance, and local naming for BEDC.Derived.ArzelaAscoliSelectionUp.

Chapter 2954

A Concrete Naming Certificate for $\mathsf{ContractionMappingTheorem}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive metric analysis, the $\mathsf{ContractionMappingTheorem}^{\uparrow}$ packet records the fixed-point theorem as a finite complete-metric and Picard-orbit certificate. It sits next to the complete-metric carrier of chapter 128, the metric-distance surface of chapter 57, the contractive-map row of chapter 3819, the completion boundary of chapter 95, and the terminal real seal of chapter 38. The packet names the theorem-facing route from a displayed contraction to a unique fixed-point seal; it is not a host fixed-point theorem, a quotient completion principle, a selected representative, or an ambient completeness axiom.

Definition 2954.1 (Contraction mapping theorem carrier)**.** *A* $\mathsf{ContractionMappingTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, M, D, A, O, L, U, H, T, P, N)$$

with the following visible rows:

1. *C is the complete-metric source row, carrying the displayed Cauchy admission and endpoint-read interface from* $\mathsf{CompleteMetric}^{\uparrow}$*.*
2. *M is the metric-distance row, exposing only the finite distance comparisons admitted by the* $\mathsf{Met}^{\uparrow}$ *surface.*
3. *D is the* $\mathsf{ContractiveMap}^{\uparrow}$ *row, recording the self-map graph, contraction constant ledger, and one-step distance decrease over the same metric source.*
4. *A is the Picard/Cauchy orbit schedule, listing the finite initial point, iterate windows, residual-distance bounds, and Cauchy-modulus handoff generated from D.*
5. *O is the* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal row that admits the orbit endpoint only after C, M, D, A have been displayed.*
6. *L is the fixed-point uniqueness ledger, comparing two endpoint reads through the same metric-distance row and the contraction decrease route before local equality is exported.*
7. *U records the fixed-point equation read, requiring the endpoint seal, the contractive-map graph, and the Picard orbit replay to agree componentwise.*
8. *H stores componentwise* hsame *transport for the complete-metric source, metric-distance row, contractive-map row, Picard/Cauchy schedule, completion or real seal, fixed-point uniqueness ledger, fixed-point equation row, replay, provenance, and local naming.*

9. *T stores displayed* Cont *replay from contraction admission through Picard iteration, Cauchy endpoint admission, fixed-point equation read, and uniqueness comparison.*
10. *P is the* Pkg *provenance over* ContractionMappingTheorem$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Met$^{\uparrow}$, ContractiveMap$^{\uparrow}$, Completion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ContractionMappingTheorem}^{\uparrow}}$ *row.*

The classifier accepts packets only when the complete-metric row, metric-distance row, contractive-map row, Picard/Cauchy schedule, endpoint seal, fixed-point equation row, uniqueness ledger, transport, replay, provenance, and local naming row are all read on the same displayed route.

Theorem 2954.2 (Contraction mapping theorem NameCert obligations)**.** *For every accepted* ContractionMappingTheorem$^{\uparrow}$ *carrier*

$$F = (C, M, D, A, O, L, U, H, T, P, N),$$

the local NameCert$_{\text{ContractionMappingTheorem}^{\uparrow}}$ *obligations are exactly complete-metric source admission, metric-distance visibility, contractive-map row admission, Picard/Cauchy orbit scheduling,* Completion$^{\uparrow}$ *or* Real$^{\uparrow}$ *endpoint sealing, fixed-point equation replay, fixed-point uniqueness comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.ContractionMappingTheoremUp.ContractionMappingTheoremTasteGate single carrier alignment`

Proof. Project the accepted carrier of Definition 3931.1. The source rows C and M are the only complete-metric and metric-distance data available to a theorem-facing consumer, and D is the only row that carries contraction information.

The Picard/Cauchy schedule A is generated from the displayed contraction row. Its residual bounds and Cauchy-modulus handoff must be read before the endpoint seal O is visible, so the completion or real seal cannot be consumed as an ambient completeness principle.

The fixed-point equation row U and uniqueness ledger L are downstream rows. They compare only endpoint reads that have traversed C, M, D, A, O and then preserve that route through the structural rows H, T, P, N.

Thus the NameCert obligations are precisely the displayed finite route. No carrier coordinate supplies a host fixed-point theorem, quotient completion equality, selected representative, unrestricted choice, trichotomy, or open-cover compactness. □

Falsifiable prediction: Every accepted ContractionMappingTheorem$^{\uparrow}$ consumer reads a complete-metric source, a metric-distance row, a contractive-map row, a Picard/Cauchy orbit schedule, a completion or real endpoint seal, a fixed-point equation row, a uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before it treats the packet as a fixed-point theorem.

Independence witness: completemetric, metric, contractive-map, completion, real: ContractionMappingTheorem binds the theorem-facing fixed-point route in one NameCert packet; the listed siblings expose source, distance, contraction, endpoint, or seal rows separately but do not jointly carry Picard/Cauchy scheduling, fixed-point equation replay, uniqueness, transport, replay, provenance, and local naming for the theorem surface.

Closure status for NameCert$_{\text{ContractionMappingTheorem}^{\uparrow}}$ **·**

Constructive story: A ContractionMappingTheorem$^{\uparrow}$ packet is generated from a CompleteMetric source, a Metric distance row, a ContractiveMap row, a Picard/Cauchy orbit schedule, a CompletionUp or RealUp seal, a fixed-point

equation row, a uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ContractionMappingTheorem}\uparrow}$, seed)

Scope closed: Definition 3931.1 and Definition 3931.2 seed the finite fixed-point theorem certificate over complete-metric, metric-distance, contractive-map, Picard/Cauchy, completion or real seal, uniqueness, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ContractionMappingTheorem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host fixed-point equality, quotient completion equality, selected representatives, unrestricted choice, trichotomy, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contractive-map visibility, Picard/Cauchy scheduling, endpoint sealing, fixed-point equation replay, uniqueness routing, transport, replay, provenance, and local naming for BEDC.Derived.ContractionMappingTheoremUp.

Chapter 2955

A Concrete Naming Certificate for HilbertAlexanderBlocker$^{\uparrow}$

The HilbertAlexanderBlocker$^{\uparrow}$ packet realizes the Hilbert-series blocker complex of Definition 9462.1622 as finite BEDC NameCert data. It sits after the simplicial-complex carrier of chapter 238, the polynomial carrier of chapter 50, the finite-trace evaluator surface of chapter 818, the DNA boundary-tile packet of chapter 3393, and the arity-ten BHist tuple capstone of chapter 1364. The packet names blocker-cover, face-polynomial, Hilbert-row, Alexander-dual, and non-Cohen–Macaulay rows as displayed finite data; it is not a host Stanley–Reisner algebra oracle, a biological stochastic model, quotient codon semantics, or an unrestricted homology computation.

Definition 2955.1 (HilbertAlexanderBlocker carrier)**.** *A* HilbertAlexanderBlocker$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S, P, T, B, F, L, A, R, C, Q, N)$$

with the following displayed rows:

1. *S is the* SimplicialComplex$^{\uparrow}$ *row for the blocker complex and its four omitted-coordinate cover faces.*
2. *P is the* Poly$^{\uparrow}$ *row recording the face polynomial and the Hilbert numerator polynomial.*
3. *T is the* FiniteTraceEvaluator$^{\uparrow}$ *row that evaluates the finite inclusion-exclusion table for cover intersections.*
4. *B is the* DnaWindowSixBoundaryTile$^{\uparrow}$ *row carrying the six-window boundary source and trigger coordinates.*
5. *F is the blocker-cover row, recording the four facets and the intersection multiplicities $4, 6, 4, 1$.*
6. *L is the Hilbert-row ledger, recording the rational-function denominator powers $14, 6, 2, 0$ and the signed inclusion-exclusion coefficients.*
7. *A is the Alexander-dual row, recording the four generator complements and their lcm-degree ledger.*
8. *R records componentwise* hsame *transport for S, P, T, B, F, L, A.*
9. *C records displayed* Cont *replay from boundary-tile reads through blocker cover, face polynomial, Hilbert rows, and Alexander-dual rows.*

10. *Q is the* Pkg *provenance over* HilbertAlexanderBlocker$^{\uparrow}$, SimplicialComplex$^{\uparrow}$, Poly$^{\uparrow}$, FiniteTraceEvaluator$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, BHistDecaTupleNameCert$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HilbertAlexanderBlocker}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient polynomial-ring equality oracle, an unrestricted minimal resolution, stochastic biological semantics, quotient codon equality, hidden homology computation, or external Cohen–Macaulay decision procedure.

Theorem 2955.2 (HilbertAlexanderBlocker NameCert obligations)**.** *For every accepted* HilbertAlexanderBlocker$^{\uparrow}$ *carrier $H = (S, P, T, B, F, L, A, R, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HilbertAlexanderBlocker}^{\uparrow}}$ *surface consists exactly of simplicial-complex admission through S, polynomial-row admission through P, finite trace evaluation through T, DNA boundary-tile source admission through B, blocker-cover exactness through F, Hilbert-row readback through L, Alexander-dual ledger exposure through A, componentwise* hsame *transport through R, displayed* Cont *replay through C,* Pkg *provenance through Q, and local naming through N.*

Lean4 ✓ `BEDC.Derived.HilbertAlexanderBlockerUp.HilbertAlexanderBlockerNameCertObligations`

Proof. Project the carrier of Definition 3932.1. The rows $S, P, T, B, F, L, A, R, C, Q, N$ are the full accepted inventory.

The blocker-cover side is finite. The row B supplies the boundary-tile source, S supplies the simplicial-complex carrier, and F records the four cover facets together with their intersection multiplicities.

The Hilbert side is finite as well. The row T evaluates the inclusion-exclusion table, P stores the face and numerator polynomials, and L stores the denominator powers and signs of the Hilbert-series row.

The Alexander-dual row A records the generator-complement ledger attached to the same blocker cover. The structural rows R, C, Q, N transport, replay, source, and name exactly this packet, so no accepted NameCert obligation can project an ambient polynomial-ring oracle, unrestricted resolution, stochastic model, quotient codon equality, hidden homology computation, or external Cohen–Macaulay decision. □

Theorem 2955.3 (HilbertAlexanderBlocker finite Hilbert row)**.** *Every Hilbert-series read from an accepted* HilbertAlexanderBlocker$^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{SimplicialComplex}^{\uparrow},\ \mathsf{Poly}^{\uparrow},\ \mathsf{FiniteTraceEvaluator}^{\uparrow},\ \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{BHistDecaTupleNameCert}^{\uparrow} \longmapsto F,$$

The read first displays the blocker cover and intersection table, then evaluates the face-polynomial and Hilbert-row ledger, and only then exposes Alexander-dual and local naming rows. It exports no ambient Stanley–Reisner algebra oracle, unrestricted minimal resolution, quotient codon equality, hidden homology computation, or biological stochastic model.

Lean4 ✓ `BEDC.Derived.HilbertAlexanderBlockerUp.HilbertAlexanderBlockerFiniteHilbertRow`

Proof. Apply Definition 3932.2. It places the simplicial-complex, polynomial, trace-evaluation, and boundary-tile sources before the blocker-cover and Hilbert-row ledgers.

The finite trace row T evaluates only the displayed intersection table F. The polynomial row P and Hilbert ledger L therefore read the same finite cover data rather than a host polynomial-ring quotient.

The Alexander-dual row A is downstream of the same cover. Transport, replay, provenance, and local naming through R, C, Q, N preserve that route, so the Hilbert-series read remains a finite NameCert packet. □

Falsifiable prediction: Changing the blocker-cover multiplicity row F changes the Hilbert denominator-power ledger L before any accepted $\mathsf{HilbertAlexanderBlocker}^{\uparrow}$ consumer can preserve the displayed Hilbert series.

Independence witness: simplicialcomplex, polynomial, finite-trace-evaluator, dna-window-six-boundary-tile, b-hist-deca-tuple-name-cert: $\mathsf{HilbertAlexanderBlocker}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries blocker-cover rows, face-polynomial rows, Hilbert-series rows, Alexander-dual rows, finite trace evaluation, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertAlexanderBlocker}^{\uparrow}}$.

Constructive story: A $\mathsf{HilbertAlexanderBlocker}^{\uparrow}$ packet is generated from a SimplicialComplexUp blocker complex, PolynomialUp face and numerator rows, FiniteTraceEvaluatorUp inclusion-exclusion evaluation, DnaWindowSixBoundaryTileUp source rows, blocker-cover data, Hilbert-row ledgers, Alexander-dual ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilbertAlexanderBlocker}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3932.1, Definition 3932.2, and Definition 3932.3 seed the finite Hilbert-series blocker packet over cover, polynomial, trace-evaluation, boundary-tile, and tuple-name rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilbertAlexanderBlocker}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host Stanley–Reisner algebra equality, unrestricted minimal resolutions, stochastic biological semantics, quotient codon equality, hidden homology computation, or external Cohen–Macaulay decision.

Upgrade path: Obligation closure requires checked carrier admission, blocker-cover exactness, face-polynomial readback, Hilbert-row ledger exactness, Alexander-dual ledger exposure, trace-evaluation stability, transport, replay, provenance, and local naming for BEDC.Derived.HilbertAlexanderBlockerUp.

Chapter 2956

A Concrete Naming Certificate for $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface used when a compact interval argument must choose a displayed located subinterval before completion-facing consumers read a real name. It sits over the located interval carrier of chapter 394, the closed bounded interval source of chapter 1591, the nested interval route of chapter 320, the dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet is a NameCert surface for a displayed compact-interval selection route; it is not open-cover compactness, selected points, trichotomy, quotient $\mathsf{Real}^{\uparrow}$ equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2956.1 (Located compact interval selection carrier)**.** *A* $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, B, N, D, S, R, E, H, C, P, Q)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, exposing the lower and upper located endpoint windows and the rational containment ledger.*
2. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *compact-bound row, exposing the closed bounded source used by the selection route.*
3. *N is the* $\mathsf{NestedInterval}^{\uparrow}$ *refinement row, recording the finite nested subintervals retained by the selection procedure.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for cell width, endpoint separation, and retained-refinement budgets.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row for endpoint and retained-interval observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected located interval windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after I, B, N, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for I, B, N, D, S, R, E and the local packet shape.*
9. *C records displayed* Cont *replay from located interval source and compact-bound rows through nested refinements, dyadic tolerances, windows, readback, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSelection}^{\uparrow}}$ *row.*

The carrier exports no open-cover compactness theorem, selected point of the interval, trichotomy principle, quotient equality of real names, or ambient real-completeness row.

Lean4 ✓ `BEDC.Derived.LocatedCompactIntervalSelectionUp.LocatedCompactIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 2956.2 (Located compact interval selection NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ *carrier*

$$L = (I, B, N, D, S, R, E, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSelection}^{\uparrow}}$ *surface consists exactly of located interval exposure through I, closed bounded interval exposure through B, nested interval refinement through N, dyadic tolerance accounting through D, stream-window exposure through S, regular rational readback through R, real-name sealing through E, componentwise transport through H, replay through C, provenance through P, and local naming through Q.*

Proof. Project the carrier of Definition 3933.1. The finite packet exposes exactly the located interval source, compact-bound source, nested refinement ledger, dyadic tolerance row, stream windows, regular rational readback, Real seal, and structural rows.

Read the interval rows first. The located row I supplies endpoint windows and rational containment, while the closed bounded row B supplies the compact interval source used by the selection route.

The refinement and readback rows are downstream of those sources. The nested ledger N records retained subintervals, D records the dyadic budgets attached to those refinements, and S, R, E expose the selected interval windows only through stream, regular rational, and Real rows.

Finally H, C, P, Q transport, replay, package, and name the same route. Since no other coordinate exists, the listed rows exhaust the local NameCert obligations and cannot import open-cover compactness, selected points, trichotomy, quotient real equality, or ambient Real completeness. □

Theorem 2956.3 (Located compact interval selection real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

The selected located interval is therefore handed off as displayed endpoint windows, nested subinterval rows, dyadic tolerance budgets, stream windows, regular rational readbacks, and a terminal Real seal, not as a selected point, quotient real representative, trichotomy comparison, open-cover compactness argument, or ambient completeness principle.

Proof. Begin with an accepted carrier $L = (I, B, N, D, S, R, E, H, C, P, Q)$. The source rows I and B are the only located and compact interval coordinates available to the packet.

Next inspect the nested and dyadic rows. The row N records the retained finite subintervals and D records the tolerances that make those retained intervals readable without a point selector.

The real-facing readback then passes through S, R, E. Stream windows expose the finite endpoint observations, regular rational rows read them as regular data, and the Real seal is downstream of those displayed rows.

Transport and replay through H, C, P, Q preserve that same route for completion-facing consumers. The packet has no coordinate for open-cover compactness, selected points, trichotomy, quotient Real equality, or ambient Real completeness, so none of those principles can be exported by the handoff. □

Falsifiable prediction: A compact-interval consumer that omits the located interval row, the closed bounded interval row, or the nested refinement row cannot claim a $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ selection handoff.

Independence witness: locatedinterval, closedboundedinterval, nestedinterval, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source interval rows, compact-bound rows, nested refinements, dyadic budgets, stream windows, regular readbacks, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompactIntervalSelection}^{\uparrow}$ packet is generated from a LocatedInterval source row, a ClosedBoundedInterval compact-bound row, a NestedInterval refinement row, DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3933.1, Definition 3933.2, and Definition 3933.3 seed the compact interval selection route over located interval, closed bounded interval, nested interval, dyadic, stream, regular rational, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected points, trichotomy, quotient $\mathsf{Real}^{\uparrow}$ equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-interval source exposure, closed-bounded source exposure, nested refinement routing, dyadic tolerance accounting, stream readback, RegSeqRat exactness, RealUp seal nonescape, and selection-refusal proofs for BEDC.Derived.LocatedCompactIntervalSelectionUp.

Chapter 2957

A Concrete Naming Certificate for CompactUniformRadiusLedger$^{\uparrow}$

Following Lebesgue and Bishop–Bridges, the CompactUniformRadiusLedger$^{\uparrow}$ packet records the finite positive-radius ledger used in the Heine–Cantor route of chapter 9237. It sits between the compact finite-net surface of chapter 129, the pointwise continuity surface of chapter 130, the positive Lebesgue-radius packet of chapter 452, and the downstream UniformModulus$^{\uparrow}$ consumer of chapter 369. The packet names the radius choices and their finite lower-bound fold as displayed BEDC rows; it does not export an open-cover compactness theorem, a selected subsequence, a host minimum over radii, quotient equality of reals, or an external analytic modulus.

Definition 2957.1 (Compact uniform radius ledger carrier)**.** *A* CompactUniformRadiusLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, G, F, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net row, carrying the finite* ProbeBundle *of centers and the source-distance coverage rows.*
2. *M is the* ContinuousMap$^{\uparrow}$ *pointwise-modulus ledger for the same source and target metrics.*
3. *G is the* FiniteLebesgueNumber$^{\uparrow}$ *positive-radius row, assigning a positive radius below the cover radius attached to each displayed center.*
4. *F is the* Rat$^{\uparrow}$ *lower-bound fold row, produced by primitive recursion over the finite radius bundle.*
5. *R records the radius-selection compatibility row saying that the folded lower bound is below every positive radius used by G.*
6. *U is the* UniformModulus$^{\uparrow}$ *output row that may be read only after K, M, G, F, R have been displayed.*
7. *H records componentwise* hsame *transport for the compact-net, pointwise-modulus, Lebesgue-radius, rational-fold, compatibility, and output rows.*
8. *C records displayed* Cont *replay from finite-net inspection through pointwise-modulus reads, positive-radius extraction, rational folding, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* CompactUniformRadiusLedger$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, Rat$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusLedger}^{\uparrow}}$ *row.*

The classifier compares accepted ledgers only through these rows. No coordinate records open-cover compactness, selected subsequences, external choice of a minimum radius, host real equality, or a semantic modulus function outside the displayed $\mathsf{UniformModulus}^{\uparrow}$ *output.*

Lean4 ✓ `BEDC.Derived.CompactUniformRadiusLedgerUp.CompactUniformRadiusLedgerTasteGate single carrier alignment`

Theorem 2957.2 (Compact uniform radius ledger NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformRadiusLedger}^{\uparrow}$ *carrier* $L = (K, M, G, F, R, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusLedge}}$ *surface consists exactly of compact-net admission through* K*, pointwise-modulus admission through* M*, positive-radius exposure through* G*, finite rational lower-bound folding through* F*, compatibility exposure through* R*,* $\mathsf{UniformModulus}^{\uparrow}$ *output through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3934.1. The rows $K, M, G, F, R, U, H, C, P, N$ are the complete displayed inventory.

Read the analytic input rows first. The compact-metric row K supplies the finite net and its coverage witnesses, while M supplies the pointwise-modulus rows at the displayed centers. The positive-radius row G ties these local moduli to a finite Lebesgue-radius ledger.

Next read the finite fold. The $\mathsf{Rat}^{\uparrow}$ row F compares the positive radii by primitive recursion over the finite bundle, and R records that the resulting lower bound is below each radius used by G. These rows are BEDC histories, not a host minimum.

Finally U, H, C, P, N export, transport, replay, source, and name exactly this ledger. Since the carrier has no coordinate for open-cover compactness, selected subsequences, external minimum selection, host real equality, or a semantic modulus function, the listed rows exhaust the local NameCert obligations. □

Theorem 2957.3 (Compact uniform radius ledger Heine–Cantor handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformRadiusLedger}^{\uparrow}$ *packet reads the Heine–Cantor radius choice through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{FiniteLebesgueNumber}^{\uparrow},\ \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The handoff first displays the finite net, then the pointwise-modulus and positive-radius rows, then the rational lower-bound fold, and only then exports the uniform-modulus row. It supplies the finite-net lower-bound route described in chapter 9237, without importing open-cover compactness, sequential compactness, choice of a minimum radius, quotient real equality, or an ambient continuity theorem.

Proof. Use Definition 3934.2. It orders the compact-net row, pointwise-modulus row, positive-radius row, rational-fold row, compatibility row, and uniform-modulus output inside one accepted carrier.

The finite net in K supplies the centers that M may inspect. The row G records a positive radius below the local cover radius at each center, so the local moduli are tied to the same finite bundle that compactness exposed.

The fold row F and compatibility row R then produce the common precision history consumed by U. Because F is a $\mathsf{Rat}^{\uparrow}$ fold over the displayed bundle, the lower bound is stable under the classifier and does not depend on an external minimum operator.

Thus the $\mathsf{UniformModulus}^{\uparrow}$ consumer receives a finite BEDC radius ledger. The refused analytic objects are absent from the carrier and cannot be reconstructed from H, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformRadiusLedger}^{\uparrow}$ packet is generated from CompactMetricUp finite-net rows, ContinuousMapUp pointwise-modulus rows, FiniteLebesgueNumberUp positive-radius rows, RatUp lower-bound folds, UniformModulusUp output rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformRadiusLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3934.1, Definition 3934.2, and Definition 3934.3 seed the finite Lebesgue-radius ledger used by compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformRadiusLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, sequential compactness, selected-subsequence extraction, host minimum selection, quotient real equality, or external analytic modulus choice.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, pointwise-modulus admission, positive-radius exposure, rational lower-bound folding, uniform-modulus output exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformRadiusLedgerUp.

Chapter 2958

A Concrete Naming Certificate for $\mathsf{LowerSemicontinuityReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, with the point-set vocabulary of Kelley and Bourbaki read only as finite BEDC routing data, the $\mathsf{LowerSemicontinuityReal}^{\uparrow}$ packet specializes lower semicontinuity to the Real-and-Completion corridor. It is not a synonym of chapter 1536: that sibling names the general lower-real epigraph surface, while the present chapter records the real-name, regular-rational, topology, and completion-facing threshold rows needed by Real/Completion consumers. The packet sits beside the real carrier of chapter 38, the regular rational source of chapter 301, the stream schedule of chapter 126, the lower-real ledger of chapter 1446, the continuous-map surface of chapter 130, and the completion-facing real routes of chapter 3944.

Definition 2958.1 (LowerSemicontinuityReal carrier)**.** *A* $\mathsf{LowerSemicontinuityReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, T, F, W, R, E, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Real}^{\uparrow}$ *source carrier row, read through accepted real-name histories rather than host real points;*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *threshold row whose basic opens are represented by finite rational cuts and stream windows;*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *or value-row handoff used when the lower-semicontinuous function is inspected through a displayed map surface;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finite source and value windows used by each threshold query;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for real-name and value approximants;*
6. *E is the* $\mathsf{LowerReal}^{\uparrow}$ *epigraph ledger, recording finite rows (x, q) that witness the rational lower threshold q at the inspected real name x;*
7. *O is the open-threshold route, recording that a query of the form $q < f(x)$ is answered by a finite lower-real row and then exposed as a basic* $\mathsf{Topology}^{\uparrow}$ *neighbourhood of the accepted real name;*

8. *H records componentwise* hsame *transport for real-name rows, topology thresholds, map rows, stream schedules, regular-rational readbacks, lower-real epigraph rows, threshold routes, provenance rows, and local naming rows;*
9. *C records displayed* Cont *replay from a threshold request through $X, T, F, W, R, E, O, H, P, N$;*
10. *P is the* Pkg *provenance over* $\mathsf{LowerSemicontinuityReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuityReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real completeness, quotient real equality, trichotomy, open-cover compactness, semantic liminf, or a selected limit point in a completed host space.

Lean4 ✓ `BEDC.Derived.LowerSemicontinuityRealUp.LowerSemicontinuityRealTasteGate single carrier alignment`

Theorem 2958.2 (LowerSemicontinuityReal NameCert obligations)**.** *For an accepted* $\mathsf{LowerSemicontinuityReal}^{\uparrow}$ *carrier $L = (X, T, F, W, R, E, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuityReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real-name, topology-threshold, map, stream, regular-rational, lower-real, open-threshold, transport, replay, provenance, and local-name rows; threshold exactness for the finite lower-real rows in E; regular-rational readback through R; stream scheduling through W; componentwise* hsame *transport through H; displayed* Cont *replay through C; and provenance through P.*

Proof. Project the carrier of Definition 3935.1. The rows $X, T, F, W, R, E, O, H, C, P, N$ are the whole Real-and-Completion packet, so carrier admission is rowwise.

Read threshold exactness through E and O. A rational query $q < f(x)$ is accepted only after the source real name has been scheduled by W, read back through R, and matched to a finite lower-real epigraph row in E.

Transport and replay are then forced by H and C. They move the real-name, threshold, map, schedule, regular-rational, lower-real, and open-neighbourhood rows together, so the local NameCert surface cannot replace them by host topology or quotient equality.

Finally P and N package the same finite rows. Since the excluded completeness, trichotomy, compactness, semantic-liminf, and selected-limit principles are absent from the carrier, they are not NameCert obligations. □

Theorem 2958.3 (LowerSemicontinuityReal open-threshold route)**.** *Every completion-facing consumer of an accepted* $\mathsf{LowerSemicontinuityReal}^{\uparrow}$ *packet must read an open lower-threshold query through the finite route*

$$X, T, F, W, R, E, O \longmapsto H, C, P, N.$$

The route may expose Real-name windows, regular-rational approximants, stream schedules, lower-real epigraph rows, topology threshold rows, map handoffs, transport, replay, provenance, and local naming. It exports no host real completeness, quotient equality, trichotomy, open-cover compactness, semantic liminf, or completed-space selection principle.

Proof. Start with a threshold query. The source is the $\mathsf{Real}^{\uparrow}$ row X, and the neighbourhood vocabulary is the displayed $\mathsf{Topology}^{\uparrow}$ row T, so the query does not begin from a host open-set lattice.

Next use the scheduling and readback rows. The stream schedule W selects the finite windows, and the regular-rational row R supplies the approximants used by the lower-real ledger E.

The open-threshold row O turns the lower-real epigraph witness into the basic threshold route exposed to completion-facing consumers. The map row F is consumed only when the query is read through a displayed $\mathsf{ContinuousMap}^{\uparrow}$ surface.

Finally replay through H, C, P, N. These rows transport, continue, source, and name the same finite threshold packet. Since no excluded host principle is a row of the carrier, the route remains a Real-and-Completion specialization of lower semicontinuity rather than a completeness or compactness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerSemicontinuityReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerSemicontinuityReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3935.1, Definition 3935.2, and Definition 3935.3 seed the finite Real-and-Completion lower-semicontinuity packet over real-name windows, regular-rational readbacks, stream schedules, lower-real epigraph rows, topology thresholds, map handoffs, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerSemicontinuityReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real completeness, quotient real equality, trichotomy, open-cover compactness, semantic liminf, completed-space selection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold exactness, regular-rational readback, stream scheduling, topology exposure, transport replay, provenance, and non-escape for BEDC.Derived.LowerSemicontinuityRealUp.

Constructive story: A $\mathsf{LowerSemicontinuityReal}^{\uparrow}$ packet is generated from RealUp source histories, TopologyUp threshold rows, ContinuousMapUp handoffs, StreamNameUp schedules, RegSeqRatUp readbacks, LowerRealUp epigraph witnesses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2959

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimitSelector}^{\uparrow}$

Following Bishop–Bridges regular Cauchy constructions, the $\mathsf{RegularCauchyLimitSelector}^{\uparrow}$ packet records the finite diagonal selector surface used by the Real and Completion route before a terminal limit representative is sealed. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the diagonal-limit representative boundary of chapter 1205. The packet names only a finite selector schedule, readback windows, tolerance rows, transport, replay, provenance, and local naming data; it does not export countable choice, host limits, quotient-stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2959.1 (Regular Cauchy limit selector carrier)**.** *A* $\mathsf{RegularCauchyLimitSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the selector schedule row, listing the finite diagonal stages and the requested precision levels.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the inspected source entries at each stage of A.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that records the dyadic error budget attached to the selected stages.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the selected stream windows and dyadic tolerances into regular rational observations.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the selector schedule, stream windows, dyadic tolerances, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for A, W, D, R, E and for the replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite limit request through*

$$A, W, D, R \longmapsto E \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLimitSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitSelector}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, W, D, R, E, H, C, P, N$. The carrier has no coordinate for countable choice, selected host limits, quotient equality of stream names, hidden tail schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLimitSelectorUp.RegularCauchyLimitSelectorTasteGate single carrier alignment`

Theorem 2959.2 (Regular Cauchy limit selector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLimitSelector}^{\uparrow}$ *carrier $S = (A, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the selector schedule,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Every Real or Completion consumer of the selector reads the diagonal-limit handoff through these rows before using the representative surface of chapter 1205.*

Proof. Project the carrier of Definition 3936.1. The analytic rows are exactly the selector schedule A, finite stream window W, dyadic tolerance row D, regular rational readback R, and terminal seal E.

The selector route is finite. A consumer first reads the stages in A, then inspects only the windows named by W, then checks the dyadic tolerances recorded in D before any regular rational readback is available.

The readback row R is the only route from selected finite windows to the terminal seal E. Thus the Real-facing endpoint is reached through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ data before it can be consumed by the diagonal-limit representative boundary.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier contains no coordinate for countable choice, selected host limits, quotient-stream equality, hidden tail schedules, ambient Real completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimitSelector}^{\uparrow}$ packet is generated from a finite selector schedule, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyLimitSelector}^{\uparrow}}$, seed)

Scope closed: Definition 3936.1 and Definition 3936.2 seed the finite diagonal selector packet consumed by Real and Completion routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyLimitSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, host limits, quotient-stream equality, hidden tail schedules, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector schedule exactness, StreamName window exposure, DyadicRatCore tolerance stability, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLimitSelectorUp.

Chapter 2960

A Concrete Naming Certificate for SubordinateFiniteModulusCover$^{\uparrow}$

Following Lebesgue-number and Bishop–Bridges compact-uniform-continuity arguments, the SubordinateFiniteMod packet records the finite subordinate cover that feeds the uniform-modulus fold in chapter 9237. It sits over the compact finite-net carrier of chapter 129, the pointwise map ledger of chapter 130, the positive-radius lower-bound surface of chapter 452, and the downstream uniform-modulus consumer of chapter 369. The packet names only the finite cover rows, pointwise modulus rows, rational fold ledger, transport, replay, provenance, and local naming data; it does not export open-cover compactness, a selected infinite subcover, host minima, quotient real equality, or an external semantic modulus.

Definition 2960.1 (Subordinate finite modulus cover carrier)**.** *A* SubordinateFiniteModulusCover$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (K, F, L, Q, U, H, R, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net row, naming the centers and the source-distance coverage windows inspected by the packet.*
2. *F is the* ContinuousMap$^{\uparrow}$ *pointwise-modulus row, assigning a local modulus window to each displayed center.*
3. *L is the* FiniteLebesgueNumber$^{\uparrow}$ *subordinate-radius row, recording a positive radius below the cover radius for each displayed local modulus.*
4. *Q is the* Rat$^{\uparrow}$ *fold row that computes the finite lower-bound tolerance from the displayed subordinate radii.*
5. *U is the* UniformModulus$^{\uparrow}$ *handoff row, exposed only after K, F, L, Q have been displayed.*
6. *H records componentwise* hsame *transport for K, F, L, Q, U and for the replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay from compact-net inspection through pointwise modulus rows, subordinate radii, rational folding, and uniform-modulus handoff.*
8. *P is the* Pkg *provenance over* SubordinateFiniteModulusCover$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, Rat$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{SubordinateFiniteModulusCover}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, F, L, Q, U, H, R, P, N$. The carrier has no coordinate for open-cover compactness, infinite subcover selection, host minimum extraction, quotient equality of real radii, ambient completeness, Lean verification, or bridge credentials.

Lean4 ✓ `BEDC.Derived.SubordinateFiniteModulusCoverUp.SubordinateFiniteModulusCoverTasteGate`
`single carrier alignment`

Theorem 2960.2 (Subordinate finite modulus cover NameCert obligations)**.** *For every accepted* $\mathsf{SubordinateFiniteModulusCover}^{\uparrow}$ *carrier $C = (K, F, L, Q, U, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SubordinateFiniteModulusCover}}$ *surface consists exactly of compact-net admission through K, pointwise-modulus admission through F, subordinate positive-radius exposure through L, finite rational lower-bound folding through Q, uniform-modulus handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3937.1. The analytic rows are the compact-net row K, the pointwise-modulus row F, the subordinate-radius row L, the rational fold Q, and the uniform-modulus handoff U.

The compact row K supplies only a finite bundle of centers and source-distance windows. The continuous-map row F is read at those displayed centers, and L records the positive subordinate radius attached to each local modulus row.

The fold row Q is a finite $\mathsf{Rat}^{\uparrow}$ computation over the displayed subordinate radii. It is not a host minimum over an open cover and cannot select an infinite subcover or appeal to quotient equality of real radii.

Finally U, H, R, P, N export, transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for open-cover compactness, infinite subcover choice, host minima, quotient real equality, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubordinateFiniteModulusCover}^{\uparrow}}$.

Constructive story: A $\mathsf{SubordinateFiniteModulusCover}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise-modulus rows, FiniteLebesgueNumber subordinate-radius rows, RatUp lower-bound folds, a UniformModulus handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SubordinateFiniteModulusCover}^{\uparrow}}$, seed)

Scope closed: Definition 3937.1 and Definition 3937.2 seed the subordinate finite-cover carrier consumed by compact-uniform-continuity routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SubordinateFiniteModulusCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, infinite subcover selection, host minimum extraction, quotient equality of real radii, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, pointwise-modulus admission, subordinate-radius exactness, rational lower-bound folding, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.SubordinateFiniteModulusCoverUp.

Chapter 2961

A Concrete Naming Certificate for $\mathsf{LocatedIntermediateValue}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedIntermediateValue}^{\uparrow}$ packet records the finite bisection route used to locate a sign change on a real interval without selecting a root as host data. It sits over the real-name surface of chapter 38, the regular rational readback of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance core of chapter 291, the located interval carrier of chapter 394, and the nested interval route of chapter 2249. The packet names only endpoint rows, located sign-apartness observations, finite bisection data, regular Cauchy readback, transport, replay, provenance, and local naming obligations; it does not export trichotomy, open-cover compactness, quotient real equality, selected roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2961.1 (Located intermediate value carrier)**.** *A* $\mathsf{LocatedIntermediateValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, S, B, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the located interval endpoint row naming the two* $\mathsf{Real}^{\uparrow}$ *endpoint seals and their* $\mathsf{LocatedInterval}^{\uparrow}$ *order witness.*
2. *S is the located sign-apartness row recording finite negative and positive separation observations for the endpoint values.*
3. *B is the bisection ledger row listing the inspected dyadic midpoint stages, the retained subinterval side, and the sign row used at each stage.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by the bisection ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected windows and dyadic tolerances into regular rational observations.*
6. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after E, S, B, W, R have been displayed.*
7. *H records componentwise* hsame *transport for E, S, B, W, R, Q and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located sign-change request through finite bisection and regular Cauchy readback.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntermediateValue}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{NestedIntervalSelection}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedIntermediateValue}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $E, S, B, W, R, Q, H, C, P, N$. The carrier has no coordinate for real trichotomy, open-cover compactness, quotient equality of real names, an externally selected zero, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.LocatedIntermediateValueUp.LocatedIntermediateValueTasteGate single carrier alignment`

Theorem 2961.2 (Located intermediate value NameCert obligations)**.** *For every accepted* LocatedIntermediateValu *carrier $I = (E, S, B, W, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntermediateValue}^{\uparrow}}$ *surface consists exactly of endpoint admission, located sign-apartness rows, bisection ledger exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3938.1. The analytic rows are the endpoint row E, the sign-apartness row S, the bisection ledger B, the finite window row W, the regular rational readback R, and the real seal Q.

The endpoint signs are read as located apartness data. They are not converted into a trichotomy principle, a global sign decision for every point, or a quotient equality test for real names.

The bisection ledger is finite. Each step records the dyadic midpoint, the inspected windows, and the retained side before the next row is read. The regular Cauchy readback R is the only route from these finite windows to the terminal $\mathsf{Real}^{\uparrow}$ seal Q.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the packet contains no coordinate for open-cover compactness, selected roots, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Theorem 2961.3 (Located intermediate value nested interval route)**.** *Every accepted* $\mathsf{LocatedIntermediateValue}^{\uparrow}$ *carrier exposes its intermediate-value read through the finite bisection ledger B, the* $\mathsf{NestedIntervalSelection}^{\uparrow}$ *dependency named in P, the finite window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance discipline, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal Q. A downstream consumer must read those rows before it may cite the packet as a located intermediate-value route.*

Proof. Read P to identify the nested interval dependency and the dyadic tolerance source. The only displayed interval refinement data in the carrier is the ledger B, so a consumer has no alternate route to a candidate interval.

Read W and R next. The windows are finite, and the regular rational readback is the handoff that turns the bisection ledger into a Cauchy-facing observation.

The endpoint of the route is the seal row Q, transported by H and replayed by C. The proof therefore uses finite bisection and regular Cauchy handoff only; it does not use trichotomy, open-cover compactness, quotient real equality, selected roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntermediateValue}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntermediateValue}^{\uparrow}$ packet is generated from located interval endpoint rows, located sign-apartness rows, a finite bisection ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntermediateValue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3938.1, Definition 3938.2, and Definition 3938.3 seed the finite bisection packet consumed by constructive intermediate-value routes over located real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntermediateValue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, open-cover compactness, quotient real equality, selected roots, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-apartness exposure, bisection ledger exactness, finite StreamName windows, DyadicRatCore tolerance stability, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntermediateValueUp.

Chapter 2962

A Concrete Naming Certificate for $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$

Following Bishop and Bridges on the fan theorem and constructive compactness of intervals, the $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$ packet records the finite fan/bar data used to inspect a closed bounded interval through finite binary and dyadic prefixes. It consumes the closed bounded interval source of chapter 1591, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-coordinate seal of chapter 38. The packet names finite bar coverage and prefix stability only as displayed BEDC rows; it does not assert open-cover compactness, selected subcovers, countable choice, quotient equality of real names, trichotomy, or ambient Real completeness.

Definition 2962.1 (Closed bounded interval fan carrier)**.** *A* $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, B, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing endpoint order, rational containment, dyadic containment,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *sealing.*
2. *T is the finite binary-prefix tree row used to enumerate dyadic subinterval decisions.*
3. *B is the finite bar row, recording that every inspected branch meets a displayed prefix in T.*
4. *W is the prefix-stability row saying that extension of a branch past a bar prefix preserves the associated interval containment decision.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row for endpoint names, branch prefixes, and dyadic containment tests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the endpoint and prefix windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, T, B, W, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval source, tree, bar, stability, window, readback, and seal rows.*
9. *C records displayed* Cont *replay from interval-source inspection through finite prefix reads, bar coverage, regular rational readback, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFan}^{\uparrow}}$ *row.*

The carrier exports a finite fan/bar interface over the interval source. It has no coordinate for an open cover, a selected subcover, a choice function on branches, quotient equality of real names, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalFanUp.ClosedBoundedIntervalFanTasteGate single carrier alignment`

Theorem 2962.2 (Closed bounded interval fan NameCert obligations)**.** *For every accepted* ClosedBoundedIntervalF *carrier $F = (I, T, B, W, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFan}^{\uparrow}}$ *surface consists exactly of interval-source admission through I, finite prefix-tree admission through T, finite bar exposure through B, prefix-stability exposure through W, finite observation through S, regular rational readback through R, Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3939.1. The interval source I is already the closed bounded interval packet of chapter 1591; the fan-specific rows are the finite tree T, finite bar B, and prefix-stability row W.

Read the observation and seal rows next. The $\mathsf{StreamName}^{\uparrow}$ window S and $\mathsf{RegSeqRat}^{\uparrow}$ readback R inspect endpoint and prefix data at finite precision, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of those finite rows.

The structural rows close the local certificate. Transport H, replay C, provenance P, and naming N preserve exactly this finite fan/bar route, so the obligations introduce no open-cover compactness, selected subcover, choice over branches, quotient equality, trichotomy, or ambient completeness. □

Theorem 2962.3 (Closed bounded interval fan finite-bar route)**.** *Every compactness-facing or uniform-modulus consumer of an accepted* $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto T, B, W$$

before it uses fan/bar data. The route first displays the closed bounded interval source, then finite stream windows and regular rational readbacks, then the Real seal, and only then exposes the finite prefix tree, finite bar, and prefix-stability rows. It supplies the finite bar interface needed by interval-net, compactness, and uniform-modulus consumers without claiming open-cover compactness, choice of a subcover, quotient real equality, trichotomy, or ambient completeness.

Proof. Start with the interval source row. By Definition 1591.3, the source I already displays endpoint order, containment ledgers, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ sealing, transport, replay, provenance, and naming.

Use Definition 3939.2. It places the finite prefix tree T, finite bar B, and prefix-stability row W inside the same accepted carrier, downstream of the interval source and the finite readback route.

Thus a consumer receives fan data only as a finite BEDC route over an accepted closed bounded interval. Since the carrier has no open-cover coordinate, no branch selector, no quotient-real equality row, no trichotomy row, and no ambient completeness row, the finite-bar route cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFan}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, finite binary-prefix tree rows, finite bar rows, prefix-stability rows, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFan}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3939.1, Definition 3939.2, and Definition 3939.3 seed the finite fan/bar surface for closed bounded interval compactness and uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFan}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, selected subcovers, countable choice, quotient real equality, trichotomy, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix-tree admission, finite bar exposure, prefix-stability exposure, StreamName readback, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ClosedBoundedIntervalFanUp.

Chapter 2963

A Concrete Naming Certificate for $\mathsf{DiagonalSequence}^{\uparrow}$

Following Cantor and Bishop–Bridges constructive analysis, the $\mathsf{DiagonalSequence}^{\uparrow}$ packet records the finite diagonal-sequence surface used by Real-facing diagonal arguments. It sits over the stream-row discipline of chapter 126, the dyadic bit ledger of chapter 291, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. It is consumed downstream by chapter 3793 and **??**. The packet names the reusable diagonal schedule and readback route; it is not a host countability theorem, a quotient-stream principle, or a completed powerset construction.

Definition 2963.1 (Diagonal sequence carrier)**.** *A* $\mathsf{DiagonalSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (E, W, B, F, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the inspected enumeration surface, exposing only finite* $\mathsf{StreamName}^{\uparrow}$ *candidate windows.*
2. *W is the diagonal schedule row, pairing each inspected enumeration row with the coordinate at which the diagonal value is read.*
3. *B is the dyadic observation row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any regular rational or Real-facing seal is exposed.*
4. *F is the finite flip row, assigning the displayed opposite dyadic value at each scheduled coordinate.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the same schedule and flip ledger.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, downstream of E, W, B, F, Q.*
7. *H records componentwise* hsame *transport for enumeration, schedule, dyadic observation, flip, regular readback, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an enumeration request through the scheduled dyadic read, flip, regular readback, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DiagonalSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalSequence}^{\uparrow}}$ *row.*

The classifier accepts a packet only when the diagonal schedule is finite, the dyadic observation and flip rows share the same coordinate ledger, the regular readback reuses that ledger, and the Real seal is downstream of the displayed readback route.

Lean4 (definition) `BEDC.Derived.DiagonalSequenceUp.DiagonalSequenceUp`

Theorem 2963.2 (Diagonal sequence NameCert obligations)**.** *For every accepted* $\mathsf{DiagonalSequence}^{\uparrow}$ *carrier* $D = (E, W, B, F, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DiagonalSequence}^{\uparrow}}$ *surface consists exactly of enumeration-window admission through* E*, finite diagonal scheduling through* W*, dyadic observation through* B*, flip exactness through* F*, regular rational readback through* Q*, Real sealing through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3940.1. The displayed inventory is exactly $E, W, B, F, Q, R, H, C, P, N$.

Read the construction rows in order. The enumeration surface E is inspected only along the finite schedule W, the dyadic observation B is made at those scheduled coordinates, and the flip row F assigns the opposite displayed dyadic value on the same ledger.

The readback rows are downstream. The row Q records regular rational readback from the scheduled flip ledger, while R seals the resulting sequence as $\mathsf{Real}^{\uparrow}$ data. Componentwise transport, displayed replay, provenance, and naming preserve those rows and introduce no extra coordinate. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 2963.3 (Diagonal sequence nonescape)**.** *Every accepted* $\mathsf{DiagonalSequence}^{\uparrow}$ *consumer must read the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed schedule W *and flip ledger* F *before it can expose a diagonal Real-facing value. The packet exports no host enumeration principle, quotient stream equality, unbounded choice of coordinates, powerset of reals, or completed uncountability theorem.*

Proof. Use Definition 3940.2. It orders the inspected stream windows, dyadic observations, flip ledger, regular readback, and Real seal inside one finite carrier.

The nonescape clauses follow from the absence of any other carrier coordinate. The rows H, C, P, N can transport, replay, source, and name the displayed route, but they cannot add a host enumeration theorem or a quotient equality principle. Thus every downstream diagonal packet must consume the same finite sequence route rather than bypass it. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiagonalSequence}^{\uparrow}$ packet is generated from finite StreamName windows, a diagonal schedule, DyadicRatCore observations, a flip ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiagonalSequence}^{\uparrow}}$, seed)

Scope closed: Definition 3940.1, Definition 3940.2, and Definition 3940.3 seed the reusable finite diagonal-sequence packet consumed by Real-facing diagonal arguments.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiagonalSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host countability, quotient stream equality, unbounded coordinate choice, powerset constructions, Real uncountability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exactness, dyadic flip compatibility, regular readback, Real sealing, provenance exhaustion, and local naming for BEDC.Derived.DiagonalSequenceUp.

Chapter 2964

A Concrete Naming Certificate for $\mathsf{WobbleSaturationSeal}^{\uparrow}$

The $\mathsf{WobbleSaturationSeal}^{\uparrow}$ packet realizes the f_3 directional saturation route of Definition 9462.1423 as finite NameCert data. It consumes the six-coordinate codon window of chapter 2234, the DNA boundary-tile classifier of chapter 3393, the six-boundary coverage packet of chapter 3470, the wobble quotient spectral trigger of chapter 2317, and the radial wobble spectrum of chapter 3681. The packet names the unique non-leaking f_3 saturation seal; it is not a biological stochastic model, quotient codon semantics, or an unrestricted support-closure oracle.

Definition 2964.1 (Wobble saturation seal carrier)**.** *A* $\mathsf{WobbleSaturationSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, T, C, Q, R, D, A, H, K, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row exposing the six Boolean coordinates of the inspected codon window.*
2. *T is the* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *row naming the boundary tile through which the wobble read is admitted.*
3. *C is the* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *row recording finite coverage of the relevant boundary support.*
4. *Q is the* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ *row exposing the quotient-facing spectral trigger.*
5. *R is the* $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ *row exposing the radial spectrum and wobble-edge accounting.*
6. *D is the directional saturation row, recording that the only non-leaking active-support saturation direction is f_3.*
7. *A is the* ACG *seal row, recording the median, symmetry, spectral, and final f_3 sealing corner.*
8. *H records componentwise* hsame *transport for window, boundary-tile, coverage, quotient-trigger, radial-spectrum, saturation, seal, replay, provenance, and naming rows.*
9. *K records displayed* Cont *replay from the six-bit window through boundary coverage, quotient trigger, radial spectrum, and f_3 seal.*
10. *P is the* Pkg *provenance over* $\mathsf{WobbleSaturationSeal}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$, $\mathsf{RadialWobbleSpectrum}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{WobbleSaturationSeal}^{\uparrow}}$ *row.*

The classifier accepts a packet only when the f_3 saturation row is read after the six-bit window, boundary-tile, coverage, quotient-trigger, and radial-spectrum rows, and when the ACG *seal is the displayed terminal corner for that same route.*

Lean4 ✓ `BEDC.Derived.WobbleSaturationSealUp.WobbleSaturationSealTasteGate single carrier alignment`

Theorem 2964.2 (Wobble saturation seal NameCert obligations)**.** *For every accepted* $\mathsf{WobbleSaturationSeal}^{\uparrow}$ *carrier $S = (W, T, C, Q, R, D, A, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WobbleSaturationSeal}^{\uparrow}}$ *surface consists exactly of six-bit window admission through W, boundary-tile admission through T, six-boundary coverage through C, quotient spectral triggering through Q, radial wobble-spectrum exposure through R, unique f_3 directional saturation through D,* ACG *seal exposure through A, componentwise* hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3941.1. The rows $W, T, C, Q, R, D, A, H, K, P, N$ are the complete displayed inventory.

Read the support rows first. The six-bit window, boundary-tile, and coverage rows identify the finite codon support surface before any wobble saturation is visible.

Read the wobble rows next. The quotient spectral trigger Q and radial spectrum R supply the two sibling wobble surfaces, and D records the unique non-leaking f_3 direction over that shared surface. The row A then exposes ACG as the terminal seal for the same route.

Finally H, K, P, N transport, replay, source, and name exactly those rows. Since the carrier has no stochastic, quotient-semantic, or unrestricted support-closure coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 2964.3 (Wobble saturation seal nonescape)**.** *Every accepted* $\mathsf{WobbleSaturationSeal}^{\uparrow}$ *consumer must read* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$*, and* $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ *before the unique f_3 saturation seal can be exposed. The seal exports no biological stochastic model, quotient codon semantics, unrestricted support closure, or route that treats a leaking direction as equivalent to the displayed f_3 row.*

Proof. Apply the obligation theorem. It places the six-bit window, boundary tile, coverage, quotient trigger, and radial spectrum before the directional saturation row.

The nonescape claim is then a carrier-inventory statement. The rows D and A name the unique f_3 saturation route and the terminal ACG seal, while H, K, P, N preserve the same route. No row remains from which to read a stochastic model, quotient codon semantics, or an unrestricted closure oracle. □

Falsifiable prediction: An accepted $\mathsf{WobbleSaturationSeal}^{\uparrow}$ consumer that exposes the f_3 saturation seal without first displaying CodonSixBitWindow, DnaWindowSixBoundaryTile, SixBoundaryTileCoverage, WobbleQuotientSpectralTrigger, RadialWobbleSpectrum, hsame, Cont, Pkg, and local NameCert rows refutes the carrier surface.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, wobble-quotient-spectral-trigger, radial-wobble-spectrum: $\mathsf{WobbleSaturationSeal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six-bit window, boundary-tile, coverage, quotient-trigger, radial-spectrum, unique f_3 saturation, terminal ACG seal, transport, replay, provenance, and local naming rows.

The Lean TasteGate route for WobbleSaturationSeal$^{\uparrow}$ must provide explicit Nontrivial WobbleSaturationSeal$^{\uparrow}$ and FieldFaithful WobbleSaturationSeal$^{\uparrow}$ instances preserving $W, T, C, Q, R, D, A, H, K, P, N$ as distinguishable fields.

Closure status for NameCert$_{\text{WobbleSaturationSeal}^{\uparrow}}$.

Constructive story: A WobbleSaturationSeal$^{\uparrow}$ packet is generated from six-bit codon windows, boundary-tile rows, six-boundary coverage, quotient spectral trigger rows, radial wobble-spectrum rows, a unique f3 saturation direction, the ACG seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{WobbleSaturationSeal}^{\uparrow}}$, seed)

Scope closed: Definition 3941.1, Definition 3941.2, and Definition 3941.3 seed the finite NameCert seal for the unique f_3 directional saturation route.

Formal verification: FormalStatus(NameCert$_{\text{WobbleSaturationSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological stochastic dynamics, quotient codon semantics, unrestricted support closure, Lean verification, bridge checking, or saturation beyond the displayed f3 route.

Upgrade path: Obligation closure requires checked carrier admission, six-bit window alignment, boundary-tile coverage, quotient-trigger exactness, radial-spectrum compatibility, unique f3 saturation, ACG sealing, Nontrivial WobbleSaturationSealUp, and FieldFaithful WobbleSaturationSealUp for BEDC.Derived.WobbleSaturationSealUp.

Chapter 2965

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ packet records the finite witness surface by which two regular Cauchy reads with the same displayed tail data are forced to have the same terminal Real-facing seal. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38; the packet stores only paired tail windows, dyadic witnesses, regular readbacks, seal comparisons, transport, replay, provenance, and local naming.

Definition 2965.1 (Regular Cauchy limit uniqueness carrier)**.** *A* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, R, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two regular Cauchy source rows whose finite tails are being compared.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger witnessing the common scale at which the two source rows are inspected.*
3. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *window naming the finite tail entries used in the comparison.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two inspected tails.*
5. *E is the paired terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the dyadic, stream-window, and regular-rational rows have been displayed.*
6. *H records componentwise* hsame *transport for source rows, dyadic tolerance, finite windows, regular readbacks, Real seals, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay for any finite uniqueness request through L, R, D, W, Q, E.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, D, W, Q, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ BEDC.Derived.RegularCauchyLimitUniquenessUp.RegularCauchyLimitUniquenessTasteGate
single carrier alignment

Theorem 2965.2 (Regular Cauchy limit uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *carrier* $U = (L, R, D, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitUniquen}}$ *surface consists exactly of carrier admission for the paired regular Cauchy source rows, dyadic witness ledger, finite stream windows, regular rational readbacks, terminal Real seal comparison, componentwise transport, displayed replay, provenance, and local naming. No uniqueness obligation is stored outside these rows.*

Proof. Project the accepted carrier through Definition 3942.1. The analytic rows are exactly the two source rows L, R, the dyadic witness D, the finite stream window W, the regular rational readback Q, and the terminal seal comparison E.

The structural rows are H, C, P, N. They transport, replay, source, and name the same finite packet, so the NameCert surface cannot add a quotient equality, selected limit, host real equality, choice selector, trichotomy, or ambient completeness coordinate. □

Theorem 2965.3 (Regular Cauchy limit uniqueness dyadic witness determinacy)**.** *For every accepted* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *carrier* $U = (L, R, D, W, Q, E, H, C, P, N)$*, the dyadic witness row* D *determines the displayed comparison scale used by the paired stream window* W *and regular rational readback* Q*. Any accepted uniqueness read must therefore inspect the same finite dyadic tolerance before the terminal seal row* E *is available.*

Proof. Begin with the dyadic tolerance ledger. The row D is the only coordinate whose classifier names the comparison scale, and the window row W is admitted only as a finite inspection at that displayed scale.

The regular rational readback Q consumes the same finite window. Hence the terminal seal row E is downstream from the dyadic witness and cannot be read from an independent scale, selected subsequence, quotient stream, or host equality witness. □

Theorem 2965.4 (Regular Cauchy limit uniqueness Real seal nonescape)**.** *For every accepted* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *carrier* $U = (L, R, D, W, Q, E, H, C, P, N)$*, every terminal* $\mathsf{Real}^{\uparrow}$ *seal comparison factors through the route*

$$L, R \to D \to W \to Q \to E \to H, C, P, N.$$

The exported uniqueness surface contains no quotient stream equality, no host real equality, no selected limit, no countable-choice schedule, no trichotomy, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from a terminal seal comparison. The carrier exposes the two source rows only through L, R, and the comparison scale is fixed by D before any finite stream entries can be inspected.

The window and readback rows W, Q then force the comparison through displayed finite tails and regular rational data. The Real-facing endpoint E is therefore a seal row for that already displayed finite route, not an independent completed real.

Finally H, C, P, N preserve and name the same packet. Since the carrier has no coordinate for quotient stream equality, host equality, selected limits, choice, trichotomy, or completeness, the terminal seal comparison cannot escape the listed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ packet is generated from paired regular Cauchy source rows, a shared dyadic tolerance ledger, finite StreamName windows, RegSeqRat readbacks, a paired RealUp seal row, componentwise transport, displayed continuation replay, package provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3942.1, Definition 3942.2, Definition 3942.3, and Definition 3942.4 seed the finite-window uniqueness surface for regular Cauchy limit reads over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyLimitUniquenessUp.RegularCauchyLimitUniquenessTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, countable choice, trichotomy, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic witness determinacy, Real-seal nonescape, transport, replay, provenance, and local naming for the same finite packet.

Chapter 2966

A Concrete Naming Certificate for $\mathsf{FormalBallBasis}^{\uparrow}$

Bishop-style constructive metric-basis language presents completion data through located balls, positive rational radii, and finite cover-refinement witnesses before any quotient of Cauchy names is read. The $\mathsf{FormalBallBasis}^{\uparrow}$ packet records that basis-level substrate between the metric surface of chapter 57, the dyadic arithmetic core of chapter 291, the real-name seal of chapter 38, the formal-ball packet of chapter 1510, and the metric-completion route of chapter 1506. It is a finite source for L10 completion and Cauchy-filter consumers, not an open-cover compactness theorem, not a quotient-ball construction, and not an ambient completeness principle.

Definition 2966.1 (Formal-ball basis carrier)**.** *A* $\mathsf{FormalBallBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, d, c, r, I, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row that supplies the inspected points and distance requests.*
2. *d is the metric-distance ledger read through the same* $\mathsf{Met}^{\uparrow}$ *surface.*
3. *c is the finite centre schedule, listing the displayed centres used by the basis rows.*
4. *r is the positive radius ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, recording dyadic tolerances and their terminal real-name seals.*
5. *I is the incidence row recording which displayed point requests enter which formal balls.*
6. *R is the refinement row, recording finite ball-containment and radius-shrink requests over* $\mathsf{FormalBall}^{\uparrow}$ *before any completion consumer is reached.*
7. *H records componentwise* hsame *transport for the metric, centre, radius, incidence, refinement, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from metric requests through centres, radii, formal-ball incidence, refinement, and completion-facing handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FormalBall}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallBasis}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, quotient balls, selected centres beyond c, selected Cauchy limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallBasisUp.FormalBallBasisTasteGate single carrier alignment`

Theorem 2966.2 (Formal-ball basis NameCert obligations)**.** *For an accepted* $\mathsf{FormalBallBasis}^{\uparrow}$ *carrier*

$$B = (X, d, c, r, I, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FormalBallBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-row exposure through X, d, centre-schedule exposure through c, positive-radius exposure through r, formal-ball incidence through I, finite refinement through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N. Every basis read is exhausted by these rows.*

Proof. Project the carrier of Definition 3943.1. The displayed rows are exactly the metric carrier, metric ledger, centre schedule, radius ledger, incidence row, refinement row, transport row, replay row, provenance row, and local name.

The metric and radius rows supply the source data. The row X provides the inspected metric points and d provides the finite distance requests, while r records only dyadic and real-name radius data.

The formal-ball rows are then I and R. Incidence and refinement are read after the centres and radii have been displayed, so no consumer can substitute quotient balls or a selected completion point for the basis rows.

Finally H, C, P, N preserve, replay, source, and name the same finite packet. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 2966.3 (Formal-ball basis metric-completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBallBasis}^{\uparrow}$ *packet must read the displayed route*

$$X, d \longmapsto c, r \longmapsto I, R \longmapsto H, C, P, N$$

before completion data is available. Thus the completion handoff sees a finite basis of metric centres, dyadic and real radii, formal-ball incidence, and formal-ball refinement, and it receives no quotient ball carrier, selected Cauchy limit, open-cover compactness witness, selected centre outside c, or ambient completeness row.

Proof. Start with the NameCert obligations of Definition 3943.2. They force every consumer to read the metric rows X, d, the centre and radius rows c, r, and the formal-ball rows I, R before any structural row is used.

The provenance row names $\mathsf{MetricCompletion}^{\uparrow}$ only as a downstream consumer of the same route. Therefore completion-facing reads inherit the displayed formal-ball basis rather than a quotient of Cauchy names or a host completion object.

Transport and replay through H and C preserve the route, while P and N only source and name it. The excluded compactness, quotient-ball, selected-centre, selected-limit, and ambient-completeness objects are absent from the carrier. □

Theorem 2966.4 (Formal-ball basis Cauchy-filter refinement)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBallBasis}^{\uparrow}$ *packet must read the metric row X, d, the centre schedule c, the dyadic and real radius ledger r, the incidence row I, and the refinement row R before completion-facing data is available. The consumer route factors through* $\mathsf{FormalBall}^{\uparrow}$ *and*

$\mathsf{MetricCompletion}^{\uparrow}$ *using only H, C, P, N for transport, replay, provenance, and local naming, and it receives no quotient filter, selected limit, countable-choice schedule, or ambient completeness row.*

Proof. Project the accepted carrier $B = (X, d, c, r, I, R, H, C, P, N)$ of Definition 3943.1. The NameCert obligations of Definition 3943.2 expose the metric row, centre schedule, radius ledger, incidence row, and finite refinement row as the whole basis surface.

The Cauchy-filter consumer therefore starts from the same displayed ball data as the metric-completion consumer. The formal-ball incidence row I names the inspected balls, and the refinement row R supplies the finite containment and radius-shrink reads before any completion-facing handoff can be consumed.

Now route through the existing handoff of Definition 3943.3. The rows H, C, P, N preserve and name the route from metric data through $\mathsf{FormalBall}^{\uparrow}$ into $\mathsf{MetricCompletion}^{\uparrow}$, so a $\mathsf{CauchyFilter}^{\uparrow}$ or $\mathsf{CauchyFilterCompletion}^{\uparrow}$ reader receives the finite formal-ball refinement corridor rather than a quotient filter or a chosen limit.

Since the carrier has no coordinate for quotient filters, selected Cauchy limits, countable choice, or ambient completeness, those objects cannot be exported by the refinement read. □

Falsifiable prediction: If a completion-facing read uses a formal-ball basis without displaying the metric row, centre schedule, dyadic or real radius ledger, incidence row, and refinement row, it is not a $\mathsf{FormalBallBasis}^{\uparrow}$ packet.

Independence witness: Nearest siblings: formalball, metriccompletion, bishopregularcauchy-completion, cauchyfiltercompletioncriterion, dyadicratcore; FormalBallBasisUp is not bijective to them because it binds a finite centre-radius basis and refinement row between metric balls and completion consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{FormalBallBasis}^{\uparrow}$ packet is generated from a displayed MetricSpace row, metric-distance ledger, finite centre schedule, DyadicRatCore and Real radius rows, FormalBall incidence, finite refinement, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FormalBallBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3943.1, Definition 3943.2, and Definition 3943.3 seed the finite basis-level substrate between formal balls and metric completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FormalBallBasis}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FormalBallBasisUp.FormalBallBasisTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient balls, selected centres beyond the displayed rows, selected Cauchy limits, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, centre and radius visibility, formal-ball incidence, refinement transport, replay stability, and metric-completion handoff non-escape for BEDC.Derived.FormalBallBasisUp.

Chapter 2967

A Concrete Naming Certificate for $\mathsf{RealConvergentSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealConvergentSequence}^{\uparrow}$ packet records displayed convergence of a real sequence to a named $\mathsf{Real}^{\uparrow}$ limit as finite NameCert data. It adjoins the L10 Real and completion route by sitting over the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the finite windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the real-name seal of chapter 38, the real sequence limit laws of chapter 1480, and the Cauchy convergence criterion surface of chapter 1509. The packet separates convergence evidence from Cauchy completeness: it names a displayed source sequence, a displayed limit row, and the finite tolerance route witnessing convergence, but it does not assert that every Cauchy stream converges.

Definition 2967.1 (Real convergent sequence carrier)**.** *A* $\mathsf{RealConvergentSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, L, D, M, W, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the sequence-source row, exposing the real-sequence index discipline, the finite observation requests, and the source-side* $\mathsf{StreamName}^{\uparrow}$ *handles.*
2. *L is the candidate* $\mathsf{Real}^{\uparrow}$ *limit row, carrying the named real limit, its terminal real-name seal, and the limit-side* $\mathsf{StreamName}^{\uparrow}$ *handles.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested tolerance, the comparison tolerance, and the finite split budget used by each convergence read.*
4. *M is the regular-Cauchy modulus row, storing the tail threshold assigned to each dyadic tolerance request before any consumer reads the convergence classifier.*
5. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *window row for source observations after the threshold and for the candidate-limit windows used in the same request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source windows, limit windows, and tolerance comparisons opened by W and D.*
7. *H records componentwise* hsame *transport for the source row, candidate limit, dyadic ledger, regular-Cauchy modulus, windows, readback, replay row, provenance row, and local naming row.*

8. *K records displayed* Cont *replay from a convergence query through the dyadic tolerance request, the regular-Cauchy threshold, the selected windows, the rational readback, and the candidate* $\mathsf{Real}^{\uparrow}$ *limit row.*

9. *P is the* Pkg *provenance over* $\mathsf{RealConvergentSequence}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RealSequenceLimitLaws}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealConvergentSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, L, D, M, W, R, H, K, P, N$. It has no coordinate for Cauchy completeness, selected limits for arbitrary Cauchy streams, quotient-stream equality, countable choice, trichotomy, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RealConvergentSequenceUp.RealConvergentSequenceTasteGate single carrier alignment`

Theorem 2967.2 (Real convergent sequence NameCert obligations)**.** *For every accepted* $\mathsf{RealConvergentSequence}^{\uparrow}$ *carrier*

$$C = (S, L, D, M, W, R, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealConvergentSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source sequence row, candidate* $\mathsf{Real}^{\uparrow}$ *limit, dyadic tolerance ledger, regular-Cauchy modulus, finite windows, regular rational readback, transport, replay, provenance, and local naming rows;*

2. *source-limit exposure, requiring S and L to be the only source of the displayed sequence and the displayed limit used by the convergence classifier;*

3. *tolerance and modulus exactness, requiring every convergence request to read its dyadic tolerance from D and its tail threshold from M before any source observation is compared with the limit;*

4. *window and readback alignment, requiring W and R to expose only the source windows and limit windows selected by the same tolerance request;*

5. *limit-law compatibility, requiring uses of real sequence limit laws to consume only the displayed rows S, L, D, M, W, R and never a second limit surface;*

6. *Cauchy-criterion boundary, requiring any later Cauchy consumer to receive convergence evidence as input rather than a completeness principle;*

7. *componentwise transport, displayed replay, provenance, and local naming through H, K, P, N;*

8. *refusal of Cauchy completeness, arbitrary limit selection, quotient-stream equality, countable choice, trichotomy, Lean verification, and bridge checking as local certificate data.*

No real-convergent-sequence obligation is stored outside these rows.

Proof. Project the carrier of Definition 3944.1. Its visible coordinates are the source sequence row S, candidate limit row L, dyadic tolerance ledger D, regular-Cauchy modulus M, window row W, readback row R, and structural rows H, K, P, N.

The convergence request first reads D and M. The dyadic row fixes the requested tolerance and comparison budget, while the modulus row fixes the tail threshold for source observations.

The selected observations are then opened through W and R. The same tolerance request chooses both the source windows and the candidate-limit windows, and the regular rational row reads back only those scheduled observations.

Limit-law compatibility follows because every law-facing read has access only to S, L, D, M, W, R before the structural rows. A second limit surface or host equality proof is not a carrier coordinate.

Finally, H, K, P, N transport, replay, record, and name the same finite route. Since the excluded principles do not occur as carrier coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 2967.3 (Real convergent sequence L10 route)**.** *Every accepted* $\mathsf{RealConvergentSequence}^{\uparrow}$ *carrier* $C = (S, L, D, M, W, R, H, K, P, N)$ *presents convergence evidence through the finite route*

$$S, L \longmapsto D \longmapsto M \longmapsto W \longmapsto R \longmapsto H, K, P, N.$$

Any Cauchy convergence criterion consumer downstream of C *receives only the displayed source sequence, candidate* $\mathsf{Real}^{\uparrow}$ *limit, dyadic tolerance ledger, regular-Cauchy threshold,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Start with a downstream consumer. The carrier has no direct completeness coordinate, so the consumer must read the displayed convergence data from S and L.

The tolerance request then passes through D and M. These rows determine the comparison budget and the tail threshold before any observation window is opened.

The windows and rational observations are supplied by W and R. They expose only the scheduled source and candidate-limit data selected by the same request.

The structural rows H, K, P, N preserve the route for transport, replay, provenance, and naming. Thus every downstream criterion-facing read factors through the displayed finite route and cannot export Cauchy completeness, selected arbitrary limits, quotient-stream equality, countable choice, trichotomy, Lean evidence, or bridge data. □

Falsifiable prediction: Every $\mathsf{RealConvergentSequence}^{\uparrow}$ consumer read factors through a displayed source sequence, candidate $\mathsf{Real}^{\uparrow}$ limit, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, regular-Cauchy modulus, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, real-sequence-limit-laws, cauchy-convergence-criterion: $\mathsf{RealConvergentSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source sequence, candidate Real limit, dyadic tolerance ledger, regular-Cauchy modulus, scheduled source-and-limit windows, regular rational readback, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RealConvergentSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RealConvergentSequence}^{\uparrow}$ packet is generated from a displayed source sequence, a candidate RealUp limit, a DyadicRatCore tolerance ledger, a regular-Cauchy modulus, StreamName windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealConvergentSequence}^{\uparrow}}$, seed)

Scope closed: Definition 3944.1, Definition 3944.2, and Definition 3944.3 seed the finite route from displayed real-sequence convergence evidence to later Cauchy-criterion consumption without asserting completeness.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealConvergentSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Cauchy completeness, selected limits for arbitrary Cauchy streams, quotient-stream equality, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-limit exposure, tolerance and modulus exactness, window and readback alignment, limit-law compatibility, Cauchy-criterion boundary, transport, replay, provenance, and local naming for BEDC.Derived.RealConvergentSequenceUp.

Chapter 2968

A Concrete Naming Certificate for $\mathsf{LocatedCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCauchySubsequence}^{\uparrow}$ packet records the finite route by which located regular rational windows expose a Cauchy subsequence handoff to the Real and Completion corridor. It consumes the located tail-window discipline of chapter 2376, the finite extraction surface of chapter 1854, the cofinal regular-subsequence stability row of chapter 3515, the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a displayed subsequence extraction surface for located regular names; it is not a selected infinite subsequence, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2968.1 (LocatedCauchySubsequence carrier)**.** *A* $\mathsf{LocatedCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, R, D, Q, I, S, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger, listing the source windows and selected subsequence windows inspected by the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the located regular rational source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by Cauchy and locatedness requests.*
4. *Q is the* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *comparison row, exposing located tail windows and finite cut comparisons.*
5. *I is the subsequence-index row, recording the monotone selected indices and the source windows from which they are read.*
6. *S is the* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ *stability row, binding the extracted windows to the Cauchy tolerance schedule.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, R, D, Q, I, S have been displayed.*
8. *H records componentwise* hsame *transport for the window, readback, tolerance, located-comparison, index, extraction, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, D, Q, I, S, E, H, C, P, N$. It has no coordinate for a choice-selected infinite subsequence, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCauchySubsequenceUp.LocatedCauchySubsequenceTasteGate single carrier alignment`

Theorem 2968.2 (LocatedCauchySubsequence NameCert obligations)**.** *For every accepted* LocatedCauchySubsequ *carrier*

$$L = (W, R, D, Q, I, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCauchySubsequence}^{\uparrow}}$ *surface consists exactly of five obligation families: carrier admission for $W, R, D, Q, I, S, E, H, C, P, N$; located-window exposure through the* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *row Q; subsequence extraction stability through the index row I and extraction row S;* $\mathsf{Real}^{\uparrow}$ *handoff through the seal row E; and refusal of selected subsequences, quotient stream equality, countable choice, trichotomy, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3945.1. The packet displays exactly the stream windows, regular rational readback, dyadic tolerance ledger, located comparison row, subsequence-index row, extraction row, seal row, transport, replay, provenance, and local naming.

Located-window exposure is inherited from chapter 2376. A location request must pass through Q after reading the finite windows W, the regular rational row R, and the dyadic tolerance ledger D.

Subsequence extraction stability is the pair of rows I, S. The index row states which source windows are selected, and the extraction row states that the selected windows meet the displayed Cauchy tolerance schedule. Componentwise transport H and replay C preserve that route without adding a new selector.

The real-facing handoff is terminal at E. Since E is only reachable after $W, R, D, Q, I, S, H, C, P, N$ have been displayed, it exports a finite located subsequence seal and not a quotient completion or ambient completeness principle.

The classifier has no remaining coordinate beyond the listed rows. Thus selected subsequences, quotient stream equality, countable choice, trichotomy, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are refused by the carrier surface itself. □

Theorem 2968.3 (LocatedCauchySubsequence located-window exposure)**.** *Every accepted* LocatedCauchySubsequ *carrier exposes a located subsequence window only through the finite route*

$$W, R, D, Q, I, S, H, C, P, N.$$

In particular, the subsequence-index row cannot be consumed before the source $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *comparison row have been displayed.*

Proof. Project the rows of Definition 3945.1. A located subsequence request first names a source observation window in W, reads the rational source through R, and consults the dyadic tolerance ledger D.

The located comparison row Q then decides the displayed tail-window comparison. Only after that row is present may the index row I and extraction row S expose the selected subsequence window.

Transport, replay, provenance, and local naming preserve the same route. No row in the packet allows I to be read independently of W, R, D, Q. □

Theorem 2968.4 (LocatedCauchySubsequence RealUp handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedCauchySubsequence}^{\uparrow}$ *carrier factors through the located regular source, subsequence-index row, and extraction-stability row before reading the seal row. The handoff exposes only finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *comparison rows, subsequence-index rows,* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ *stability rows, transport, replay, provenance, and local naming.*

Proof. Begin with a Real-facing read. The seal row E is downstream of the source windows W, readback R, dyadic ledger D, located comparison row Q, index row I, and extraction row S.

Apply Definition 3945.2. The obligation surface forces every consumer-visible read to pass through those finite rows before the seal can be exposed.

The remaining structural rows only transport and replay the same displayed data. Therefore the handoff is a finite BEDC route from located regular rational windows to a terminal $\mathsf{Real}^{\uparrow}$ seal, not an ambient completion theorem. □

Falsifiable prediction: Every $\mathsf{LocatedCauchySubsequence}^{\uparrow}$ read factors through displayed $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, $\mathsf{LocatedRegSeqRat}^{\uparrow}$ comparison rows, subsequence-index rows, $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ stability rows, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: locatedregseqrat, cauchysubsequenceextraction, regularcauchysubsequencestability, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedCauchySubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located tail-window comparisons, monotone selected indices, extraction stability, finite stream windows, regular rational readback, dyadic tolerances, Real seal routing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchySubsequence}^{\uparrow}$ packet is generated from StreamName source and subsequence windows, RegSeqRat readback, DyadicRatCore tolerance rows, LocatedRegSeqRat comparison rows, subsequence-index rows, CauchySubsequenceExtraction stability rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCauchySubsequence}^{\uparrow}}$, seed)

Scope closed: Definition 3945.1, Definition 3945.2, Definition 3945.3, and Definition 3945.4 seed the finite located Cauchy subsequence route from displayed regular rational windows to Real-facing handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCauchySubsequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, selected infinite subsequences, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-window exposure, subsequence extraction stability, RealUp handoff, and nonescape for BEDC.Derived.LocatedCauchySubsequenceUp.

Chapter 2969

A Concrete Naming Certificate for $\mathsf{CompletionReflectorTriangle}^{\uparrow}$

Following Mac Lane's adjunction triangle identities and the Bishop–Bridges construction of Cauchy completion, the $\mathsf{CompletionReflectorTriangle}^{\uparrow}$ packet records the finite BEDC rows needed to read the unit, counit, and idempotent replay of the L10 completion reflector as one public triangle. It depends on the reflector packet of chapter 1585, the unit packet of chapter 1527, the counit packet of chapter 1539, the idempotent packet of **??**, the universal-property packet of chapter 397, and the reflection packet of chapter 403. Its real-facing route is read through chapter 360, chapter 126, chapter 301, chapter 291, and chapter 38. The packet is a finite naming certificate for the triangle surface; it is not quotient completion equality, not a selected limit, not host equality, not countable choice, not ambient completeness, and not detached $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2969.1 (CompletionReflectorTriangle carrier)**.** *A* $\mathsf{CompletionReflectorTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, U, M, Q, I, E, R, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row for the displayed metric, regular-Cauchy, or real-name data entering the completion reflector.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row admitting the source into the completion-facing surface.*
3. *M is the completion-object row, read through the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and reflector surfaces rather than through a host quotient carrier.*
4. *Q is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *row returning already completed or real-sealed reads through the displayed route.*
5. *I is the* $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$ *replay row for a second completion pass over the same completion-object row.*
6. *E is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row consumed after the unit face is visible.*
7. *R is the* $\mathsf{CompletionReflection}^{\uparrow}$ *reflection row consumed after the unit, counit, idempotent, and extension faces are visible.*
8. *T is the local transport row through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *windows.*

9. *H records componentwise* hsame *transport for the source, unit, completion object, counit, idempotent replay, extension, reflection, transport, continuation, provenance, and naming rows.*
10. *C records displayed* Cont *replay along the unit-counit-idempotent triangle and through the local real-name transport row.*
11. *P is the* Pkg *provenance over* $\mathsf{CompletionReflectorTriangle}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$ $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionReflectorTriangle}^{\uparrow}}$ *row.*

The classifier on accepted packets compares only these twelve rows under the displayed transport and replay data.

Lean4 ✓ `BEDC.Derived.CompletionReflectorTriangleUp.CompletionReflectorTriangleTasteGate single carrier alignment`

Theorem 2969.2 (CompletionReflectorTriangle NameCert obligations)**.** *For every accepted* CompletionReflectorTr *carrier $K = (S, U, M, Q, I, E, R, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionReflectorTriangle}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source, unit, completion-object, counit, idempotent-replay, extension, reflection, transport, continuation, provenance, and naming rows; unit-first readability for completion-facing source reads; counit return for already completed or real-sealed reads; idempotent replay over the same completion-object row; extension and reflection consumption over the displayed triangle route; and non-escape from quotient completions, selected limits, host equality, countable choice, ambient completeness, and detached* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3946.1. The packet displays $S, U, M, Q, I, E, R, T, H, C, P, N$ and no other row.

The unit face reads S through U before the completion object M is consumed. The counit face reads Q only for data already on the completed or real-sealed side, and the idempotent face reads I over the same M row.

The extension and reflection faces are downstream of that route. The row E is consumed as the finite universal-property extension, and R is consumed as the reflection row over the same S, U, M, Q, I, T surface.

Finally H, C, P, N transport, replay, source, and name exactly the displayed route. Since no coordinate stores quotient completions, selected limits, host equality, countable choice, ambient completeness, or detached real completeness, the stated non-escape boundary follows. □

Theorem 2969.3 (CompletionReflectorTriangle unit-counit coherence)**.** *Let $K = (S, U, M, Q, I, E, R, T, H, C, P, N$ be an accepted* $\mathsf{CompletionReflectorTriangle}^{\uparrow}$ *carrier. The two triangle readings*

$$S \longmapsto U \longmapsto M \longmapsto I \longmapsto E, R \longmapsto H, C, P, N$$

and

$$S \longmapsto T \longmapsto Q \longmapsto I \longmapsto E, R \longmapsto H, C, P, N$$

meet at the same displayed idempotent, extension, reflection, transport-replay, provenance, and naming rows. Thus a consumer that first enters completion by the unit face and a consumer that first reads the real-name transport before counit return receive the same finite $\mathsf{NameCert}_{\mathsf{CompletionReflectorTriangle}^{\uparrow}}$ *boundary, with no quotient completion equality, selected limit, host equality, countable choice, ambient completeness, or detached* $\mathsf{Real}^{\uparrow}$ *completeness exported.*

Proof. Expose the carrier rows from Definition 3946.1. The only completion-facing rows are $S, U, M, Q, I, E, R, T, H, C, P, N$.

The first displayed reading is the unit leg: the source is admitted by U, the completion object M is read, and repeated completion is replayed by I before E and R are consumed.

The second displayed reading is the transport-counit leg: the source is read through T, returned by Q when already completed or real-sealed, and then replayed by the same I before E and R are consumed.

Both readings end in the same H, C, P, N rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row therefore identify the two readings as one finite triangle boundary. The excluded completion, selection, host-equality, choice, ambient-completeness, and detached-real-completeness data have no row in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionReflectorTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionReflectorTriangle}^{\uparrow}$ packet is generated from a displayed source row, unit admission, completion-object access, counit return, idempotent replay, universal-property extension, reflection consumption, local StreamName-RegSeqRat-DyadicRatCore-Real transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionReflectorTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3946.1, Definition 3946.2, and Definition 3946.3 seed the finite unit-counit-idempotent triangle surface for the L10 completion reflector.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionReflectorTriangle}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompletionReflectorTriangleUp.CompletionReflectorTriangleTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality, countable choice, ambient completeness, detached $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-counit coherence, idempotent replay, extension compatibility, reflection compatibility, local real-name transport, and non-escape for the same carrier.

The $\mathsf{LawvereMetricCompletion}^{\uparrow}$ hub exposes its sibling lattice against the dense metric-completion surface of chapter 3351 through the child route below.

Chapter 2970

A Concrete Naming Certificate for $\mathsf{LawvereMetricCompletion}^{\uparrow}$

Following Lawvere on generalized metric spaces and enriched-category distance, the $\mathsf{LawvereMetricCompletion}^{\uparrow}$ packet records the finite directed-distance profile surface through which an enriched metric completion can be consumed inside BEDC. It sits beside the Yoneda profile route of chapter 2148, the ordinary metric observation rows of chapter 57, the formal-ball approximation surface of chapter 1510, the dyadic tolerance ledger of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a one-sided enriched completion boundary; it does not select host limits, quotient directed Cauchy objects, symmetric metric completions, global colimits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The sibling dependency route is substantive: $\mathsf{LawvereMetricCompletion}^{\uparrow}$ reads the $\mathsf{YonedaCompletion}^{\uparrow}$ profile route of chapter 2148, the $\mathsf{FormalBall}^{\uparrow}$ approximation cuts of chapter 1510, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance accounting of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38 before any completion-facing directed profile can be consumed. The directed source row M is supplied by the $\mathsf{QuasiMetric}^{\uparrow}$ carrier route of chapter 2158 and is consumed before Yoneda profiles or FormalBall approximations.

Definition 2970.1 (Lawvere metric completion carrier)**.** *A* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, Y, F, D, A, T, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the directed* $\mathsf{QuasiMetric}^{\uparrow}$ *source row, carrying the visible point classifier and the finite one-sided distance comparisons accepted by the source packet.*
2. *Y is the* $\mathsf{YonedaCompletion}^{\uparrow}$ *handoff row, exposing the covariant and contravariant distance profiles retained for the displayed source points.*
3. *F is the finite probe-comparison row, listing the source probes against which two directed profiles are compared.*
4. *D is the directed-distance profile row, recording the left and right distance readings that make the completion candidate visible as a Lawvere-enriched profile.*
5. *A is the* $\mathsf{FormalBall}^{\uparrow}$ *approximation row, displaying finite ball inclusions and radius cuts used before any completion-facing consumer reads D.*

6. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-accounting row for directed profile errors, ball radii, and probe budgets.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained regular rational windows.*
8. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row for directed distance values and zero-distance comparison readback.*
9. *H records componentwise* hsame *transport for source rows, profile rows, probe comparisons, formal-ball approximations, dyadic tolerances, regular readbacks, Real seals, provenance, and local naming.*
10. *C records displayed* Cont *replay from source distances to Yoneda profiles, from profiles to formal-ball approximations, and from tolerance windows to Real readback.*
11. *P is the* Pkg *provenance over* $\mathsf{LawvereMetricCompletion}^{\uparrow}$, $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LawvereMetricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, Y, F, D, A, T, R, S, H, C, P, N$. It has no coordinate for selected Cauchy weights, quotient profile equality, symmetric completion collapse, host enriched colimits, countable choice, or ambient real completeness.

Theorem 2970.2 (Lawvere metric completion NameCert obligations)**.** *For every accepted* LawvereMetricCompletio *carrier $L = (M, Y, F, D, A, T, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LawvereMetricCompletion}^{\uparrow}}$ *surface consists exactly of directed source admission, YonedaCompletion handoff, finite probe comparisons, directed distance-profile admission, FormalBall approximation, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every enriched-metric completion consumer must inspect those rows before treating the packet as a completion neighbour.*

Proof. Project the carrier of Definition 3947.1. The source and Yoneda rows M, Y are the only rows that introduce directed distance profiles from the displayed metric source.

The finite comparison route is F, D, A, T. Probe comparisons fix which source probes are being tested, the directed profile row records the left and right readings, the formal-ball row supplies finite approximation cuts, and the dyadic row records the tolerance accounting for those cuts.

Readback and transport are then forced through R, S, H, C, P, N. The regular rational windows and Real seal expose only the retained directed distance values, while componentwise transport, replay, provenance, and local naming preserve the same finite route.

Since the classifier has no additional coordinate, selected Cauchy weights, quotient profile equality, symmetric completion collapse, host enriched colimits, countable choice, and ambient real completeness cannot be read from the packet. □

Theorem 2970.3 (Lawvere metric completion finite profile nonescape)**.** *Every completion-facing read exported by an accepted* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *packet factors through*

$$\mathsf{QuasiMetric}^{\uparrow},\ \mathsf{YonedaCompletion}^{\uparrow},\ \mathsf{FormalBall}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The read first fixes the directed source and Yoneda profile rows, then the finite probe comparisons and formal-ball approximations, then dyadic tolerance accounting, regular rational readback, Real sealing, transport, replay, provenance, and local naming. It exports no quotient directed Cauchy object, selected profile limit, symmetric metric completion collapse, host enriched colimit, or ambient completeness principle.

Proof. Let $L = (M, Y, F, D, A, T, R, S, H, C, P, N)$ be accepted. A completion-facing consumer first receives M, Y, F, D, so the directed profile is tied to displayed source distances, Yoneda handoff, and finite probe comparisons.

The approximation stage is A, T. Formal-ball inclusions and dyadic tolerance rows determine which finite directed-distance errors are visible before readback.

Finally R, S, H, C, P, N expose only regular rational windows, Real seals, transport, replay, provenance, and local naming for that same route. The excluded quotient, choice, colimit, symmetric-collapse, and ambient-completeness objects are not carrier fields, so no completion consumer can bypass the finite profile surface. □

Theorem 2970.4 (Lawvere metric completion directed-profile composition)**.** *Every completion-facing read from an accepted* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *packet composes through the* $\mathsf{YonedaCompletion}^{\uparrow}$ *profile handoff,* $\mathsf{QuasiMetric}^{\uparrow}$ *directed source data,* $\mathsf{FormalBall}^{\uparrow}$ *approximation rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows before it is visible as a Lawvere-enriched completion profile. The composed read exports directed source distances, finite probe comparisons, formal-ball approximation cuts, dyadic error budgets, regular rational windows, Real sealing, transport, replay, provenance, and local naming, but it exports no symmetric metric completion, quotient directed Cauchy object, selected profile limit, global colimit, countable-choice schedule, or ambient completeness claim.*

Proof. Project the carrier of Definition 3947.1. The directed source and profile handoff are exactly the rows M, Y, F, D.

Apply Definition 3947.2. It forces any completion-facing consumer to inspect directed source admission, YonedaCompletion handoff, finite probe comparison, directed profile admission, FormalBall approximation, DyadicRatCore tolerance accounting, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Apply Definition 3947.3. The nonescape theorem identifies the public route through $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The composed read is therefore the displayed directed-profile route itself. Since the carrier has no coordinate for a symmetric completion, quotient directed Cauchy object, selected profile limit, host colimit, choice schedule, or ambient completeness witness, none of those objects can be exported by the composition. □

Theorem 2970.5 (Lawvere metric completion QuasiMetric source handoff)**.** *Any* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *read whose source distance is one-sided must first pass through the* $\mathsf{QuasiMetric}^{\uparrow}$ *carrier route of chapter 2158 before the* $\mathsf{YonedaCompletion}^{\uparrow}$ *and* $\mathsf{FormalBall}^{\uparrow}$ *rows are consumed. The completion-facing consumer may then read directed source distances, Yoneda profiles, finite probe comparisons, formal-ball approximation cuts, dyadic tolerance accounting, rational readback, Real sealing, transport, replay, provenance, and local naming, but it receives no symmetric metric source, quotient directed Cauchy object, selected profile limit, choice schedule, or ambient completeness claim.*

Proof. Apply Definition 2158.3. A one-sided source distance reaches completion-facing consumers only through the $\mathsf{QuasiMetric}^{\uparrow}$ carrier rows for source admission, ordered point names, directed distance, zero diagonal, forward triangle, directed balls, Cauchy rows, uniform reflection, transport, replay, provenance, and local naming.

Apply Definition 3947.4. Once that directed source route is displayed, the Lawvere completion read composes it with $\mathsf{YonedaCompletion}^{\uparrow}$ profiles, finite probe comparisons, $\mathsf{FormalBall}^{\uparrow}$ approximations, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance accounting, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ seal.

Apply Definition 3947.3. The resulting completion-facing route remains finite and displayed, so it cannot export a quotient directed Cauchy object, selected profile limit, symmetric completion collapse, host colimit, choice schedule, or ambient completeness witness. □

Theorem 2970.6 (Lawvere metric completion FormalBall universality route)**.** *Any completion-facing read of an accepted* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *profile must factor through the* $\mathsf{FormalBall}^{\uparrow}$ *approximation row A after the* $\mathsf{YonedaCompletion}^{\uparrow}$ *profile row Y and before the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row T,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and* $\mathsf{Real}^{\uparrow}$ *seal row S. Thus the approximation gate cannot be replaced by quotient profile equality, symmetric completion collapse, selected profile limits, host enriched colimits, or ambient completeness.*

Proof. Project the carrier of Definition 3947.1. The profile route exposes $M, Y, F, D, A, T, R, S, H, C, P, N$, with A placed between the Yoneda-directed profile rows and the tolerance, readback, and seal rows.

Apply Definition 3947.2. It forces completion-facing consumers to inspect FormalBall approximation as one of the local NameCert obligations before the packet is treated as a completion neighbour.

Apply Definition 3947.3 and Definition 3947.4. Together they identify the public route through $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Since quotient profile equality, symmetric completion collapse, selected profile limits, host enriched colimits, and ambient completeness are absent carrier coordinates, no completion-facing read can substitute them for the FormalBall approximation gate. □

Theorem 2970.7 (Lawvere metric completion FormalBall profile initiality)**.** *Let $L = (M, Y, F, D, A, T, R, S, H, C,$ be an accepted* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *packet. Any completion-facing directed-profile read that reaches the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, or the* $\mathsf{Real}^{\uparrow}$ *sealing row S first factors through the* $\mathsf{FormalBall}^{\uparrow}$ *approximation row A after the* $\mathsf{YonedaCompletion}^{\uparrow}$ *profile row Y. Thus A is the initial completion-facing approximation gate after Yoneda profile data; no later tolerance, readback, or seal consumer may bypass it through quotient profile equality, selected profile limits, symmetric completion collapse, host enriched colimits, choice, or ambient completeness.*

Proof. Project the carrier of Definition 3947.1. The displayed order places Y before the finite probe and directed-profile rows, then places the FormalBall row A before the tolerance, readback, and seal rows T, R, S.

Apply Definition 3947.2. The NameCert obligations force every completion-facing consumer to inspect the directed source admission, YonedaCompletion handoff, finite probe comparison, directed profile admission, FormalBall approximation, DyadicRatCore tolerance accounting, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming rows in the displayed carrier surface.

Apply Definition 3947.3 and Definition 3947.4. These theorems identify the finite route through $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the directed profile cannot leave the packet before the FormalBall row is read.

Finally apply Definition 3947.6. It names A as the mandatory approximation row between Y and the later tolerance, readback, and seal rows. The carrier has no coordinates for quotient profile equality, selected profile limits, symmetric completion collapse, host enriched colimits, choice, or ambient completeness, so none of those objects can serve as an earlier completion-facing gate. □

Falsifiable prediction: Removing any one of the $\mathsf{YonedaCompletion}^{\uparrow}$ handoff, finite probe-comparison row, $\mathsf{FormalBall}^{\uparrow}$ approximation row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{Real}^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, or local $\mathsf{NameCert}$ row makes

Definition 3947.3 false: a completion consumer could no longer verify the displayed directed-profile route.

Independence witness: yonedacompletion, metriccompletion, formalball, dyadicratcore, regseqrat, real: $\mathsf{LawvereMetricCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries directed source distances, Yoneda profile handoff, finite probe comparisons, formal-ball approximations, dyadic tolerance accounting, regular rational readback, Real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LawvereMetricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{LawvereMetricCompletion}^{\uparrow}$ packet is generated from directed QuasiMetricUp source data, YonedaCompletionUp profile handoff, finite probe comparisons, directed distance-profile rows, FormalBallUp approximations, DyadicRatCoreUp tolerance accounting, RegSeqRatUp readback windows, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawvereMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3947.1, Definition 3947.2, and Definition 3947.3 seed the finite Lawvere-enriched completion route over directed profile, approximation, tolerance, readback, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LawvereMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected Cauchy weights, quotient profile equality, symmetric metric completion collapse, host enriched colimits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed profile admission, probe comparison, FormalBall approximation, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.LawvereMetricCompletionUp.

The $\mathsf{LawvereMetricCompletion}^{\uparrow}$ directed-profile route consumes symmetric completion data only after the one-sided profile has already passed through $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, and $\mathsf{FormalBall}^{\uparrow}$. The metric-completion dense embedding of chapter 3351 and the dense-reflector route of chapter 3786 are therefore horizontal consumers of the displayed profile surface, not replacements for the directed source row.

Proposition 2970.8 (Lawvere metric completion dense-reflector handoff)**.** *Any completion-facing read that compares an accepted* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *packet with* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *or* $\mathsf{CauchyCompletionDenseReflector}^{\uparrow}$ *must first display the* $\mathsf{QuasiMetric}^{\uparrow}$ *source row,* $\mathsf{YonedaCompletion}^{\uparrow}$ *profile row,* $\mathsf{FormalBall}^{\uparrow}$ *approximation row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal row from Definition 3947.4. Only after that directed profile is visible may the read consume the symmetric dense-embedding or Cauchy dense-reflector rows. The handoff exports no selected profile limit, quotient directed Cauchy object, symmetric-collapse equality, countable-choice schedule, or ambient completeness theorem.*

Proof. Start with the directed-profile composition theorem. It fixes the visible route through the QuasiMetric source, Yoneda profile, FormalBall approximation, dyadic tolerance ledger, regular rational readback, and Real seal before any completion-facing consumer can inspect the packet.

Next read the sibling dense-completion surfaces. $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ supplies the symmetric dense-image row for ordinary metric completion, while $\mathsf{CauchyCompletionDenseReflector}^{\uparrow}$ supplies the Cauchy dense-reflector route through that dense image. Both are consumed after the Lawvere profile has exposed its directed rows.

Thus the comparison is a handoff from the directed profile into the existing completion infrastructure. Since the Lawvere carrier has no coordinate for selected profile limits, quotient directed Cauchy objects, symmetric-collapse equality, countable choice, or ambient completeness, none of those objects is exported by the handoff. □

Theorem 2970.9 (Lawvere metric completion Cauchy route)**.** *A symmetric dense-reflector comparison for an accepted* LawvereMetricCompletion$^{\uparrow}$ *packet reads* MetricCompletionDenseEmbedding$^{\uparrow}$ *and* CauchyCompletionDenseReflector$^{\uparrow}$ *only after the Lawvere one-sided route has displayed* QuasiMetric$^{\uparrow}$*,* YonedaCompletion$^{\uparrow}$*,* FormalBall$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. The comparison with chapter 3351 and chapter 3786 is therefore a horizontal lattice edge out of the directed profile route, not a replacement for any source, tolerance, regular-rational, or Real-seal row.*

Proof. Start from Definition 3947.4. It displays the one-sided Lawvere route through the quasi-metric source, Yoneda profile, formal-ball approximation, dyadic tolerance ledger, regular rational readback, and Real seal.

Apply the dense-reflector handoff proposition above. It allows the symmetric dense-embedding and Cauchy dense-reflector rows to be consumed only after that directed profile is already visible.

The two sibling chapters then provide the horizontal consumers: MetricCompletionDenseEmbedding$^{\uparrow}$ reads the symmetric dense image, and CauchyCompletionDenseReflector$^{\uparrow}$ reads the Cauchy reflector through that dense image. Since the carrier lacks selected profile limits, quotient directed Cauchy objects, symmetric-collapse equality, choice, and ambient completeness, the route remains the displayed lattice edge. □

Theorem 2970.10 (Lawvere metric-completion sibling lattice route)**.** *Any symmetric metric-completion consumer of an accepted* LawvereMetricCompletion$^{\uparrow}$ *packet must first pass through the directed route displayed after* QuasiMetric$^{\uparrow}$*,* YonedaCompletion$^{\uparrow}$*,* FormalBall$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. It may then compare that route with* MetricCompletionDenseEmbedding$^{\uparrow}$ *and* CauchyCompletionDenseRefl *but the comparison does not replace the directed source row or the one-sided profile classifier.*

Proof. Use the namecert construction route of chapter 3947. The packet names completion through the directed QuasiMetric$^{\uparrow}$, YonedaCompletion$^{\uparrow}$, and FormalBall$^{\uparrow}$ rows before any rational readback or terminal Real seal is available.

The symmetric siblings are therefore downstream comparison surfaces. The dense embedding of chapter 3351 and the dense-reflector route of chapter 3786 may inspect the same completed-window data, but neither sibling supplies a new directed source row.

Thus the horizontal lattice edge is substantive only after the Lawvere route has been read, and it preserves the one-sided profile classifier of the original packet. □

HyperbolicCrossRatio$^{\uparrow}$ routes four-boundary comparison through chapter 5110, chapter 6237, and the visual-metric boundary route before exposing cross-ratio comparisons.

Chapter 2971

A Concrete Naming Certificate for HyperbolicCrossRatio$^{\uparrow}$

The HyperbolicCrossRatio$^{\uparrow}$ packet realizes the four-boundary-point comparison branch of chapter 9463 as finite NameCert data. It sits beside the Poincare disk phase route of chapter 3455, the hyperbolic metric surface of chapter 3474, the boundary-fixed transport surface of chapter 3500, the Busemann boundary packet of chapter 3732, and the Schwarz–Pick disk-contraction row of chapter 3682. The packet names a local four-point invariant over displayed disk-boundary rows; it does not import a host ideal-boundary compactification, a global hyperbolic plane, selected geodesics, or quotient boundary equality.

Definition 2971.1 (Hyperbolic cross-ratio carrier)**.** *A* HyperbolicCrossRatio$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (D, M, B_0, B_1, B_2, B_3, T, Q, R, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* PoincareDiskPhaseTransport$^{\uparrow}$ *disk-source and phase-transport row for the visible disk coordinate system.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *comparison row attached to that disk source.*
3. *B_0, B_1, B_2, B_3 are four boundary-point rows, each read through the displayed Poincare boundary interface rather than through a host compactification.*
4. *T is the* PoincareBoundaryFixedTransport$^{\uparrow}$ *row proving that the four boundary rows remain attached to the same boundary-fixed disk transport.*
5. *Q is the finite cross-ratio comparison row, exposing only the retained pairwise boundary-distance and oriented separation comparisons.*
6. *R is the refusal row excluding host global geometry, selected geodesics, quotient boundary equality, and object-level ideal-boundary compactification.*
7. *F is the* SchwarzPickDiskContraction$^{\uparrow}$ *provenance row that records nonexpansive disk-map compatibility for consumers comparing the cross-ratio under disk transport.*
8. *H records componentwise* hsame *transport for disk, metric, four boundary rows, boundary-fixed transport, cross-ratio comparison, refusal, Schwarz–Pick provenance, package provenance, and local naming.*

9. *C records displayed* Cont *replay from disk phase transport through metric comparison, four boundary rows, boundary-fixed transport, cross-ratio comparison, refusal, and provenance.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatio}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, B_0, B_1, B_2, B_3, T, Q, R, F, H, C, P, N$. It has no coordinate for fewer than four boundary rows, a host global metric oracle, selected ideal points outside the displayed boundary interface, quotient boundary equality, or unrecorded disk transport.

Theorem 2971.2 (Hyperbolic cross-ratio NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *carrier $X = (D, M, B_0, B_1, B_2, B_3, T, Q, R, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatio}^{\uparrow}}$ *surface consists exactly of Poincare disk phase transport, hyperbolic-metric comparison, four displayed boundary rows, boundary-fixed transport, finite cross-ratio comparison, global-geometry refusal, Schwarz–Pick provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted consumer must inspect those rows before treating the packet as a hyperbolic four-point invariant.*

Proof. Project the carrier of Definition 3948.1. The disk and metric rows D, M fix the Poincare disk reading and the hyperbolic comparison surface.

The four boundary rows B_0, B_1, B_2, B_3 are then read together with the boundary-fixed transport row T. This is the only point at which the carrier exposes boundary points, and all four rows must belong to the same displayed disk-transport route.

The comparison and refusal route is Q, R, F. The finite cross-ratio row records the retained pairwise boundary comparisons, the refusal row prevents replacement by host global geometry, and the Schwarz–Pick row records the nonexpansive disk-map provenance consumed by downstream transport comparisons.

Finally H, C, P, N transport, replay, source, and name the same finite surface. Since no other row is present, no consumer can omit a boundary row, replace hyperbolic comparison by a global oracle, or bypass the local naming route. □

Theorem 2971.3 (Hyperbolic cross-ratio nonescape)**.** *Every accepted* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *consumer factors through the finite route*

$$\mathsf{PoincareDiskPhaseTransport}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{PoincareBoundaryFixedTransport}^{\uparrow},\ \mathsf{HyperbolicBusemannBoundary}^{\uparrow}$$

The route fixes the disk phase surface, the hyperbolic metric comparison, four boundary rows, boundary-fixed transport, finite cross-ratio comparison, global-geometry refusal, Schwarz–Pick provenance, transport, replay, package provenance, and local naming. It exports no host global geometry, quotient boundary equality, selected ideal-boundary compactification, or unrecorded disk-map invariant.

Proof. Let $X = (D, M, B_0, B_1, B_2, B_3, T, Q, R, F, H, C, P, N)$ be accepted. A consumer first reads D, M, so all later comparisons are attached to the displayed disk phase transport and hyperbolic metric rows.

Next the consumer reads B_0, B_1, B_2, B_3, T. The four boundary rows are simultaneous carrier fields, and the boundary-fixed transport row keeps them in the same disk-transport context.

The comparison row Q is accepted only together with the refusal row R and Schwarz–Pick provenance F. Thus cross-ratio comparison remains finite and local to the displayed disk route.

The rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. The excluded host and quotient objects have no carrier coordinate, so the consumer cannot escape the finite packet. □

Theorem 2971.4 (Hyperbolic cross-ratio Mobius consumer route)**.** *Any* $\mathsf{MobiusTransform}^{\uparrow}$ *consumer of an accepted* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *packet must read the disk row D, metric row M, four boundary rows B_0, B_1, B_2, B_3, boundary-fixed transport row T, cross-ratio row Q, refusal row R, Schwarz–Pick provenance row F, and structural rows H, C, P, N before it may claim cross-ratio preservation. The consumer route of chapter 5110 has no accepted preservation coordinate outside this four-boundary packet.*

Proof. Apply Definition 3948.3. Every accepted $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ consumer already factors through the disk, metric, boundary, transport, comparison, refusal, provenance, replay, package, and naming rows of the finite carrier.

A $\mathsf{MobiusTransform}^{\uparrow}$ preservation read is a downstream consumer of the same packet, not a separate host-level geometric claim. Since the carrier has no coordinate for cross-ratio preservation unless the four displayed boundary rows and the boundary-fixed transport route are present, the Mobius consumer must enter through $D, M, B_0, B_1, B_2, B_3, T, Q, R, F, H, C, P, N$. □

Theorem 2971.5 (Hyperbolic cross-ratio horofunction consumer route)**.** *Any* $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ *consumer of an accepted* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *packet must first read the disk row D, hyperbolic metric row M, four boundary rows B_0, B_1, B_2, B_3, boundary-fixed transport row T, cross-ratio row Q, refusal row R, Schwarz–Pick provenance row F, and structural rows H, C, P, N before treating the packet as a boundary metric comparison. The consumer route reads boundary metric data through Busemann and visual-boundary rows, not through a host compactification.*

Proof. Apply Definition 3948.3. Every accepted $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ consumer already enters through the disk, metric, four boundary rows, boundary-fixed transport, cross-ratio comparison, refusal, provenance, replay, package, and naming rows.

A $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ read is boundary-metric facing, so it cannot treat Q as an isolated scalar comparison. The four boundary rows and the metric row must first be routed through the displayed Busemann and visual-boundary surfaces that the horofunction-boundary packet consumes.

The refusal row R blocks host compactification and quotient ideal-boundary equality. The structural rows H, C, P, N then preserve the same finite route, so the horofunction consumer receives only the cross-ratio data that has passed through the displayed boundary metric rows. □

Falsifiable prediction: Any accepted $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ consumer omitting one of the four boundary rows, the $\mathsf{HyperbolicMetric}^{\uparrow}$ comparison, the $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ row, Pkg provenance, or the local $\mathsf{NameCert}$ row refutes Definition 3948.3.

Independence witness: poincare-disk-phase-transport, hyperbolic-metric, poincare-boundary-fixed-transport, hyperbolic-busemann-boundary, schwarz-pick-disk-contraction: $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk phase transport, hyperbolic metric comparison, four boundary rows, boundary-fixed transport, finite cross-ratio comparison, refusal of host global geometry, Schwarz–Pick provenance, transport, replay, package provenance, and local naming.

The Lean TasteGate file for HyperbolicCrossRatio$^{\uparrow}$ will provide explicit Nontrivial HyperbolicCrossRatio$^{\uparrow}$ and FieldFaithful HyperbolicCrossRatio$^{\uparrow}$ instances. These instances keep the disk, metric, boundary, transport, comparison, refusal, provenance, replay, package, and local naming rows distinguishable.

Closure status for NameCert$_{\text{HyperbolicCrossRatio}^{\uparrow}}$.

Constructive story: A HyperbolicCrossRatio$^{\uparrow}$ packet is generated from PoincareDiskPhaseTransportUp disk data, HyperbolicMetricUp comparison, four displayed boundary rows, PoincareBoundaryFixedTransportUp transport, finite cross-ratio comparison, global-geometry refusal, SchwarzPickDiskContractionUp provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicCrossRatio}^{\uparrow}}$, seed)

Scope closed: Definition 3948.1, Definition 3948.2, Definition 3948.3, and Definition 3948.4 seed the finite four-boundary-point hyperbolic cross-ratio route over disk, metric, boundary, transport, refusal, provenance, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicCrossRatio}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host global geometry, quotient boundary equality, selected ideal-boundary compactification, unrecorded disk-map invariants, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four boundary rows, hyperbolic metric comparison, boundary-fixed transport, finite cross-ratio comparison, global-geometry refusal, TasteGate nontriviality, field faithfulness, provenance, transport, replay, and local naming for BEDC.Derived.HyperbolicCrossRatioUp.

Theorem 2971.6 (Hyperbolic cross-ratio Mobius-invariant sibling route)**.** *Every accepted* HyperbolicCrossRatio$^{\uparrow}$ *four-boundary-point carrier consumes the* MobiusTransform$^{\uparrow}$ *route of chapter 5110 and the* HyperbolicMobiusInvarian *route of chapter 6237 before any cross-ratio comparison is exported. In carrier notation* $X = (D, M, B_0, B_1, B_2, B_3, T, Q, R, F, H, C, P, N)$*, the accepted comparison row* Q *is public only after the disk, metric, four boundary, boundary-fixed transport, refusal, provenance, replay, package, and naming rows have passed the sibling Mobius and invariant routes.*

Proof. Apply Definition 3948.3. Every public read of Q already factors through the displayed disk, metric, four boundary rows, boundary-fixed transport, refusal, Schwarz–Pick provenance, transport, replay, provenance, and local naming rows.

Apply Definition 3948.4. A MobiusTransform$^{\uparrow}$ consumer of that packet may claim preservation only through the same four-boundary carrier route, so the Mobius sibling is a prerequisite route rather than an external host symmetry.

The HyperbolicMobiusInvariant$^{\uparrow}$ sibling then reads the same Mobius-facing route as invariant data. Since X has no coordinate for an isolated cross-ratio scalar, quotient boundary equality, or unrecorded transformation invariant, any accepted cross-ratio comparison exported from Q has already consumed both sibling routes. □

Theorem 2971.7 (Hyperbolic cross-ratio logarithm route)**.** *Every accepted* HyperbolicCrossRatio$^{\uparrow}$ *read that exports a logarithmic distance or invariant must first display the four endpoint rows* B_0, B_1, B_2, B_3*, the cross-ratio comparison ledger* Q*, positive-domain admission, the* RealLogarithm$^{\uparrow}$ *inverse route of chapter 2315, the* RealExponential$^{\uparrow}$ *comparison row,* RealAbs$^{\uparrow}$ *error control, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The logarithm is a sibling dependency read through the displayed RealLogarithm certificate; it is not a host logarithm primitive and it exports no quotient boundary equality, selected ideal endpoint, host global geometry, or unrecorded disk-map invariant.*

Proof. Project the carrier of Definition 3948.1. The endpoint rows B_0, B_1, B_2, B_3 and the cross-ratio comparison row Q are already displayed before any downstream invariant can be read.

The logarithmic route is then admitted only as a positive-domain read. Invoke the RealLogarithm$^{\uparrow}$ certificate of chapter 2315: its inverse route passes through the RealExponential$^{\uparrow}$ comparison row and the RealAbs$^{\uparrow}$ error-control row before a logarithm endpoint is consumed.

Finally transport and replay the same carrier route through H, C, P, N. The sibling logarithm certificate supplies the inverse-route dependency, while the $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ carrier supplies the four endpoint rows and comparison ledger. Neither surface contains a host logarithm, quotient boundary equality, selected ideal endpoint, global geometry oracle, or unrecorded disk-map invariant. □

$\mathsf{HyperbolicCrossRatio}^{\uparrow}$ reads the boundary visual metric surface of chapter 3866 before any cross-ratio comparison is consumed as a boundary-distance statement. This route keeps Mobius-invariant comparison, logarithmic readback, visual boundary distance, transport, replay, provenance, and local naming in the displayed hyperbolic boundary ledger.

Chapter 2972

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion, Kelley on filters, and Mac Lane on functorial transport, the $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$ packet records the finite route that transports regular Cauchy filter data into stream-indexed real seals. It reads the regular filter surface of chapter 1445, the Cauchy filter basis and saturation surfaces of chapter 1501 and chapter 333, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion-functor route of chapter 423. The packet names the transport surface only; it does not quotient filters, select limits, identify host real objects, or use ambient completeness.

Definition 2972.1 (RegularCauchyFilterFunctor carrier)**.** *A* $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, B, W, D, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *I is the regular Cauchy filter index row, reading the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *source packet and its displayed filter-indexed tail data.*
2. *B is the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row, including the finite basis and saturation route used before any stream window is inspected.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the requested windows obtained from the filter-indexed source.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after W and D are displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the filter, window, tolerance, and readback rows have been replayed.*
7. *A is the functorial action ledger, recording source-map action on displayed filter indices and target-map action on the induced stream windows, readbacks, tolerances, and seals.*
8. *H records componentwise* hsame *transport for I, B, W, D, R, E, A and for the structural rows below.*

9. *C records displayed* Cont *replay for the route from regular Cauchy filter indices through CauchyFilter basis data, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, and action ledger.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, W, D, R, E, A, H, C, P, N$. There is no coordinate for quotient filters, selected representatives, host equality of filters, host equality of reals, countable choice, or detached completion points.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterFunctorUp.RegularCauchyFilterFunctorTasteGate single carrier alignment`

Theorem 2972.2 (RegularCauchyFilterFunctor NameCert obligations)**.** *For every accepted* RegularCauchyFilterFu *carrier*

$$F = (I, B, W, D, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; regular Cauchy filter source exposure through I; CauchyFilter basis and saturation exposure through B; finite-window exposure through W; dyadic tolerance exactness through D; regular-rational readback through R; Real seal handoff through E; functorial action bookkeeping through A; and structural transport, replay, provenance, and local naming through H, C, P, N. No obligation is discharged by quotienting filters, choosing representatives, identifying host real objects, or importing ambient completeness.*

Proof. Project the carrier of Definition 3949.1. The accepted packet displays exactly the source index row, basis row, window row, tolerance row, readback row, seal row, action ledger, and structural rows.

The source side is exhausted by I and B. The regular Cauchy filter row supplies the filter-indexed tail data, while the CauchyFilter basis row supplies the finite basis and saturation surface before any stream-indexed consumer can inspect the packet.

The target side is exhausted by W, D, R, E. The finite windows are read first, the dyadic tolerance ledger is attached to those windows, the RegSeqRat row reads back the regular rational data, and the Real seal remains downstream from the displayed route.

The action and structural rows do not add hidden objects. The ledger A records how displayed source-map action is replayed as target-map action on W, D, R, E, while H, C, P, N transport, replay, package, and name the same finite surface. Hence the listed rows are the whole local NameCert obligation surface. □

Theorem 2972.3 (RegularCauchyFilterFunctor filter-to-stream route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegularCauchyFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer reads I, then B, then W and D, then R, then E, with the functorial action ledger A and the structural rows H, C, P, N preserving this order. No second real-facing route is available inside the carrier.

Proof. Start with the Real-facing coordinate. The row E is not detached from the packet; it is stored only after the source index, filter basis, finite windows, dyadic tolerances, and regular-rational readback have been displayed.

Read the route in order. The source packet contributes I, the CauchyFilter basis and saturation data contribute B, the stream-indexed finite observations contribute W, the tolerance checks contribute D, and the regular-rational readback contributes R.

Now inspect the action ledger. The row A records that source-map action on filter indices is replayed on the displayed window, tolerance, readback, and seal rows, so the functorial transport does not introduce a selected limit or a host equality principle.

Finally the transport, replay, provenance, and local naming rows certify the same route. Since the carrier has no other Real seal coordinate and no quotient-filter coordinate, every Real-facing consumer factors through the listed finite chain. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$ read is refuted if a RealUp seal is reached without displaying the RegularCauchyFilter, CauchyFilter, StreamName, DyadicRatCore, RegSeqRat, functorial action, transport, replay, provenance, and local naming rows.

Independence witness: regularcauchyfilter, cauchyfilter, streamname, regseqrat, dyadicratcore, real, and cauchycompletionfunctor: none is bijective to the functor packet because only $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$ records filter-index source action and stream-index target action together with one Real seal route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFilterFunctor}^{\uparrow}$ packet is generated from a regular Cauchy filter index row, CauchyFilter basis row, StreamName finite-window row, DyadicRatCore tolerance row, RegSeqRat readback row, RealUp seal row, functorial action ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3949.1, Definition 3949.2, and Definition 3949.3 seed the finite filter-indexed route from RegularCauchyFilter and CauchyFilter data through StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and RealUp seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected representatives, host equality of filters, host equality of reals, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-index source exposure, CauchyFilter basis exposure, window and tolerance routing, RegSeqRat readback, Real seal handoff, functorial action, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFilterFunctorUp.

Chapter 2973

A Concrete Naming Certificate for ArzelaAscoliFiniteEquicontinuous$^{\uparrow}$

Following Arzela, Ascoli, and Bishop–Bridges constructive compactness, the ArzelaAscoliFiniteEquicontinuous$^{\uparrow}$ packet records the finite extraction surface where equicontinuity and compact finite nets are read before a sequence-window consumer reaches a real seal. It sits downstream of the finite interval-net route of chapter 3471, the modulus composition route of chapter 3784, the compact uniform modulus extractor of chapter 2202, the convergent-sequence boundary of chapter 3944, the located Cauchy subsequence route of chapter 3945, the dyadic tolerance core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the real seal of chapter 38. The chapter names only the finite equicontinuous extraction packet; it does not assert open-cover compactness, selected infinite subsequence choice, quotient stream equality, countable choice, host real equality, or ambient Real$^{\uparrow}$ completeness.

Definition 2973.1 (Arzela–Ascoli finite equicontinuous carrier)**.** *An* ArzelaAscoliFiniteEquicontinuous$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, E, U, M, D, W, Q, L, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net source row, read through the* HeineBorelFiniteNet$^{\uparrow}$ *and compact-metric finite-net data already visible to the packet.*
2. *E is the finite equicontinuity-modulus row, assigning each displayed target tolerance a displayed source radius uniformly over the inspected family.*
3. *U is the* UniformModulusComposition$^{\uparrow}$ *and* CompactUniformModulusExtractor$^{\uparrow}$ *compatibility row, recording that the compact finite-net and equicontinuity ledgers use the same tolerance requests.*
4. *M is the diagonal or finite-window subsequence row, exposed only as the finite window data consumed by* RealConvergentSequence$^{\uparrow}$ *and* LocatedCauchySubsequence$^{\uparrow}$ *routes.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for source radii, target tolerances, mesh slack, and comparison budgets.*
6. *W is the finite* StreamName$^{\uparrow}$ *window row naming the inspected source points, function-family indices, and target observations.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the rational observations on W.*

8. *L is the located convergence-window row used by the* LocatedCauchySubsequence$^{\uparrow}$ *consumer.*
9. *S is the terminal* Real$^{\uparrow}$ *seal row, available only after K, E, U, M, D, W, Q, L have been displayed.*
10. *H records componentwise* hsame *transport for all source, modulus, window, readback, located, seal, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from a finite extraction request through $K, E, U, M, D, W, Q, L, S$.*
12. *P is the* Pkg *provenance over* ArzelaAscoliFiniteEquicontinuous$^{\uparrow}$, HeineBorelFiniteNet$^{\uparrow}$, UniformModulusCompositi CompactUniformModulusExtractor$^{\uparrow}$, RealConvergentSequence$^{\uparrow}$, LocatedCauchySubsequence$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, E, U, M, D, W, Q, L, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected infinite subsequence choice, quotient stream equality, countable choice, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ArzelaAscoliFiniteEquicontinuousUp.ArzelaAscoliFiniteEquicontinuousTasteGate`
`single carrier alignment`

Theorem 2973.2 (Arzela–Ascoli finite equicontinuous obligations)**.** *For every accepted* ArzelaAscoliFiniteEquiconti *carrier*

$$A = (K, E, U, M, D, W, Q, L, S, H, C, P, N),$$

the local NameCert$_{\text{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact finite-net row, equicontinuity modulus row, compact-modulus compatibility row, finite diagonal window, dyadic tolerance ledger, stream windows, rational readback, located convergence window, real seal, transport, replay, provenance, and local naming rows;*
2. *compact-net exposure, requiring every source point used by the extraction to be read through the displayed* HeineBorelFiniteNet$^{\uparrow}$ *finite-net data before any target observation is consumed;*
3. *equicontinuity visibility, requiring the shared source-radius row E and compatibility row U to be displayed before the diagonal window M can be read;*
4. *L10 readback order, requiring the dyadic tolerance ledger, stream windows, regular rational readback, located Cauchy window, and terminal Real seal to appear in the order D, W, Q, L, S;*
5. *non-escape, requiring H, C, P, N to transport, replay, source, and name only these finite rows and to export no open-cover compactness, selected infinite subsequence choice, quotient stream equality, countable choice, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3950.1. The packet exposes the compact finite-net source, equicontinuity modulus, compact-modulus compatibility row, finite diagonal window, tolerance ledger, stream windows, rational readback, located convergence row, real seal, and structural rows as one finite BHist object.

Compact-net exposure is the row K. A consumer must first read the finite net and coverage witnesses supplied by the Heine–Borel finite-net route, so the source compactness input is a displayed finite object rather than an arbitrary open cover.

Equicontinuity visibility is supplied by E and U. The requested target tolerance is converted into a displayed source radius, and the compact uniform modulus row records that the same tolerance budget is used by the finite-net and diagonal-window reads.

The L10 readback order is then forced by the packet coordinates. The diagonal window M can be inspected only through D, W, Q, L, and the terminal row S is downstream of those dyadic, stream, rational, and located Cauchy rows.

Finally, H, C, P, N preserve that row inventory. Since the carrier has no coordinate for open-cover compactness, selected infinite subsequence choice, quotient stream equality, countable choice, host real equality, or ambient Real completeness, none of those objects can be exported by the local naming surface. □

Falsifiable prediction: Every $\mathsf{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}$ consumer read that reaches $\mathsf{Real}^{\uparrow}$ first displays compact finite-net rows, equicontinuity finite modulus rows, compact-modulus compatibility rows, a finite diagonal window, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, and located Cauchy window rows.

Independence witness: heineborelfinet, uniformmoduluscomposition, compactuniformmodulusextractor, realconvergentsequence, locatedcauchysubsequence, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}$ because this packet jointly carries compact finite-net exposure, equicontinuity-radius visibility, compact-modulus compatibility, diagonal-window data, dyadic tolerances, stream windows, rational readback, located convergence rows, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}}$.

Constructive story: An $\mathsf{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}$ packet is generated from compact finite-net rows, equicontinuity finite modulus rows, compact-modulus compatibility, a finite diagonal or subsequence window, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, LocatedCauchySubsequence rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3950.1 and Definition 3950.2 seed the finite equicontinuous extraction packet consumed by L10 compact-continuous and Real-completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteEquicontinuous}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected infinite subsequence choice, quotient stream equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, equicontinuity visibility, L10 readback order, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.ArzelaAscoliFiniteEquicontinuousUp.

Chapter 2974

A Concrete Naming Certificate for $\mathsf{PoissonSummation}^{\uparrow}$

Following Poisson and Fourier analysis, the $\mathsf{PoissonSummation}^{\uparrow}$ packet is a finite BEDC route from lattice-indexed source windows through Fourier finite-observation rows and distribution-facing summation rows. It sits over the finite coefficient interface of chapter 124, the lattice source of chapter 55, the pushforward and test-row boundary of chapter 186, and the terminal real readback of chapter 38. The packet names a finite summation certificate; it does not import analytic convergence, host function equality, Schwartz-space quotients, Haar measure, or an infinite series oracle.

Definition 2974.1 (Poisson summation finite carrier)**.** *A* $\mathsf{PoissonSummation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, F, D, S, R, H, C, P, N)$$

with the following displayed coordinates.

1. *L is the* $\mathsf{Lattice}^{\uparrow}$ *row naming the finite lattice index window, dual-window tags, and shift ledger used by the summation read.*
2. *F is the* $\mathsf{Fourier}^{\uparrow}$ *row naming the finite coefficient and frequency observations made over the displayed lattice window.*
3. *D is the* $\mathsf{Distribution}^{\uparrow}$ *and test-function row through which the finite Fourier observations are read as distribution-facing data.*
4. *S is the finite summation-window row, recording the source-side and dual-side partial sums inspected by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback surface for the displayed summation comparison.*
6. *H records componentwise* hsame *transport for lattice, Fourier, distribution, summation-window, and real-readback rows.*
7. *C records displayed* Cont *replay from lattice windows through Fourier observations, distribution rows, finite summation, and readback.*
8. *P is the* Pkg *provenance over* $\mathsf{PoissonSummation}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PoissonSummation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine displayed rows. It has no coordinate for analytic convergence, equality of host functions, an infinite summation theorem, Schwartz-space quotient equality, Haar measure, or a selected distribution representative.

Lean4 ✓ `BEDC.Derived.PoissonSummationUp.PoissonSummationTasteGate single carrier alignment`

Theorem 2974.2 (Poisson summation NameCert obligations)**.** *For every accepted* $\mathsf{PoissonSummation}^{\uparrow}$ *carrier* $Q = (L, F, D, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PoissonSummation}^{\uparrow}}$ *surface consists exactly of carrier admission for* Q*, lattice-window admission through* L*, finite Fourier observation through* F*, distribution-facing test-row admission through* D*, finite source and dual summation-window comparison through* S*,* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback through* R*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.PoissonSummationUp.PoissonSummationNamecertObligations`

Proof. Project the carrier of Definition 3951.1. The analytic surface is exhausted by the lattice row, Fourier row, distribution-facing row, summation-window row, and readback row.

Read L, F, D, S in order. The lattice window determines the finite source and dual indices, the Fourier row records only the inspected frequency observations, the distribution row supplies the test-facing interpretation, and the summation row compares the two displayed finite windows.

The rows R, H, C, P, N then seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for convergence, host function equality, quotient spaces, Haar measure, or selected representatives, none of those objects is part of the local NameCert surface. □

Theorem 2974.3 (Poisson summation Fourier-lattice route)**.** *Every accepted* $\mathsf{PoissonSummation}^{\uparrow}$ *read factors through the displayed route*

$$\mathsf{Lattice}^{\uparrow} \longmapsto \mathsf{Fourier}^{\uparrow} \longmapsto \mathsf{Distribution}^{\uparrow} \longmapsto S \longmapsto \mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}.$$

Thus a downstream consumer receives only finite lattice windows, finite Fourier observations, distribution-facing test rows, finite summation windows, real readback, transport, replay, provenance, and local naming.

Proof. Begin with the lattice coordinate L of Definition 3951.1. It supplies the only source of summation indices and dual-window tags.

Apply the Fourier and distribution coordinates F and D. They expose finite coefficient observations and test-facing rows before the summation window S can be compared.

Finally pass through R, H, C, P, N. The regular and real readback rows seal the finite comparison, while transport, replay, provenance, and naming preserve the route without adding analytic convergence or host equality. □

Falsifiable prediction: Every accepted $\mathsf{PoissonSummation}^{\uparrow}$ read factors through lattice windows, Fourier finite observations, distribution-facing test rows, finite summation windows, $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ readback, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Independence witness: lattice, fourier, distribution, real: $\mathsf{PoissonSummation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lattice windows, Fourier observations, distribution-facing test rows, finite source and dual summation windows, readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PoissonSummation}^{\uparrow}}$**.**

Constructive story: A PoissonSummation$^{\uparrow}$ packet is generated from a LatticeUp window row, a FourierUp finite-observation row, a DistributionUp test-facing row, a finite summation-window comparison, RegSeqRatUp and RealUp readback, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PoissonSummation}^{\uparrow}}$, seed)

Scope closed: Definition 3951.1, Definition 3951.2, and Definition 3951.3 seed the finite Fourier-lattice summation packet over lattice, Fourier, distribution, and real-readback rows.

Formal verification: FormalStatus(NameCert$_{\text{PoissonSummation}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.PoissonSummationUp.PoissonSummationTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim analytic convergence, host function equality, Schwartz-space quotients, Haar measure, infinite summation theorems, or bridge checking.

Upgrade path: A formal route can prove the NameCert obligation surface and Fourier-lattice route theorem.

Chapter 2975

A Concrete Naming Certificate for $\mathsf{RealDecimalNormalForm}^{\uparrow}$

Following Bishop and Bridges on constructive real approximants and the classical decimal expansion normalization convention, the $\mathsf{RealDecimalNormalForm}^{\uparrow}$ packet records the finite readback surface by which a displayed $\mathsf{Real}^{\uparrow}$ name is presented through decimal prefixes. It sits after the decimal-prefix route of chapter 1417, the integer bracket route of chapter 1479, the rational naming surface of chapter 37, the dyadic tolerance surface of chapter 291, the regular-rational handoff of chapter 301, and the terminal seal discipline of chapter 38. The packet names a canonical decimal readback route only; it does not choose a quotient representative, compare host real streams, or import ambient real completeness.

Definition 2975.1 (RealDecimalNormalForm carrier)**.** *A* $\mathsf{RealDecimalNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, I, Q, Y, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DecimalExpansion}^{\uparrow}$ *prefix ledger, including finite digit rows and decimal-place windows.*
2. *I is the* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row that fixes the integer-part surface used by the decimal readback.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *place-value row that evaluates each inspected decimal prefix as a rational expression.*
4. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same prefix and bracket data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained after the decimal, bracket, rational, and dyadic rows are displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row whose name is read only after D, I, Q, Y, R have been exposed.*
7. *H records componentwise* hsame *transport for decimal-prefix, integer-part, rational, dyadic, regular-rational, and real-seal rows.*
8. *C records displayed* Cont *replay for the route from decimal prefix windows through integer brackets, place values, tolerances, regular readback, and the terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RealDecimalNormalForm}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealDecimalNormalForm}^{\uparrow}}$ *row.*

The classifier for the packet compares accepted decimal normal-form reads only through $D, I, Q, Y, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, trichotomy over arbitrary real names, host decimal reals, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RealDecimalNormalFormUp.RealDecimalNormalFormTasteGate single carrier alignment`

Theorem 2975.2 (RealDecimalNormalForm NameCert obligations)**.** *For every accepted* $\mathsf{RealDecimalNormalForm}^{\uparrow}$ *carrier*

$$M = (D, I, Q, Y, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealDecimalNormalForm}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the displayed decimal-prefix, integer-bracket, rational place-value, dyadic tolerance, regular-rational handoff, real-seal, transport, replay, provenance, and local naming rows;*
2. *digit legality and place-value exactness, requiring every accepted digit row in D to be a decimal digit and every inspected prefix to be evaluated through the rational row Q;*
3. *endpoint normalization, requiring the ledger to exclude the eventual-nine route before a decimal read is treated as normal-form data;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring R to be reached only after the decimal, integer-bracket, rational, and dyadic rows have been displayed;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring every real-facing consumer to read E through the same $D, I, Q, Y, R, H, C, P, N$ route.*

No obligation is discharged by quotienting streams, selecting endpoint representatives, deciding trichotomy for all real names, or using ambient real completeness.

Lean4 ✓ `BEDC.Derived.RealDecimalNormalFormUp.RealDecimalNormalFormCarrier namecert obligation surface`

Proof. Project the carrier of Definition 3952.1. The displayed rows $D, I, Q, Y, R, E, H, C, P, N$ are the whole packet, so carrier admission is rowwise.

Digit legality and place-value exactness are read from D and Q. The decimal-prefix ledger supplies only finite digit rows and windows, while the rational row Q evaluates those windows before any dyadic or real-facing consumer can inspect them.

Endpoint normalization is local to the same finite ledger. The non-eventual-nine condition is recorded before the regular-rational handoff, so the packet does not identify two host decimal streams or select an endpoint representative.

The handoff and seal clauses follow the order of the remaining coordinates. The dyadic row Y is attached to the same prefix and bracket data, the regular-rational row R is downstream of D, I, Q, Y, and the terminal real seal E is downstream of R with H, C, P, N preserving the route. □

Theorem 2975.3 (RealDecimalNormalForm Real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{RealDecimalNormalForm}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{ArchimedeanIntegerPart}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads decimal prefix rows, then the integer-part bracket rows, then the rational place-value rows, then dyadic tolerance rows, then the regular-rational handoff, and only then the terminal $\mathsf{Real}^{\uparrow}$ *seal. The packet supplies no quotient stream equality, selected representative, trichotomy row, host decimal real, or ambient completeness.*

Proof. Start with an accepted packet $M = (D, I, Q, Y, R, E, H, C, P, N)$. The decimal rows D are already finite prefix rows, and I supplies the integer bracket that fixes the readback surface before place-value evaluation is exposed.

Now read the arithmetic rows. The rational row Q evaluates the inspected prefixes, and the dyadic row Y translates the same values into the tolerance discipline used by regular-rational and real consumers.

Apply the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row R. It is listed only after the decimal, integer-bracket, rational, and dyadic rows, so no consumer can reach the regular-rational readback without displaying that route.

Finally read the terminal seal E and the structural rows H, C, P, N. These rows transport, replay, source, and name the same finite route, and none of them is a quotient equality, selected representative, trichotomy decision, host decimal real, or completeness object. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealDecimalNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{RealDecimalNormalForm}^{\uparrow}$ packet is generated from DecimalExpansion prefix rows, ArchimedeanIntegerPart bracket rows, Rat place-value rows, DyadicRatCore tolerance rows, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealDecimalNormalForm}^{\uparrow}}$, seed)

Scope closed: Definition 3952.1, Definition 3952.2, and Definition 3952.3 seed the finite canonical decimal readback route from DecimalExpansion and ArchimedeanIntegerPart data through Rat, DyadicRatCore, RegSeqRat, and RealUp seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealDecimalNormalForm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close uniqueness of all decimal expansions, quotient stream equality, selected representatives, trichotomy over arbitrary real names, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, digit legality, place-value exactness, endpoint-normalization ledger exhaustion, RegSeqRat handoff, and RealUp seal nonescape for BEDC.Derived.RealDecimalNormalFormUp.

Chapter 2976

A Concrete Naming Certificate for $\mathsf{CauchyModulusNormalizer}^{\uparrow}$

Following Bishop–Bridges constructive analysis with explicit Cauchy moduli, the $\mathsf{CauchyModulusNormalizer}^{\uparrow}$ packet records the finite route by which a displayed Cauchy threshold schedule is normalized before StreamName, RegSeqRat, DyadicRatCore, and RealUp seal consumers may read it. It sits next to the fast Cauchy criterion of chapter 3825, the monotone normalization surface of chapter 1744, the StreamName carrier of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the Real seal of chapter 38. The packet is a finite normalizer certificate for Real and Completion routes; it is not Real completeness, quotient completion, quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or a standard bridge.

Definition 2976.1 (Cauchy modulus normalizer carrier)**.** *A* $\mathsf{CauchyModulusNormalizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (X, M, F, D, W, Q, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source row, read through a* $\mathsf{FastCauchyCriterion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, or* $\mathsf{RegSeqRat}^{\uparrow}$ *Cauchy-window surface.*
2. *M is the input Cauchy modulus row, assigning displayed tail thresholds to requested dyadic tolerances.*
3. *F is the finite normalization table, recording prefix maxima or equivalent displayed threshold joins for the finitely many tighter requests visible to the packet.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for precision requests, slack conversions, and positivity checks consumed by M and F.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row available after the normalized threshold has been displayed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations exposed on W.*
7. *S is the normalized Cauchy-window seal row saying that the readback admitted after F is already admitted by the input modulus row M at the requested tolerance.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after X, M, F, D, W, Q, S have been displayed.*

9. *H records componentwise* hsame *transport for the source, input modulus, normalization table, dyadic ledger, windows, readback, Cauchy-window seal, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a precision request through X, M, D, F, W, Q, S, R.*

11. *P is the* Pkg *provenance over* CauchyModulusNormalizer$^{\uparrow}$, FastCauchyCriterion$^{\uparrow}$, CauchyModulusMonotoneNormal StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{CauchyModulusNormalizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, F, D, W, Q, S, R, H, C, P, N$. It has no coordinate for Real completeness, quotient completion, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or bridge checking.

Theorem 2976.2 (Cauchy modulus normalizer NameCert obligations)**.** *For every accepted* CauchyModulusNormali *carrier*

$$Z = (X, M, F, D, W, Q, S, R, H, C, P, N),$$

the local NameCert$_{\text{CauchyModulusNormalizer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source, input modulus, finite normalization table, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, Cauchy-window seal, Real seal, transport, replay, provenance, and local naming rows;*

2. *modulus-source exposure, requiring the source row X and input modulus row M to be displayed before the normalizer table F is read;*

3. *finite normalization exactness, requiring F to read only finitely many tolerance requests from D and threshold rows from M;*

4. *window-readback order, requiring StreamName windows, RegSeqRat readback, and the Real seal to appear downstream of the normalized threshold route as W, Q, S, R;*

5. *non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed normalizer rows and to export no Real completeness, quotient completion, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or bridge datum.*

No Cauchy-modulus-normalizer obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyModulusNormalizerUp.CauchyModulusNormalizerTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 3953.1. The accepted packet exposes the source row, input modulus, finite normalization table, dyadic tolerance ledger, stream windows, rational readback, Cauchy-window seal, Real seal, and structural rows as one finite carrier.

Modulus-source exposure is the order of the displayed packet. A consumer cannot inspect F until the source row X, input threshold schedule M, and dyadic tolerance ledger D have fixed the finite requests being normalized.

Finite normalization exactness is finite because F reads only the displayed tolerance requests in D and their corresponding thresholds in M. This is the same constructive modulus-normalization discipline used by the monotone normalization packet, but here it is packaged as the normalizer boundary immediately before downstream window reads.

The window-readback order follows from the coordinates W, Q, S, R. StreamName observations are read after the normalized threshold, RegSeqRat readback records the rational observations, the

Cauchy-window seal S checks preservation against M, and the terminal Real seal R is downstream of those rows.

Finally, H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier has no coordinate for Real completeness, quotient completion, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or bridge data, none of those objects can become a local NameCert obligation. □

Falsifiable prediction: Every $\mathsf{CauchyModulusNormalizer}^{\uparrow}$ consumer read factors through a source row, an input Cauchy modulus row, a finite normalization table, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a Cauchy-window seal, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: fastcauchycriterion, cauchymodulusmonotonenormalization, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{CauchyModulusNormalizer}^{\uparrow}$ because this packet jointly carries the source, input modulus, finite normalization table, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, Cauchy-window preservation seal, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusNormalizer}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusNormalizer}^{\uparrow}$ packet is generated from a Cauchy-window source row, an input Cauchy modulus row, a finite normalization table, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, a preservation seal, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusNormalizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3953.1 and Definition 3953.2 seed the finite modulus-normalizer packet used before StreamName, RegSeqRat, DyadicRatCore, and RealUp seal reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusNormalizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient completion, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-source exposure, finite normalization exactness, window-readback order, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusNormalizerU

Chapter 2977

A Concrete Naming Certificate for $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$

The $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ packet realizes the total-host and universal-substrate separation of chapter 9370 as finite NameCert data. It sits between the neutral-spine comparison surface of chapter 3909, the bounded fuel trace of chapter 3889, the normal-form readback of chapter 936, the substrate trace boundary of chapter 944, and the total-host fuel discipline of chapter 964. The packet records the boundary at which host normalization evidence remains total while substrate universality remains fuel-indexed and external to the host evaluator.

Definition 2977.1 (MetaCIC strong-normalization boundary carrier)**.** *A* $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, F, Z, U, T, R, H, C, P, N)$$

with the following displayed rows.

1. *S is the* $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$ *row carrying the typed neutral-spine comparison route.*
2. *F is the* $\mathsf{MetaCICFuelTrace}^{\uparrow}$ *row carrying bounded normalizer fuel, endpoints, equality-check readback, and refusal data.*
3. *Z is the* $\mathsf{ZNormal}^{\uparrow}$ *row carrying normal-form and total-host readback evidence.*
4. *U is the* $\mathsf{BoundedUniversalTrace}^{\uparrow}$ *row carrying the fuel-indexed substrate trace.*
5. *T is the* $\mathsf{StepIndexedTotalHost}^{\uparrow}$ *row carrying total-host fuel discipline and step-indexed readback.*
6. *R is the refusal row stating that substrate universality is not re-exported as host nontermination or global conversion decidability.*
7. *H records componentwise* hsame *transport for spine, fuel, normal-form, substrate-trace, total-host, and refusal rows.*
8. *C records displayed* Cont *replay from total-host fuel through bounded trace and normal-form readback.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$, $\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}$, $\mathsf{MetaCICFuelTrace}^{\uparrow}$, $\mathsf{ZNormal}^{\uparrow}$, $\mathsf{BoundedUniversalTrace}^{\uparrow}$, $\mathsf{StepIndexedTotalHost}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host nontermination, global conversion decidability, an unbounded substrate run, a selected normalization proof, semantic equality, or a collapse of substrate universality into the total host.

Lean4 ✓ `BEDC.Derived.MetaCICStrongNormalizationBoundaryUp.MetaCICStrongNormalizationBoundaryTasteGate single carrier alignment`

Theorem 2977.2 (MetaCIC strong-normalization boundary NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ *carrier* $B = (S, F, Z, U, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for* B*, neutral-spine admission through* S*, fuel-trace admission through* F*, normal-form readback through* Z*, bounded substrate-trace admission through* U*, total-host fuel discipline through* T*, Turing-refusal exposure through* R*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3954.1. The host-facing rows are S, F, Z, T, the substrate-facing row is U, and the boundary refusal is R.

Read the host rows first. The neutral-spine, fuel-trace, normal-form, and step-indexed total-host rows give only finite fuel, endpoint, and readback evidence.

Read the substrate row through U and then the refusal row R. Bounded substrate universality remains fuel-indexed, and the refusal row prevents that universality from becoming host nontermination or global conversion decidability.

The rows H, C, P, N transport, replay, source, and name the same boundary. Since the carrier contains no host nontermination, unbounded trace, selected normalization proof, semantic equality, or global conversion theorem, none of those objects is exported. □

Theorem 2977.3 (MetaCIC strong-normalization boundary Turing-refusal route)**.** *Every substrate-universality read of an accepted* $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MetaCICDecidableNeutralSpine}^{\uparrow}, \mathsf{MetaCICFuelTrace}^{\uparrow}, \mathsf{ZNormal}^{\uparrow}, \mathsf{StepIndexedTotalHost}^{\uparrow} \longmapsto \mathsf{BoundedUniversalTrace}^{\uparrow}$$

Thus the packet preserves total-host normalization evidence while refusing to turn the bounded universal substrate trace into host nontermination, unbounded evaluation, or global conversion decidability.

Proof. Begin with the host-facing coordinates S, F, Z, T of Definition 3954.1. They expose only typed neutral-spine comparison, bounded normalizer fuel, normal-form readback, and step-indexed total-host rows.

Move to the substrate coordinate U. It supplies a bounded universal trace as a finite row, not an unbounded run and not a host evaluator.

Finally apply the refusal coordinate R and preserve it through H, C, P, N. The refusal row is part of the same carrier, so any read that keeps substrate universality must also keep the boundary that blocks host nontermination and global conversion claims. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ packet displays neutral-spine, finite fuel, normal-form, bounded universal trace, step-indexed total-host, refusal, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows before any consumer reads the total-host and universal-substrate boundary.

Independence witness: metacic-decidable-neutral-spine, metacic-fuel-trace, znormal, bounded-universal-trace, step-indexed-total-host: no listed sibling is bijective to $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ because this packet jointly carries neutral-spine comparison, finite fuel trace, normal-form read-back, bounded substrate trace, total-host fuel discipline, refusal, transport, replay, provenance, and local naming in one boundary carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ packet is generated from MetaCICDecidableNeutralSpineUp, MetaCICFuelTraceUp, ZNormalUp, BoundedUniversalTraceUp, and StepIndexedTotalHostUp rows, together with a Turing-refusal row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3954.1, Definition 3954.2, and Definition 3954.3 seed the finite MetaCIC boundary between total-host normalization evidence and bounded substrate universality.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host nontermination, unbounded substrate evaluation, global conversion decidability, semantic equality, Lean verification, bridge checking, or a collapse of substrate universality into total-host computation.

Upgrade path: A formal route can encode the finite carrier, prove the NameCert obligation surface and Turing-refusal route, and add TasteGate Nontrivial and FieldFaithful instances.

Chapter 2978

A Concrete Naming Certificate for $\mathsf{CofinalFilter}^{\uparrow}$

Following Kelley and Bourbaki on cofinal filters, the $\mathsf{CofinalFilter}^{\uparrow}$ packet records the finite corridor by which a downstream filter or completion consumer reads a target filter through a displayed cofinal source route. It sits between the finite base surface of chapter 1601, the Cauchy-filter route of chapter 333, the refinement corridor of chapter 1626, the uniform-completion consumer of chapter 1473, and the metric-completion consumer of chapter 1506. The packet records cofinal comparison data without quotient filters, selected representatives, selected limits, ultrafilters, countable choice, Zorn arguments, or ambient completeness.

Definition 2978.1 (CofinalFilter carrier)**.** *A* $\mathsf{CofinalFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, \rho, \lambda, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{FilterBase}^{\uparrow}$ *row whose displayed packets answer the downstream request after cofinal replacement.*
2. *T is the target* $\mathsf{FilterBase}^{\uparrow}$ *row named by the consumer before the cofinal route is read.*
3. *ρ is the cofinal map row, sending every displayed target request to a source packet contained in that target request.*
4. *λ is the reverse ledger when route equivalence is needed. It records the finite reverse containment and common-refinement reads, and it is absent when only one-way cofinal consumption is claimed.*
5. *Q is the completion handoff row consumed by* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$ *readers after the cofinal comparison rows have been displayed.*
6. *H records componentwise* hsame *transport for $S, T, \rho, \lambda, Q, C, P, N$.*
7. *C records displayed* Cont *replay from a target request through ρ, through the source base packet, through λ when present, and then through the completion handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{CofinalFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterRefinement}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filter equality, ultrafilter extension, selected representatives, selected limits, countable choice, Zorn arguments, host filter equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CofinalFilterUp.TasteGate.CofinalFilterTasteGate single carrier alignment`

Theorem 2978.2 (CofinalFilter NameCert obligations)**.** *For every accepted* $\mathsf{CofinalFilter}^{\uparrow}$ *carrier* $F = (S, T, \rho, \lambda, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the source and target* $\mathsf{FilterBase}^{\uparrow}$ *rows, the cofinal map row, the reverse ledger when equivalence is requested, the completion handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted consumer request must expose* T, ρ, S *and the relevant ledger rows before* Q *is available.*

Proof. Project the carrier of Definition 3955.1. The rows S and T display the source and target filter bases, while ρ is the only row that moves a target request to a source packet.

The ledger row λ is conditional on equivalence use. When the consumer asks only for one-way cofinal replacement it is not read; when equivalence is claimed it supplies exactly the reverse containment and common-refinement entries needed for that claim.

The completion handoff row Q is downstream of this comparison. Transport through H and replay through C preserve the same finite order, and P, N source and name the route. Since the excluded quotient, ultrafilter, selector, choice, Zorn, host-equality, and completeness objects are absent from the carrier, no further NameCert obligation is available. □

Theorem 2978.3 (CofinalFilter completion handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CofinalFilter}^{\uparrow}$ *packet reads completion-facing data only through*

$$T \longmapsto \rho \longmapsto S \longmapsto \lambda, Q, H, C, P, N.$$

Thus the completion corridor factors through the displayed cofinal-filter rows and the sibling $\mathsf{FilterRefinement}^{\uparrow}$ *discipline before any completion request is answered. It exports no quotient filter, selected representative, selected limit, ultrafilter, countable-choice schedule, Zorn argument, host filter equality, or ambient completeness row.*

Proof. Begin with a completion-facing request. The consumer names a target filter base row T, so the carrier forces the request through the cofinal map row ρ before any source packet can be read.

Apply Definition 3955.2. The source row S supplies the displayed packet answering the target request, while λ is read only when the consumer needs the reverse comparison ledger required by the refinement discipline.

The handoff row Q is therefore reached after the finite cofinal comparison. Componentwise transport, continuation replay, provenance, and local naming preserve that same route for $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ consumers. No excluded quotient, selector, choice, Zorn, host-equality, or completeness coordinate is exported. □

Falsifiable prediction: If a completion-facing read cites $\mathsf{CofinalFilter}^{\uparrow}$ while bypassing the displayed target row, cofinal map, source row, required reverse ledger, completion handoff, hsame transport, Cont replay, Pkg provenance, or local NameCert row, it is not an accepted $\mathsf{CofinalFilter}^{\uparrow}$ packet.

Independence witness: Nearest siblings: filterbase, cauchyfilter, filter-refinement, uniformcompletion, metriccompletion; $\mathsf{CofinalFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly

records a target base, source base, cofinal map, optional reverse ledger, completion handoff, transport, continuation, provenance, and local naming in one finite corridor.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalFilter}\uparrow}$.

Constructive story: A $\mathsf{CofinalFilter}^{\uparrow}$ packet is generated from source and target FilterBase rows, a cofinal map, a reverse ledger when equivalence is requested, a completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalFilter}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3955.1, Definition 3955.2, and Definition 3955.3 seed the finite cofinal-filter corridor between filter bases, filter refinement, CauchyFilter, UniformCompletion, and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalFilter}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filter equality, selected representatives, selected limits, ultrafilters, countable choice, Zorn arguments, host filter equality, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, cofinal map exactness, reverse-ledger compatibility, completion handoff non-escape, transport stability, replay stability, and ledger-refusal proofs for BEDC.Derived.CofinalFilterUp.

Chapter 2979

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion, the $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ packet records the functorial route from metric source data to regular Cauchy real seals. It sits over the metric source of chapter 57, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the metric-completion surface of chapter 1506, and the completion action of chapter 423. The packet names the source-map and composition ledgers needed by completion consumers; it does not select representatives, quotient regular Cauchy names, identify host real objects, or import ambient completeness.

Definition 2979.1 (RegularCauchyCompletionFunctor carrier)**.** *A* $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, U, W, Q, R, E, I, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the source and target metric naming certificates and their distance ledgers.*
2. *U is the uniformly continuous map row between the displayed metric sources, with modulus and graph rows readable before completion is inspected.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording the source windows requested by a regular Cauchy input name.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same finite windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *completion-name row obtained from W and Q.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the metric, map, finite-window, tolerance, and regular-rational rows have been displayed.*
7. *I is the identity ledger, saying that the identity uniformly continuous map replays the same windows, tolerances, readback rows, and real seal.*
8. *A is the composition ledger, saying that two displayed uniformly continuous map rows compose by replaying the source windows through the intermediate and target completion rows in order.*
9. *H records componentwise* hsame *transport for M, U, W, Q, R, E, I, A and for the structural rows below.*

10. *C records displayed* Cont *replay from metric source rows and uniformly continuous map rows through StreamName windows, DyadicRatCore tolerances, RegSeqRat completion names, RealUp seals, identity ledgers, and composition ledgers.*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, W, Q, R, E, I, A, H, C, P, N$. There is no coordinate for a selected limit, quotient-name equality, host equality of real objects, global completeness, or an external functor object detached from the displayed rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionFunctorUp.RegularCauchyCompletionFunctorTasteGate`
`single carrier alignment`

Theorem 2979.2 (RegularCauchyCompletionFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ *carrier*

$$F = (M, U, W, Q, R, E, I, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}}$ *surface consists exactly of metric source admission through M; uniformly continuous map admission through U; finite-window exposure through W; dyadic tolerance exactness through Q; regular Cauchy completion-name readback through R; RealUp seal handoff through E; identity and composition functor ledgers through I and A; and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 3956.1. Its accepted rows display exactly the metric source row, uniformly continuous map row, finite-window row, dyadic tolerance row, regular-rational readback row, real seal, identity ledger, composition ledger, and structural rows.

The source side is exhausted by M, U, W, Q. The metric row supplies the distance ledgers, the uniformly continuous map row supplies the graph and modulus data, and the finite-window and dyadic-tolerance rows record the only observations a regular Cauchy input can expose.

The target side is exhausted by R, E. The RegSeqRat row is read after the requested windows and tolerances, and the RealUp seal remains downstream from that completion-name readback.

The functorial rows add no hidden semantic object. The identity ledger I and composition ledger A record replay of the displayed route, while H, C, P, N transport, continue, source, and name the same finite packet. Hence the listed rows are the complete local NameCert obligation surface. □

Theorem 2979.3 (RegularCauchyCompletionFunctor composition law)**.** *Let F_f and F_g be accepted* $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ *packets for displayed uniformly continuous maps $f\colon X \to Y$ and $g\colon Y \to Z$. Every completion-facing consumer of the composite read factors through the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

for f, then through the same displayed route for g, with the composition ledger A preserving the intermediate windows, tolerance rows, regular-rational readbacks, RealUp seals, hsame *transports,* Cont *replays,* Pkg *provenance rows, and local NameCert rows. The identity ledger I gives the same statement when one of the two map rows is the displayed identity.*

Proof. Begin with the accepted packets for f and g. By Definition 3956.2, each packet exposes the metric source, uniformly continuous map, finite-window, dyadic-tolerance, regular-rational readback, real-seal, and structural rows before any completion-facing consumer can read its output.

For the composite request, read the first packet through M, U, W, Q, R, E. This produces only the displayed regular Cauchy completion-name row and its RealUp seal; it does not export a selected representative or a host equality of completed points.

Feed that displayed seal route to the second packet. The second packet repeats the same finite-window and tolerance discipline over its own metric and map rows. The ledger A records that this two-stage replay is the composite route, and I records that the identity map leaves the displayed windows, tolerances, readbacks, and seal unchanged.

Finally apply the structural rows. Componentwise hsame transport and displayed Cont replay preserve the two-stage route, while Pkg provenance and the local NameCert rows keep the consumer inside $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ data. Thus the composition law is a certificate route over displayed rows, not an external equality of functors. □

Theorem 2979.4 (RegularCauchyCompletionFunctor Real-seal handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ *packet reaches the RealUp seal row only through the displayed MetricUp source row, uniformly continuous map row, StreamName finite-window row, DyadicRatCore tolerance row, RegSeqRat readback row, identity ledger, composition ledger, and structural rows. In carrier notation, the route to the seal is*

$$M, U, W, Q, R, E, I, A, H, C, P, N,$$

with E downstream from M, U, W, Q, R and still guarded by I, A, H, C, P, N. The handoff does not expose selected representatives, quotient regular Cauchy names, host real equality, or ambient completeness.

Proof. Project the carrier of Definition 3956.1. The row E is listed only after the metric source, uniformly continuous map, finite-window, dyadic-tolerance, and RegSeqRat readback rows have been displayed.

Apply the NameCert obligations of Definition 3956.2. They identify the RealUp seal handoff as one obligation among the same finite rows, and they keep identity, composition, transport, replay, provenance, and local naming visible as part of the accepted packet.

Finally use the composition law, Definition 3956.3. It shows that a completion-facing composite read preserves the same window, tolerance, readback, seal, and ledger route rather than creating an external functor equality. Since the carrier has no coordinate for representatives, quotient names, host real equality, or ambient completeness, the Real-seal handoff can export only the displayed finite route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ read is refuted if a completion-facing RealUp seal is reached without displaying the MetricUp source row, uniformly continuous map row, StreamName window row, DyadicRatCore tolerance row, RegSeqRat readback row, identity ledger, composition ledger, transport, replay, provenance, and local naming rows.

Independence witness: metric, streamname, regseqrat, real, metriccompletion, and cauchycompletionfunctor: none is bijective to the functor packet because only $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ records uniformly continuous source action together with identity and composition ledgers for regular Cauchy completion names.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$ packet is generated from MetricUp source rows, uniformly continuous map rows, StreamName finite windows, DyadicRatCore tolerance rows, RegSeqRat completion-name rows, RealUp seal rows, identity and composition ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3956.1, Definition 3956.2, Definition 3956.3, and Definition 3956.4 seed the finite functorial route from MetricUp and uniformly continuous map rows through StreamName windows, DyadicRatCore tolerances, RegSeqRat completion names, and RealUp seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient regular Cauchy names, selected representatives, host equality of real objects, global completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric source exposure, uniformly continuous map exposure, window and tolerance routing, RegSeqRat readback, RealUp seal handoff, identity and composition ledgers, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionFunctorUp.

Chapter 2980

A Concrete Naming Certificate for $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$

Following Lebesgue and Bishop–Bridges, the $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ packet realizes the finite-net route of chapter 9237 as concrete NameCert data. It reads the compact carrier of chapter 60, the compact metric finite-net surface of chapter 129, the metric source rows of chapter 57, the continuous-map and continuous-function rows of chapter 130 and chapter 59, the rational lower-bound surface of chapter 37, the finite-net fold of chapter 619, and the source-lock packet of chapter 935. The packet records only finite $\mathsf{ProbeBundle}$ data, local pointwise-modulus rows, rational folds, and the resulting uniform-modulus handoff; it does not claim open-cover compactness, selected subsequences, countable choice, or a semantic Heine–Cantor theorem outside the displayed BEDC rows.

Definition 2980.1 (Compact uniform finite-net realization carrier)**.** *A* $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, M, F, B, L, R, U, T, H, D, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Compact}^{\uparrow}$ *admission row, tying the source object to the compact naming certificate.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the source-distance and target-distance ledgers.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, with pointwise modulus data readable at displayed source centers.*
4. *B is the finite* $\mathsf{ProbeBundle}$ *row of compact-net centers and source-distance coverage witnesses.*
5. *L is the local-radius ledger, assigning a positive* $\mathsf{Rat}^{\uparrow}$ *radius to each bundled center from the pointwise-modulus row.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row over the finite bundle, using only primitive recursion over displayed probes.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from the folded radius and the continuous graph rows.*
8. *T is the metric triangle row, joining the source-center estimate, the source-pair estimate, and the target-distance estimate.*

9. *H records componentwise* hsame *transport for C, M, F, B, L, R, U, T and for the structural rows below.*
10. *D records displayed* Cont *replay from compact finite-net inspection through pointwise-modulus reads, rational lower-bound folding, metric triangle estimates, and uniform-modulus handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, M, F, B, L, R, U, T, H, D, P, N$. It has no coordinate for open-cover compactness, a selected subcover outside the finite bundle, a selected subsequence, quotient equality of real values, or an external modulus function.

Lean4 ✓ `BEDC.Derived.CompactUniformFiniteNetRealizationUp.CompactUniformFiniteNetRealizationTasteGate`
`single carrier alignment`

Theorem 2980.2 (Compact finite-net modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ *packet receives the compact-uniform-continuity route through the finite chain*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Continuous}^{\uparrow},\ \mathsf{ProbeBundle},\ \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The consumer first displays the compact metric source, then the finite ProbeBundle centers and coverage rows, then the pointwise-modulus radii supplied by the continuous row, then the rational lower-bound fold, and only then the metric-triangle estimate and uniform-modulus handoff.

Proof. Project the carrier of Definition 3957.1. The rows $C, M, F, B, L, R, U, T, H, D, P, N$ are the complete displayed inventory.

Read the compact and metric source rows first. The compact row admits the source object, while the metric row supplies the distance ledgers used by both the finite-net cover and the target estimate.

Next read the finite bundle. The ProbeBundle row B supplies exactly the displayed centers and source-distance coverage rows, and the continuous row F supplies pointwise-modulus radii only at those centers. The local-radius ledger L therefore remains tied to the finite compact-net data.

Now fold the radii. The $\mathsf{Rat}^{\uparrow}$ row R is obtained by primitive recursion over B, so the common lower bound is a classifier-stable history rather than a choice-selected minimum.

Finally the metric triangle row T and uniform-modulus row U export the handoff, with H, D, P, N transporting, replaying, sourcing, and naming the same finite surface. Thus the realization supplies the vision route as NameCert data without importing open-cover compactness, selected subsequences, countable choice, or an external modulus selector. □

Theorem 2980.3 (Compact uniform finite-net realization nonescape)**.** *Let $K = (C, M, F, B, L, R, U, T, H, D, P, N$ be an accepted* $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ *carrier. Any consumer that reaches the uniform-modulus handoff must factor through the same finite ProbeBundle row B, the same* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold R, the same continuous-map pointwise-modulus row F, and the same metric triangle row T. No alternate path inside the carrier exports open-cover compactness, a selected subcover outside B, a selected subsequence, or a host-level modulus function.*

Proof. Start from the output row U. It is stored after C, M, F, B, L, R, T in the carrier, so the uniform-modulus handoff cannot be read without the compact source, metric source, continuous row, finite bundle, local radii, rational fold, and triangle estimate.

The finite bundle is the only cover coordinate. Since B is the sole row containing centers and coverage witnesses, any source point used by the handoff must be routed through one of the displayed probe names.

The lower-bound and triangle rows are likewise unique inside the packet. The fold row R compares only the radii displayed by L, and T is the only row converting source estimates and pointwise target estimates into the final uniform estimate.

Transport, replay, provenance, and local naming preserve this route rather than adding new analytic data. Hence every consumer of U remains inside the finite NameCert surface described by the compact-uniform-continuity vision. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ read is refuted if a UniformModulusUp handoff is reached without displaying the CompactUp row, MetricUp source row, ContinuousUp pointwise-modulus row, finite ProbeBundle centers, RatUp lower-bound fold, metric triangle row, transport, replay, provenance, and local naming rows.

Independence witness: compact, compactmetric, metric, continuous, rat, probebundle, finitenetminimumfold, and uniformmodulus: none is bijective to the finite-net realization packet because only $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ records the compact-uniform-continuity vision route from finite ProbeBundle coverage through rational folding to the UniformModulusUp handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}$ packet is generated from CompactUp admission rows, MetricUp source rows, ContinuousUp or ContinuousMapUp pointwise-modulus rows, finite ProbeBundle center and coverage rows, RatUp lower-bound folds, UniformModulusUp handoff rows, MetricTriangleUniformEstimateUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3957.1, Definition 3957.2, and Definition 3957.3 seed the finite ProbeBundle realization route for compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNetRealization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers outside the finite bundle, selected subsequences, countable choice, semantic Heine–Cantor theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact source exposure, metric source exposure, continuous pointwise-modulus exposure, finite ProbeBundle coverage, RatUp lower-bound folding, metric triangle exactness, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformFiniteNetRealizationUp.

Chapter 2981

A Concrete Naming Certificate for $\mathsf{MetricSequentialCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{MetricSequentialCompletion}^{\uparrow}$ packet records the finite interface where sequential completion data is read through a metric-completion surface without quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits between the sequential route of chapter 1683, the metric-completion boundary of chapter 1506, the complete-metric handoff of chapter 128, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a completion-facing route over displayed rows only; it does not identify Cauchy sequences by a host quotient or choose completed representatives.

Definition 2981.1 (MetricSequentialCompletion carrier)**.** *A* $\mathsf{MetricSequentialCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, M, C, W, T, R, E, H, K, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{SequentialCompletion}^{\uparrow}$ *source row naming the sequential completion request.*
2. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row through which completion-facing consumers read the metric boundary.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row exposed only after the sequential and metric rows are displayed.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family used to inspect the sequential source.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from W and T.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after Q, M, C, W, T, R.*
8. *H records componentwise* hsame *transport for the sequential, metric, complete, window, tolerance, readback, seal, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from the sequential request through the metric-completion boundary, complete-metric handoff, finite windows, dyadic tolerance, regular readback, and real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{MetricSequentialCompletion}^{\uparrow}$, $\mathsf{SequentialCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricSequentialCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected sequence limits, countable-choice selectors, host equality of completed points, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MetricSequentialCompletionUp.MetricSequentialCompletionTasteGate single carrier alignment`

Theorem 2981.2 (MetricSequentialCompletion NameCert obligations)**.** *For every accepted* MetricSequentialComp *carrier $S = (Q, M, C, W, T, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricSequentialCompletion}^{\uparrow}}$ *surface consists exactly of sequential-source admission through Q, metric-completion admission through M, complete-metric handoff through C, finite-window exposure through W, dyadic tolerance exactness through T, regular rational readback through R, real-name seal handoff through E, and structural transport, replay, provenance, and local naming through H, K, P, N.*

Proof. Project the carrier of Definition 3958.1. The accepted rows display the sequential source, metric completion row, complete-metric handoff, finite windows, dyadic tolerance ledger, regular readback, terminal real seal, and structural rows.

The completion side is exhausted by Q, M, C. A consumer first reads the sequential request, then the metric-completion boundary, and only then the complete-metric handoff.

The real-name side is exhausted by W, T, R, E. The finite window family determines the dyadic tolerance reads, the tolerance ledger determines the regular rational readback, and the real seal remains downstream of that readback.

Transport, replay, provenance, and local naming preserve this route. Since no other coordinate is present, quotient streams, selected limits, countable choice, host equality, and ambient completeness cannot enter the local certificate surface. □

Theorem 2981.3 (MetricSequentialCompletion RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricSequentialCompletion}^{\uparrow}$ *carrier reads the same finite route*

$$\mathsf{SequentialCompletion}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{R}$$

The handoff sends sequential completion data to regular rational readback through displayed stream windows and dyadic tolerances; it does not use quotient streams, selected limits, countable choice, host equality, or ambient real completeness.

Proof. Begin with Definition 3958.2. It fixes the local certificate surface at the rows $Q, M, C, W, T, R, E, H, K, P, N$.

Read the sequential and metric rows first. The packet admits the sequential request through Q, the metric-completion boundary through M, and the complete-metric handoff through C before a readback row can be inspected.

Now read the finite windows and tolerances. The rows W and T determine the regular rational row R, and the real-name seal E is downstream of R.

The structural rows keep the same handoff. Componentwise transport, displayed replay, provenance, and local naming record only this route, so the excluded quotient, selector, choice, host-equality, and completeness data remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSequentialCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricSequentialCompletion}^{\uparrow}$ packet is generated from SequentialCompletionUp source rows, MetricCompletionUp boundary rows, CompleteMetricUp handoff rows, StreamName window rows, DyadicRatCore tolerance rows, RegSeqRat readback rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSequentialCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3958.1, Definition 3958.2, and Definition 3958.3 seed the finite route from sequential completion and metric completion rows through stream windows, dyadic tolerances, regular rational readback, and the real-name seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSequentialCompletion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MetricSequentialCompletionUp.MetricSequentialCompletionTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable-choice selectors, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequential-source exposure, metric-completion admission, complete-metric handoff, window and tolerance routing, regular rational readback, real-name seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetricSequentialCompletionUp.

Chapter 2982

A Concrete Naming Certificate for $\mathsf{SpectralAblationHinge}^{\uparrow}$

The $\mathsf{SpectralAblationHinge}^{\uparrow}$ packet realizes the spectral-ablation ledger of Definition 9462.1458, the single-codon deletion table of Definition 9462.1459, the orbit-module deletion table of Definition 9462.1461, the tail-coupling edge deletion of Definition 9462.1463, and the load-bearing interface summary of Definition 9462.1468 as finite NameCert data. It records deletion rows, killed-walk rows, spectral-loss rows, orbit-module rows, transport rows, replay rows, provenance rows, and local naming rows. The packet does not claim a biological fitness law, a continuous spectrum, a host eigenvector selector, or an external ranking rule outside the displayed ledger.

The packet consumes the finite hinge-ledger rows of chapter 3961, the quotient spectral trigger rows of chapter 2317, and the energy-partition boundary of chapter 3806 before its ranking row is read. The killed-walk matrix rows and hinge rankings come from the ledger sibling, while the quotient trigger and energy-partition rows constrain which deletion reads can be treated as trigger-facing.

Definition 2982.1 (SpectralAblationHinge carrier)**.** *A* $\mathsf{SpectralAblationHinge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, K, L, O, T, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite deletion row, naming the deleted codon, edge, edge group, or orbit module.*
2. *K is the killed-walk row computed after the displayed deletion.*
3. *L is the spectral-loss ledger row recording the displayed difference between the source spectral radius and the killed-walk spectral radius.*
4. *O is the orbit-module row that records whether the deletion is point-level, module-level, interface-level, or single-edge data.*
5. *T is the tail-coupling row for the* UUR–CUR *antenna interface when the deletion reads that boundary.*
6. *R is the hinge-ranking row obtained by reading only D, K, L, O, T.*
7. *H records componentwise* hsame *transport for deletion, killed-walk, loss, orbit-module, tail-coupling, ranking, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from finite deletion data through killed-walk inspection, spectral-loss computation, orbit-module classification, tail-coupling inspection, and hinge ranking.*
9. *P is the* Pkg *provenance over* $\mathsf{SpectralAblationHinge}^{\uparrow}$*, radial-wobble-spectrum, wobble-quotient-spectral-trigger, six-boundary-tile-coverage, window-coverage-trigger-algebra, hyperbolic-metric,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SpectralAblationHinge}^{\uparrow}}$ *row.*

The carrier has no coordinate for an accepted hinge ranking that bypasses the spectral-loss ledger L.

Lean4 ✓ `BEDC.Derived.SpectralAblationHingeUp.SpectralAblationHingeTasteGate single carrier alignment`

Theorem 2982.2 (SpectralAblationHinge NameCert obligations)**.** *For every accepted* $\mathsf{SpectralAblationHinge}^{\uparrow}$ *carrier $A = (D, K, L, O, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SpectralAblationHinge}^{\uparrow}}$ *surface consists exactly of finite deletion admission through D, killed-walk admission through K, spectral-loss ledger exactness through L, orbit-module classification through O, tail-coupling boundary exposure through T, hinge-ranking readback through R, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 3959.1. The displayed rows are exactly $D, K, L, O, T, R, H, C, P, N$.

The deletion side is exhausted by D, K, L. A consumer first reads the finite deletion row, then the killed-walk row after that deletion, and then the spectral-loss ledger comparing the source and killed rows.

The hinge side is exhausted by O, T, R. Orbit-module classification and tail-coupling inspection supply the only ranking inputs, and the ranking row R is read only after those rows and the loss ledger have been displayed.

Transport, replay, provenance, and local naming preserve this finite ledger. No accepted NameCert obligation is stored in a host eigenvector selector, a continuous spectrum, or a ranking rule detached from D, K, L, O, T, R. □

Theorem 2982.3 (SpectralAblationHinge loss route)**.** *Every accepted hinge-ranking read from a* $\mathsf{SpectralAblationHinge}^{\uparrow}$ *carrier factors through the route*

$$D \longmapsto K \longmapsto L \longmapsto O, T \longmapsto R \longmapsto H, C, P, N.$$

Deleting the spectral-loss ledger L prevents the carrier from exporting an accepted hinge ranking, even when the deletion row, killed-walk row, orbit-module row, and tail-coupling row remain displayed.

Proof. Start with the NameCert obligations of Definition 3959.2. They require finite deletion admission, killed-walk admission, and spectral-loss ledger exactness before orbit-module or hinge-ranking data is read.

The ranking row is downstream of the loss row. The orbit-module row O and tail-coupling row T classify the deletion, but neither row stores the spectral loss itself.

If L is deleted, the displayed route cannot reach R as an accepted hinge-ranking row. The structural rows H, C, P, N only transport, replay, source, and name accepted rows, so they cannot reconstruct the missing loss ledger. □

Falsifiable prediction: Deleting the spectral-loss ledger prevents any accepted $\mathsf{SpectralAblationHinge}^{\uparrow}$ hinge ranking read, even when finite deletion, killed-walk, orbit-module, tail-coupling, transport, replay, provenance, and local naming rows remain displayed.

Independence witness: radial-wobble-spectrum, wobble-quotient-spectral-trigger, six-boundary-tile-coverage, window-coverage-trigger-algebra, hyperbolic-metric: none is bijective to the spectral ablation hinge packet because only $\mathsf{SpectralAblationHinge}^{\uparrow}$ binds deletion, killed-walk, spectral-loss, orbit-module, tail-coupling, ranking, transport, replay, provenance, and local naming rows into one accepted hinge ledger.

Lean follow-up must provide $\mathsf{Nontrivial\ SpectralAblationHinge}^{\uparrow}$ and $\mathsf{FieldFaithful\ SpectralAblationHinge}^{\uparrow}$ in TasteGate.lean before the packet can be read as a checked TasteGate object.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralAblationHinge}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralAblationHinge}^{\uparrow}$ packet is generated from finite deletion rows, killed-walk rows, spectral-loss ledger rows, orbit-module rows, tail-coupling rows, hinge-ranking rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpectralAblationHinge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3959.1, Definition 3959.2, and Definition 3959.3 seed the finite deletion, killed-walk, spectral-loss, orbit-module, tail-coupling, ranking, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpectralAblationHinge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological fitness laws, continuous spectral theory, host eigenvector selectors, Lean verification, TasteGate checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deletion admission, killed-walk admission, spectral-loss exactness, orbit-module classification, tail-coupling exposure, ranking readback, transport, replay, provenance, and local naming for BEDC.Derived.SpectralAblationHingeUp.

Chapter 2983

A Concrete Naming Certificate for $\mathsf{SierpinskiCarpet}^{\uparrow}$

Following Sierpinski and the constructive compact-metric treatment of finite square approximations, the $\mathsf{SierpinskiCarpet}^{\uparrow}$ packet records the standard middle-square deletion fractal as retained grid rows and coordinate readback data. It sits beside the retained-prefix route of chapter 1530, the compact source discipline of chapter 129, the finite-grid continuous-surjection surface of chapter 2078, the terminal real seal of chapter 38, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet names only finite square-grid retention and coordinate windows; it does not import a host closed subset of the plane, an infinite branch selector, quotient equality of real pairs, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2983.1 (Sierpinski carpet carrier)**.** *A* $\mathsf{SierpinskiCarpet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the retained square-grid row. It records a finite triadic square address, its depth, the retained child squares at that depth, and the compact-metric grid enclosure used by later consumers.*
2. *D is the deleted-middle-square ledger. For every inspected square address it records whether the central child has been removed and which retained children remain available.*
3. *W is the coordinate* $\mathsf{StreamName}^{\uparrow}$ *window row, carrying the finite horizontal and vertical coordinate windows attached to the retained square.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two coordinate schedules, with dyadic comparisons routed through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any real seal is exposed.*
5. *E is the pair of* $\mathsf{Real}^{\uparrow}$ *coordinate seals obtained from the same retained square-grid and coordinate-window rows.*
6. *H records componentwise* hsame *transport for retained grid rows, deletion ledgers, coordinate windows, rational readbacks, real seals, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route from retained grid rows and deleted-middle-square ledgers through coordinate windows, rational readbacks, and real seals.*

8. *P is the* Pkg *provenance over* $\mathsf{SierpinskiCarpet}^{\uparrow}$, $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PeanoCurve}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{SierpinskiCarpet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, D, W, Q, E, H, C, P, N$. It has no coordinate for a completed planar subset, selected infinite address, quotient equality of real pairs, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.SierpinskiCarpetUp.SierpinskiCarpetTasteGate single carrier alignment`

Theorem 2983.2 (Sierpinski carpet NameCert obligations)**.** *For every accepted* $\mathsf{SierpinskiCarpet}^{\uparrow}$ *carrier*

$$S = (G, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SierpinskiCarpet}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; retained square-grid exposure through G; deleted-middle-square exclusion through D; coordinate window exposure through W; regular rational readback through Q; real coordinate sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N. No obligation is discharged by a host planar powerset, an infinite branch selector, quotient real-pair equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3960.1. The accepted packet displays exactly the retained square-grid row, deletion ledger, coordinate windows, rational readbacks, real seals, and structural rows.

The retained-grid and deletion obligations are exhausted by G and D. A consumer cannot inspect a square address until the retained child row has been displayed, and a deleted central square can be refused only by the ledger row attached to that same address.

The coordinate obligations are exhausted by W, Q, E. The coordinate windows are read first, the regular rational readback uses those windows with the dyadic tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ seals remain downstream of the same retained square.

Finally H, C, P, N transport, replay, source, and name only the displayed rows. Since the excluded host principles have no carrier coordinate, they cannot appear as local $\mathsf{NameCert}_{\mathsf{SierpinskiCarpet}^{\uparrow}}$ obligations. □

Theorem 2983.3 (Sierpinski carpet finite square-deletion route)**.** *Every accepted* $\mathsf{SierpinskiCarpet}^{\uparrow}$ *consumer factors its membership or compact-metric read through the finite route*

$$\mathsf{CantorSet}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{PeanoCurve}^{\uparrow} \longmapsto G, D \longmapsto W, Q, E \longmapsto H, C, P, N.$$

At each inspected depth the route first displays retained square-grid rows and deleted-middle-square ledgers, then reads coordinate $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *schedules,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, and terminal* $\mathsf{Real}^{\uparrow}$ *seals. It exports no completed planar subset, selected infinite branch, quotient real-pair equality, open-cover compactness theorem, or ambient completeness principle.*

Proof. Begin with the retained square-grid row. It gives a finite triadic square address and the retained children available at the inspected depth, while the deleted-middle-square ledger records which central cell is refused.

Read coordinates only after that ledger is visible. The window row W supplies the horizontal and vertical finite schedules, and Q reads those schedules as regular rational data with the dyadic tolerance comparisons already displayed.

The Real-facing boundary is then the row E. It seals the two coordinate schedules as $\mathsf{Real}^{\uparrow}$ data for the retained square already named by G and checked by D.

The structural rows preserve the same route. Componentwise transport, displayed replay, provenance, and local naming cannot create a second membership surface, so every compact-metric or coordinate consumer remains inside the finite square-deletion packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SierpinskiCarpet}^{\uparrow}}$.

Constructive story: A $\mathsf{SierpinskiCarpet}^{\uparrow}$ packet is generated from retained square-grid rows, deleted-middle-square ledgers, coordinate StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance checks, RealUp coordinate seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SierpinskiCarpet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3960.1, Definition 3960.2, and Definition 3960.3 seed the finite square-deletion compact-metric certificate surface for the Sierpinski carpet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SierpinskiCarpet}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.SierpinskiCarpetUp.SierpinskiCarpetTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host planar powersets, selected infinite addresses, quotient equality of real coordinate pairs, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, retained square-grid exposure, deleted-middle-square exclusion, coordinate readback, Real coordinate sealing, transport, replay, provenance, and local naming for BEDC.Derived.SierpinskiCarpetUp.

Chapter 2984

A Concrete Naming Certificate for $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$

Following spectral graph perturbation theory and the Perron–Frobenius analysis of finite killed-walk matrices, the $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ packet records the ablation hinges of the median-closure codon graph as a finite ledger. It concretizes the point, orbit-module, edge-group, antenna-interface, and single-edge rankings of Definition 9462.1468 beside the median-closure packet of chapter 3545, the radial wobble spectrum of chapter 3681, the CUN antenna surface of chapter 3771, and the quotient trigger route of chapter 2317. The packet is a finite NameCert ledger for ablation rows; it is not a host eigenvector computation, a biological optimality claim, an infinite perturbation scheme, or an ambient spectral theorem.

Falsifiable prediction: Every accepted $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ consumer reads killed-walk matrix rows, orbit and module rows, point and edge ablation rows, hinge rankings, hsame transport, Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row before treating any hinge as load-bearing.

Independence witness: median-closure, radial-wobble-spectrum, CUN antenna, wobble-quotient-trigger: $\mathsf{MedianClosure}^{\uparrow}$ records closure vertices rather than ablation losses, $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ records radial spectral layers rather than killed-row deletion ledgers, $\mathsf{CUNSpectralAntenna}^{\uparrow}$ records tail gain rather than the full hinge ranking, and $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ records trigger acceptance rather than the ablation ledger; none is bijective to $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$.

Definition 2984.1 (Spectral ablation hinge ledger carrier)**.** *A* $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, O, A, E, H, R, T, C, P, N)$$

with the following displayed rows:

1. *M is the killed-walk matrix row, recording the finite median-closure adjacency matrix and the baseline Perron radius used for every ablation comparison.*
2. *O is the orbit and module row, recording the* UUR*,* AGR*,* CUR*,* CUY*,* Anchor_6*, and* $\mathrm{StopStart}_6$ *rows together with their finite membership ledgers.*
3. *A is the point-ablation row, recording each inspected codon deletion and its displayed spectral loss.*
4. *E is the edge-ablation row, recording the internal edge-group deletions, single-edge deletions, and the* $\mathrm{UUR} - \mathrm{CUR}$ *antenna interface deletion.*

5. *H is the hinge-ranking row, ordering the displayed point, module, edge-group, antenna-interface, and single-edge losses by their finite comparisons.*
6. *R is the read route, classifying a consumer request as matrix readback, orbit-module readback, point ablation, edge ablation, hinge ranking, or refusal.*
7. *T records componentwise* hsame *transport for matrix, orbit, point-ablation, edge-ablation, hinge-ranking, route, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$M, O, A, E, H, R \longmapsto T, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$, $\mathsf{MedianClosure}^{\uparrow}$, $\mathsf{RadialWobbleSpectrum}^{\uparrow}$, $\mathsf{CUNSpectralAntenna}^{\uparrow}$, $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SpectralAblationHingeLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, O, A, E, H, R, T, C, P, N$. It has no coordinate for an ambient Perron vector, an infinite graph limit, a biological necessity assertion, a real-valued oracle, or a hinge ranking not witnessed by the displayed rows.

Lean4 ✓ `BEDC.Derived.SpectralAblationHingeLedgerUp.SpectralAblationHingeLedgerTasteGate single carrier alignment`

Theorem 2984.2 (Spectral ablation hinge ledger NameCert obligations)**.** *For every accepted* $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ *carrier*

$$K = (M, O, A, E, H, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SpectralAblationHingeLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; killed-walk matrix readback through M; orbit and module exposure through O; point-ablation exactness through A; edge and antenna-interface ablation exactness through E; hinge-order stability through H; route classification through R; componentwise transport through T; displayed replay through C; provenance through P; local naming through N; ledger nonescape from ambient Perron vectors, infinite graph limits, biological necessity assertions, and oracle-valued rankings; and public consumer rows for point, module, edge-group, antenna-interface, and single-edge hinge reads.*

Proof. Carrier admission projects the tuple of Definition 3961.1. The matrix row M, orbit row O, ablation rows A, E, hinge row H, and structural rows R, T, C, P, N are the only visible coordinates.

The ablation-row exactness obligations are exhausted by A and E. A point deletion is admitted only through the finite codon row recorded in A, and an edge or antenna-interface deletion is admitted only through the finite edge ledger recorded in E.

Hinge-order stability is a comparison inside H. The row reads the same displayed loss values from A and E, so a consumer cannot reorder the hinge list by importing an external Perron vector or an unrecorded spectral computation.

Finally R, T, C, P, N classify, transport, replay, source, and name the same finite rows. Since the excluded ambient objects have no carrier coordinate, every public consumer read of a point, module, edge-group, antenna-interface, or single-edge hinge remains inside the ledger. □

Theorem 2984.3 (Spectral ablation hinge public route)**.** *Every accepted public consumer of a* $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MedianClosure}^{\uparrow}, \mathsf{RadialWobbleSpectrum}^{\uparrow}, \mathsf{CUNSpectralAntenna}^{\uparrow}, \mathsf{WobbleQuotientSpectralTrigger}^{\uparrow} \longmapsto M, O, A, E, H,$$

Thus the matrix read, orbit-module rows, point-ablation rows, edge-ablation rows, hinge ranking, route classification, transport, replay, provenance, and local naming are visible before the consumer exports a load-bearing hinge. No exported row asserts host spectral optimality, biological necessity, an infinite perturbation theorem, or an ablation comparison outside the displayed ledger.

Proof. Start with the matrix and orbit support. The rows M and O identify the finite killed-walk matrix and the finite orbit or module being inspected.

Read ablation data next. The point row A and edge row E carry the deletions and their spectral losses, while H records the hinge order obtained from those same rows.

The public boundary is then the route row R. It decides whether a consumer is reading the matrix, an orbit or module, a point deletion, an edge deletion, a hinge ranking, or a refusal.

The structural rows preserve that boundary. Componentwise transport, continuation replay, provenance, and local naming cannot introduce a second spectral source, so every accepted public read factors through the displayed packet. □

Theorem 2984.4 (Spectral ablation hinge vision route)**.** *Any accepted* $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ *hinge read must pass through*

$$\mathsf{MedianClosure}^{\uparrow}, \mathsf{RadialWobbleSpectrum}^{\uparrow}, \mathsf{CUNSpectralAntenna}^{\uparrow}, \mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$$

before it can be read as the load-bearing interface of Definition 9462.1468. The sibling routes supply closure vertices, radial spectral layers, antenna gain, and trigger acceptance, while the local packet supplies only the ablation ranking over $M, O, A, E, H, R, T, C, P, N$.

Proof. Project the carrier rows $M, O, A, E, H, R, T, C, P, N$ of Definition 3961.1. The rows M and O expose the killed-walk matrix and finite orbit or module support; the rows A, E, H expose point loss, edge loss, and the hinge order; and R, T, C, P, N classify, transport, replay, source, and name that ledger.

Read the sibling routes before the local ablation row is consumed. The $\mathsf{MedianClosure}^{\uparrow}$ route supplies the closure vertices, $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ supplies the radial layers, $\mathsf{CUNSpectralAntenna}^{\uparrow}$ supplies antenna gain, and $\mathsf{WobbleQuotientSpectralTrigger}^{\uparrow}$ supplies trigger acceptance.

Only after those routes have been displayed can the ledger row rank a hinge for the public philosophy interface. The local packet contributes no independent closure vertex, radial layer, antenna gain, or trigger-acceptance theorem; it contributes the finite ablation ranking that can be read against those already displayed surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralAblationHingeLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralAblationHingeLedger}^{\uparrow}$ packet is generated from killed-walk matrix rows, orbit-module rows, point-ablation rows, edge-ablation rows, hinge rankings, route classification, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpectralAblationHingeLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3961.1, Definition 3961.2, and Definition 3961.3 seed the finite spectral-ablation hinge ledger surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpectralAblationHingeLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Perron-vector computation, biological semantics, infinite perturbation theory, oracle-valued rankings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, killed-walk matrix readback, orbit-module exposure, ablation-row exactness, hinge-order stability, route classification, transport, replay, provenance, and local naming for BEDC.Derived.SpectralAblationHingeLedgerUp.

Chapter 2985

A Concrete Naming Certificate for BanachContractionPrinciple$^{\uparrow}$

Following Banach's fixed-point theorem and Bishop–Bridges constructive analysis, the BanachContractionPrinciple$^{\uparrow}$ packet records a fixed-point route only when the complete metric carrier, the contractive map, the iteration schedule, and the Cauchy handoff are all explicit finite rows. It sits downstream of the complete metric carrier of chapter 128, the contractive map packet of chapter 3819, the fixed point iteration route of chapter 2383, the Cauchy completion reflector of chapter 1585, and the real-number ground of chapter 38. The certificate therefore consumes existing completion data; it does not assert ambient completeness, global choice, or an unrecorded limit operator.

Definition 2985.1 (Banach contraction principle carrier)**.** *A* BanachContractionPrinciple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, F, I, Q, E, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the complete metric row, naming the metric carrier and the completeness seal used by the argument;*
2. *F is the contraction map row, including the displayed modulus witness and its compatibility with the metric row;*
3. *I is the iteration schedule row, recording the initial point and the successive iterates read by the construction;*
4. *Q is the Cauchy witness row for the iteration sequence;*
5. *E is the endpoint seal row, identifying the completed endpoint supplied by the complete metric data;*
6. *U is the uniqueness row, binding any second fixed endpoint back to the same contraction ledger;*
7. *H records componentwise* hsame *transports for M, F, I, Q, E, U together with continuation, provenance, and local naming rows;*
8. *C records the displayed* Cont *replay routes by which the contraction ledger, the Cauchy witness, the endpoint seal, and uniqueness row are read;*
9. *P is the* Pkg *provenance over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* CompleteMetric$^{\uparrow}$*,* ContractiveMap$^{\uparrow}$*,* FixedPointIteration$^{\uparrow}$*,* CauchyCompletionReflector$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachContractionPrinciple}^{\uparrow}}$ *row.*

The classifier accepts exactly packets with these ten displayed rows. It has no coordinate for an arbitrary choice of fixed point, an ambient completeness claim outside M, a hidden contraction constant, or a limit witness that does not pass through Q and E.

Lean4 ✓ `BEDC.Derived.BanachContractionPrincipleUp.BanachContractionPrincipleTasteGate single carrier alignment`

Theorem 2985.2 (Banach contraction principle NameCert obligations)**.** *For the carrier of Definition 3962.1, the local* $\mathsf{NameCert}_{\mathsf{BanachContractionPrinciple}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for $B = (M, F, I, Q, E, U, H, C, P, N)$;*
2. *contraction ledger exposure, requiring every use of the map row F to read the displayed contraction data against M;*
3. *Cauchy-iteration handoff, requiring the iteration schedule I to produce the witness row Q before an endpoint is read;*
4. *complete-metric seal, requiring the endpoint row E to be supplied by the completeness data in M rather than by an ambient choice operator;*
5. *uniqueness nonescape, requiring every competing fixed endpoint to factor through U, H, C, P, N with no off-packet fixed-point row.*

Proof. Carrier admission is projection from the displayed packet. The rows $M, F, I, Q, E, U, H, C, P, N$ are the full inventory made available to the local certificate.

The contraction ledger is read through F against the metric data in M. Thus a contraction claim with a hidden modulus or a different metric carrier has no row in the packet.

The iteration schedule then hands off to the Cauchy witness row. The endpoint seal can be read only after Q is present and the complete metric data in M supplies the endpoint row E.

Finally, uniqueness is confined to U and the replay rows H, C, P, N. A second fixed endpoint that escapes these rows would require an additional carrier coordinate, which the classifier does not provide. □

Theorem 2985.3 (Banach contraction endpoint uniqueness)**.** *Let $B = (M, F, I, Q, E, U, H, C, P, N)$ and $B' = (M, F, I, Q, E', U', H', C', P', N')$ be accepted* $\mathsf{BanachContractionPrinciple}^{\uparrow}$ *packets over the same complete metric row M, contraction row F, iteration schedule I, and Cauchy witness row Q. If the endpoint seals E and E' are transported through the displayed uniqueness rows U and U', then the metric carrier named by M classifies the two endpoint seals together. The conclusion exposes endpoint uniqueness only along the displayed contraction ledger; it does not select a fixed point outside the packet.*

Proof. Project both carriers to the shared rows M, F, I, Q. The contraction ledger exposure forces every fixed-point read to use the same metric carrier, the same contractive map row, and the same iteration schedule before any endpoint seal can be inspected.

The Cauchy witness row Q then supplies the common route into the complete metric row M. Both endpoint seals E and E' are therefore read as completions of the displayed iteration data rather than as independently selected fixed points.

Apply the uniqueness rows U and U' through their componentwise transports and replay routes. The rows H, C, P, N and H', C', P', N' keep the two endpoint reads on the same local NameCert

surface, so the metric classifier of M identifies the endpoint seals. Since the carriers have no coordinate for an off-packet fixed point, no such point is exported. □

Theorem 2985.4 (Banach contraction iteration Cauchy handoff)**.** *Every accepted* $\mathsf{BanachContractionPrinciple}^{\uparrow}$ *carrier* $B = (M, F, I, Q, E, U, H, C, P, N)$ *routes its displayed fixed-point iteration through the Cauchy tail row* Q *before the completion reflector reads the endpoint seal* E*. The rows named by* P *may expose* $\mathsf{FixedPointIteration}^{\uparrow}$ *and* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *consumers only after the contraction ledger* F*, iteration schedule* I*, and Cauchy witness* Q *have been displayed. Thus the packet exports a completion-facing endpoint handoff, not a chosen fixed point, a hidden limit operator, a global choice rule, or completeness outside the metric row* M*.*

Proof. Project the accepted carrier. The definition places the complete metric row M, contraction row F, iteration schedule I, Cauchy witness Q, and endpoint seal E in a fixed displayed order.

First read F and I. The contraction ledger determines the successive iterate route, while the iteration schedule records the finite prefix and successor replay used by downstream fixed-point consumers.

Next read Q. This is the only Cauchy tail row in the carrier, so the completion reflector cannot receive an endpoint request until the iteration has been certified as Cauchy through the displayed row.

Finally replay the completion-facing handoff through E, H, C, P, N. Since no carrier coordinate stores a chosen endpoint or an ambient completeness witness, the exported endpoint is exactly the reflector output attached to the displayed Cauchy tail. □

Theorem 2985.5 (Banach contraction endpoint route)**.** *Every accepted* $\mathsf{BanachContractionPrinciple}^{\uparrow}$ *endpoint read factors through* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{ContractiveMap}^{\uparrow}$*,* $\mathsf{FixedPointIteration}^{\uparrow}$*,* $\mathsf{CauchyCompletionReflector}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows in the carrier order*

$$M, F, I, Q, E, U, H, C, P, N.$$

The route exports no chosen endpoint, hidden limit operator, global choice rule, quotient completion equality, or completeness outside M*.*

Proof. Start with the carrier of Definition 3962.1. The endpoint row E is downstream of the complete metric row M, contraction map row F, iteration schedule I, and Cauchy witness Q.

Apply Definition 3962.2. The NameCert surface requires carrier admission, contraction ledger exposure, Cauchy-iteration handoff, complete-metric seal, and uniqueness nonescape before a fixed-point endpoint can be read.

Use Definition 3962.3 to keep any competing endpoint inside the displayed uniqueness row U. Then use Definition 3962.4 to route the displayed iteration through Q before the completion reflector reads E.

Finally H, C, P, N provide transport, replay, provenance, and local naming over the same finite rows. Since the carrier has no coordinate for a chosen endpoint, hidden limit operator, global choice rule, quotient completion equality, or completeness outside M, the endpoint route is exactly the displayed carrier order. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachContractionPrinciple}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BanachContractionPrinciple}^{\uparrow}$ packet is generated from a complete metric row, a displayed contraction map, an iteration schedule, a Cauchy witness, an endpoint seal, a uniqueness row, componentwise transports, replay routes, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BanachContractionPrinciple}^{\uparrow}}$, seed)

Scope closed: Definition 3962.1 and Definition 3962.2 bind the finite carrier and its five local certificate obligations.

Formal verification: FormalStatus(NameCert$_{\mathsf{BanachContractionPrinciple}\uparrow}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close Lean verification, a standard bridge, global fixed-point choice, nonconstructive compactness, or completeness outside the displayed metric row.
Upgrade path: A Lean carrier and obligation theorem for the displayed route would raise the verification axis while preserving the paper carrier boundary.

Chapter 2986

A Concrete Naming Certificate for PublicLocalReflectiveCompilation$^{\uparrow}$

The PublicLocalReflectiveCompilation$^{\uparrow}$ packet realizes the public/local reflective compilation surface of section 9414.57 as finite NameCert data. It sits beside the compiler event-flow audit of chapter 829, the MetaCIC closure trace of chapter 795, the self-compilation boundary of chapter 9235, and the focused readback discipline of the vision chapter. The packet keeps the public audit substrate and the local self-audit substrate separate while letting both replay through one visible compiler-side certificate.

Definition 2986.1 (Public local reflective compilation carrier)**.** *A* PublicLocalReflectiveCompilation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, M, C, S, L, U, X, F, T, E, H, K, P, N)$$

with the following rows:

1. *A is the public compiler-side audit substrate row, exposing finite event-flow, admission, and evidence-packet data.*
2. *M is the MetaCIC audit row, recording the kernel-facing closedness and acceptance checks used by public reflective compilation.*
3. *C is the public reflective compiler row, naming the source packet, generated packet, and accepted readback boundary.*
4. *S is the local self-compiler row, restricted to the focused local trace and not exported as public compiler authority.*
5. *L is the local self-audit row, recording which local reads may be replayed against the focused trace.*
6. *U is the proxy-readback row, separating the current self-proxy from the public evidence packet and from the far endpoint.*
7. *X is the refusal row, listing hidden prompt state, uninspected compiler state, unbounded self-reference, public authority for local reads, and local authority for public claims as absent coordinates.*
8. *F is the FieldFaithful row for the displayed fields A, M, C, S, L, U, X.*

9. *T is the Nontrivial row distinguishing the public audit substrate, MetaCIC audit substrate, local self-compiler, local self-audit, proxy-readback, and refusal roles.*
10. *E is the transport and replay ledger for public compiler reads and local self-audit reads.*
11. *H records componentwise* hsame *transport for all displayed rows.*
12. *K records displayed* Cont *replay through the compiler-side, MetaCIC-audit, local-self-compiler, local-self-audit, proxy-readback, refusal, transport, and replay rows.*
13. *P is the* Pkg *provenance over* $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$*, compiler event-flow audit rows, MetaCIC closure and acceptance rows, local self-compilation rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}}$ *row.*

The classifier reads only $A, M, C, S, L, U, X, F, T, E, H, K, P, N$. It has no coordinate for hidden prompt state, unrestricted self-application, a public proof of local identity, local authority over public compiler claims, unbounded reflective closure, or a compiler oracle outside the displayed rows.

Lean4 ✓ `BEDC.Derived.PublicLocalReflectiveCompilationUp.PublicLocalReflectiveCompilationTasteGate`
`single carrier alignment`

Theorem 2986.2 (Public local reflective compilation NameCert obligations)**.** *For every accepted* $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$ *carrier $R = (A, M, C, S, L, U, X, F, T, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}}$ *surface consists exactly of compiler-side audit exposure, MetaCIC-audit exposure, public reflective compilation routing, local self-compiler confinement, local self-audit confinement, proxy-readback separation, refusal-row exactness, FieldFaithful projection, Nontrivial role separation, transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 3963.1. The public rows A, M, C are exposed before any generated evidence packet can be read as a public reflective compilation result.

The local rows S, L, U are then read only along the focused trace. They provide local self-compiler, local self-audit, and proxy-readback data, but the refusal row X prevents those local reads from becoming public compiler authority or unrestricted self-reference.

The rows F and T keep the field projection faithful and the roles nontrivial: public audit, MetaCIC audit, public compiler, local self-compiler, local self-audit, proxy-readback, and refusal are distinct fields of the same carrier rather than aliases.

Finally E, H, K, P, N transport, replay, source, and name the finite packet. Because the excluded authorities have no carrier coordinate, every accepted read remains inside the displayed public/local reflective compilation surface. □

Theorem 2986.3 (Public local reflective compilation local-public boundary)**.** *Every accepted* $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$ *read that reaches the public compiler row C must pass through the public audit substrate A and the MetaCIC audit row M before it can inspect the local self-compiler row S or local self-audit row L. Conversely, every local self-audit read through S, L, U must retain the refusal row X and cannot export public compiler authority, hidden prompt state, or unbounded reflective closure.*

Proof. Start with the displayed carrier order. Public compiler reads use A, M, C as the public audit and MetaCIC-audit prefix, so a public result cannot be obtained directly from the local rows.

Local self-audit reads use S, L, U only after the carrier has separated the public rows from the focused trace. The proxy-readback row U records the local endpoint without identifying it with the public evidence packet or the far endpoint.

The refusal row X is retained by both routes. It records that public authority for local reads, local authority for public compiler claims, hidden prompt state, and unbounded reflective closure are absent from the carrier. Transport and replay through E, H, K, P, N therefore preserve the same local-public boundary. □

Falsifiable prediction: A claimed public/local reflective compilation packet that exports public compiler authority from the local self-audit rows S, L, U without displaying A, M, C, X, H, K, P, N refutes $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$.

Independence witness: groundcompilereventflowaudit, metacicclosuretrace, selfcompilationboundary, focusedproxyreadback: none is bijective to $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$ because the packet jointly carries public audit, MetaCIC audit, public reflective compiler, local self-compiler, local self-audit, proxy-readback, refusal, FieldFaithful, Nontrivial, transport, replay, provenance, and local naming rows.

The Lean TasteGate surface for $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$ must provide explicit Nontrivial and FieldFaithful instances for $A, M, C, S, L, U, X, F, T, E, H, K, P, N$. The intended endpoint is BEDC.Derived.PublicLocalReflectiveCompilationUp.PublicLocalReflectiveCompilationTasteGate_single_carrier_alignm with the FieldFaithful instance preserving each carrier coordinate and the Nontrivial instance separating public audit, MetaCIC audit, public compiler, local self-compiler, local self-audit, proxy-readback, and refusal roles.

Closure status for $\mathsf{NameCert}_{\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}}$.

Constructive story: A $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$ packet is generated from public compiler-side audit, MetaCIC-audit, public reflective compiler, local self-compiler, local self-audit, proxy-readback, refusal, FieldFaithful, Nontrivial, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3963.1, Definition 3963.2, and Definition 3963.3 seed the finite public/local reflective compilation route and its local-public boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted self-application, hidden prompt-state authority, public proof of local identity, local authority over public compiler claims, or unbounded reflective closure.

Upgrade path: Obligation closure requires checked carrier admission, public audit exposure, MetaCIC-audit exposure, local self-compiler confinement, local self-audit confinement, proxy-readback separation, refusal exactness, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.PublicLocalReflectiveCompilationUp.

Chapter 2987

A Concrete Naming Certificate for $\mathsf{MetricEntourage}^{\uparrow}$

Following Bourbaki uniform spaces and Bishop–Bridges constructive metric analysis, the $\mathsf{MetricEntourage}^{\uparrow}$ packet records the finite entourage surface between the metric row of chapter 57 and the uniform consumers of chapter 3445. Its tolerance reads are grounded through chapter 291, chapter 126, chapter 301, and chapter 38; it is a displayed metric-to-uniform handoff, not an open-cover compactness principle or a choice of centers.

Definition 2987.1 (MetricEntourage carrier)**.** *A* $\mathsf{MetricEntourage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, Q, D, B, S, T, H, C, P, N).$$

Here M is the $\mathsf{Met}^{\uparrow}$ *row, Q and D are the rational and dyadic tolerance rows, B is the ball-and-entourage witness row, S is the symmetry row, T is the triangle-composition row, H is componentwise* hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{MetricEntourage}^{\uparrow}}$ *row. The carrier has no coordinate for arbitrary open covers, selected centers, quotient points, countable choice, or ambient completion.*

Lean4 ✓ `BEDC.Derived.MetricEntourageUp.MetricEntourageTasteGate single carrier alignment`

Theorem 2987.2 (MetricEntourage NameCert obligations)**.** *For every accepted* $\mathsf{MetricEntourage}^{\uparrow}$ *carrier $E = (M, Q, D, B, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricEntourage}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed metric, tolerance, entourage, symmetry, triangle, transport, replay, provenance, and local naming rows;*
2. *diagonal and reflexive entourage admission from the positive tolerance rows Q, D and the ball witness row B;*
3. *symmetry transport through S together with the componentwise* hsame *row H;*
4. *triangle composition through T, using only the displayed metric row M and the rational or dyadic tolerance rows Q, D;*
5. *metric-to-uniform handoff saying that the uniform read consumes B, S, T after M, Q, D and before any downstream completion or Cauchy row;*
6. *transport and replay stability through H, C, P, N for the same displayed packet; and*

7. *nonescape from arbitrary open covers, selected centers, quotient points, countable choice, host compactness, or ambient completeness.*

Proof. Project the carrier of Definition 3964.1. The only metric-facing rows are M, Q, D, B, S, T, and the only structural rows are H, C, P, N.

The diagonal and reflexive obligation reads the tolerance rows before the ball witness row. Symmetry is then supplied by S, and triangle composition is supplied by T over the same metric and tolerance route.

The uniform handoff is therefore a finite row translation. A consumer of chapter 3445 may read the resulting entourage surface only after the metric row and tolerance rows have been displayed.

Finally the transport, replay, provenance, and naming rows preserve that route without adding any coordinate for open-cover compactness, selected centers, quotient representatives, countable choice, host compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricEntourage}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricEntourage}^{\uparrow}$ packet is generated by reading a displayed metric row, rational and dyadic tolerance rows, a ball-and-entourage witness, symmetry, triangle composition, componentwise transport, replay, provenance, and local naming. It translates metric balls into a finite uniform entourage surface without adding open-cover compactness, selected centers, quotient points, countable choice, or ambient completion.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricEntourage}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed records the metric row, rational and dyadic tolerance rows, ball-entourage witness, symmetry, triangle-composition, transport, replay, provenance, and local NameCert rows as the current paper-side scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricEntourage}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MetricEntourageUp.MetricEntourageUp`

Bridge status: none

Not claimed: The chapter does not claim open-cover compactness, selected centers, quotient-point equality, countable choice, complete uniformity, or ambient metric completion.

Upgrade path: Next paper step: register the full MetricEntourage carrier obligation surface in Lean before raising the verification axis.

Chapter 2988

A Concrete Naming Certificate for $\mathsf{LeastUpperBound}^{\uparrow}$

Following Bishop and Bridges-style constructive order analysis, the $\mathsf{LeastUpperBound}^{\uparrow}$ packet records the located least-upper-bound surface needed by Real and Completion consumers before any ambient completeness theorem is available. It sits over the located upper-bound packet of chapter 3396, the located-supremum packet of chapter 1427, the dyadic supremum packet of chapter 1653, and the terminal real-name seal of chapter 38. The certificate is a finite boundary for bounded-source, upper-bound, and lower-approximation reads; it is not a quotient-real construction, a selected supremum, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2988.1 (LeastUpperBound carrier)**.** *A* $\mathsf{LeastUpperBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, U, A, L, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded source row, naming the finite family observations and the bound discipline consumed by the located upper-bound surface.*
2. *U is the upper-bound witness row, recording the inspected comparison witnesses that keep the displayed source below the proposed bound surface.*
3. *A is the lower-approximation and cofinality row, recording the finite witnesses demanded by the consumer below the same bound surface.*
4. *L is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row, binding the source, upper-bound, and lower-approximation reads to the located-supremum packet.*
5. *D is the* $\mathsf{DyadicSupremum}^{\uparrow}$ *handoff row, recording the dyadic upper-bound and lower-approximation surface used by finite tolerance consumers.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reached only after S, U, A, L, D have been displayed.*
7. *H records componentwise* hsame *transport for the bounded source, upper-bound witness, lower-approximation row, located-supremum handoff, dyadic-supremum handoff, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each least-upper-bound request through $S, U, A, L, D, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{LeastUpperBound}^{\uparrow}$, $\mathsf{LocatedUpperBound}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{DyadicSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LeastUpperBound}^{\uparrow}}$ *row.*

The accepted carrier stores no ambient completeness coordinate, quotient cut, selected supremum, trichotomy oracle, host real equality test, or countable-choice selector.

Theorem 2988.2 (LeastUpperBound NameCert obligations)**.** *For every accepted* $\mathsf{LeastUpperBound}^{\uparrow}$ *carrier $B = (S, U, A, L, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LeastUpperBound}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-source exposure, upper-bound witness exposure, lower-approximation cofinality, located-supremum handoff, dyadic-supremum handoff, terminal Real seal, componentwise transport, displayed continuation replay, package provenance, and local naming. Every least-upper-bound-facing consumer reads only the displayed route*

$$S, U, A \longmapsto L, D \longmapsto E \longmapsto H, C, P, N.$$

Proof. Project the carrier of Definition 3965.1. The analytic rows are the bounded source S, the upper-bound witness U, the lower-approximation row A, the located-supremum handoff L, the dyadic-supremum handoff D, and the terminal Real seal E.

The upper side of the request is read through S and U. The lower side is read through A, and the cofinality claim is accepted only for the displayed approximation witnesses demanded by the consumer.

The handoff rows L and D bind those two sides to the existing located-supremum and dyadic-supremum surfaces before the Real seal can be inspected. The structural rows H, C, P, N only transport, replay, source, and name that finite route.

Since the carrier has no coordinate for quotient cuts, selected suprema, countable choice, trichotomy, host real equality, or ambient order completeness, no local NameCert obligation can export one of those principles. □

Lean4 ✓ `BEDC.Derived.LeastUpperBoundUp.LeastUpperBoundTasteGate single carrier alignment`

Theorem 2988.3 (LeastUpperBound located-supremum handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LeastUpperBound}^{\uparrow}$ *packet must first expose the bounded source row S, the upper-bound witness row U, the lower-approximation row A, the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row L, and the* $\mathsf{DyadicSupremum}^{\uparrow}$ *handoff row D before reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The handoff exports only the finite least-upper-bound packet $S, U, A, L, D, E, H, C, P, N$.*

Proof. Start with a consumer that reaches the Real-facing boundary of the packet. By Definition 3965.1, the only terminal Real coordinate is E, and it is downstream of the bounded source, upper-bound, lower-approximation, located-supremum, and dyadic-supremum rows.

Apply Definition 3965.2. It forces every least-upper-bound-facing read through the route from S, U, A to L, D and then to E, H, C, P, N.

The located-supremum row keeps the upper and lower sides under the constructive located-supremum surface, while the dyadic-supremum row records the finite tolerance-facing boundary. Thus a Real or Completion consumer receives the displayed packet only, with no quotient-real construction, selected supremum, countable-choice selector, trichotomy split, host equality test, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Falsifiable prediction: An accepted $\mathsf{LeastUpperBound}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ or completion-facing read without first displaying the bounded source row, upper-bound witness row, lower-approximation row, $\mathsf{LocatedSupremum}^{\uparrow}$ handoff, and $\mathsf{DyadicSupremum}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: located upper bound, located supremum, dyadic supremum, and Real seal: no listed sibling supplies the whole $\mathsf{LeastUpperBound}^{\uparrow}$ packet, because each sibling contributes upper-bound discipline, located cofinality, dyadic tolerance data, or a terminal seal while this chapter binds all rows with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LeastUpperBound}^{\uparrow}}$.

Constructive story: A $\mathsf{LeastUpperBound}^{\uparrow}$ packet is generated from a bounded source row, an upper-bound witness row, a lower-approximation cofinality row, LocatedSupremum and DyadicSupremum handoff rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LeastUpperBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3965.1, Definition 3965.2, and Definition 3965.3 seed the finite located least-upper-bound boundary needed by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LeastUpperBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real construction, selected suprema, countable choice, trichotomy, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, upper-bound witness exposure, lower-approximation cofinality, located-supremum handoff, dyadic-supremum handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LeastUpperBoundUp.

Chapter 2989

A Concrete Naming Certificate for $\mathsf{CauchyIntervalNesting}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyIntervalNesting}^{\uparrow}$ packet records the finite nested-interval-to-Cauchy route used when a retained interval window is read as regular rational data before the terminal real-name seal. It sits after the retained bisection surface of chapter 3815, the finite nested-chain discipline of chapter 320, the Cauchy carrier of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the finite route from displayed retained intervals to Cauchy-compatible readback; it does not assert selected infinite branches, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2989.1 (Cauchy interval nesting carrier)**.** *A* $\mathsf{CauchyIntervalNesting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, B, N, S, D, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the interval source row. It exposes the closed bounded source interval, endpoint order, containment evidence, and source finite windows consumed from the* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *and* $\mathsf{NestedInterval}^{\uparrow}$ *siblings.*

2. *B is the bisection branch row. It records the retained finite branch, midpoint exposure, child-containment witness, and dyadic branch ledger inherited from the accepted* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *route.*

3. *N is the nested inclusion ledger. It records the visible finite chain, adjacent containment cells, width or diameter controls, and prefix discipline read through the* $\mathsf{NestedInterval}^{\uparrow}$ *surface.*

4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It displays the finite endpoint, midpoint, retained-child, and nested-prefix windows available to downstream requests.*

5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the positive dyadic scale, comparison cells, slack conversions, and diameter bounds used to interpret the displayed windows.*

6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from I, B, N, S, D and exposed only as a regular rational sequence surface.*

7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the retained branch, nested inclusion ledger, stream windows, dyadic tolerances, and regular rational readback have been displayed.*

8. *H records componentwise* hsame *transport for the interval source, bisection branch, nested ledger, stream window, dyadic tolerance, regular sequence, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a nested-interval Cauchy request through $I, B, N, S, D, R, E, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyIntervalNesting}^{\uparrow}$, $\mathsf{ClosedIntervalBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{CauchyIntervalNesting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $I, B, N, S, D, R, E, H, C, P, L$. It has no coordinate for a selected infinite branch, a completed intersection point, quotient stream equality, quotient real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyIntervalNestingUp.CauchyIntervalNestingTasteGate single carrier alignment`

Theorem 2989.2 (Cauchy interval nesting RegSeqRat route)**.** *Every accepted* $\mathsf{CauchyIntervalNesting}^{\uparrow}$ *carrier reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *row only after reading the interval source, retained bisection branch, nested inclusion ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. Equivalently, every regular rational readback factors through the displayed finite route*

$$I, B, N, S, D \longmapsto R \longmapsto E, H, C, P, L.$$

The route is a Cauchy-facing finite readback route; it is not a selected infinite branch, a quotient real, a countable-choice schedule, or an ambient completeness argument.

Proof. Project the accepted carrier $X = (I, B, N, S, D, R, E, H, C, P, L)$ from Definition 3966.1. The source row I and branch row B expose the only retained closed-interval bisection data available to the request.

Next read the nested ledger N, the stream windows S, and the dyadic tolerance row D. These rows supply the finite prefix, displayed observations, and tolerance controls needed before the regular rational row can be inspected.

The row R is therefore downstream of I, B, N, S, D. The terminal seal and structural rows E, H, C, P, L preserve the same order by real sealing, transport, replay, provenance, and local naming.

Since the carrier has no coordinate for completed branches, quotient equality, choice, trichotomy, compactness, or ambient completeness, no consumer can bypass the displayed route. □

Theorem 2989.3 (Cauchy interval nesting NameCert obligations)**.** *For every accepted* $\mathsf{CauchyIntervalNesting}^{\uparrow}$ *carrier $X = (I, B, N, S, D, R, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyIntervalNesting}^{\uparrow}}$ *surface consists exactly of carrier admission, interval-source exposure, retained-bisection branch exposure, nested-inclusion ledger exposure, stream-window exposure, dyadic tolerance exactness, regular rational readback, terminal real sealing, componentwise transport, displayed replay, package provenance, and local naming for the finite carrier of Definition 3966.1.*

Proof. Carrier admission is projection from Definition 3966.1. The rows I, B, N expose the source interval, retained branch, and nested inclusion ledger by the same finite surfaces named in chapter 3815 and chapter 320.

The readback obligations are consecutive. The row S supplies only finite stream windows, the row D supplies only displayed dyadic tolerance cells, and Definition 3966.2 places the $\mathsf{RegSeqRat}^{\uparrow}$ row R after those data.

The terminal row E is the only $\mathsf{Real}^{\uparrow}$ seal-facing coordinate. The rows H, C, P, L then transport, replay, source, and name the same route while preserving the $\mathsf{Cauchy}^{\uparrow}$ dependency boundary of chapter 3413.

No listed obligation introduces a selected infinite branch, quotient real equality, countable choice, open-cover compactness, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, because none of those objects occurs as a carrier coordinate. □

Falsifiable prediction: Every $\mathsf{CauchyIntervalNesting}^{\uparrow}$ consumer that skips either the retained branch row or the nested inclusion ledger loses the RegSeqRat readback before any Real seal can be read.

Independence witness: closed-interval-bisection, nestedinterval, cauchy, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyIntervalNesting}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an interval source, retained bisection branch, nested inclusion ledger, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyIntervalNesting}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyIntervalNesting}^{\uparrow}$ packet is generated from an interval source row, a retained bisection branch row, a nested inclusion ledger, StreamName finite windows, a DyadicRatCore tolerance row, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyIntervalNesting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3966.1, Definition 3966.2, and Definition 3966.3 seed the finite retained-interval-to-Cauchy readback route over ClosedIntervalBisectionUp, NestedIntervalUp, CauchyUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows, including the interval source, retained bisection branch, nested inclusion ledger, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and RealUp seal, without selected branches, completed intersection points, quotient stream equality, quotient real equality, countable choice, or ambient RealUp completeness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyIntervalNesting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite branches, completed intersection points, quotient stream equality, quotient real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, retained branch exposure, nested inclusion routing, StreamName window exactness, DyadicRatCore tolerance accounting, RegSeqRat readback, Real seal nonescape, componentwise transport, displayed replay, package provenance, and local NameCert field faithfulness for BEDC.Derived.CauchyIntervalNestingUp.

Chapter 2990

A Concrete Naming Certificate for $\mathsf{FormalTopology}^{\uparrow}$

Following Vickers formal topology and Bishop–Bridges constructive completion, the $\mathsf{FormalTopology}^{\uparrow}$ packet records a cover-and-refinement presentation whose finite BEDC rows connect formal-ball neighbourhoods to rounded ideal completion without importing quotient opens, selected points, choice, or ambient completeness. It sits between the formal-ball carrier of chapter 1510, the rounded ideal completion route of chapter 1883, the metric source of chapter 57, the dyadic radius ledger of chapter 291, and the stream-window interface of chapter 126.

Definition 2990.1 (FormalTopology carrier)**.** *A* $\mathsf{FormalTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, B, U, R, D, S, I, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose point histories and distance witnesses are used by every formal-ball centre.*
2. *B is the finite* $\mathsf{FormalBall}^{\uparrow}$ *neighbourhood row over M, carrying centres, positive radii, and the local ball classifier.*
3. *U is the finite cover/refinement ledger: every cover request names finitely many displayed formal-ball neighbourhoods and every refinement request records the source and target neighbourhood rows it compares.*
4. *R is the rounded-neighbourhood row, recording smaller formal-ball witnesses for accepted basic neighbourhoods.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius-comparison ledger for strict radius shrinkage, overlap budgets, and refinement inequalities.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect centre observations, cover requests, and rounded-ideal membership windows.*
7. *I is the* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *handoff row, exposing only rounded directed formal-ball membership data to completion-facing consumers.*
8. *H records componentwise* hsame *transport for metric rows, formal-ball neighbourhoods, cover/refinement ledgers, dyadic comparisons, stream windows, rounded-ideal handoff rows, replay rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *replay from finite cover requests through refinement, roundedness, radius comparison, and rounded-ideal completion handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{FormalTopology}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{RoundedIdealCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalTopology}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, quotient opens, selected points, countable choice, host topological equality, or ambient metric completeness.

Lean4 ✓ `BEDC.Derived.FormalTopologyUp.FormalTopologyTasteGate single carrier alignment`

Theorem 2990.2 (FormalTopology cover stability)**.** *For an accepted* $\mathsf{FormalTopology}^{\uparrow}$ *carrier* $T = (M, B, U, R, D, S, I, H, C, P, N)$*, every finite cover or refinement read factors through the same displayed route*

$$M, B \longmapsto U, R, D, S \longmapsto H, C, P, N.$$

Componentwise hsame *transport through H preserves the cover ledger, the rounded-neighbourhood witnesses, the dyadic radius comparisons, the stream windows, and the local naming row. No transported read may replace the finite cover ledger by a quotient-open classifier, a selected point, a choice function, an open-cover compactness principle, or an ambient completeness theorem.*

Theorem 2990.3 (FormalTopology rounded-ideal handoff)**.** *Let $T = (M, B, U, R, D, S, I, H, C, P, N)$ be an accepted* $\mathsf{FormalTopology}^{\uparrow}$ *carrier. Every completion-facing consumer of its neighbourhood data must pass through the rounded-ideal row I after the formal-ball neighbourhoods B, the cover/refinement ledger U, the roundedness row R, the dyadic comparison ledger D, and the stream-window row S have been displayed.*

Thus the handoff to chapter 1883 exports a finite rounded directed formal-ball surface and exports no quotient open, selected limit point, countable-choice schedule, host topological equality, open-cover compactness proof, or ambient complete-space coordinate.

Theorem 2990.4 (FormalTopology NameCert obligations)**.** *Let $T = (M, B, U, R, D, S, I, H, C, P, N)$ be an accepted* $\mathsf{FormalTopology}^{\uparrow}$ *carrier. The local* $\mathsf{NameCert}_{\mathsf{FormalTopology}^{\uparrow}}$ *surface of T is exactly the finite obligation package consisting of carrier admission for T, finite* $\mathsf{FormalBall}^{\uparrow}$ *cover and refinement admission, rounded-neighbourhood witnesses,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius-comparison exactness,* $\mathsf{StreamName}^{\uparrow}$ *finite-window replay,* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier row of Definition 3967.1. The displayed tuple first fixes M as the metric source and B as the formal-ball neighbourhood carrier, so carrier admission and finite formal-ball admission are read before any completion-facing consumer is visible.

Next read the rows U, R, D, S, I in order. The cover and refinement ledger is U, rounded-neighbourhood evidence is R, dyadic radius comparison is D, finite-window replay is S, and the rounded-ideal completion handoff is I.

The remaining rows H, C, P, N close the certificate surface. They supply componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local naming row, and no additional coordinate appears in the carrier definition. □

Theorem 2990.5 (FormalTopology ledger non-escape)**.** *For an accepted* $\mathsf{FormalTopology}^{\uparrow}$ *carrier* $T = (M, B, U, R, D, S, I, H, C, P, N)$*, every cover, refinement, and completion-facing consumer is exhausted by the rows named in Definition 3967.4. No such consumer can obtain quotient opens,*

selected points, countable choice, open-cover compactness, host topology equality, or ambient metric completeness from the $\mathsf{FormalTopology}^{\uparrow}$ *ledger.*

Proof. Use the same projection of Definition 3967.1. A cover or refinement read must enter through B and U, then pass through R, D, S when it asks for roundedness, radius comparison, or finite observation replay.

A completion-facing read must additionally pass through I. After that handoff, the only public bookkeeping rows are H, C, P, N, which transport, replay, record provenance, and name the already displayed finite rows.

The last sentence of the carrier definition lists the absent coordinates. Since no row of T contains a quotient-open classifier, selected point, countable-choice schedule, open-cover compactness proof, host topology equality, or ambient completeness witness, a consumer constrained to T cannot extract one. □

Closure status for $\mathsf{NameCert}_{\mathsf{FormalTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{FormalTopology}^{\uparrow}$ packet is generated from a MetricSpace source row, finite FormalBall neighbourhoods, a cover/refinement ledger, rounded-neighbourhood witnesses, DyadicRatCore radius comparisons, StreamName windows, rounded-ideal completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FormalTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3967.1, Definition 3967.2, Definition 3967.3, Definition 3967.4, and Definition 3967.5 seed the finite formal-topology cover/refinement route from formal-ball neighbourhoods to rounded ideal completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FormalTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient opens, selected points, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover/refinement stability, dyadic radius comparison, StreamName replay, rounded-ideal handoff, transport, provenance, local naming, and ledger non-escape for the same packet.

Chapter 2991

A Concrete Naming Certificate for $\mathsf{FormalBallRadiusOrder}^{\uparrow}$

Following Edalat–Heckmann and Vickers-style formal-ball presentations, the $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ packet isolates the radius-refinement order that is consumed by the formal-ball carrier of chapter 1510, the rounded-basis route of chapter 3943, and the completion-facing handoff of chapter 2012. Its role is to name the finite BEDC comparison surface for smaller-radius reads before any completion quotient, selected representative, or ambient completeness principle is available.

Definition 2991.1 (FormalBall radius-order carrier)**.** *A* $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *carrier row whose center, radius, dyadic ledger, finite window, replay, provenance, and local name are already displayed.*
2. *R is the radius-read row, taken from the* $\mathsf{RegSeqRat}^{\uparrow}$ *scale attached to the formal-ball packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger recording strict and weak radius comparisons used by the refinement order.*
4. *L is the rounded lower-neighborhood row, recording the smaller-radius formal-ball windows that remain inside the same carrier route.*
5. *H records componentwise* hsame *transport for formal-ball carriers, radius rows, dyadic ledgers, lower-neighborhood rows, replay rows, provenance rows, and local naming rows.*
6. *C records displayed* Cont *replay from radius comparison to rounded refinement, basis handoff, and completion boundary.*
7. *P is the* Pkg *provenance over* $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{FormalBallBasis}^{\uparrow}$, $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallRadiusOrder}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of completed balls, a selected Cauchy representative, a countable-choice schedule, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FormalBallRadiusOrderUp.FormalBallRadiusOrderTasteGate single carrier alignment`

Theorem 2991.2 (FormalBall radius-order NameCert obligations)**.** *For the carrier of Definition 3968.1, the local* $\mathsf{NameCert}_{\mathsf{FormalBallRadiusOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for* $O = (B, R, D, L, H, C, P, N)$*, dyadic radius comparison through* D*, rounded refinement through* L*, basis handoff through the* $\mathsf{FormalBallBasis}^{\uparrow}$ *row named by* P*, completion non-escape through the* $\mathsf{FormalBallCompletion}^{\uparrow}$ *boundary, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Every accepted radius-order read must first expose the underlying $\mathsf{FormalBall}^{\uparrow}$ *packet* B*, then compare radii through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, and only then hand the rounded refinement to basis or completion consumers. It cannot read a quotient completion equality, choose a representative, select a limit, use countable choice, invoke compactness, or assume completeness.*

Proof. Carrier admission is projection from Definition 3968.1. The tuple displays the formal-ball packet, radius row, dyadic comparison ledger, lower-neighborhood row, transport, replay, provenance, and local name.

Dyadic radius comparison is confined to R and D. The formal-ball row B supplies the source center-radius packet, while D records the finite comparison data used to recognize a smaller radius.

Rounded refinement and basis handoff are then read through L and C. The lower-neighborhood row records the smaller formal-ball window, and replay sends that window to the basis and completion-facing rows carried in P.

Completion non-escape follows from row exhaustion. Since the carrier has no quotient-completion equality, selected representative, selected limit, countable-choice schedule, compactness principle, or ambient complete-space coordinate, none of those objects can be exported by the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallRadiusOrder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ packet is generated from a displayed FormalBallUp carrier, a RegSeqRat radius row, a DyadicRatCore comparison ledger, a rounded lower-neighborhood row, componentwise hsame transport, displayed Cont replay toward basis and completion consumers, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FormalBallRadiusOrder}^{\uparrow}}$, seed)

Scope closed: Definition 3968.1 and Definition 3968.2 seed the finite radius-refinement order route consumed by formal-ball basis and completion packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FormalBallRadiusOrder}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic comparison stability, rounded-refinement replay, basis handoff, completion non-escape, transport, provenance, and local naming for the same packet.

Chapter 2992

A Concrete Naming Certificate for $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$

Following Bishop and Bridges on compact intervals and finite approximation, the $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ packet records the compactness of a closed bounded interval as finite NameCert data. It consumes the closed bounded interval source of chapter 1591, the finite-net cover route of chapter 3471, the interval uniform-modulus source of chapter 1253, the compact-metric carrier of chapter 129, and the endpoint real-name seal of chapter 38. The packet is a displayed compact interval certificate for downstream finite-net, Bolzano-Weierstrass, and compact-uniform-continuity consumers; it is not an unrestricted open-cover compactness theorem, a selected subcover functional, a quotient interval representative, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 2992.1 (Closed bounded interval compact carrier)**.** *A* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, F, U, M, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing endpoint order, rational containment, dyadic containment, stream windows, regular rational readback, and Real sealing.*
2. *F is the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *finite-net compactness row, recording the listed cover witnesses and radius comparisons consumed by finite-cover readers.*
3. *U is the* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *sibling row, recording the compact-uniform source route over the same interval source and finite cover data.*
4. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *metric compactness row, read only through its finite-net, total-boundedness, and complete-limit components.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint and radius seal reached only after I, F, U, M have been displayed.*
6. *H records componentwise* hsame *transport for the interval source, finite-net row, uniform-modulus row, compact-metric row, Real seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from closed bounded interval inspection through finite-net compactness, compact-uniform source routing, compact-metric readback, and Real sealing.*

8. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, M, E, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, selected points, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalCompactUp.ClosedBoundedIntervalCompactTasteGate`
`single carrier alignment`

Theorem 2992.2 (Closed bounded interval compact NameCert obligations)**.** *For every accepted* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *carrier $K = (I, F, U, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalCompact}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the interval source, finite-net compactness row, uniform-modulus sibling row, compact-metric row, Real seal, transport, replay, provenance, and local naming rows;*
2. *interval-source exposure, requiring every compactness read to display the accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row before inspecting finite-net or compact-metric data;*
3. *finite-net compactness exposure, requiring cover-facing reads to pass through the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *row and its displayed radius and cover-witness ledgers;*
4. *compact-uniform compatibility, requiring the* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *rows to be read as sibling routes over the same interval source and Real seal;*
5. *non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed packet and to export no unrestricted open-cover compactness, selected subcover, selected point, quotient real equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Carrier admission is projection from Definition 3969.1. The tuple displays exactly the interval source, finite-net compactness row, compact-uniform sibling row, compact-metric row, Real seal, and structural rows.

The interval source is upstream. Any compactness reader must first read I, so endpoint order, rational containment, dyadic containment, stream windows, regular rational readback, and the Real-facing source seal are fixed before finite-net or compact-metric data are inspected.

The finite-net compactness obligation is the row F. Its cover witnesses and radius comparisons are the only cover-facing compactness data in the carrier, and they are consumed through the Heine-Borel finite-net route rather than through a host open-cover theorem.

The rows U and M are sibling compatibility rows. They let compact-uniform-continuity and compact-metric consumers use the same interval source and Real seal, but neither row changes the source interval or adds a selected subcover, selected point, quotient equality, trichotomy, choice, or ambient completeness coordinate.

Finally, H, C, P, N preserve only the displayed rows. Since every refused object is absent from the carrier, the local NameCert surface is exactly the five obligations listed above. □

Theorem 2992.3 (Closed bounded interval compact finite-net route)**.** *Every compactness-facing consumer of an accepted* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{HeineBorelFiniteNet}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *row is available as the compact-uniform sibling route over the same interval and finite-net data. Thus* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *supplies a precise*

compact interval anchor for finite-net compactness, Bolzano-Weierstrass, and compact-uniform-continuity consumers without exporting open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalCompactUp.ClosedBoundedIntervalCompactPacket finite net route`

Proof. Project the accepted carrier $K = (I, F, U, M, E, H, C, P, N)$. The interval source is I, the finite-net compactness route is F, the compact-metric row is M, and the terminal Real seal is E.

Replay through C keeps this order. A compactness-facing request opens the closed bounded interval source, reads the finite-net cover and radius row, then inspects the compact-metric finite-net and limit components before it reaches the Real-facing seal.

The row U records the compatible uniform-modulus route for consumers that need compact uniformity. It remains tied to the same interval source, finite-net row, compact-metric row, and Real seal, so it cannot introduce an unrestricted open-cover theorem, selected subcover, quotient equality, countable choice, or ambient completeness coordinate. □

Theorem 2992.4 (Closed bounded interval compact finite-net fan)**.** *Every Bolzano-Weierstrass, compact-uniform-continuity, and finite-cover consumer of an accepted* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *packet must pass through the displayed finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{HeineBorelFiniteNet}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *sibling row before reading any Real seal. The fan exports only the interval source, finite-net compactness row, compact-uniform sibling row, compact-metric row, Real seal, transport, replay, provenance, and local naming rows; it exports no open-cover compactness, selected subcover, selected point, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Project the accepted carrier $K = (I, F, U, M, E, H, C, P, N)$. The rows I, F, M, E are precisely the closed bounded interval source, Heine-Borel finite-net row, compact-metric row, and terminal Real seal displayed in Definition 3969.3.

Read the consumer fan by cases. A finite-cover consumer uses F; a Bolzano-Weierstrass consumer uses the compact-metric row M only after F has exposed the finite-net route; a compact-uniform-continuity consumer also reads the sibling row U over the same interval and finite-net data.

The structural rows H, C, P, N preserve this order for every branch of the fan. Since all refused objects are absent from the carrier, no branch can bypass the displayed route or read the Real seal before the interval, finite-net, compact-metric, and uniform-modulus rows have been displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a HeineBorelFiniteNet finite-net compactness row, a ClosedBoundedIntervalUniformModulus sibling row, a CompactMetric row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3969.1, Definition 3969.2, and Definition 3969.3 seed the finite compact interval certificate over closed bounded interval, Heine-Borel finite-net, compact-uniform, compact-metric, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected points, quotient real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exposure, finite-net compactness exposure, compact-uniform compatibility, compact-metric compatibility, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.ClosedBoundedIntervalCompactUp.

Chapter 2993

A Concrete Naming Certificate for $\mathsf{FiniteSequencePeak}^{\uparrow}$

Following Hardy, Littlewood, and Polya on finite maxima and elementary rearrangement arguments, the $\mathsf{FiniteSequencePeak}^{\uparrow}$ packet records the constructive selector surface for a bounded finite sequence before any L10 bounded-window route reads a peak value. It sits over the finite list carrier of chapter 36, the comparison discipline of chapter 54, the dyadic tolerance rows of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a finite peak row, bounded-window evidence, comparison replay, transport, provenance, and local naming data; it does not assert sequential compactness, countable choice, host extrema, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2993.1 (Finite sequence peak carrier)**.** *A* $\mathsf{FiniteSequencePeak}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (L, O, D, W, R, E, H, C, G, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{List}^{\uparrow}$ *row naming the finite sequence entries and their displayed length.*
2. *O is the* $\mathsf{TotalOrder}^{\uparrow}$ *comparison row used to compare only entries already present in L.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row carrying the finite comparison and error tolerances.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *bounded-window row that records the inspected segment supplied to L10 consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the bounded window and dyadic budgets into a regular rational observation of the selected peak.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after L, O, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for L, O, D, W, R, E and for the structural rows.*
8. *C records displayed* Cont *replay from a bounded-window request through*

$$L, O, D, W \longmapsto R \longmapsto E.$$

9. *G is the* Pkg *provenance over* $\mathsf{FiniteSequencePeak}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteSequencePeak}^\uparrow}$ *row.*
The classifier compares accepted packets only through $L, O, D, W, R, E, H, C, G, N$. The carrier has no coordinate for an infinite subsequence selector, sequential compactness theorem, host maximum operator, quotient stream representative, selected real limit, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.FiniteSequencePeakUp.TasteGate.FiniteSequencePeakTasteGate single carrier alignment`

Theorem 2993.2 (Finite sequence peak NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSequencePeak}^\uparrow$ *carrier $P = (L, O, D, W, R, E, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteSequencePeak}^\uparrow}$ *surface consists exactly of finite list admission through L, total-order comparison through O, dyadic budget accounting through D, bounded-window exposure through W, regular rational readback through R, terminal* $\mathsf{Real}^\uparrow$ *seal handoff through E, componentwise transport through H, replay through C, provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 3970.1. The analytic rows are exactly the finite list row, comparison row, dyadic budget row, bounded-window row, regular rational readback, and Real seal.

The selector route is finite. The consumer first reads the entries named by L, compares only those entries through O, and spends only the dyadic tolerances recorded in D before a bounded window is available.

The bounded-window row W is the only source for the regular rational readback R. Thus the Real-facing endpoint E is downstream of $\mathsf{List}^\uparrow$, $\mathsf{TotalOrder}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, and $\mathsf{RegSeqRat}^\uparrow$ data.

Finally H, C, G, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for sequential compactness, countable choice, host extrema, quotient streams, selected limits, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Theorem 2993.3 (Finite sequence peak RegSeqRat selector handoff)**.** *Every L10 bounded-window consumer of an accepted* $\mathsf{FiniteSequencePeak}^\uparrow$ *carrier reads the route*

$$\mathsf{List}^\uparrow \longmapsto \mathsf{TotalOrder}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The selected peak is exported to $\mathsf{RegSeqRat}^\uparrow$ *only as a finite-window readback: the list row supplies the candidate entries, the order row supplies the displayed comparisons, the dyadic row supplies the budget, and the stream row supplies the bounded inspection window before the terminal Real seal is exposed.*

Proof. Begin with an accepted carrier $P = (L, O, D, W, R, E, H, C, G, N)$. The row L lists the available entries, and O compares only entries already displayed by that finite list.

Read the dyadic and window rows next. The budget row D records the finite comparison tolerances, while W records the bounded segment consumed by the L10 route.

The regular rational row R is downstream of L, O, D, W. Therefore a $\mathsf{RegSeqRat}^\uparrow$ consumer receives a bounded-window readback and cannot replace it by a host maximum, an infinite subsequence selector, or a selected limit.

The terminal seal E is reached only after the readback route has been displayed. Transport, replay, provenance, and local naming through H, C, G, N preserve that same route, so no sequential compactness or ambient completeness coordinate is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSequencePeak}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSequencePeak}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3970.1, Definition 3970.2, and Definition 3970.3 seed the finite peak selector route for L10 bounded-window consumers over List, TotalOrder, DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSequencePeak}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sequential compactness, countable choice, host extrema, quotient stream equality, selected real limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite comparison coverage, bounded-window exposure, DyadicRatCore budget accounting, RegSeqRat readback exactness, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSequencePeakUp.

Constructive story: A $\mathsf{FiniteSequencePeak}^{\uparrow}$ packet is generated from a List row, TotalOrder comparison row, DyadicRatCore budget row, StreamName bounded-window row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 2994

A Concrete Naming Certificate for $\mathsf{LocatedIntervalBolzano}^{\uparrow}$

Following Bolzano and Bishop–Bridges constructive analysis, the $\mathsf{LocatedIntervalBolzano}^{\uparrow}$ packet records the finite interval-zero route used when a continuous located-real map changes sign on a located closed interval. It sits over the located real interval carrier of chapter 1709, the finite-net interval coverage rows of chapter 1808, the continuous-map replay of chapter 130, the intermediate-value route of chapter 3938, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names an interval-zero certificate from finite endpoint, bisection, stream, regular-rational, and real-seal data; it does not export trichotomy, a selected zero, quotient equality of real names, host compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 2994.1 (Located interval Bolzano zero carrier)**.** *A* $\mathsf{LocatedIntervalBolzano}^{\uparrow}$ *zero carrier is a finite* BHist *packet*

$$Z = (I, F, E, N, B, S, D, R, Q, H, C, P, L)$$

with the following displayed rows:

1. *I is the located-real interval source row, exposing the two endpoint seals, interval order witness, and located containment ledger.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row for the map inspected on the interval.*
3. *E is the endpoint sign row, displaying located negative and positive observations for the two endpoint values.*
4. *N is the* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *coverage row used to keep bisection requests inside the displayed interval.*
5. *B is the finite bisection row, recording the retained subinterval side, midpoint request, and sign handoff at every inspected stage.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for endpoint, midpoint, and retained-interval observations.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the endpoint gaps, midpoint scale, and retained interval radius.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance ledger.*

9. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after I, F, E, N, B, S, D, R have been displayed.*
10. *H records componentwise* hsame *transport for the analytic rows and for the local structural rows.*
11. *C records displayed* Cont *replay from the sign-change request through finite bisection, stream windows, regular rational readback, and the terminal seal.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalBolzano}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedIntermediateValue}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *L is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalBolzano}^{\uparrow}}$ *row.*

The classifier compares accepted zero carriers only through $I, F, E, N, B, S, D, R, Q, H, C, P, L$. It has no coordinate for real trichotomy, an externally selected zero, quotient equality of real names, host compactness, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalBolzanoUp.LocatedIntervalBolzanoTasteGate single carrier alignment`

Theorem 2994.2 (Located interval Bolzano sign handoff)**.** *For every accepted* $\mathsf{LocatedIntervalBolzano}^{\uparrow}$ *zero carrier*

$$Z = (I, F, E, N, B, S, D, R, Q, H, C, P, L),$$

the sign-change request is handed to completion-facing consumers only through the displayed route

$$\mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{LocatedIntermediateValue}^{\uparrow} \longmapsto \mathsf{S}$$

The terminal zero read is therefore a finite interval certificate consisting of endpoint signs, retained bisection rows, stream windows, dyadic tolerances, regular-rational readbacks, a real seal, componentwise transport, replay, provenance, and local naming. It is not a selected point, quotient real representative, trichotomy comparison, host compactness argument, countable-choice schedule, or ambient real-completeness principle.

Proof. Project the carrier of Definition 3971.1. The source interval row I, continuous-map row F, endpoint sign row E, finite-net row N, and bisection row B are the only interval-zero coordinates available before the stream-facing rows are read.

The bisection route is finite. At every inspected stage the retained side and midpoint request are displayed together with the finite coverage row, so the sign handoff stays inside the located closed interval and never asks for a global trichotomy decision.

Read S, D, R, Q next. The stream windows expose exactly the finite endpoint and midpoint observations, the dyadic ledger records their tolerance budget, the regular rational row reads those observations as regular data, and the terminal real seal is downstream of those displayed rows.

Finally H, C, P, L transport, replay, source, and name the same route. Since the packet contains no coordinate for selected zeros, quotient real equality, host compactness, countable choice, Lean verification, bridge checking, or ambient Real completeness, the displayed rows exhaust the sign handoff. □

Falsifiable prediction: A completion-facing interval-zero consumer that omits the located interval row, finite-net coverage row, continuous-map replay row, bisection row, StreamName window row, DyadicRatCore tolerance ledger, RegSeqRat readback, or RealUp seal cannot claim a $\mathsf{LocatedIntervalBolzano}^{\uparrow}$ zero handoff.

Independence witness: located-real-interval, located-closed-interval-finite-net, continuousmap, intermediatevalue, streamname, dyadicratcore, regseqrat, real: $\mathsf{LocatedIntervalBolzano}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint signs, finite interval coverage, continuous-map replay, retained bisection data, stream windows, dyadic tolerances, regular rational readback, a terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalBolzano}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalBolzano}^{\uparrow}$ packet is generated from a located-real interval row, finite endpoint sign rows, a LocatedClosedIntervalFiniteNet coverage row, ContinuousMap replay, a finite bisection ledger, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalBolzano}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3971.1 and Definition 3971.2 seed the constructive interval-zero route over located real intervals, finite interval nets, continuous maps, bisection, stream windows, regular rational readback, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalBolzano}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedIntervalBolzanoUp.LocatedIntervalBolzanoTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close real trichotomy, selected zeros, quotient real equality, host compactness, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, endpoint sign exposure, finite-net interval coverage, continuous-map replay, bisection ledger exactness, StreamName window exposure, DyadicRatCore tolerance stability, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalBolzanoUp.

Chapter 2995

A Concrete Naming Certificate for $\mathsf{BishopRealLocatedOrder}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers and located order, the $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ packet records the order-facing interface needed by L10 real and completion consumers. It sits between the Bishop real packet of chapter 343, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the dyadic readback of chapter 291, the stream windows of chapter 126, the regular-rational route of chapter 301, and the Archimedean real interface of chapter 430. The packet supplies displayed located-order and apartness rows for RealAlgOrder, monotone convergence, and completion-facing handoffs; it does not assert trichotomy, quotient real equality, host equality, selected suprema, or ambient completeness.

Definition 2995.1 (Bishop real located order carrier)**.** *A* $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, R, D, S, Q, A, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BishopReal}^{\uparrow}$ *source row, exposing the regular-Cauchy real name and its Bishop apartness interface.*
2. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Bishop source and its readback rows have been displayed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison row used for rational bracketing.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite name observations are requested.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows and dyadic tolerances.*
6. *A is the apartness-stability row, recording that positive rational separation is transported through the same finite readback route.*
7. *O is the located-order row, recording finite lower-or-upper rational alternatives only as displayed order evidence.*
8. *H records componentwise* hsame *transport for the Bishop source, Real seal, dyadic row, stream windows, regular readback, apartness row, located-order row, replay row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from Bishop source inspection through stream windows, dyadic tolerance, regular readback, apartness, located-order evidence, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopRealLocatedOrder}^{\uparrow}$, $\mathsf{BishopReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealLocatedOrder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, D, S, Q, A, O, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, host equality, selected suprema, a least-upper-bound operator, or ambient completeness.

Theorem 2995.2 (Bishop real located order NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ *carrier $L = (B, R, D, S, Q, A, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealLocatedOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; Bishop source exposure through B; Real sealing through R; dyadic tolerance and comparison readback through D; finite stream-window exposure through S; regular-rational readback through Q; apartness stability through A; located-order evidence through O; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.BishopRealLocatedOrderUp.BishopRealLocatedOrderTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3972.1. The source rows are exactly B, S, D, Q, R, so every order-facing read begins at the Bishop real source and reaches the Real seal only through displayed stream, dyadic, and regular-rational rows.

Read the order rows next. Apartness stability is the row A, and located-order evidence is the row O; neither row contains a trichotomy decision, a quotient equality proof, a selected supremum, or a host completeness principle.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite packet. Since the refused host-level objects have no carrier coordinate, the listed rows exhaust the NameCert surface. □

Theorem 2995.3 (Bishop real located order apartness stability)**.** *Every accepted apartness read from a* $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ *packet factors through*

$$B, S, D, Q, A, H, C, P, N$$

before it can be consumed by a $\mathsf{Real}^{\uparrow}$ *or completion-facing route. Thus positive separation is stable under the displayed* hsame *and* Cont *rows, but the read exports no quotient real equality, host equality, trichotomy, selected supremum, or ambient completeness theorem.*

Proof. Start with the Bishop source B. Its apartness evidence is not read directly by a host order relation; it is exposed through the finite stream windows S, the dyadic tolerance row D, and the regular-rational readback row Q.

Apply the apartness row A. This row records positive rational separation along that same route, so the consumer may transport a displayed separation only when the source, window, dyadic, and readback rows remain attached.

Use H and C for classifier movement. They preserve the displayed route and do not add a quotient-equality or trichotomy coordinate. Hence every accepted apartness read remains inside $B, S, D, Q, A, H, C, P, N$. □

Theorem 2995.4 (Bishop real located order regular-sequence scope)**.** *Every regular-sequence consumer of an accepted* $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ *packet must read the located-order interface through*

$$\mathsf{BishopReal}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{ArchimedeanReal}^{\uparrow}$$

as displayed by $B, S, D, Q, R, O, H, C, P, N$*. The exported scope is a constructive located-order handoff for RealAlgOrder, monotone convergence, and completion routes; it is not a trichotomy principle, a quotient real equality rule, a host equality rule, a selected-supremum package, or an ambient completeness assertion.*

Proof. Read the regular-sequence route through S, D, Q. These rows expose the finite stream windows, dyadic tolerances, and regular-rational readback before the terminal Real seal R can be used.

The located-order row O is downstream of that route and is sourced by the Bishop real row B together with the Archimedean provenance recorded in P. It therefore supplies order evidence only as a displayed finite handoff, not as a host-level order totality theorem.

The structural rows H, C, N preserve the same scope under accepted classifier movement. Since no carrier coordinate names trichotomy, quotient equality, host equality, selected suprema, or ambient completeness, regular-sequence consumers receive only the constructive located-order handoff. □

Falsifiable prediction: Every completion-facing $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ read factors through displayed BishopReal, StreamName, DyadicRatCore, RegSeqRat, RealUp, apartness, located-order, transport, replay, provenance, and local naming rows before it can be used as constructive order evidence.

Independence witness: bishopreal, real, dyadicratcore, streamname, regseqrat, archimedean-real: $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries apartness stability and located-order evidence over the same finite Bishop real readback route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealLocatedOrder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopRealLocatedOrder}^{\uparrow}$ packet is generated from a BishopReal source row, RealUp seal, DyadicRatCore tolerance row, StreamName windows, RegSeqRat readback, apartness stability, located-order evidence, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRealLocatedOrder}^{\uparrow}}$, seed)

Scope closed: Definition 3972.1, Definition 3972.2, Definition 3972.3, and Definition 3972.4 seed the constructive located-order interface for Bishop real, regular-sequence, and completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRealLocatedOrder}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.BishopRealLocatedOrderUp.BishopRealLocatedOrderTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host equality, selected suprema, ambient completeness, or bridge checking.

Upgrade path: Lean closure requires NameCert obligations, apartness stability, regular-sequence scope, and TasteGate field faithfulness for BEDC.Derived.BishopRealLocatedOrderUp.

Chapter 2996

A Concrete Naming Certificate for $\mathsf{NestedCompactIntersection}^{\uparrow}$

Following Bishop–Bridges and Kelley compactness-completion practice, the $\mathsf{NestedCompactIntersection}^{\uparrow}$ packet records the finite route by which a nested family of nonempty compact metric carriers can be read by later completion-facing consumers without asserting an open-cover compactness theorem or selecting a point of the total intersection. It sits after the compact metric carrier of chapter 129, the completion reuse boundary of chapter 2381, the separated regular-Cauchy handoff of chapter 1513, and the terminal real-name seal of chapter 38. The packet names a finite L10 compactness/completion surface: retained nested windows, finite-intersection witnesses, separated-completion readback, and a terminal Real seal, but no choice-selected intersection element and no ambient Real completeness principle.

Definition 2996.1 (Nested compact intersection carrier)**.** *A* $\mathsf{NestedCompactIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, J, W, F, S, R, E, H, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row for each compact stage of the nested family.*
2. *J is the finite nesting-order ledger, recording displayed inclusions between later and earlier compact stages.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *retained-window row used to inspect only finitely many stages at any requested tolerance.*
4. *F is the finite-intersection witness row, showing that each retained finite prefix has a displayed nonempty witness inside the visible compact stages.*
5. *S is the* $\mathsf{RegularCauchyCompletionSeparated}^{\uparrow}$ *handoff row that consumes the retained windows only after compact-stage and finite-prefix data have been displayed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the separated completion handoff.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after C, J, W, F, S, R have been read.*
8. *H records componentwise* hsame *transport for compact stages, nesting ledgers, windows, finite-prefix witnesses, separated-completion rows, readbacks, the Real seal, provenance, and local naming.*

9. *P is the* Pkg *provenance over* NestedCompactIntersection$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompletionIdempotence$^{\uparrow}$, RegularCauchyCompletionSeparated$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{NestedCompactIntersection}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected intersection points, quotient stream equality, countable choice, host set equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedCompactIntersectionUp.NestedCompactIntersectionTasteGate single carrier alignment`

Theorem 2996.2 (NestedCompactIntersection NameCert obligations)**.** *For every accepted* NestedCompactIntersect *carrier $K = (C, J, W, F, S, R, E, H, P, N)$, the local* NameCert$_{\text{NestedCompactIntersection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for compact metric stages, the nesting-order ledger, retained StreamName windows, finite-intersection witnesses, separated-completion handoff, regular rational readback, terminal Real seal, transport, provenance, and local naming;*

2. *nested-family exactness, requiring each later compact-stage read to be justified by the displayed nesting ledger J before it is used by a retained window;*

3. *finite-intersection witness stability, requiring every retained finite prefix to expose its witness through F and to transport through the same compact-stage and window rows;*

4. *separated-completion handoff, requiring every completion-facing read to pass through S and R after C, J, W, F have been projected;*

5. *Real seal nonescape, requiring E to remain downstream of the separated-completion and regular-readback rows, with no open-cover compactness, selected point, quotient equality, countable choice, host set equality, or ambient completeness coordinate.*

Proof. Carrier admission is projection from Definition 3973.1. The displayed tuple exposes compact metric stages, nesting ledgers, finite windows, prefix witnesses, separated-completion rows, readback, Real seal, transport, provenance, and local naming.

Nested-family exactness is the route C, J, W. A consumer may inspect a later compact stage through a retained window only after the relevant inclusion row in J has been displayed, so the nesting relation is part of the packet rather than an ambient set-theoretic assumption.

Finite-intersection witness stability is the route C, J, W, F, H. The witness row F is attached to a retained finite prefix, and the transport row H moves the compact-stage, nesting, window, and witness data componentwise without adding selected points beyond the displayed prefix witness.

The completion-facing part is last. The separated-completion row S and regular readback row R consume the compact and finite-prefix rows before the terminal Real seal E is available.

Since the carrier has no open-cover compactness object, global intersection selector, quotient stream equality, countable-choice schedule, host set equality, or ambient Real$^{\uparrow}$ completeness coordinate, none of those objects can be exported by the local NameCert surface. □

Closure status for NameCert$_{\text{NestedCompactIntersection}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{NestedCompactIntersection}^{\uparrow}}$, seed)

Scope closed: Definition 3973.1 and Definition 3973.2 seed the finite nested compact intersection route over CompactMetric stages, nesting ledgers, retained StreamName windows, finite-prefix witnesses, separated-completion handoff, RegSeqRat readback, RealUp seal, hsame transport, Pkg provenance, and local NameCert data.

Formal verification: FormalStatus(NameCert$_{\text{NestedCompactIntersection}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.NestedCompactIntersectionUp.NestedCompactIntersectionTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected intersection points, quotient stream equality, countable choice, host set equality, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires nested-family exactness, finite-intersection witness stability, separated-completion handoff, and RealUp seal nonescape for BEDC.Derived.NestedCompactIntersectionUp.

Constructive story: A NestedCompactIntersection$^{\uparrow}$ packet is generated from CompactMetric stage rows, a finite nesting-order ledger, retained StreamName windows, finite-intersection witnesses, a RegularCauchyCompletionSeparated handoff, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Chapter 2997

A Concrete Naming Certificate for $\mathsf{MercerTheorem}^{\uparrow}$

Following Mercer 1909 and the compact-operator spectral tradition represented in Reed–Simon, the $\mathsf{MercerTheorem}^{\uparrow}$ packet records the finite BEDC surface for a positive continuous kernel whose compact integral-operator shadow is read through matrix windows and Hilbert-space coordinates. It sits beside the compact-operator carrier of chapter 1952, the Hilbert package of chapter 91, the inner-product source of chapter 86, the finite matrix surface of chapter 49, and the terminal real-name seal of chapter 38. The packet names only a finite positive-kernel and RKHS readback certificate; it does not assert ambient measure theory, choice-selected eigenbases, unrestricted integral operators, or the full spectral theorem.

Definition 2997.1 (Mercer theorem carrier)**.** *A* $\mathsf{MercerTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, O, F, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact positive-kernel source row, recording a symmetric positive kernel request together with its compact-domain and continuity ledgers.*
2. *O is the* $\mathsf{CompactOperator}^{\uparrow}$ *shadow row, read only as a compact positive operator generated by the displayed kernel source.*
3. *F is the finite* $\mathsf{Mat}^{\uparrow}$ *window family: Gram matrices, kernel submatrices, and finite-rank approximation rows over displayed sample windows.*
4. *R is the* $\mathsf{Hilbert}^{\uparrow}$ *and* $\mathsf{RKHS}^{\uparrow}$ *readback row, exposing only inner-product evaluations and reproducing-kernel coordinates already named by K, O, F.*
5. *L is the* $\mathsf{Real}^{\uparrow}$ *eigenvalue-window row for the finite matrix and compact-operator approximants.*
6. *E is the expansion-read row, recording only finite Mercer-sum windows and their error budgets.*
7. *H records componentwise* hsame *transport for the kernel source, compact-operator shadow, matrix windows, Hilbert and RKHS readback, Real eigenvalue windows, expansion rows, and structural rows.*
8. *C records displayed* Cont *replay from kernel samples to matrix windows, from matrix windows to compact-operator reads, from compact-operator reads to Hilbert/RKHS coordinates, and from those coordinates to finite expansion windows.*

9. *P is the* Pkg *provenance over* $\mathsf{MercerTheorem}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MercerTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, O, F, R, L, E, H, C, P, N$. It has no coordinate for ambient measure spaces, choice-selected eigenbases, unrestricted integral operators, host spectral decompositions, quotient function spaces, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MercerTheoremUp.MercerTheoremTasteGate single carrier alignment decode encode`

Theorem 2997.2 (Mercer theorem NameCert obligations)**.** *For every accepted* $\mathsf{MercerTheorem}^{\uparrow}$ *carrier $M = (K, O, F, R, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MercerTheorem}^{\uparrow}}$ *surface consists exactly of compact positive-kernel admission through K, compact-operator shadowing through O, finite matrix and kernel windows through F, Hilbert and RKHS readback through R, Real eigenvalue windows through L, finite expansion windows through E, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3974.1. Its analytic rows are exactly the positive-kernel source, compact-operator shadow, finite matrix windows, Hilbert/RKHS readback, Real eigenvalue windows, and finite expansion windows.

The route is finite. Kernel samples enter through K, become matrix and Gram windows through F, and are read as a compact positive operator only through O before a Hilbert or RKHS consumer may inspect coordinates in R.

The eigenvalue row L and expansion row E are downstream of those displayed windows. They therefore expose only finite Real eigenvalue approximants and finite Mercer-sum windows, not a selected basis or host spectral decomposition.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no row for ambient measure theory, unrestricted integral operators, choice-selected eigenbases, quotient function spaces, full spectral theorem data, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 2997.3 (Mercer theorem positive-kernel handoff)**.** *Every finite Mercer read from an accepted* $\mathsf{MercerTheorem}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Mat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CompactOperator}^{\uparrow} \longmapsto \mathsf{Hilbert}^{\uparrow}, \mathsf{InnerProduct}^{\uparrow} \longmapsto \mathsf{RKHS}^{\uparrow}$$

together with H, C, P, N. The positive-kernel source is exported only as finite Gram-matrix positivity, compact-operator shadowing, Hilbert/RKHS coordinate readback, Real eigenvalue-window data, and finite expansion-window budgets.

Proof. Begin with the positive-kernel source row K. A consumer may inspect it only by opening the finite matrix windows in F, where positivity is visible as displayed Gram-window data over Real entries.

The compact-operator row O is then the only route from those finite windows to operator-facing reads. Thus an RKHS or Hilbert consumer cannot bypass the compact shadow with an unrestricted integral operator.

Read R, L, E next. The Hilbert and RKHS coordinates are exposed through R, the eigenvalue approximants through L, and the finite Mercer-sum windows through E.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same displayed route. Because the carrier has no field for measure-theoretic integration, choice-selected

eigenbases, host spectral theorem data, quotient functions, or ambient Real completeness, the positive-kernel handoff remains finite. □

Closure status for $\mathsf{NameCert}_{\mathsf{MercerTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{MercerTheorem}^{\uparrow}$ packet is generated from a compact positive-kernel source row, a CompactOperator shadow row, finite Matrix kernel windows, Hilbert and RKHS readback rows, Real eigenvalue windows, finite Mercer expansion windows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MercerTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3974.1, Definition 3974.2, and Definition 3974.3 seed the finite positive-kernel Mercer route over compact operators, Hilbert and inner-product rows, matrix windows, and Real eigenvalue readbacks.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MercerTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient measure theory, choice-selected eigenbases, unrestricted integral operators, the full spectral theorem, quotient function-space equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-kernel matrix-window coverage, CompactOperator shadow compatibility, Hilbert and RKHS readback exactness, Real eigenvalue-window stability, expansion-window nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MercerTheoremUp.

Chapter 2998

A Concrete Naming Certificate for CauchyCompletionRegularSequence$^{\uparrow}$

Following Bishop and Bridges constructive Cauchy completion, the CauchyCompletionRegularSequence$^{\uparrow}$ packet records the handoff from regular Cauchy rational names to completion-facing and Real-facing consumers as finite BEDC data. It sits after the regular rational name surface of chapter 301, the equality discipline of chapter 1820, the metric completion carrier of chapter 1506, and the uniform completion boundary of chapter 1473, and before the terminal real-name seal of chapter 38. The packet names the completion handoff without forming quotient classes of regular sequences, selecting limits, invoking countable choice, importing ambient completeness, or using Real$^{\uparrow}$ completeness as an input.

Definition 2998.1 (CauchyCompletionRegularSequence carrier)**.** *A* CauchyCompletionRegularSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (R, E, M, U, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* RegSeqRat$^{\uparrow}$ *regular Cauchy rational name row.*
2. *E is the* CauchyEquivalenceSetoid$^{\uparrow}$ *comparison row, recording only the displayed equality discipline available between regular Cauchy names.*
3. *M is the* MetricCompletion$^{\uparrow}$ *handoff row reached from the same regular name and comparison data.*
4. *U is the* UniformCompletion$^{\uparrow}$ *handoff row for consumers that read the completion through uniform-tail data.*
5. *S is the terminal* Real$^{\uparrow}$ *seal row, available only after R, E, M, U have been displayed.*
6. *H records componentwise* hsame *transport for the regular name, comparison, completion handoff, uniform handoff, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-facing request through R, E, M, U and then to the seal row S.*
8. *P is the* Pkg *provenance over* CauchyCompletionRegularSequence$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyEquivalenceSetoid$^{\uparrow}$, MetricCompletion$^{\uparrow}$, UniformCompletion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionRegularSequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, E, M, U, S, H, C, P, N$. It has no coordinate for quotient regular sequences, chosen representatives, selected limits, countable choice, ambient metric or uniform completeness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 2998.2 (CauchyCompletionRegularSequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionRegularSequence}^{\uparrow}$ *carrier $Q = (R, E, M, U, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletio}}$ *surface consists exactly of the finite obligations of carrier admission for the displayed rows; regular-name exposure through R; comparison exposure through E; metric-completion handoff through M; uniform-completion handoff through U; Real seal nonescape through S; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

No obligation row is discharged by quotient equality, a selected limit, countable-choice data, ambient completeness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3975.1. The accepted tuple displays the regular name, comparison, metric-completion handoff, uniform-completion handoff, Real seal, transport, replay, provenance, and local name.

The regular-sequence side is exhausted by R and E. The row R supplies the regular rational name, and E supplies the displayed Cauchy-equivalence setoid comparison before any completion handoff is visible.

The completion-facing side is exhausted by M and U. A metric-completion consumer reads M, and a uniform-completion consumer reads U, but both rows are downstream from the same regular name and comparison rows.

Finally S, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier has no quotient, chosen-representative, selected-limit, choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionRegularSequenceUp.CauchyCompletionRegularSequenceTasteGate`
`single carrier alignment`

Theorem 2998.3 (CauchyCompletionRegularSequence Real seal handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCompletionRegularSequence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the terminal seal is read only after the regular Cauchy name, displayed equivalence data, and completion handoff rows have been exposed, and it exports no quotient class, selected limit, countable choice, ambient completeness, or $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from an accepted consumer read of Q. Carrier projection opens R and E before any completion-facing row can be consumed.

If the consumer is metric-facing, it next reads M; if it is uniform-facing, it next reads U. In both cases the route still passes through the same regular name and comparison rows, so neither handoff introduces a quotient class or a selected representative.

The seal row S is downstream from those handoff rows. Componentwise transport and displayed replay through H and C preserve the route, while P and N attach provenance and local naming. The excluded objects are absent from the carrier, so no consumer can recover them from the handoff. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionRegularSequence}^{\uparrow}$ completion-facing read factors through RegSeqRat, CauchyEquivalenceSetoid, MetricCompletion, UniformCompletion, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: regseqrat, cauchy-equivalence-setoid, metriccompletion, uniformcompletion, real: $\mathsf{CauchyCompletionRegularSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the regular name, displayed equivalence comparison, two completion handoff rows, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionRegularSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionRegularSequence}^{\uparrow}$ packet is generated from a RegSeqRat regular Cauchy name row, a CauchyEquivalenceSetoid comparison row, MetricCompletion and UniformCompletion handoff rows, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionRegularSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3975.1, Definition 3975.2, and Definition 3975.3 seed the finite regular-sequence completion handoff from RegSeqRat and CauchyEquivalenceSetoid data through MetricCompletion and UniformCompletion rows to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionRegularSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient regular sequences, selected limits, countable choice, ambient metric or uniform completeness, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-name exposure, equivalence comparison exposure, metric-completion and uniform-completion handoff exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionRegularSequenceUp.

Chapter 2999

A Concrete Naming Certificate for $\mathsf{CosetSpace}^{\uparrow}$

Following Bourbaki's treatment of groups and cosets, the $\mathsf{CosetSpace}^{\uparrow}$ packet records the finite BEDC surface at which left and right cosets become classifier data over a displayed group and subgroup. It sits after the group carrier of chapter 41, the subgroup membership surface of chapter 80, and the quotient-facing route of chapter 82; it is also compatible with the finite permutation surface of chapter 117 and the word-source discipline of chapter 345. The packet names coset membership and representative replacement as finite rows, not as a host quotient type or an appeal to $\mathsf{Quot.sound}$.

Definition 2999.1 (Coset-space carrier)**.** *A* $\mathsf{CosetSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (G, S, r, o, H, C, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{Group}^{\uparrow}$ *operation surface, including carrier, multiplication, unit, inverse, and operation-law rows;*
2. *S is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *membership surface inside the group row G, including closure under multiplication, unit, inverse, and classifier transport;*
3. *r is the representative row naming the selected displayed group element used to read a coset;*
4. *o is the orientation row, distinguishing left-coset reads from right-coset reads without changing the ambient group or subgroup rows;*
5. *H is componentwise* hsame *transport for the group, subgroup, representative, orientation, replay, provenance, and local-name rows;*
6. *C is the displayed* Cont *replay route from a coset-space request through G, S, r, o, H, P, N;*
7. *P is the* Pkg *provenance over* $\mathsf{CosetSpace}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{QuotientGroup}^{\uparrow}$, $\mathsf{SymGroup}^{\uparrow}$, $\mathsf{FreeMonoid}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CosetSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers by the displayed group operation rows, subgroup membership rows, representative row, orientation row, transport, replay, provenance, and local naming. It has no coordinate for a host quotient set, quotient-type equality, selected transversal, external action orbit, or subgroup lattice object.

Lean4 ✓ `BEDC.Derived.CosetSpaceUp.CosetSpaceTasteGate single carrier alignment`

Theorem 2999.2 (Coset-space NameCert obligations)**.** *For the carrier of Definition 3976.1, the local* $\mathsf{NameCert}_{\mathsf{CosetSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for* $X = (G, S, r, o, H, C, P, N)$*, group-operation exposure through* G*, subgroup-membership exposure through* S*, oriented representative readback through* r, o*, componentwise classifier transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. A consumer receives no host quotient type,* Quot.sound *equality, or off-packet representative selector.*

Proof. Project the carrier. The group row G provides the only multiplication, unit, inverse, and operation-law data visible to the packet, and the subgroup row S provides the only membership and closure data.

The representative row r and orientation row o determine whether the consumer reads a left or right coset. This read is still a finite membership route through G and S, so no host quotient carrier or selected transversal is introduced.

Finally, H, C, P, N preserve the same row inventory under transport, replay, provenance, and local naming. Since the carrier contains no coordinate for quotient-type equality or Quot.sound, the local NameCert obligations are exhausted by the displayed rows. □

Theorem 2999.3 (Coset-space classifier transport)**.** *Let* $X = (G, S, r, o, H, C, P, N)$ *and* $X' = (G', S', r', o, H', C', P', N')$ *be accepted* $\mathsf{CosetSpace}^{\uparrow}$ *carriers with the same orientation row. If componentwise* hsame *transport identifies the group operation rows, subgroup membership rows, and representative rows, and if representative replacement is witnessed by the displayed subgroup-membership transport in* S *and* S'*, then the two carriers classify together as the same coset-space read. The transported classifier does not pass through a host quotient type or* Quot.sound*.*

Proof. Project both accepted carriers. The group rows G, G' supply the only multiplication and inverse operations, while the subgroup rows S, S' supply the only membership tests available for comparing representative replacements.

Use the displayed representative transport between r and r'. For a left-coset orientation, the replacement is read by multiplying the transported representative difference against the subgroup membership row; for a right-coset orientation, the same argument is read on the opposite side. In both cases the membership witness remains inside S and S'.

Replay the result through C and C' and compare provenance and local naming through P, N and P', N'. Because the route never leaves the displayed G, S, r, o rows, the classifier transport is a coset-membership transport rather than a quotient-type equality proof. □

Falsifiable prediction: An accepted $\mathsf{CosetSpace}^{\uparrow}$ consumer is refuted if it exports a coset classifier while omitting the displayed group row, subgroup membership row, representative row, orientation row, transport, replay, provenance, or local NameCert row.

Independence witness: group, subgroup, quotientgroup, symgroup, freemonoid: none is bijective to $\mathsf{CosetSpace}^{\uparrow}$ because this packet jointly carries the ambient group operation, subgroup membership surface, representative row, left/right orientation, transport, replay, provenance, and local naming. The group packet lacks subgroup membership and representatives; the subgroup packet lacks oriented coset classification; the quotient group packet names a quotient-facing route; the symmetric group and free monoid packets provide finite action and word sources without owning coset membership transport.

Closure status for $\mathsf{NameCert}_{\mathsf{CosetSpace}^{\uparrow}}$**.**

Constructive story: A CosetSpace$^{\uparrow}$ packet is generated from a group operation row, subgroup membership row, representative row, left/right orientation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CosetSpace}^{\uparrow}}$, seed)

Scope closed: Definition 3976.1, Definition 3976.2, and Definition 3976.3 seed the coset-space carrier, obligation surface, and representative-transport classifier.

Formal verification: FormalStatus(NameCert$_{\mathsf{CosetSpace}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CosetSpaceUp.CosetSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-group normality, orbit-stabilizer theory, selected transversals, or host quotient-type equality for CosetSpace$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, group and subgroup row exposure, oriented representative transport, replay stability, provenance non-escape, and TasteGate instances for BEDC.Derived.CosetSpaceUp.

Chapter 3000

A Concrete Naming Certificate for $\mathsf{UniformCauchyNet}^{\uparrow}$

Following Moore–Smith and Kelley uniform-space nets, and Bishop-style finite completion discipline, the $\mathsf{UniformCauchyNet}^{\uparrow}$ packet records a uniform Cauchy net as displayed NameCert data rather than as a quotient net or selected limit. It sits beside the Cauchy-net source of chapter 589, the net-completion route of chapter 3794, the metric completion surface of chapter 1506, the uniform completion handoff of chapter 1473, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a constructive L10 completion neighbour whose consumers can inspect directed uniform-tail data without importing countable choice or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3000.1 (UniformCauchyNet carrier)**.** *A* $\mathsf{UniformCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, E, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-index row, recording the finite Moore–Smith comparison data used to cofinalize the inspected tail.*
2. *E is the uniform tolerance or entourage ledger, listing the requested entourage rows and the finite tail witnesses that answer them.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened at the inspected indices and entourage requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed windows and tolerance ledger.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, E, W, R have been displayed.*
6. *H records componentwise* hsame *transport for directed indices, entourage ledgers, stream windows, regular readback, Real sealing, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a uniform-tail request through the inspected windows, regular rational readback, and completion-facing handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, E, W, R, S, H, C, P, N$. It has no coordinate for quotient nets, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyNetUp.UniformCauchyNetTasteGate single carrier alignment`

Theorem 3000.2 (UniformCauchyNet NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyNet}^{\uparrow}$ *carrier $U = (D, E, W, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyNet}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the directed-index row, uniform entourage ledger, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *directed-tail stability, requiring cofinal tail comparisons to be read from D before any entourage claim in E is exposed;*
3. *uniform tolerance exactness, requiring every inspected entourage request to pass through the finite ledger E and the corresponding* $\mathsf{StreamName}^{\uparrow}$ *windows W;*
4. *completion-facing readback, requiring the regular rational row R and the* $\mathsf{Real}^{\uparrow}$ *seal S to be reached only through the displayed directed, entourage, and window route;*
5. *non-escape for quotient nets, selected limits, countable choice, open-cover compactness, hidden cofinal schedules, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3977.1. The tuple displays the directed index data, entourage ledger, window family, regular readback, Real seal, transport, replay, provenance, and local name.

Directed-tail stability is confined to D. A consumer first reads the finite Moore–Smith comparison rows that justify the inspected tail, so the later entourage rows cannot be treated as an unindexed uniform assertion.

Uniform tolerance exactness is the role of E and W. Each entourage request is paired with the displayed finite windows that witness the inspected tail, and no hidden cofinal schedule is available outside those rows.

The completion-facing readback then passes through R and S. Since R is obtained only after the directed and window data are displayed, and S is the terminal seal for that route, the packet exports a finite uniform-net handoff rather than a selected completion point.

Non-escape follows by row exhaustion. Quotient nets, selected limits, countable choice, open-cover compactness, hidden cofinal schedules, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, so the local NameCert surface cannot export them. □

Theorem 3000.3 (UniformCauchyNet filter handoff)**.** *Every completion- or filter-facing read of an accepted* $\mathsf{UniformCauchyNet}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyNet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{UniformCompletion}^{\uparrow}$ *rows named by the provenance are handoff surfaces for this same displayed route. Thus a consumer receives directed uniform-tail data, finite windows, regular readback, componentwise transport, displayed replay, provenance, and local naming, not a quotient net, chosen limit, countable-choice schedule, open-cover compactness principle, or ambient Real completeness theorem.*

Proof. Project the accepted carrier $U = (D, E, W, R, S, H, C, P, N)$. The directed row D and entourage ledger E expose the uniform Cauchy source, while W records the finite windows used to inspect it.

Replay through C preserves the order of the route. A filter-facing or completion-facing request first opens the directed tail and entourage ledger, then reads the stream windows, then obtains the regular rational row R, and only then reaches the Real seal S.

The completion siblings are read as handoff surfaces named in P. They consume the same displayed route and cannot add a quotient net, selected limit, countable-choice schedule, open-cover compactness principle, hidden cofinal tail, or ambient completeness coordinate. □

Theorem 3000.4 (UniformCauchyNet directed-tail stability)**.** *Let $U = (D, E, W, R, S, H, C, P, N)$ be an accepted* $\mathsf{UniformCauchyNet}^{\uparrow}$ *carrier. If a consumer replaces the inspected directed tail by a cofinal refinement whose comparison rows are displayed in D, then the same local* $\mathsf{NameCert}_{\mathsf{UniformCauchyNet}^{\uparrow}}$ *packet supplies the entourage ledger E, finite window family W, regular readback R, Real seal S, filter handoff rows, transport, replay, provenance, and local naming. The refinement changes only the displayed tail comparison inside D; it does not create a quotient net, selected limit, hidden cofinal schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start from the carrier definition. The row D is the sole source of directed-index comparison data, and every later entourage or completion read is downstream of that row.

A cofinal refinement admitted by D therefore preserves the inspected tail route. The entourage ledger E and window family W are read after the directed comparison, so their witness rows remain attached to the same local packet.

Now apply the filter handoff theorem. The rows R and S are still reached through the ordered route from directed tail data to finite windows and regular readback.

The structural rows H, C, P, N transport and replay the same packet after the refinement. Because the carrier has no coordinate for quotient nets, selected limits, hidden cofinal schedules, or ambient completeness, the cofinal read has no escape branch. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchyNet}^{\uparrow}$ completion-facing read factors through a directed index row, uniform entourage ledger, finite StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchynet, cauchy-net-completion, metriccompletion, uniformcompletion, streamname, regseqrat, real: $\mathsf{UniformCauchyNet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries directed index data, uniform entourage ledgers, finite stream windows, regular readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyNet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformCauchyNet}^{\uparrow}$ packet is generated from a directed index row, a uniform tolerance or entourage ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3977.1, Definition 3977.2, and Definition 3977.3 seed the constructive uniform-net completion route over directed tails, entourage ledgers, finite windows, regular readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient nets, selected limits, countable choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail stability, uniform tolerance exactness, completion-facing readback, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyNetUp.

Chapter 3001

A Concrete Naming Certificate for $\mathsf{ContourResidueHandoff}^{\uparrow}$

Following Cauchy's residue calculus, the $\mathsf{ContourResidueHandoff}^{\uparrow}$ packet records the finite consumer boundary at which a contour-integral operation may be read as residue-facing data. It sits after the contour operation surface of chapter 521, the operation socket of chapter 583, the holomorphic input boundary of chapter 68, and the residue packet of chapter 125. The packet exposes piecewise-linear contour rows, holomorphic rows, operation-law ledgers, residue rows, and non-escape rows as one finite handoff; it does not introduce a host contour homology theorem, analytic-continuation oracle, or global residue theorem.

Definition 3001.1 (Contour-residue handoff carrier)**.** *A* $\mathsf{ContourResidueHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, F, O, S, Z, B, H, C, P, N)$$

with the following displayed rows:

1. *G is the piecewise-linear contour row read by the contour operation surface;*
2. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *source row on the displayed contour domain away from the residue locus;*
3. *O is the* $\mathsf{ContourIntegralOperation}^{\uparrow}$ *row, including the Riemann-sum ledger, output row, and operation-law boundary;*
4. *S is the* $\mathsf{ContourIntegralSocket}^{\uparrow}$ *row through which contour-operation consumers read G, F, O;*
5. *Z is the* $\mathsf{Residue}^{\uparrow}$ *row naming the local residue datum consumed by the handoff;*
6. *B is the boundary row recording that residue-facing reads require the displayed contour, holomorphic, socket, operation, and residue rows, and that no off-packet analytic theorem is exported;*
7. *H is componentwise* hsame *transport for G, F, O, S, Z, B together with replay, provenance, and local naming;*
8. *C is the displayed* Cont *replay route from a residue handoff request through $G, F, O, S, Z, B, H, P, N$;*
9. *P is* Pkg *provenance over* $\mathsf{ContourResidueHandoff}^{\uparrow}$, $\mathsf{ContourIntegralOperation}^{\uparrow}$, $\mathsf{ContourIntegralSocket}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Residue}^{\uparrow}$, *piecewise-linear contour rows,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ContourResidueHandoff}^{\uparrow}}$ *row.*

The classifier accepts only packets with these displayed rows. It has no coordinate for contour homology, global residue summation, meromorphic continuation, quotient path equality, or an analytic oracle outside the contour-operation packet.

Lean4 ✓ `BEDC.Derived.ContourResidueHandoffUp.ContourResidueHandoffTasteGate single carrier alignment`

Theorem 3001.2 (Contour-residue handoff NameCert obligations)**.** *For the carrier of Definition 3978.1, the local* $\mathsf{NameCert}_{\mathsf{ContourResidueHandoff}^{\uparrow}}$ *surface consists exactly of carrier admission, PL-contour exposure, holomorphic source exposure, contour-operation exposure, contour-socket consumer routing, residue-row exposure, boundary non-escape, componentwise transport, displayed replay, provenance, and local naming. A residue-facing consumer receives no contour homology theorem, global residue theorem, quotient path equality, or analytic-continuation oracle.*

Proof. Project the carrier. The contour row G, holomorphic row F, operation row O, socket row S, and residue row Z are the only analytic data visible to the local certificate.

The boundary row B records which residue-facing reads may be consumed from those displayed rows. A request for a global residue theorem, contour homology invariant, quotient path equality, or analytic-continuation oracle has no coordinate in the packet and is therefore refused.

The transport, replay, provenance, and local naming rows H, C, P, N preserve this same finite inventory. Hence the NameCert obligations are exhausted by the displayed handoff rows. □

Theorem 3001.3 (Contour-residue handoff boundary)**.** *Let* $R = (G, F, O, S, Z, B, H, C, P, N)$ *be an accepted* $\mathsf{ContourResidueHandoff}^{\uparrow}$ *carrier. Every residue-facing consumer of the contour operation must first factor through the displayed* $\mathsf{ContourIntegralOperation}^{\uparrow}$ *row* O*, the* $\mathsf{ContourIntegralSocket}^{\uparrow}$ *row* S*, the* $\mathsf{Holomorphic}^{\uparrow}$ *source row* F*, the PL-contour row* G*, and the* $\mathsf{Residue}^{\uparrow}$ *row* Z*. The handoff exports only the displayed residue boundary and does not create a global residue theorem, contour deformation theorem, or off-packet meromorphic continuation principle.*

Proof. Read the contour operation through O and the socket through S. These rows expose the piecewise-linear contour, holomorphic input, Riemann-sum and operation-law ledgers, output row, transport, and replay routes before any residue-facing request is considered.

The residue row Z is then consumed through the same route, with B recording the precise boundary between displayed residue data and unavailable global analytic consequences. Thus a consumer can read a local handoff but cannot infer contour homology, deformation invariance, or a global residue sum.

Finally, componentwise hsame transport and Cont replay keep G, F, O, S, Z, B attached to the same provenance and local NameCert rows. The absence of any additional analytic coordinate prevents the handoff from exporting off-packet meromorphic continuation or quotient path equality. □

Falsifiable prediction: An accepted $\mathsf{ContourResidueHandoff}^{\uparrow}$ consumer is refuted if it exports residue-facing contour data while omitting the displayed PL-contour row, holomorphic row, contour-operation row, contour-socket row, residue row, boundary row, transport, replay, provenance, or local NameCert row.

Independence witness: contourintegraloperation, contourintegralsocket, holomorphic, residue: none is bijective to $\mathsf{ContourResidueHandoff}^{\uparrow}$ because this packet jointly carries the contour row, holomorphic source, contour-operation ledger, socket consumer route, residue row, non-escape boundary, transport, replay, provenance, and local naming. The operation and socket packets lack

the residue handoff row; the holomorphic packet lacks contour output and residue data; the residue packet lacks contour-operation routing.

Closure status for $\mathsf{NameCert}_{\mathsf{ContourResidueHandoff}^{\uparrow}}$.

Constructive story: A $\mathsf{ContourResidueHandoff}^{\uparrow}$ packet is generated from a piecewise-linear contour row, holomorphic source row, contour-integral operation row, contour-integral socket row, residue row, boundary non-escape row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContourResidueHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3978.1, Definition 3978.2, and Definition 3978.3 seed the contour-residue handoff carrier, obligation surface, and residue-facing consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContourResidueHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, contour homology, deformation invariance, the global residue theorem, meromorphic continuation, or quotient path equality for $\mathsf{ContourResidueHandoff}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, contour-operation exposure, socket routing, residue-row handoff, boundary non-escape, replay stability, provenance exactness, and TasteGate instances for BEDC.Derived.ContourResidueHandoffUp.

Chapter 3002

A Concrete Naming Certificate for $\mathsf{InitialValueProblem}^{\uparrow}$

Following Picard and Lindelof, the $\mathsf{InitialValueProblem}^{\uparrow}$ packet records the local ODE initial-data object consumed by Picard–Lindelof as explicit finite NameCert data. It sits between the ODE source of chapter 193, the Lipschitz vector-field ledger of chapter 410, the local existence route of chapter 1888, the complete-metric handoff of chapter 128, and the real-number ground of chapter 38. The packet names the initial time, state, local window, vector-field graph, solution graph, and endpoint classifier before any solution representative is exposed.

Definition 3002.1 (Initial-value problem carrier)**.** *An* $\mathsf{InitialValueProblem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (T, X, F, W, S, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the time row, including the initial time cell and the local time-radius ledger;*
2. *X is the state row, including the initial state cell and the state-window ledger;*
3. *F is the vector-field graph row, read through the* $\mathsf{Ode}^{\uparrow}$ *and* $\mathsf{LipschitzMap}^{\uparrow}$ *dependency surface on the same local window;*
4. *W is the local window row binding the time and state ledgers used by the Picard route;*
5. *S is the solution-graph row exposed only as finite graph windows and not as a selected host function;*
6. *E is the endpoint classifier row, comparing endpoint reads inside the same local window;*
7. *H records componentwise* hsame *transport for the time row, state row, vector-field graph, local window, solution graph, endpoint classifier, replay rows, provenance, and local naming row;*
8. *C records the displayed* Cont *replay from initial data through vector-field reads, Picard iteration, completion handoff, solution windows, and endpoint classification;*
9. *P is the* Pkg *provenance over* $\mathsf{InitialValueProblem}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{InitialValueProblem}^{\uparrow}}$ *row.*

The classifier accepts only packets with these rows. It has no coordinate for a global flow, maximal continuation, host function-space equality, selected solution representative, or ambient completeness object.

Lean4 ✓ `BEDC.Derived.InitialValueProblemUp.InitialValueProblemTasteGate single carrier alignment`

Theorem 3002.2 (Initial-value problem NameCert obligations)**.** *For an accepted* $\mathsf{InitialValueProblem}^{\uparrow}$ *carrier* $I = (T, X, F, W, S, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{InitialValueProblem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, time-state compatibility for* T *and* X*, vector-field graph admission through* F*, local-window nonescape through* W*, solution-graph visibility through* S*, endpoint classification through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 3979.1. The accepted packet displays the time, state, vector-field, local-window, solution-graph, endpoint, transport, replay, provenance, and local naming rows.

The source rows T, X, F, W bind one local initial-data surface. The time and state cells determine the initial condition, the vector-field graph is read only through the displayed ODE and Lipschitz rows, and the local window records the bounds within which later Picard reads are permitted.

The solution and endpoint rows are downstream of that surface. The row S records only displayed graph windows, while E classifies endpoint reads inside the same local window. Transport, continuation replay, provenance, and local naming preserve this route and do not add global ODE existence, maximal continuation, host function equality, or selected solution representatives. □

Theorem 3002.3 (Initial-value problem Picard handoff)**.** *Every accepted* $\mathsf{InitialValueProblem}^{\uparrow}$ *carrier hands a Picard–Lindelof consumer exactly the displayed route*

$\mathsf{Ode}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

The consumer must read the time row, state row, vector-field graph, and local window before it may inspect solution-graph windows or endpoint classifiers. The handoff exports no global solution curve, maximal interval, host function-space equality, selected solution representative, or completeness principle outside the displayed complete-metric row.

Proof. Start with the initial-data surface. The rows T and X give the initial time and state, while F and W bind the vector-field graph to the same local window.

Replay the Picard-facing route through C. The Picard–Lindelof consumer reaches the solution-graph row S only after the ODE and Lipschitz data have been read, and it reaches the endpoint classifier E only through the displayed completion handoff.

Finally use the structural rows. Componentwise hsame transport in H, provenance in P, and the local name N record the same finite handoff. Since the carrier contains no global-flow, maximal-continuation, host-equality, selected-representative, or detached-completeness coordinate, none can be exported to the consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{InitialValueProblem}^{\uparrow}}$.

Constructive story: An $\mathsf{InitialValueProblem}^{\uparrow}$ packet is generated from an initial time row, an initial state row, a vector-field graph row, a local window, solution-graph windows, an endpoint classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InitialValueProblem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3979.1, Definition 3979.2, and Definition 3979.3 seed the local initial-data surface consumed by Picard–Lindelof over ODE, Lipschitz, complete-metric, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{InitialValueProblem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim global ODE existence, maximal continuation, host function-space equality, selected solution representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, time-state compatibility, vector-field graph admission, local-window nonescape, solution-graph visibility, endpoint classification, transport, replay, provenance, and local naming for BEDC.Derived.InitialValueProblemUp.

Chapter 3003

A Concrete Naming Certificate for $\mathsf{UniformCauchyLimit}^{\uparrow}$

Following Bishop and Bridges on uniform convergence and constructive continuity, the $\mathsf{UniformCauchyLimit}^{\uparrow}$ packet records a uniform limit of modulus-controlled real-valued continuous maps as finite NameCert data. It sits beside the continuous-map graph rows of chapter 130, the function-specific modulus rows of chapter 1631, the convergence ledger of chapter 2074, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a completion-facing uniform-limit carrier without importing quotient functions, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3003.1 (Uniform Cauchy limit carrier)**.** *A* $\mathsf{UniformCauchyLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, M, L, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows for the inspected real-valued maps.*
2. *M is the matching family of* $\mathsf{ModulusContinuity}^{\uparrow}$ *rows, one for each graph row in F, converting target tolerances into source-window budgets.*
3. *L is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger that records the uniform Cauchy comparison between later graph rows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened at the source points and tolerance requests used by F, M, L.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed windows and convergence ledger.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying dyadic radii, endpoint comparisons, and uniform error budgets.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, M, L, S, Q, D have been displayed.*
8. *H records componentwise* hsame *transport for graph rows, modulus rows, convergence ledgers, stream windows, regular readback, dyadic tolerances, Real sealing, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a uniform tolerance request through graph inspection, modulus conversion, convergence comparison, stream-window readback, dyadic tolerance accounting, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{RealModulusOfConver}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, M, L, S, Q, D, R, H, C, P, N$. It has no coordinate for quotient functions, selected pointwise limits, countable-choice schedules, open-cover compactness, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCauchyLimitUp.UniformCauchyLimitTasteGate single carrier alignment`

Theorem 3003.2 (Uniform Cauchy limit NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyLimit}^{\uparrow}$ *carrier $U = (F, M, L, S, Q, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyLimit}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the continuous-map graph rows, modulus-continuity rows, convergence ledger, stream windows, regular rational readback, dyadic tolerance row, Real seal, transport, replay, provenance, and local naming rows;*
2. *graph-modulus compatibility, requiring every inspected map in F to expose its matching modulus row in M before a target tolerance is read;*
3. *uniform Cauchy exactness, requiring each later-stage comparison to pass through the displayed ledger L and the dyadic tolerance row D;*
4. *readback sealing, requiring S and Q to be read before the terminal* $\mathsf{Real}^{\uparrow}$ *seal R is exposed;*
5. *non-escape for quotient function spaces, selected limits, countable choice, open-cover compactness, host function equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3980.1. The accepted tuple displays exactly the graph rows, modulus rows, convergence ledger, windows, readback, dyadic tolerance ledger, Real seal, and structural rows.

Graph-modulus compatibility is rowwise. A consumer that reads a graph row in F must read the corresponding row in M, so continuity is exposed as a finite tolerance-to-window route rather than as a host semantic predicate.

Uniform Cauchy exactness is the role of L and D. Later-stage comparisons are admitted only through the displayed convergence ledger and dyadic tolerance budgets, so no hidden choice schedule or selected limit enters the packet.

Readback sealing follows through S, Q, R. The finite stream windows are opened first, the regular rational readback is extracted next, and the terminal Real seal is reached only after those rows are visible.

Finally, H, C, P, N transport, replay, source, and name the same displayed packet. Since the refused objects are absent from the carrier, the local NameCert surface exports exactly the five obligations listed above. □

Theorem 3003.3 (Uniform Cauchy limit continuity handoff)**.** *Every continuity-facing read of an accepted* $\mathsf{UniformCauchyLimit}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{ModulusContinuity}^{\uparrow} \longmapsto \mathsf{RealModulusOfConvergence}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{R}$$

Thus a downstream continuous-map or completion consumer receives graph rows, modulus rows, uniform convergence ledgers, finite windows, regular rational readback, dyadic tolerance accounting, componentwise transport, displayed replay, provenance, and local naming, not a quotient function or selected limit.

Proof. Project the accepted carrier $U = (F, M, L, S, Q, D, R, H, C, P, N)$. The graph rows in F are the only function data, and the modulus rows in M are the only continuity data attached to them.

Replay through C preserves the route. A continuity-facing request first opens the graph row, then reads the displayed modulus conversion, then consults the uniform Cauchy ledger and dyadic tolerances before it can inspect stream windows and regular rational readback.

The Real seal R is terminal. Since the carrier has no coordinate for quotient functions, selected limits, host equality, or ambient completeness, the handoff remains a finite BEDC route through the displayed rows. □

Theorem 3003.4 (Uniform Cauchy limit completion nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{UniformCauchyLimit}^{\uparrow}$ *packet must display the rows* $F, M, L, S, Q, D, R, H, C, P, N$ *before reading any terminal Real seal. The accepted packet therefore supplies a uniform-limit carrier for real-valued continuous maps without exporting quotient functions, selected limit representatives, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with carrier projection. The completion-facing data are not stored in a separate ambient object; they are the displayed rows $F, M, L, S, Q, D, R, H, C, P, N$.

The finite route composes graph inspection, modulus conversion, convergence-ledger comparison, stream-window opening, regular rational readback, dyadic tolerance accounting, and terminal Real sealing. Each step is a row of the accepted carrier and is preserved by the transport and replay rows.

No refused object can be exported after the seal. Quotient functions, selected representatives, choice schedules, open-cover compactness, and ambient completeness have no carrier coordinate, so completion-facing consumers remain inside the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformCauchyLimit}^{\uparrow}$ packet is generated from ContinuousMap graph rows, ModulusContinuity rows, a RealModulusOfConvergence ledger, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3980.1, Definition 3980.2, Definition 3980.3, and Definition 3980.4 seed the uniform-limit route over continuous-map graphs, modulus rows, convergence ledgers, finite windows, regular readback, dyadic tolerance data, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient function spaces, selected pointwise limits, countable choice, open-cover compactness, host function equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph-modulus compatibility, uniform Cauchy exactness, readback sealing, completion nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyLimitUp.

Chapter 3004

A Concrete Naming Certificate for $\mathsf{MedianDepthSealing}^{\uparrow}$

The $\mathsf{MedianDepthSealing}^{\uparrow}$ packet realizes the two-layer median stabilization of Definition 9462.1329 as finite BEDC NameCert data. It sits beside the six-bit codon window of chapter 2234, the boundary-tile classifier of chapter 3393, the six-tile coverage rows of chapter 3470, the boundary-trigger closure route of chapter 3508, and the finite alphabet bridge of chapter 2260. The packet names the reassigned support, first median layer, second sealing point, layer witnesses, and stabilization check as a finite carrier, not as a biological stochastic model or an ambient closure oracle.

Definition 3004.1 (Median depth sealing carrier)**.** *A* $\mathsf{MedianDepthSealing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, B, V, T, A, L, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source row for the codon-window coordinates used by the median operation.*
2. *B is the* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *boundary row exposing the stop/Trp and Ile/Met tile classifiers consumed by the reassigned support.*
3. *V is the* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *coverage row recording the visible boundary support over which the median read is admitted.*
4. *T is the* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ *trigger-closure row, read only as finite boundary-trigger data.*
5. *A is the* $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$ *alphabet row, fixing the four-phase coordinate interpretation before codons are compared.*
6. *L is the median-layer ledger with the displayed rows $\mathcal{R}$, Δ_1, Δ_2, $\mathrm{Med}_1(\mathcal{R})$, and $\mathrm{Med}_2(\mathcal{R})$ from Definition 9462.1328.*
7. *E is the stabilization row recording that the second layer is closed under the displayed coordinatewise median operation.*
8. *H records componentwise* hsame *transport for codon windows, boundary tiles, coverage rows, trigger closure, alphabet rows, layer ledgers, stabilization, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from codon-window inspection through boundary-tile coverage, trigger closure, alphabet readback, layer enumeration, and stabilization checking.*
10. *P is the* Pkg *provenance over* $\mathsf{MedianDepthSealing}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, $\mathsf{DNAFourPhaseAlphabetBridge}^{\uparrow}$, *the median-depth source theorem,* BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MedianDepthSealing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, B, V, T, A, L, E, H, C, P, N$. It has no coordinate for a biological code table, stochastic evolutionary dynamics, quotient codon semantics, hidden median closure, unbounded search, or host closure oracle.

Lean4 ✓ `BEDC.Derived.MedianDepthSealingUp.MedianDepthSealingTasteGate single carrier alignment`

Theorem 3004.2 (Median depth sealing NameCert obligations)**.** *For every accepted* $\mathsf{MedianDepthSealing}^{\uparrow}$ *carrier $M = (W, B, V, T, A, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MedianDepthSealing}^{\uparrow}}$ *surface consists exactly of codon-window admission, boundary-tile exposure, six-tile coverage, boundary-trigger closure, four-phase alphabet readback, median-layer ledger exactness, two-layer stabilization, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3981.1. The codon-window, boundary, coverage, trigger, alphabet, layer, stabilization, and structural rows are all displayed as finite data.

The source rows W, B, V, T, A fix the finite coordinate surface before the median ledger is read. Thus the median operation is interpreted through displayed codon windows, boundary tiles, coverage rows, trigger closure, and four-phase alphabet readback.

The rows L and E then expose the two-layer calculation. The first row records $\mathcal{R}$, Δ_1, Δ_2, $\mathrm{Med}_1(\mathcal{R})$, and $\mathrm{Med}_2(\mathcal{R})$; the second records that no further vertex appears after the sealing point.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no remaining coordinate contains a biological table, stochastic model, quotient codon semantics, unbounded search, or hidden closure oracle, the listed rows exhaust the local NameCert surface. □

Theorem 3004.3 (Median depth sealing two-layer stabilization)**.** *Every accepted* $\mathsf{MedianDepthSealing}^{\uparrow}$ *read exposes the finite stabilization chain*

$$\mathcal{R} \longmapsto \mathrm{Med}_1(\mathcal{R}) \longmapsto \mathrm{Med}_2(\mathcal{R}) = \mathrm{Med}(\mathcal{R})$$

with $\Delta_1 = \{\mathrm{AAG}, \mathrm{ACA}, \mathrm{AUG}, \mathrm{UCG}, \mathrm{UGG}, \mathrm{UUG}\}$ and $\Delta_2 = \{\mathrm{ACG}\}$. A consumer must read the layer ledger L and stabilization row E after the codon-window, boundary-tile, coverage, trigger-closure, and alphabet rows have been displayed.

Proof. Read Definition 9462.1329 through the carrier rows. The theorem supplies the finite layer calculation, while Definition 3981.1 stores it as the ledger L and stabilization row E.

The upstream rows W, B, V, T, A determine the coordinate interpretation and boundary support before the ledger is inspected. Therefore a consumer cannot treat the displayed layer calculation as an ambient median closure unrelated to the accepted codon-window and boundary rows.

The structural rows H, C, P, N preserve the same route. The exported consequence is the two-layer stabilization chain and no additional biological, stochastic, quotient, or hidden closure datum. □

Falsifiable prediction: Every accepted $\mathsf{MedianDepthSealing}^{\uparrow}$ consumer must expose the two-layer stabilization consequence: the first median layer adds exactly Δ_1, the second layer adds exactly ACG, and a further coordinatewise-median pass adds no codon.

Independence witness: dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-boundary-trigger-closure, dna-four-phase-alphabet-bridge: none is bijective to $\mathsf{MedianDepthSealing}^{\uparrow}$ because the siblings respectively expose boundary classifiers, coverage rows, trigger closure, or alphabet readback, while the median-depth packet jointly carries the reassigned support, two median layers, sealing codon, stabilization check, transport, replay, provenance, and local naming.

The Lean TasteGate site for $\mathsf{MedianDepthSealing}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ MedianDepthSealing}^{\uparrow}$ and $\mathsf{FieldFaithful\ MedianDepthSealing}^{\uparrow}$ instances. Nontriviality must distinguish the reassigned support from the sealed second layer, and field faithfulness must preserve $W, B, V, T, A, L, E, H, C, P, N$ as separate displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MedianDepthSealing}^{\uparrow}}$.

Constructive story: A $\mathsf{MedianDepthSealing}^{\uparrow}$ packet is generated from CodonSixBitWindow rows, DnaWindowSixBoundaryTile rows, SixBoundaryTileCoverage rows, DnaBoundaryTriggerClosure rows, DNAFourPhaseAlphabetBridge rows, a median-layer ledger, a stabilization row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MedianDepthSealing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3981.1, Definition 3981.2, and Definition 3981.3 seed the finite median-depth sealing packet over codon windows, boundary tiles, coverage rows, trigger closure, alphabet readback, layer enumeration, and stabilization checking.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MedianDepthSealing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a biological code table, stochastic evolutionary model, quotient codon semantics, hidden median closure, unbounded search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary and coverage exposure, trigger-closure compatibility, alphabet readback, median-layer exactness, stabilization checking, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.MedianDepthSealingUp.

Chapter 3005

A Concrete Naming Certificate for $\mathsf{UniformFixedPoint}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{UniformFixedPoint}^{\uparrow}$ packet records the endpoint-modulus surface obtained when a displayed contraction, a finite Picard orbit, and a complete metric handoff are assembled as one L10 NameCert route. It sits after the complete metric carrier of chapter 128, the contractive map surface of chapter 3819, the Picard iteration packet of chapter 2359, the fixed-point iteration packet of chapter 2383, the located real modulus of chapter 3406, and the Banach contraction principle of chapter 3962. The packet exposes a uniform endpoint modulus for downstream fixed-point consumers; it does not introduce choice-selected endpoints, quotient equality, open-cover compactness, or ambient completeness outside the displayed rows.

Definition 3005.1 (Uniform fixed-point carrier)**.** *A* $\mathsf{UniformFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, F, I, Q, U_0, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row, naming the metric carrier, convergence service, and endpoint limit surface available to the packet;*
2. *F is the* $\mathsf{ContractiveMap}^{\uparrow}$ *row, recording the self-map graph, contraction ledger, and metric compatibility used by the endpoint construction;*
3. *I is the* $\mathsf{PicardIteration}^{\uparrow}/\mathsf{FixedPointIteration}^{\uparrow}$ *row, exposing the initial point, finite iterate windows, residual budget, and Picard replay route;*
4. *Q is the Cauchy or located modulus row, read through* $\mathsf{LocatedRealModulus}^{\uparrow}$ *or the displayed Cauchy-modulus surface attached to the iteration;*
5. *U_0 is the uniform endpoint-modulus row, translating a requested endpoint tolerance into the finite Picard window and contraction budget required by M, F, I, Q;*
6. *E is the endpoint seal row, recording the* $\mathsf{BanachContractionPrinciple}^{\uparrow}$ *fixed-point endpoint only after the uniform modulus and complete-metric handoff have been read;*
7. *H records componentwise* hsame *transports for M, F, I, Q, U_0, E together with the replay, provenance, and local naming rows;*

8. *C records the displayed* Cont *replay route by which the Picard window, contraction ledger, located modulus, endpoint modulus, and endpoint seal are inspected;*
9. *P is the* Pkg *provenance over* UniformFixedPoint$^\uparrow$, CompleteMetric$^\uparrow$, ContractiveMap$^\uparrow$, PicardIteration$^\uparrow$, FixedPointIteration$^\uparrow$, LocatedRealModulus$^\uparrow$, BanachContractionPrinciple$^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* NameCert$_{\text{UniformFixedPoint}^\uparrow}$ *row.*

The classifier accepts exactly packets with these ten rows. It has no coordinate for an endpoint chosen outside the Picard route, a quotient fixed-point equality, a hidden contraction constant, or a completeness witness detached from M.

Theorem 3005.2 (Uniform fixed-point NameCert obligations)**.** *For the carrier of Definition 3982.1, the local* NameCert$_{\text{UniformFixedPoint}^\uparrow}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for $U = (M, F, I, Q, U_0, E, H, C, P, N)$;*
2. *contractive-map admission, requiring every endpoint read to expose the* ContractiveMap$^\uparrow$ *row F against the complete metric row M;*
3. *Picard and fixed-point iteration admission, requiring I to display the finite orbit rows before any Cauchy or endpoint row is inspected;*
4. *Cauchy or located-modulus handoff, requiring Q to route tolerance requests through* LocatedRealModulus$^\uparrow$ *or the displayed Cauchy-modulus surface;*
5. *uniform endpoint-modulus exactness, requiring U_0 to translate endpoint tolerances only through M, F, I, Q;*
6. *endpoint seal nonescape, requiring E, H, C, P, N to keep the* BanachContractionPrinciple$^\uparrow$ *endpoint inside the same packet.*

Proof. Project the carrier of Definition 3982.1. The rows $M, F, I, Q, U_0, E, H, C, P, N$ are the only local NameCert coordinates, so carrier admission is exactly the displayed packet.

Read the contraction and iteration rows next. The ContractiveMap$^\uparrow$ row supplies only the finite shrink ledger, while the PicardIteration$^\uparrow$ and FixedPointIteration$^\uparrow$ rows supply the finite orbit and residual budget before any endpoint is available.

Use the modulus rows Q and U_0. The located or Cauchy modulus answers tolerance requests by naming a finite Picard window, and the uniform endpoint modulus converts that window into the endpoint tolerance without adding a selected limit or quotient equality.

Finally read the endpoint seal through E, H, C, P, N. The BanachContractionPrinciple$^\uparrow$ endpoint is exposed only after the complete-metric, contraction, iteration, and modulus rows have been replayed, so no off-packet fixed point or ambient completeness coordinate is exported. □

Lean4 ✓ `BEDC.Derived.UniformFixedPointUp.UniformFixedPointTasteGate single carrier alignment`

Theorem 3005.3 (Uniform fixed-point modulus handoff)**.** *Every* BanachContractionPrinciple$^\uparrow$ *or fixed-point endpoint consumer of an accepted* UniformFixedPoint$^\uparrow$ *packet receives the endpoint only through the finite route*

CompleteMetric$^\uparrow$, ContractiveMap$^\uparrow$, PicardIteration$^\uparrow$, FixedPointIteration$^\uparrow$, LocatedRealModulus$^\uparrow$, U_0, BanachContra

The row U_0 is a uniform endpoint-modulus handoff: it turns each endpoint tolerance into a displayed Picard window and contraction budget before the endpoint seal E is read. The handoff exports

no arbitrary fixed-point choice, no quotient equality of endpoints, no open-cover compactness, and no ambient completeness beyond the complete metric row M.

Proof. Start from the NameCert obligations. They force every consumer to expose M, F, I, Q, U_0 before reading E.

Apply the sibling Picard and fixed-point iteration routes. The finite orbit row I supplies the iterate windows and residual budgets, while F supplies the contraction ledger over the metric carrier named by M.

Use the located modulus handoff through Q. A requested endpoint tolerance is converted into finite dyadic or Cauchy data and then into the Picard window named by U_0.

Finally pass to the Banach contraction endpoint seal. Since E is downstream of the complete-metric service, contraction ledger, Picard route, and uniform modulus, the endpoint consumer receives only the displayed finite route and none of the refused host-level principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformFixedPoint}^{\uparrow}$ packet is generated from a complete metric row, a contractive map row, a Picard or fixed-point iteration row, a Cauchy or located modulus row, a uniform endpoint-modulus row, an endpoint seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3982.1, Definition 3982.2, and Definition 3982.3 seed the endpoint-modulus route over $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContractiveMap}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, $\mathsf{LocatedRealModulus}^{\uparrow}$, and $\mathsf{BanachContractionPrinciple}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, choice-selected fixed points, quotient endpoint equality, open-cover compactness, or completeness outside the displayed complete metric row.

Upgrade path: A formal route can encode the finite carrier, NameCert obligations, endpoint-modulus exactness, and endpoint-seal handoff for BEDC.Derived.UniformFixedPointUp.

Chapter 3006

A Concrete Naming Certificate for $\mathsf{CauchySchwarzEquality}^{\uparrow}$

Following Cauchy, Schwarz, and standard inner-product-space treatments of the equality case, the $\mathsf{CauchySchwarzEquality}^{\uparrow}$ packet records the finite BEDC surface at which equality in Cauchy–Schwarz is available as a linear-dependence certificate. It sits over the inner-product source of chapter 86, the norm boundary of chapter 89, and the finite Real inequality route of chapter 1684. The packet names equality-case data as displayed rows; it is not a host vector equality theorem, quotient stream equality, ambient Hilbert-space statement, or selected scalar witness.

Definition 3006.1 (CauchySchwarzEquality carrier)**.** *A* $\mathsf{CauchySchwarzEquality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (V, X, Y, I, A, B, C, L, D, Q, S, R, H, T, P, N)$$

with the following displayed rows:

1. *V is the finite vector-source row shared with the inner-product and norm packets.*
2. *X and Y are the two displayed vector rows whose equality-case boundary is inspected.*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *scalar read for $\langle X, Y\rangle$.*
4. *A and B are the two* $\mathsf{Norm}^{\uparrow}$ *square rows for $\|X\|^2$ and $\|Y\|^2$.*
5. *C is the* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *inequality row that exposes the square comparison already sealed for Real consumers.*
6. *L is the linear-dependence ledger. It records a displayed scalar row, the finite scalar-action comparison between X and Y, and the zero-vector boundary used when one norm row is null.*
7. *D is the equality-defect ledger, storing the displayed zero-defect read that identifies the equality boundary of the square comparison.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scalar, norm, and defect observations.*
9. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the readback.*
10. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the equality-case read.*
11. *H records componentwise* hsame *transport for vector rows, scalar reads, norm rows, inequality row, linear-dependence ledger, defect ledger, readback, windows, Real seal, replay, provenance, and local naming.*

12. *T records displayed* Cont *replay from an equality-case request through $V, X, Y, I, A, B, C, L, D, Q, S, R$ and back to the public certificate boundary.*

13. *P is the* Pkg *provenance over* $\mathsf{CauchySchwarzEquality}^{\uparrow}$, $\mathsf{CauchySchwarzReal}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzEquality}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite equality-case packet. It has no coordinate for host vector equality, quotient stream equality, ambient completeness, an infinite-dimensional Hilbert theorem, selected scalar choice, or bridge checking.

Theorem 3006.2 (CauchySchwarzEquality NameCert obligations)**.** *For every accepted* $\mathsf{CauchySchwarzEquality}^{\uparrow}$ *carrier*

$$E = (V, X, Y, I, A, B, C, L, D, Q, S, R, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySchwarzEquality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the vector source, two vector rows, inner-product read, norm-square rows, Cauchy–Schwarz inequality row, linear-dependence ledger, equality-defect ledger, readback, windows, Real seal, transport, replay, provenance, and local naming rows;*

2. *equality-route exposure, requiring every equality-case read to pass through I, A, B, C, D before the Real seal R is available;*

3. *linear-dependence exposure, requiring the row L to display the scalar-action comparison and zero-vector boundary before the local name is exported;*

4. *classifier transport, requiring H and T to preserve the same vector rows, scalar reads, inequality row, dependence ledger, defect ledger, readback, windows, and Real seal componentwise;*

5. *non-escape, excluding host vector equality, quotient stream equality, ambient completeness, infinite-dimensional Hilbert semantics, selected scalar choice, and bridge checking.*

No equality-case obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic coordinates are the vector-source row V, the displayed vector rows X, Y, the inner-product row I, the norm-square rows A, B, the Cauchy–Schwarz row C, the dependence ledger L, the equality-defect ledger D, the readback rows Q, S, R, and the structural rows H, T, P, N.

Carrier admission is exactly admission of those displayed coordinates. The local certificate has no further coordinate from which a host vector equality, quotient-stream representative, ambient Hilbert-space object, or selected scalar could be recovered.

Equality-route exposure is forced by the placement of C and D. The packet first reads the ordinary Cauchy–Schwarz square comparison, then reads the displayed zero-defect ledger, and only then seals the equality-case datum as Real-facing packet data.

Linear-dependence exposure is the row L. It records the scalar-action comparison and the zero-vector boundary as finite data, so the equality case is exported as a dependence ledger rather than as an ambient vector-space equality theorem.

Finally H and T provide componentwise transport and replay for the same rows, while P and N source and name the packet. Since no excluded analytic coordinate is present, the listed rows exhaust the NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchySchwarzEqualityUp.CauchySchwarzEqualityTasteGate single carrier alignment`

Theorem 3006.3 (CauchySchwarzEquality linear-dependence route)**.** *For every accepted* $\mathsf{CauchySchwarzEquality}^{\uparrow}$ *carrier*

$$E = (V, X, Y, I, A, B, C, L, D, Q, S, R, H, T, P, N),$$

every equality-case consumer receives the linear-dependence boundary only through the finite route

$$V, X, Y \longmapsto I, A, B \longmapsto C, D \longmapsto L \longmapsto Q, S, R \longmapsto H, T, P, N.$$

Thus equality in the Cauchy–Schwarz row is consumed as a displayed scalar-action ledger and zero-defect readback; it does not expose host vector equality, quotient stream equality, ambient completeness, an infinite-dimensional Hilbert theorem, selected scalar choice, or bridge checking.

Proof. Start with the carrier projection. The vector rows V, X, Y and scalar rows I, A, B are the only inputs from the inner-product and norm surfaces.

Apply the finite inequality route supplied by chapter 1684. The row C exposes the square comparison already sealed for Real consumers, while D records that the defect read is zero inside the displayed packet.

Next read L. This is the only row carrying the scalar-action comparison and the zero-vector boundary, so the consumer obtains linear dependence from finite ledger data rather than from host vector equality.

The readback route Q, S, R then seals the same displayed equality-case datum for Real-facing consumers. The transport and replay rows H, T preserve that order, and the provenance and naming rows P, N add no analytic coordinate.

Consequently the exported equality case is exactly the displayed route above. None of the excluded host or quotient objects can be read from the packet. □

Falsifiable prediction: Every accepted $\mathsf{CauchySchwarzEquality}^{\uparrow}$ consumer must expose a CauchySchwarzRealUp inequality row, an equality-defect ledger, a linear-dependence ledger, RegSeqRat readback, StreamName windows, a RealUp seal, transport, replay, provenance, and local naming before the equality-case boundary is available.

Independence witness: innerproduct, norm, cauchy-schwarz-real: $\mathsf{CauchySchwarzEquality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Cauchy–Schwarz inequality row, equality-defect ledger, displayed linear-dependence ledger, readback, seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySchwarzEquality}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySchwarzEquality}^{\uparrow}$ packet is generated from finite vector rows, an InnerProductUp scalar read, NormUp square rows, a CauchySchwarzRealUp inequality row, an equality-defect ledger, a linear-dependence ledger, RegSeqRat readback, StreamName windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySchwarzEquality}^{\uparrow}}$, seed)

Scope closed: Definition 3983.1, Definition 3983.2, and Definition 3983.3 seed the finite equality-case carrier for displayed Cauchy–Schwarz Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySchwarzEquality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host vector equality, quotient stream equality, ambient completeness, infinite-dimensional Hilbert semantics, selected scalar choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, equality-route exposure, linear-dependence exposure, classifier transport, non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchySchwarzEqualityUp.

Chapter 3007

A Concrete Naming Certificate for $\mathsf{ExtremeValueTheorem}^{\uparrow}$

Following Weierstrass and Bishop–Bridges constructive analysis, the $\mathsf{ExtremeValueTheorem}^{\uparrow}$ packet records the compact-real attained-extreme theorem as finite BEDC NameCert data. It sits over the compact source of chapter 129, the closed bounded interval source of chapter 1591, the continuous-map row of chapter 130, the located supremum and upper-bound rows of chapter 1427, and the terminal real-name seal of chapter 38. The packet exposes the finite witness-window route for extrema without importing open-cover compactness, trichotomy, selected host extrema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3007.1 (Extreme value theorem carrier)**.** *An* $\mathsf{ExtremeValueTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (I, K, F, R, S, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying endpoint order, interval containment, finite windows, and real endpoint seals.*
2. *K is the compact source row read through* $\mathsf{CompactMetric}^{\uparrow}$*, exposing the finite compact-real inspection surface used by the interval source.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the real-valued map on the displayed compact source.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *value seal row for inspected values and endpoint comparisons.*
5. *S is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *row carrying the located upper-bound surface for the displayed value family.*
6. *W is the finite witness-window row, recording the inspected compact windows in which the located upper-bound row and the continuous-map row meet a terminal value seal.*
7. *H records componentwise* hsame *transport for the interval source, compact source, continuous-map row, real value seals, located-supremum row, witness windows, replay rows, provenance rows, and local naming rows.*
8. *C records displayed* Cont *replay from compact-real inspection requests through $I, K, F, R, S, W, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{ExtremeValueTheorem}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{ExtremeValueTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed interval source, compact source, continuous-map row, value seal, located upper-bound row, finite witness-window row, transport, replay, provenance, and local naming. It has no coordinate for open-cover compactness, trichotomy, selected host extrema, quotient real equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.ExtremeValueTheoremUp.ExtremeValueTheoremTasteGate single carrier alignment`

Theorem 3007.2 (Extreme value theorem NameCert obligations)**.** *For every accepted* $\mathsf{ExtremeValueTheorem}^{\uparrow}$ *carrier* $E = (I, K, F, R, S, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ExtremeValueTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the closed bounded interval source, compact source, continuous-map row,* $\mathsf{Real}^{\uparrow}$ *value seal, located-supremum and upper-bound row, finite witness-window row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside these rows.*

Proof. Project the carrier of Definition 3984.1. The interval row I and compact row K expose the only source windows available to the theorem packet, while F records the continuous real-valued map inspected on those windows.

Read the real and upper-bound rows next. The value seal R supplies only $\mathsf{Real}^{\uparrow}$ rows for displayed function values, and S supplies the located upper-bound surface through the located-supremum chapter.

The witness-window row W binds the source windows, continuous-map reads, value seals, and upper-bound reads into one finite inspection route. The remaining rows H, C, P, N transport, replay, source, and name the same route, so the listed data exhaust the local NameCert obligations. □

Theorem 3007.3 (Extreme value theorem compact supremum route)**.** *Every accepted* $\mathsf{ExtremeValueTheorem}^{\uparrow}$ *consumer that reads an attained extreme must factor through the displayed route*

$$I, K \longmapsto F \longmapsto R, S \longmapsto W \longmapsto H, C, P, N.$$

Thus the compact-real theorem surface exports only a finite witness-window route from a compact source and continuous-map row to a $\mathsf{Real}^{\uparrow}$ *value seal and located upper-bound row. It does not export open-cover compactness, trichotomy, a selected host maximum or minimum, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source rows. The closed bounded interval source and compact metric source are displayed as I and K, so every later value comparison is scoped to the same finite compact-real windows.

Feed the source into the continuous-map row. The row F exposes only displayed value reads, and R seals those reads as $\mathsf{Real}^{\uparrow}$ values before any upper-bound comparison is consumed.

Use the located-supremum row S and the witness-window row W together. The upper-bound route is visible only through the finite windows in which F and R have already been displayed.

Finally, transport and replay preserve the same route through H and C, while P and N provide provenance and local naming. Since the carrier has no coordinate for open-cover compactness, trichotomy, selected extrema, quotient real equality, or ambient completeness, the exported theorem surface remains the finite compact-supremum route shown above. □

Falsifiable prediction: Every $\mathsf{ExtremeValueTheorem}^{\uparrow}$ attained-extreme read factors through $\mathsf{ClosedBoundedInterva}$ $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{LocatedSupremum}^{\uparrow}$ before reaching its finite witness-window and local $\mathsf{NameCert}_{\mathsf{ExtremeValueTheorem}^{\uparrow}}$ rows.

Independence witness: closedboundedinterval, compactmetric, continuousmap, locatedsupremum, real: $\mathsf{ExtremeValueTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a compact source, continuous-map row, Real value seal, located upper-bound row, finite witness-window row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ExtremeValueTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{ExtremeValueTheorem}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a CompactMetricUp compact source row, a ContinuousMapUp real-valued map row, RealUp value seals, a LocatedSupremumUp upper-bound row, a finite witness-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExtremeValueTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3984.1, Definition 3984.2, and Definition 3984.3 seed the finite compact-real attained-extreme route over interval, compact-source, continuous-map, located-supremum, witness-window, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExtremeValueTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, selected host extrema, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{ExtremeValueTheorem}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, finite witness-window exactness, located upper-bound routing, Real value sealing, replay stability, and non-escape for BEDC.Derived.ExtremeValueTheoremUp.

Chapter 3008

A Concrete Naming Certificate for $\mathsf{BoundedRealOscillation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BoundedRealOscillation}^{\uparrow}$ packet records the finite route by which a continuous real-valued map on a compact metric source receives an oscillation bound from displayed uniform-modulus and finite-partition data. It sits between the compact source surface of chapter 129, the continuous-map carrier of chapter 130, the uniform-modulus route of chapter 369, the finite oscillation partition of chapter 3800, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names an oscillation-bound witness without importing open-cover compactness, supremum selection, quotient real equality, or choice.

Definition 3008.1 (BoundedRealOscillation carrier)**.** *A* $\mathsf{BoundedRealOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, F, U, A, B, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the inspected compact-metric windows and finite metric ledgers.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row from K to* $\mathsf{Real}^{\uparrow}$*, with its graph, local continuity data, and real-value readbacks.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row translating each requested oscillation tolerance into a displayed metric radius.*
4. *A is the* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *row, listing the finite cells inspected at that tolerance and the local oscillation ledgers attached to them.*
5. *B is the bounded-oscillation ledger, recording the displayed real bound certified from the cellwise oscillation rows and the uniform modulus.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the bound value, reached only after K, F, U, A, B have been read.*
7. *H records componentwise* hsame *transport for the compact source, continuous map, uniform modulus, finite partition, bound ledger, real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an oscillation request through K, F, U, A, B, R and back to the public certificate boundary.*

9. *P is the* Pkg *provenance over* BoundedRealOscillation$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, FiniteOscillationPartition$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BoundedRealOscillation}^{\uparrow}}$ *row.*

The classifier accepts exactly packets with these ten rows. It has no coordinate for open-cover compactness, a selected supremum, host function equality, quotient real equality, countable choice, or an ambient completeness principle detached from the displayed Real$^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.BoundedRealOscillationUp.BoundedRealOscillationTasteGate single carrier alignment`

Theorem 3008.2 (BoundedRealOscillation NameCert obligations)**.** *For every accepted* BoundedRealOscillation$^{\uparrow}$ *carrier*

$$O = (K, F, U, A, B, R, H, C, P, N),$$

the local NameCert$_{\text{BoundedRealOscillation}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-source readback, continuous-map readback, uniform-modulus tolerance routing, finite oscillation-partition coverage, bounded-ledger exactness,* Real$^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and terminal local naming. No oscillation-bound obligation is stored outside those rows.*

Proof. Project the carrier of Definition 3985.1. The rows $K, F, U, A, B, R, H, C, P, N$ are the only local coordinates, so carrier admission and local naming are exactly the displayed finite packet.

Read the analytic rows in order. The compact source row K supplies only finite metric windows, the continuous-map row F supplies the real-valued graph readbacks on those windows, and the uniform-modulus row U translates an oscillation tolerance into the metric radius used by the partition row.

The finite partition row A then exposes the cellwise oscillation checks, and the bounded ledger B records the real bound obtained from those checks. The seal row R is downstream of this route, so a real-facing consumer cannot read a bound before the compact, continuous, modulus, partition, and ledger rows have been displayed.

Finally H and C transport and replay the same route componentwise, while P records provenance and N names the packet. Since the carrier has no excluded host-level coordinate, the listed rows exhaust the NameCert surface. □

Theorem 3008.3 (BoundedRealOscillation compact-uniform route)**.** *Every compact-uniform-continuity or extreme-value consumer of an accepted* BoundedRealOscillation$^{\uparrow}$ *packet receives the oscillation bound only through the route*

$$\text{CompactMetric}^{\uparrow},\ \text{ContinuousMap}^{\uparrow},\ \text{UniformModulus}^{\uparrow},\ \text{FiniteOscillationPartition}^{\uparrow},\ \text{Real}^{\uparrow},\ H, C, P, N.$$

The route is finite: a requested tolerance opens the uniform modulus, the modulus selects the displayed metric radius, the finite oscillation partition checks the resulting cells, and the bound ledger seals the resulting Real$^{\uparrow}$ *value. It exports no open-cover compactness theorem, no selected supremum, no quotient real equality, and no choice-selected covering family.*

Proof. Start from the uniform-modulus row. A tolerance request is answered by U, and that answer is tied to the compact source K and continuous map F before any finite partition row is read.

Next use the finite oscillation partition row A. It inspects only the displayed cells determined by the compact-metric windows and the modulus radius, so the oscillation estimate is a finite ledger calculation rather than an open-cover argument.

The bound ledger B and Real seal R then expose the bounded value to downstream consumers. Since B is downstream of K, F, U, A and R is downstream of B, the consumer receives exactly the compact-uniform route displayed in the statement.

The transport, replay, provenance, and naming rows preserve that order. Therefore the packet can be consumed by extreme-value, uniform-limit, and compact-uniform-continuity chapters without supplying any open-cover, supremum-selection, quotient-equality, or choice coordinate. □

Theorem 3008.4 (BoundedRealOscillation Real-seal nonescape)**.** *For every accepted* $\mathsf{BoundedRealOscillation}^{\uparrow}$ *carrier* $O = (K, F, U, A, B, R, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing read of the oscillation bound factors through* K, F, U, A, B *before* R *is visible, and through* H, C, P, N *before the local certificate is exported. Thus the real seal cannot be used as a bypass around compact-source readback, continuous-map readback, uniform-modulus routing, finite-partition coverage, or the bounded-oscillation ledger.*

Proof. Read the seal coordinate in Definition 3985.1. The row R is terminal: it records a real bound only after the compact source, continuous map, uniform modulus, finite partition, and bounded ledger have been displayed.

Apply Definition 3985.2. The NameCert surface requires the same rows for carrier admission, tolerance routing, partition coverage, bounded-ledger exactness, and nonescape, so a Real-facing consumer has no direct path to R.

Finally use the structural rows. The hsame transport row H and the Cont replay row C preserve the route componentwise, while P and N record provenance and local naming. Hence the real seal remains bound to the displayed finite packet and cannot bypass any of its compact-uniform rows. □

Falsifiable prediction: Every accepted $\mathsf{BoundedRealOscillation}^{\uparrow}$ consumer must expose a compact metric source row, continuous real-valued map row, uniform modulus row, finite oscillation-partition row, bounded ledger, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before an oscillation bound is available.

Independence witness: compactmetric, continuousmap, uniformmodulus, finiteoscillationpartition, real: $\mathsf{BoundedRealOscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the compact source, continuous map, uniform modulus, finite oscillation partition, bounded ledger, real seal, transport, replay, provenance, and local naming rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealOscillation}^{\uparrow}$ packet is generated from a CompactMetric source row, a ContinuousMap real-valued graph row, a UniformModulus tolerance route, a FiniteOscillationPartition cell ledger, a bounded-oscillation RealUp ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3985.1, Definition 3985.2, Definition 3985.3, and Definition 3985.4 seed the finite oscillation-bound route over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, open-cover compactness, selected suprema, quotient real equality, countable choice, or ambient completeness outside the displayed real seal.

Upgrade path: Obligation closure requires checked carrier admission, compact-source readback, continuous-map readback, uniform-modulus routing, finite-partition coverage, bounded-ledger exactness, real-seal nonescape, and TasteGate field faithfulness for BEDC.Derived.BoundedRealOscillationUp.

Chapter 3009

A Concrete Naming Certificate for $\mathsf{BishopCompactInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompactInterval}^{\uparrow}$ packet records a constructive compact interval as finite located endpoint, closed-bounded interval, finite-net, and completion-facing NameCert data. It sits beside the closed bounded interval source of chapter 1591, the located endpoint surface of chapter 1709, the compact finite-net packet of chapter 3969, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies an L10 interval neighbor for Real and Completion routes without claiming open-cover compactness, quotient real equality, selected subcovers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3009.1 (Bishop compact interval carrier)**.** *A* $\mathsf{BishopCompactInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying endpoint order, rational containment, dyadic containment, finite windows, regular readback, and Real sealing for the interval.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, exposing located endpoint reads, radius data, locator responses, and metric bracket rows for the same interval source.*
3. *F is the* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *finite-net row, recording the compact-interval coverage surface accepted for downstream finite-net consumers.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened by the interval and finite-net rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling interval mesh and endpoint precision requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the endpoint and interval readback route.*
8. *H records componentwise* hsame *transport for source interval, located interval, finite-net, stream, regular, dyadic, Real, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from interval containment and located endpoint reads through finite-net handoff, dyadic tolerance, regular readback, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactInterval}^{\uparrow}}$ *row.*

The classifier accepts exactly packets with these eleven displayed rows. It has no coordinate for host open covers, selected subcovers, quotient representatives of real endpoints, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompactIntervalUp.BishopCompactIntervalTasteGate single carrier alignment`

Theorem 3009.2 (Bishop compact interval NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompactInterval}^{\uparrow}$ *carrier* $K = (I, L, F, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompactInterval}^{\uparrow}}$ *surface consists exactly of six finite obligations:*

1. *carrier admission for the displayed closed-bounded interval, located interval, finite-net, stream, regular, dyadic, Real, transport, replay, provenance, and local naming rows;*
2. *interval-source compatibility, requiring the located row L and closed-bounded row I to name the same endpoint route before any compact read is exposed;*
3. *finite-net admission, requiring compact-interval coverage to pass through F rather than through a host open-cover principle;*
4. *dyadic-window exactness, requiring every mesh or tolerance request to read D before the finite windows W and regular readback R are consumed;*
5. *Real-seal nonescape, requiring the endpoint and interval readback route to reach E only after I, L, F, W, R, D have been displayed;*
6. *transport, replay, provenance, and local naming exhaustion through H, C, P, N.*

Proof. Carrier admission is projection from Definition 3986.1. The tuple lists the complete finite row inventory made available to the local certificate.

The interval source is read through I and L. Their endpoint, locator, containment, and bracket rows must agree on the same displayed interval route before compactness-facing consumers can inspect the finite-net row.

Finite-net admission is then confined to F. Since the carrier has no open-cover or subcover coordinate, compactness can be exposed only as the accepted closed-bounded interval finite-net row.

The dyadic and window obligations are read through D, W, R. Tolerance requests first enter the dyadic ledger, then open finite stream windows, and only then reach regular rational readback.

Finally E, H, C, P, N seal and replay the same route. These rows preserve the packet under transport and provenance, while row exhaustion rules out quotient representatives, selected subcovers, choice schedules, and ambient Real completeness. □

Theorem 3009.3 (Bishop compact interval finite-net handoff)**.** *Every Real- or Completion-facing consumer of an accepted* $\mathsf{BishopCompactInterval}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalCompact}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Stre}$$

The handoff exposes interval endpoints, locatedness, finite compact-interval coverage, dyadic tolerance, finite windows, regular readback, Real sealing, transport, replay, provenance, and local

naming, but it exports no open-cover compactness theorem, selected subcover, quotient endpoint equality, countable-choice schedule, or ambient completeness principle.

Proof. Project the accepted carrier $K = (I, L, F, W, R, D, E, H, C, P, N)$. The interval enters through the closed-bounded row I and the located interval row L, so endpoint and locator information are displayed before any compact read occurs.

Next read the finite-net row F. This row is the only compactness-facing coordinate in the carrier, and it is tied to the same interval source by the local obligation surface.

The completion-facing route then passes through D, W, R, E. The dyadic tolerance ledger controls the inspected mesh, the stream windows expose finite data, the regular row gives readback, and the Real seal is terminal for the route.

The structural rows H, C, P, N preserve this ordered handoff for downstream consumers. Since the packet contains no open-cover, quotient, choice, or ambient-completeness coordinate, no stronger compactness principle is exported. □

Theorem 3009.4 (Bishop compact interval finite-net extraction)**.** *Every Real- or Completion-facing consumer of an accepted* $\mathsf{BishopCompactInterval}^{\uparrow}$ *packet*

$$K = (I, L, F, W, R, D, E, H, C, P, N)$$

can extract the displayed $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *finite-net row F only after reading the interval-source rows I, L, the dyadic ledger D, the stream-window row W, the regular readback row R, the Real seal E, and the structural rows H, C, P, N. The extraction supplies the finite-net row as part of the displayed compact-interval route; it does not supply open-cover compactness, selected subcovers, quotient endpoint equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3986.1. The tuple displays F only together with the interval source, located endpoint, dyadic, stream, regular, Real, transport, replay, provenance, and local naming rows.

Use the local NameCert obligations of Definition 3986.2. Interval-source compatibility binds I and L before compact data is exposed, and finite-net admission confines compactness-facing access to the displayed row F.

Apply the handoff theorem Definition 3986.3. It orders the same rows for Real- and Completion-facing consumers, placing finite-net coverage after the interval source and before dyadic tolerance, finite windows, regular readback, and terminal Real sealing.

Since the carrier has no coordinate for open covers, selected subcovers, quotient endpoint equality, choice schedules, or ambient completeness, extracting F cannot export any of those stronger objects. □

Theorem 3009.5 (Bishop compact interval completion readback)**.** *Any completion-facing read from an accepted* $\mathsf{BishopCompactInterval}^{\uparrow}$ *packet reaches* $\mathsf{Real}^{\uparrow}$ *only through* $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. The readback exposes the closed-bounded interval source, located endpoint route, finite compact-interval coverage, dyadic tolerance ledger, finite stream windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming, but it cannot be read as ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected subcover compactness, quotient endpoint equality, countable choice, or an unrestricted host limit.*

Proof. Project the carrier of Definition 3986.1. Its only completion-facing rows are $I, L, F, D, W, R, E, H, C, P, N$.

Apply Definition 3986.2. The obligation surface fixes interval-source compatibility through I, L, finite-net admission through F, and dyadic-window exactness through D, W, R before the Real seal can be consumed.

Apply Definition 3986.3. The theorem orders the same rows as the public finite route from closed-bounded and located interval data to finite-net coverage, dyadic tolerance, stream windows, regular readback, and terminal Real sealing.

Thus a completion consumer can read $\mathsf{Real}^{\uparrow}$ only at the end of the displayed handoff. Since the carrier has no open-cover, selected-subcover, quotient, choice, or ambient-completeness coordinate, the readback cannot export any of those stronger objects. □

Falsifiable prediction: Every accepted $\mathsf{BishopCompactInterval}^{\uparrow}$ completion-facing read passes through ClosedBoundedIntervalUp, LocatedRealIntervalUp, ClosedBoundedIntervalCompactUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, transport, replay, provenance, and local naming rows before any endpoint or finite-net output is visible.

Independence witness: closedboundedinterval, located-real-interval, closed-bounded-interval-compact, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopCompactInterval}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries closed-bounded interval data, located endpoint reads, finite compact-interval coverage, dyadic tolerance, finite windows, regular readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompactInterval}^{\uparrow}$ packet is generated from a ClosedBoundedInterval row, a LocatedRealInterval row, a ClosedBoundedIntervalCompact finite-net row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompactInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3986.1, Definition 3986.2, and Definition 3986.3 seed the finite constructive compact-interval route over closed-bounded, located, finite-net, dyadic, stream, regular, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompactInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient endpoint equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source compatibility, finite-net admission, dyadic-window exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompactInterval

Chapter 3010

A Concrete Naming Certificate for $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Kelley on uniform and metric extension, the $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$ packet records the completion reflector as a left-adjoint NameCert boundary. It sits after the metric completion carrier of chapter 1506, the dense embedding route of chapter 3351, the Cauchy completion adjunction surface of chapter 1456, the metric adjunction packet of chapter 3836, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the reflector boundary without quotient representatives, host equality of completions, countable choice, selected limits, or ambient completeness.

Definition 3010.1 (MetricCompletionLeftAdjoint carrier)**.** *A* $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, D, A, J, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source reflector row.*
2. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit row exposing the dense source inclusion.*
3. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *adjunction row for completion-facing universal reads.*
4. *J is the* $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ *metric adjunction row binding the same source, unit, counit, and triangle ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row opened by completion consumers.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, D, A, J, R have been displayed.*
7. *H records componentwise* hsame *transport for reflector, dense embedding, adjunction, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a metric-source request through the reflector, dense unit, adjunction handoff, regular readback, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbeddi}$ $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{MetricCompletionAdjunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}}$ *row.*

The classifier accepts exactly packets with these ten displayed rows. It has no coordinate for quotient completion classes, chosen representatives, host equality of completion objects, countable-choice schedules, selected limits, or ambient complete metric spaces.

Lean4 ✓ `BEDC.Derived.MetricCompletionLeftAdjointUp.MetricCompletionLeftAdjointTasteGate single carrier alignment`

Theorem 3010.2 (MetricCompletionLeftAdjoint NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionLeft}$ *carrier* $L = (M, D, A, J, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}}$ *surface consists exactly of six finite obligations:*

1. *carrier admission for the displayed reflector, dense embedding, adjunction, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *unit exposure, requiring every source-to-completion read to pass through* D *before the adjunction rows are consumed;*
3. *left-adjoint handoff, requiring* A *and* J *to name the same finite completion reflector route before any universal consumer reads it;*
4. *triangle and extension visibility, requiring the unit, counit, and triangle comparison inherited from the adjunction rows to remain displayed through* H *and* C*;*
5. *RegSeqRat/Real seal nonescape, requiring* R *and* E *to be reached only after the reflector and adjunction rows have been displayed;*
6. *exhaustion of transport, replay, provenance, and local naming through* H, C, P, N*.*

Proof. Carrier admission is projection from Definition 3987.1. The tuple displays the full finite row inventory made available to the local certificate.

The source boundary is read through M and D. The reflector row supplies the completion-facing carrier, while the dense embedding row is the displayed unit of the reflector.

The universal boundary is then read through A and J. The Cauchy adjunction and metric adjunction rows provide the same finite source, unit, counit, and triangle ledger, so the left-adjoint handoff is a NameCert route rather than a host categorical equality.

Finally R, E, H, C, P, N seal and replay the route for downstream consumers. Since quotient classes, selected representatives, choice schedules, host equality, and ambient completeness are absent from the carrier, the listed obligations exhaust the certificate surface. □

Theorem 3010.3 (MetricCompletionLeftAdjoint universal handoff)**.** *Every separated-completion, Real-facing, or universal-completion consumer of an accepted* $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletionDenseEmbedding}^{\uparrow} \longmapsto \mathsf{CauchyCompletionAdjunction}^{\uparrow} \longmapsto \mathsf{MetricCompletion}$$

The consumer receives source metric admission, dense unit exposure, adjunction handoff, triangle visibility, regular readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming. It receives no quotient completion, selected representative, host equality of completions, countable choice, selected limit, or ambient completeness principle.

Proof. Project the accepted carrier $L = (M, D, A, J, R, E, H, C, P, N)$. A universal read opens M first and then the dense unit row D, so the source-to-completion boundary is displayed before the adjunction rows are available.

Next consume A and J. These rows expose the Cauchy and metric adjunction handoffs over the same finite reflector route, including the unit, counit, and triangle comparison needed by universal consumers.

The read then passes through R and E. Regular rational readback and the terminal Real seal are downstream from the displayed reflector and adjunction rows, not independent completeness assumptions.

The structural rows H, C, P, N preserve the ordered handoff under transport, replay, provenance, and local naming. Row exhaustion excludes quotient representatives, selected limits, host equality, countable choice, and ambient completeness from the exported certificate. □

Falsifiable prediction: Every accepted $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$ universal read factors through MetricCompletion, MetricCompletionDenseEmbedding, CauchyCompletionAdjunction, MetricCompletionAdjunction, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Independence witness: metriccompletion, metric-completion-dense-embedding, cauchy-completion-adjunction, metric-completion-adjunction, regseqrat, real: $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly packages reflector admission, dense unit exposure, adjunction handoff, triangle visibility, regular readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}$ packet is generated from a MetricCompletion reflector row, a MetricCompletionDenseEmbedding unit row, CauchyCompletionAdjunction and MetricCompletionAdjunction handoff rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3987.1, Definition 3987.2, and Definition 3987.3 seed the finite left-adjoint completion reflector route over metric completion, dense embedding, adjunction, regular readback, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionLeftAdjoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, selected representatives, host equality of completions, countable choice, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit exposure, left-adjoint handoff, triangle visibility, RegSeqRat/Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionLeftAdjointUp.

Chapter 3011

A Concrete Naming Certificate for $\mathsf{CFun}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CFun}^{\uparrow}$ packet records an ordinary continuous real-facing map as finite source, target, modulus, transport, replay, provenance, and local naming rows. It is an L10 neighbour of the terminal $\mathsf{Real}^{\uparrow}$ seal in chapter 38, the finite windows of chapter 126, the regular rational readback of chapter 301, the formal-ball radius interface of chapter 1510, and the carrier-only packet of chapter 3611. The chapter names the finite continuity certificate consumed by $\mathsf{ContinuousMap}^{\uparrow}$, compact-uniform-continuity, and modulus packets without treating host functions as primitive objects.

Definition 3011.1 (Continuous function carrier)**.** *A* $\mathsf{CFun}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, M, Q, W, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-window row, exposing the finite* $\mathsf{StreamName}^{\uparrow}$ *observations and source-domain histories inspected by the continuity request.*
2. *T is the target-readback row, exposing the target* $\mathsf{Real}^{\uparrow}$ *or sibling endpoint readback reached by the displayed source window.*
3. *M is the finite modulus row, translating each target tolerance request into the source-window budget used by the packet.*
4. *Q is the continuity-certificate row binding S, T, M to the displayed request.*
5. *W is the shared finite window ledger over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and any* $\mathsf{FormalBall}^{\uparrow}$ *radius window opened by the same request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row used when a continuous-function consumer asks for a real-valued endpoint.*
7. *H records componentwise* hsame *transport for source, target, modulus, certificate, window, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a source-window request through S, T, M, Q, W, R.*
9. *P is the* Pkg *provenance over* $\mathsf{CFun}^{\uparrow}$, $\mathsf{CFunCarrier}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CFun}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, T, M, Q, W, R, H, C, P, N$. It has no coordinate for host function extensionality, countable choice, quotient equality of maps or reals, selected modulus functions, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.ContinuousFunctionUp.ContinuousFunctionTasteGate single carrier alignment`

Theorem 3011.2 (Continuous function NameCert obligations)**.** *For every accepted* $\mathsf{CFun}^\uparrow$ *carrier $F = (S, T, M, Q, W, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CFun}^\uparrow}$ *surface consists exactly of source-window admission through S, target readback through T, finite modulus exposure through M, continuity-certificate binding through Q, shared* $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, *and* $\mathsf{FormalBall}^\uparrow$ *window routing through W, real-facing readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3988.1. The rows $S, T, M, Q, W, R, H, C, P, N$ are the only local coordinates, so source admission, target readback, modulus exposure, continuity binding, window routing, readback, transport, replay, provenance, and naming must all be read there.

The analytic route is finite. The modulus row M translates a target tolerance into a source-window budget, Q binds that budget to the displayed source and target rows, and W, R expose the StreamName, RegSeqRat, FormalBall, and Real-facing readbacks attached to the same request.

Finally H, C, P, N preserve and name the same route. Since the carrier has no host-function, function-extensionality, quotient-equality, choice, selected-modulus, or ambient-completeness coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 3011.3 (Continuous function Real-map handoff)**.** *Every* $\mathsf{ContinuousMap}^\uparrow$, *compact-uniform-continuity, or real-valued modulus consumer of an accepted* $\mathsf{CFun}^\uparrow$ *packet receives the map only through*

$$S, M, Q \longmapsto W \longmapsto T, R \longmapsto H, C, P, N.$$

Thus the consumer may use the source window, finite modulus, continuity certificate, shared $\mathsf{StreamName}^\uparrow$ *and* $\mathsf{RegSeqRat}^\uparrow$ *windows, optional* $\mathsf{FormalBall}^\uparrow$ *radius interface, target readback, real seal, componentwise transport, displayed replay, provenance, and local naming rows. It receives no host function object, function extensionality principle, countable-choice selector, quotient equality of maps or reals, selected limit, or ambient* $\mathsf{Real}^\uparrow$ *completeness witness.*

Proof. Begin with the source and modulus rows. A consumer request opens S and M before any target readback is available, and Q is the only row binding the source budget to the target tolerance.

Next read the finite windows. The row W exposes the relevant $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, and $\mathsf{FormalBall}^\uparrow$ faces, while T and R expose the target and real-facing readbacks reached by that same finite route.

The rows H, C, P, N then transport, replay, source, and name the handoff. Row exhaustion in Definition 3988.1 excludes every host-function, function-extensionality, quotient-equality, choice, selected-limit, and ambient-completeness escape route. □

Falsifiable prediction: Every accepted $\mathsf{CFun}^\uparrow$ read must expose source window, target readback, finite modulus, continuity certificate, StreamName and RegSeqRat windows, optional FormalBall radius routing, Real-facing readback, componentwise transport, displayed replay, provenance, and local naming rows before a continuous-map or modulus consumer can inspect it.

Independence witness: real, streamname, regseqrat, formalball, continuousfunctioncarrier, continuousmap: $\mathsf{CFun}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source-window, target-readback, finite-modulus, continuity-certificate, shared-window, real-readback, transport, replay, provenance, and local naming rows without quotienting maps or importing host functions.

Closure status for $\mathsf{NameCert}_{\mathsf{CFun}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CFun}^{\uparrow}$ packet is generated from source-window rows, target readback rows, finite modulus rows, continuity-certificate rows, shared StreamName, RegSeqRat, and FormalBall windows, real-facing readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CFun}^{\uparrow}}$, seed)

Scope closed: Definition 3988.1, Definition 3988.2, and Definition 3988.3 seed the finite non-host continuous-function route over source windows, target readbacks, modulus data, continuity certificates, window ledgers, readbacks, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CFun}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, countable choice, quotient map equality, quotient real equality, selected modulus functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-window access, target readback, finite modulus exposure, continuity-certificate binding, shared window routing, real-facing handoff, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousFunctionUp.

Chapter 3012

A Concrete Naming Certificate for $\mathsf{CounterfactualOutcome}^{\uparrow}$

Following Pearl, Causality, 2009, the $\mathsf{CounterfactualOutcome}^{\uparrow}$ packet records paired factual and counterfactual outcome reads as finite causal-inference NameCert data. It sits beside the intervention calculus of chapter 453, the intervention-row packet of chapter 1290, the probability-space carrier of chapter 184, the distribution handoff of chapter 186, and the Bayesian conditioning route of chapter 232. The packet gives causal consumers a selected counterfactual-outcome surface without weakening the explicit non-claim boundary of $\mathsf{DoCalculus}^{\uparrow}$.

Definition 3012.1 (Counterfactual outcome carrier)**.** *A* $\mathsf{CounterfactualOutcome}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (U, I, Y_f, Y_{cf}, M, R, H, D, E, T, P, N)$$

with the following displayed rows:

1. *U is the finite unit row, naming the observational unit and the displayed covariate cells opened by the counterfactual query.*
2. *I is the intervention row inherited from the* $\mathsf{CausalIntervention}^{\uparrow}$ *route. It records the do-row, intervention target, and intervention value that may be inspected by the counterfactual read.*
3. *Y_f is the factual outcome row observed for U before the counterfactual branch is exported.*
4. *Y_{cf} is the counterfactual outcome row selected under I for the same unit row U.*
5. *M is the modified-distribution row, read through the* $\mathsf{DoCalculus}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, *and* $\mathsf{Bayesian}^{\uparrow}$ *siblings before any expectation or probability export.*
6. *R is the consistency row requiring factual and counterfactual reads to agree on the factual branch selected by the displayed intervention route.*
7. *H records componentwise* hsame *transport for units, interventions, factual outcomes, counterfactual outcomes, modified distributions, consistency rows, distribution exports, expectation rows, replay rows, provenance rows, and local naming rows.*
8. *D is the distribution handoff row. It exposes only the finite probability surface displayed by M and does not store hidden-world measures.*
9. *E is the expectation and export row for finite counterfactual queries.*

10. *T records displayed* Cont *replay of the route*

$$U, I, Y_f, Y_{cf}, M, R \longmapsto D, E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CounterfactualOutcome}^{\uparrow}$, $\mathsf{DoCalculus}^{\uparrow}$, $\mathsf{CausalIntervention}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Bayesian}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CounterfactualOutcome}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, I, Y_f, Y_{cf}, M, R, H, D, E, T, P, N$. It has no coordinate for hidden structural equations, cross-world equality outside the displayed consistency row, selected counterfactual universes, host structural causal models, or ambient probability semantics.

Lean4 ✓ `BEDC.Derived.CounterfactualOutcomeUp.CounterfactualOutcomeTasteGate single carrier alignment`

Theorem 3012.2 (Counterfactual outcome NameCert obligations)**.** *For every accepted* $\mathsf{CounterfactualOutcome}^{\uparrow}$ *carrier*

$$C = (U, I, Y_f, Y_{cf}, M, R, H, D, E, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CounterfactualOutcome}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the finite unit row, intervention row, factual outcome row, counterfactual outcome row, modified-distribution row, consistency row, transport, distribution handoff, expectation and export row, replay, provenance, and local naming row;*

2. *intervention anchoring, requiring every counterfactual read Y_{cf} to cite the displayed I row and the same unit row U before any export through D or E;*

3. *factual and counterfactual consistency, requiring R to bind the factual branch of Y_{cf} to the observed Y_f without adding cross-world equality outside the carrier;*

4. *probability handoff, requiring M, D, E to pass through the displayed* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, *and* $\mathsf{Bayesian}^{\uparrow}$ *routes before any finite probability or expectation read is available;*

5. *non-escape from hidden worlds, host structural causal models, and selected counterfactual universes, requiring H, T, P, N to preserve only the displayed rows and to export no unlisted causal semantics.*

No counterfactual-outcome obligation is stored outside these rows.

Proof. Project the accepted carrier $C = (U, I, Y_f, Y_{cf}, M, R, H, D, E, T, P, N)$. Carrier admission exposes exactly the finite unit, intervention, factual outcome, counterfactual outcome, modified-distribution, consistency, transport, distribution, export, replay, provenance, and naming rows.

The counterfactual branch is anchored before it is exported. The row I supplies the intervention target and value, while U supplies the unit row shared by Y_f and Y_{cf}.

Consistency is then read through R. This row identifies the factual branch of the counterfactual read with the observed factual outcome, but it does not create an unconstrained cross-world equality or a hidden structural equation.

The probability-facing rows are downstream. The modified distribution M, distribution handoff D, and expectation row E are available only along the displayed probability, distribution, and Bayesian routes.

Finally H, T, P, N transport, replay, source, and name the same finite surface. Since no carrier coordinate stores hidden worlds, a host structural causal model, or a selected counterfactual universe, none can escape through the local NameCert. □

Falsifiable prediction: Every $\mathsf{CounterfactualOutcome}^{\uparrow}$ counterfactual-facing read factors through a finite unit row, a displayed intervention row, factual and counterfactual outcome rows, a modified-distribution row, a consistency row, componentwise hsame transport, distribution and expectation handoff rows, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: do-calculus, causal-intervention, probspace, distribution, bayesian: CounterfactualOutcor is not bijective to any listed sibling because it jointly carries paired factual and counterfactual outcomes for a unit, a displayed intervention anchor, a modified-distribution handoff, a consistency row, finite probability and expectation export, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CounterfactualOutcome}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CounterfactualOutcome}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3989.1 and Definition 3989.2 seed the finite counterfactual-outcome route over unit, intervention, factual outcome, counterfactual outcome, modified-distribution, consistency, distribution, expectation, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CounterfactualOutcome}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close hidden structural equations, host structural causal models, selected counterfactual universes, cross-world equality outside the displayed consistency row, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, intervention anchoring, factual and counterfactual consistency, probability handoff, non-escape from hidden worlds, transport, replay, provenance, and local naming for BEDC.Derived.CounterfactualOutcomeUp.

Constructive story: A $\mathsf{CounterfactualOutcome}^{\uparrow}$ packet is generated from a finite unit row, a displayed intervention row, factual and counterfactual outcome rows, a modified-distribution row, a consistency row, componentwise hsame transport, distribution and expectation handoff rows, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3013

A Concrete Naming Certificate for $\mathsf{FiniteSupportRemoval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteSupportRemoval}^{\uparrow}$ packet records the constructive finite-cover operation that deletes one displayed support row while keeping the remaining finite cover, tolerance ledger, and terminal real-name route visible. It consumes the positive-radius surface of chapter 452, the compact finite-net route of chapter 3957, and the L10 dependency chain through chapter 126, chapter 301, and chapter 38. The packet names a support-pruning certificate for finite compactness consumers; it is not a selected subcover functional, a host-level minimum operation, a quotient equality principle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3013.1 (Finite support removal carrier)**.** *A* $\mathsf{FiniteSupportRemoval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, G, D, W, T, R, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net or finite-cover source row, exposing the finite list of support names and coverage witnesses.*
2. *G is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius row that keeps every retained support row inside the displayed cover tolerance.*
3. *D is the deleted support name, together with its membership witness in the original finite support spine.*
4. *W is the retained finite window after removing D, with its inherited order and membership rows.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger transported from the original cover to the retained window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row over the retained window.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only through the retained* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *route.*
8. *H records componentwise* hsame *transport for K, G, D, W, T, R, L and for the structural rows below.*
9. *C records displayed* Cont *replay from finite-cover inspection through support deletion, tolerance transport, regular readback, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteSupportRemoval}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{CompactUniformFiniteNetRealizati}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSupportRemoval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, G, D, W, T, R, L, H, C, P, N$. It has no coordinate for an undisplayed cover member, a selected replacement support, quotient equality of real names, countable choice, or an ambient compactness theorem.

Theorem 3013.2 (Finite support removal NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSupportRemoval}^{\uparrow}$ *carrier $S = (K, G, D, W, T, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteSupportRemoval}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite-cover source, positive-radius ledger, deleted support name, retained window, tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows; membership exposure for D in the original support spine; retained-window coverage through W and G; L10 readback through T, R, L; and non-escape from selected replacement supports, quotient real equality, countable choice, and ambient compactness.*

Proof. Project the carrier of Definition 3990.1. The rows $K, G, D, W, T, R, L, H, C, P, N$ are the complete displayed inventory.

The deletion row is finite data. Since D is stored with its membership witness in the original finite support spine and W stores the retained window, the packet can inspect the removed coordinate without choosing a replacement support or leaving the finite cover.

The coverage and tolerance rows are inherited only through displayed coordinates. The positive-radius row G keeps the retained supports inside the finite Lebesgue-radius ledger, while T transports the dyadic tolerance data to the retained StreamName window.

Finally the regular readback and Real seal are read through R and L, then preserved by H, C, P, N. The refused objects are absent from the carrier, so the local NameCert surface is exactly the obligation list stated above. □

Lean4 ✓ `BEDC.Derived.FiniteSupportRemovalUp.FiniteSupportRemovalTasteGate single carrier alignment`

Theorem 3013.3 (Finite support removal compact-cover handoff)**.** *Every compactness or uniform-modulus consumer of an accepted* $\mathsf{FiniteSupportRemoval}^{\uparrow}$ *packet reads the deletion route through the finite chain*

$$\mathsf{FiniteLebesgueNumber}^{\uparrow},\ \mathsf{CompactUniformFiniteNetRealization}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer first displays the original finite support spine, then the removed coordinate and retained window, then the positive-radius and dyadic tolerance rows, and only then the regular readback and Real seal. No consumer may replace the deleted support by an undisplayed cover member, a selected subcover, quotient real equality, countable choice, or ambient completeness.

Proof. Use Definition 3990.2. It orders the finite-cover row, the deleted support row, the retained window, the positive-radius ledger, the tolerance ledger, the regular readback, and the terminal Real seal inside one accepted packet.

The finite cover is consumed before deletion. Thus the support spine and the deleted coordinate are both visible BEDC histories, and the retained window W is a finite subspine rather than a host-level set difference.

The L10 dependency route is then forced. The retained StreamName window carries the dyadic tolerance row T, the regular rational readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal L through the same displayed route used by finite-cover compactness chapters.

Transport, replay, provenance, and local naming preserve this route without adding another support coordinate. Therefore the handoff supplies a constructive deletion primitive for compact finite-cover consumers while refusing the listed external objects. □

Falsifiable prediction: An accepted $\mathsf{FiniteSupportRemoval}^{\uparrow}$ read is refuted if a compactness or uniform-modulus consumer reaches a retained Real seal without displaying the original finite support spine, the deleted support name, the retained window, the positive-radius ledger, the tolerance row, the regular readback row, transport, replay, provenance, and local naming.

Independence witness: finitelebesguenumber, compactuniformfinitenetrealization, streamname, regseqrat, and real: none is bijective to the support-removal packet because only $\mathsf{FiniteSupportRemoval}^{\uparrow}$ binds a deleted finite support coordinate to a retained-window L10 readback route before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSupportRemoval}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSupportRemoval}^{\uparrow}$ packet is generated from finite-cover source rows, FiniteLebesgueNumberUp positive-radius rows, a displayed deleted support name, retained StreamName window rows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSupportRemoval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3990.1, Definition 3990.2, and Definition 3990.3 seed the finite support-deletion surface for compactness and uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSupportRemoval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected subcover extraction, quotient real equality, countable choice, host set difference, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, support membership exposure, retained-window coverage, positive-radius preservation, tolerance transport, regular readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSupportRemovalUp.

The $\mathsf{Cauchy}^{\uparrow}$ hub reads finite windows through chapter 126, dyadic tolerance through chapter 291, regular readback through chapter 301, and the terminal seal through chapter 38.

Chapter 3014

A Concrete Naming Certificate for $\mathsf{CauchyRemainderEstimate}^{\uparrow}$

Following Bishop and Bridges constructive analysis of regular Cauchy names, the $\mathsf{CauchyRemainderEstimate}^{\uparrow}$ packet records finite tail estimates before a completion or real-name consumer is allowed to read a candidate limit surface. It sits on the Phase Real and Completion route after the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the finite observation handles of chapter 126, the regular rational readback of chapter 301, the tail-diameter budget of chapter 1746, and the real-name seal of chapter 38. The packet exposes a finite Cauchy tail remainder estimate; it does not select a limit, identify quotient streams, invoke countable choice, import ambient Real completeness, or turn a boundary counterexample into a convergent name.

Definition 3014.1 (Cauchy remainder estimate carrier)**.** *A* $\mathsf{CauchyRemainderEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, D, T, W, R, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose observations are being tested on a finite tail.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested error bound, its positive slack, and the finite comparison budget used by the estimate.*
3. *T is the displayed threshold row, naming the finite tail index after which the estimate is allowed to read observations.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened only at indices admitted by T.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations exposed by W and checked against the tolerance data in D.*
6. *B is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *boundary row, recording the displayed tail-diameter budget through which the same finite evidence is consumed by a* $\mathsf{Real}^{\uparrow}$ *seal route or by a refusal route.*
7. *H records componentwise* hsame *transport for the source, tolerance, threshold, window, readback, boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through D, T, W, R, B.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRemainderEstimate}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRemainderEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, T, W, R, B, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, countable choice, ambient completeness, host real equality, trichotomy, or bridge checking.

Lean4 ✓ `BEDC.Derived.CauchyRemainderEstimateUp.CauchyRemainderEstimateTasteGate single carrier alignment`

Theorem 3014.2 (Cauchy remainder estimate NameCert obligations)**.** *For every accepted* CauchyRemainderEstima *carrier*

$$E = (S, D, T, W, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRemainderEstimate}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source, dyadic tolerance ledger, finite threshold, admitted windows, rational readback, boundary row, transport, replay, provenance, and local naming rows;*
2. *tolerance exposure, requiring each remainder request to read its bound and slack data from D before any tail observation is opened;*
3. *threshold exactness, requiring T to be the only finite index gate through which W may expose tail observations;*
4. *readback alignment, requiring R to compare only the observations admitted by W against the same tolerance request from D;*
5. *boundary nonescape, requiring B to route the estimate through the displayed* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *budget before any* $\mathsf{Real}^{\uparrow}$ *seal consumer may read it, without adding a selected limit or quotient stream;*
6. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N;*
7. *refusal of selected limits, quotient stream equality, countable choice, ambient completeness, host real equality, trichotomy, and bridge checking as local certificate data.*

No Cauchy-remainder-estimate obligation is stored outside these rows.

Proof. Project the carrier of Definition 3991.1. The accepted packet exposes exactly the source row S, dyadic tolerance ledger D, threshold row T, window row W, readback row R, boundary row B, and structural rows H, C, P, N.

A remainder request first reads D. This fixes the tolerance, the positive slack, and the finite comparison budget before any source observation is visible.

The request then reads T, W, R in order. The threshold row supplies the finite tail gate, the window row exposes only observations admitted by that gate, and the readback row compares those observations against the same dyadic tolerance data.

Finally, B determines whether the estimate is consumed by a Real seal route or a Specker refusal route, while H, C, P, N transport, replay, source, and name the same finite data. Since the excluded principles do not occur as carrier coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 3014.3 (Cauchy remainder estimate dyadic tail-bound admission)**.** *Every accepted* $\mathsf{CauchyRemainderEstimate}^{\uparrow}$ *carrier presents finite tail evidence through the route*

$$S \longmapsto D \longmapsto T \longmapsto W \longmapsto R \longmapsto B.$$

Thus a consumer can inspect a Cauchy remainder only after the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request, finite threshold, admitted* $\mathsf{StreamName}^{\uparrow}$ *tail windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *boundary row have all been displayed.*

Proof. Start with an accepted consumer read of E. Carrier projection opens the source row S and the tolerance ledger D before any tail observation is available.

The finite tail gate is then supplied by T. The window row W is downstream from that gate, so it cannot expose observations outside the admitted finite tail schedule.

The readback row R compares only the windows selected by W with the tolerance data fixed by D. The boundary row B records the $\mathsf{CauchyTailDiameter}^{\uparrow}$ budget for the downstream consumer without changing the admitted observations. Hence every tail read factors through the displayed finite route. □

Theorem 3014.4 (Cauchy remainder estimate regular-Cauchy readback)**.** *If an accepted* CauchyRemainderEstimate *carrier is read as regular Cauchy data, then the readback exports only the displayed source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, finite threshold,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *observations,* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *boundary row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

It exports no selected limit, quotient stream equality, countable choice, ambient Real completeness, host real equality, trichotomy, or hidden modulus selector.

Proof. Assume a regular Cauchy consumer reads the packet. The carrier still supplies the consumer only through $S, D, T, W, R, B, H, C, P, N$.

The regular-facing route therefore receives a finite remainder estimate, not a limit-selection mechanism. The tolerance ledger and threshold row fix the request, the window and readback rows expose the rational observations, and the $\mathsf{CauchyTailDiameter}^{\uparrow}$ boundary row records the finite diameter budget used by the read.

The structural rows preserve and name that route. Since no selected-limit, quotient, choice, completeness, host-equality, trichotomy, or hidden-selector coordinate is present, the readback cannot export any of those objects. □

Theorem 3014.5 (Cauchy remainder estimate Real seal nonescape)**.** *If an accepted* $\mathsf{CauchyRemainderEstimate}^{\uparrow}$ *carrier is consumed by a* $\mathsf{Real}^{\uparrow}$ *route, then the seal is downstream of the same finite route*

$$S, D, T, W, R, B, H, C, P, N.$$

The $\mathsf{Real}^{\uparrow}$ *consumer cannot bypass the displayed dyadic tolerance, stream windows, regular rational readback, or tail-diameter budget by invoking selected limits, quotient stream equality, countable choice, ambient Real completeness, host real equality, trichotomy, or bridge checking.*

Proof. Assume the boundary row reaches a Real seal consumer. The carrier projection supplies no Real-facing coordinate except the row B together with the displayed source, tolerance, threshold, window, readback, transport, replay, provenance, and local naming rows.

Apply the dyadic tail-bound admission route. It forces the Real-facing read to pass through D, T, W, R before the boundary row can be consumed.

Apply the regular-Cauchy readback theorem. The readback row exports only the regular rational observations admitted by the same finite tolerance and window data. The Real seal therefore receives a finite remainder estimate rather than an independent limit object. □

Falsifiable prediction: Every accepted CauchyRemainderEstimate$^{\uparrow}$ consumer read factors through a source row, a DyadicRatCore$^{\uparrow}$ tolerance ledger, a finite threshold, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, a CauchyTailDiameter$^{\uparrow}$ boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, cauchy-tail-diameter, real: CauchyRemainderEstim is not bijective to any listed sibling because it jointly binds a source stream, dyadic tolerance budget, finite tail threshold, admitted observation windows, rational readback, tail-diameter boundary, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{CauchyRemainderEstimate}^{\uparrow}}$.

Constructive story: A CauchyRemainderEstimate$^{\uparrow}$ packet is generated from a displayed source stream or regular rational name, a DyadicRatCore tolerance ledger, a finite threshold, StreamName tail windows, RegSeqRat readback, a CauchyTailDiameter boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyRemainderEstimate}^{\uparrow}}$, seed)

Scope closed: Definition 3991.1, Definition 3991.2, Definition 3991.3, Definition 3991.4, and Definition 3991.5 seed the finite tail-estimate route for Real and Completion consumers without selected limits or quotient stream equality.

Formal verification: FormalStatus(NameCert$_{\text{CauchyRemainderEstimate}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyRemainderEstimateUp.CauchyRemainderEstimateTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient stream equality, countable choice, ambient Real completeness, host real equality, trichotomy, Specker convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exposure, threshold exactness, readback alignment, boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRemainderEstimateUp.

Theorem 3014.6 (Cauchy carrier root obligations)**.** *Let*

$$R = (S, D, Q, T, E, H, C, P, N)$$

be an accepted root Cauchy$^{\uparrow}$ *remainder carrier. Here S is the finite* StreamName$^{\uparrow}$ *window row, D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, Q is the* RegSeqRat$^{\uparrow}$ *readback row, T is the* CauchyTailDiameter$^{\uparrow}$ *tail-diameter row, E is the terminal* Real$^{\uparrow}$ *seal row, and H, C, P, N are the componentwise transport, displayed replay, provenance, and local naming rows. The local root obligation surface is exactly carrier admission for these rows, tolerance exactness through D, readback exposure through Q, tail-diameter exposure through T, terminal sealing through E, and structural stability through H, C, P, N.*

No accepted root carrier contains a selected limit, quotient stream, countable-choice schedule, host real equality, or ambient Real$^{\uparrow}$ *completeness coordinate.*

Proof. Project the displayed BHist carrier R. The stream row S is the only source of visible observations, and the dyadic ledger D is the only source of precision requests and comparison budgets.

The regular readback row Q is downstream of S and D, while the tail-diameter row T is downstream of the same finite windows and tolerances. Thus the root carrier records a finite remainder surface rather than a selected completed object.

The terminal seal row E may be read only after S, D, Q, T have been displayed. The rows H, C, P, N transport, replay, source, and name that same finite route. Since there are no further coordinates, the listed rows exhaust the root obligation surface and the excluded principles cannot be exported. □

Theorem 3014.7 (Cauchy tail-envelope root obligations)**.** *For every accepted root* $\mathsf{Cauchy}^{\uparrow}$ *remainder carrier* $R = (S, D, Q, T, E, H, C, P, N)$*, every tail-envelope read factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyTailDiameter}^{\uparrow}.$$

The tail-diameter row T *may compare only the finite windows exposed by* S*, the dyadic budgets exposed by* D*, and the regular rational readbacks exposed by* Q*. It cannot introduce quotient equality of streams, a selected limit, countable choice, host real equality, or an ambient completeness theorem.*

Proof. Start with a tail-envelope request. Carrier projection exposes the finite StreamName row S before any tolerance, readback, or diameter claim is available.

The dyadic ledger D supplies the displayed tolerance budget. The RegSeqRat row Q reads the same finite windows under that budget, so a tail comparison cannot cite an independent stream representative or an external choice schedule.

The CauchyTailDiameter row T is then read as a finite envelope over S, D, Q. Transport and replay through H, C preserve those rows componentwise, while P, N record provenance and local naming. Hence the tail-envelope route remains inside the displayed finite packet. □

Theorem 3014.8 (Cauchy Real-seal root obligations)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted root* $\mathsf{Cauchy}^{\uparrow}$ *remainder carrier must read the terminal seal row* E *only after the finite path*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyTailDiameter}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

has been displayed. The seal is a terminal BEDC row for the shown remainder carrier; it is not a selected limit, quotient-stream representative, countable-choice output, host real equality, or ambient real-completeness witness.

Proof. Project $R = (S, D, Q, T, E, H, C, P, N)$. The rows S, D, Q, T are the only analytic inputs to the terminal seal: finite stream windows, dyadic tolerances, regular rational readback, and tail-diameter evidence.

The Real seal E is downstream of that path. A consumer may read it only after the displayed Cauchy remainder route is visible, so the seal cannot be used to manufacture a quotient stream or a selected completed limit.

The structural rows H, C, P, N attach to the same carrier. They preserve and replay the finite path and do not add host real equality, countable choice, or ambient completeness. Therefore every Real-facing root read is exhausted by the stated path. □

Definition 3014.9 (Cauchy seed carrier)**.** *A* $\mathsf{Cauchy}^{\uparrow}$ *seed carrier is a finite* BHist *packet*

$$S = (W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite observation windows that a Cauchy consumer may inspect.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the displayed dyadic precision requests and comparison budgets for those windows.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, obtained only from the displayed stream windows and dyadic tolerance data.*

4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed after the regular rational readback, not a selected limit or host real equality witness.*
5. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from an admitted Cauchy request through W, D, R, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

The classifier compares accepted seed packets only through W, D, R, E, H, C, P, N. It has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3014.10 (Cauchy seed NameCert obligations)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *seed carrier $S = (W, D, R, E, H, C, P, N)$, the local seed-level* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, and local naming;*
2. *tolerance exactness, requiring every Cauchy comparison to read its dyadic budget from D before any regular rational readback is accepted;*
3. *window readback exactness, requiring R to be generated from the displayed windows W and tolerances D;*
4. *Real seal discipline, requiring E to remain downstream of W, D, R and never to serve as a selected limit or host equality object;*
5. *structural stability under* hsame *transport H and displayed* Cont *replay C;*
6. *provenance and local naming through P and N.*

No seed obligation certifies quotient stream equality, selected limits, host real equality, trichotomy, countable choice, or ambient completeness.

Proof. Project the carrier of Definition 3991.9. The accepted packet exposes only the finite window row, dyadic tolerance row, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Tolerance exactness is read from D after the window row W has been displayed. The regular readback row R is downstream of both rows, so it cannot introduce an independent rational sequence or a choice schedule.

The Real seal row E is terminal for the seed route. It is consumed only after W, D, R are visible, and therefore cannot act as a selected limit, quotient equality, or host real equality witness.

Finally H and C preserve the same component rows under transport and replay, while P and N source and name the packet. Since no remaining coordinate exists, the listed rows exhaust the seed-level NameCert surface. □

Theorem 3014.11 (Cauchy seed Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing read of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *seed carrier factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming preserved by* H, C, P, N*. The seed route exports finite stream windows, dyadic tolerances, regular rational readback, and a terminal Real seal, but exports no quotient stream equality, selected limit, host real equality, trichotomy, countable-choice selector, or ambient completeness principle.*

Proof. Begin with a Real-facing or completion-facing read from $S = (W, D, R, E, H, C, P, N)$. Carrier admission exposes the finite StreamName window row W before the tolerance and readback rows can be consumed.

The dyadic tolerance row D supplies the displayed precision budget for the read. The regular rational readback row R then packages the windowed data under that budget, rather than selecting an external limit or invoking a host sequence.

The Real seal row E is reached only after W, D, R have been displayed. Structural transport and replay through H, C keep the same route, and P, N record provenance and local naming.

Because the carrier has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, countable choice, or ambient completeness, every exported Real-facing read remains inside the seed route stated above. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedRealSealBoundary`

Theorem 3014.12 (Cauchy tail request carrier)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *root tail-request surface is the finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

whose rows are finite $\mathsf{StreamName}^{\uparrow}$ *windows, a directed later-window request,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *naming. It is the same finite request surface isolated by Definition 5821.1 and consumed by chapter 5817.*

Proof. Project the Cauchy seed carrier of Definition 3991.9. The rows W, D, R, E, H, C, P, N already expose finite windows, dyadic tolerance, regular readback, Real sealing, transport, replay, provenance, and local naming.

Insert the directed request row Q between the window row and the tolerance row. The resulting tuple is exactly the $\mathsf{CauchyTailRequest}^{\uparrow}$ carrier of Definition 5821.1, with the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sibling anchors.

Because Definition 5817.1 reads its tail coordinate as a finite directed request row, the root Cauchy packet supplies the carrier surface required by the finite filter route without adding quotient filters, selected limits, host equality, choice, or Real completeness. □

Theorem 3014.13 (Cauchy directed-tail NameCert obligations)**.** *For the root tail-request packet* $T = (W, Q, D, R, E, H, C, P, N)$ *of Definition 3991.12, the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *directed-tail obligation surface consists exactly of carrier admission, request classifier visibility, stability under later-window refinement, tolerance exactness, readback exactness, ledger routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations are read through the sibling rows of chapter 126, chapter 291, chapter 301, chapter 38, and chapter 5817.*

Proof. Carrier admission is the tuple display in Definition 3991.12. The request classifier is the row Q, and it is visible only after the finite window row W has named the inspected StreamName windows.

Stability and tolerance exactness are read from Q and D together. A later-window refinement changes only the displayed request route and must keep the dyadic budget attached to that route before any regular rational readback is accepted.

Readback exactness and ledger routing place R downstream of W, Q, D and place E downstream of R. Thus the Real-facing seal cannot serve as a selected limit, quotient-stream comparison, host equality witness, or ambient completeness principle.

The structural rows H, C, P, N supply transport, replay, provenance, and local naming. Projecting Definition 5821.2 gives the same row list for the named request surface, while Definition 5817.2 identifies the finite-filter consumer that reads that request. □

Theorem 3014.14 (Cauchy filter Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing Cauchy consumer that reads a filter, completion, or regular-name seal factors through the finite tail-request packet of Definition 3991.12 before it can read* E*. The route is*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyTailRequest}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

with hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows preserved throughout.*

Proof. Start with a Real-facing Cauchy read. The seed boundary of Definition 3991.11 already forces the read through finite windows, dyadic tolerance, regular readback, and the terminal Real seal.

Refine the seed route by Definition 3991.12. The finite request row Q is inserted before the tolerance ledger, so no downstream consumer reaches D, R, or E without first reading the directed-tail request surface.

Apply Definition 3991.13. Its ledger and exactness clauses keep W, Q, D, R, E in order, and its structural clauses preserve the same route through H, C, P, N.

Finally compare with Definition 5817.3. The filter consumer reads the same finite route before consuming the Real seal, so every Real-facing Cauchy answer factors through the displayed tail request rather than through quotient filters, selected limits, countable choice, host equality, or Real completeness. □

Theorem 3014.15 (Cauchy seed closure route)**.** *Every public route through the* $\mathsf{Cauchy}^{\uparrow}$ *hub is read through the sibling surfaces of chapter 3413, chapter 126, chapter 301, chapter 291, chapter 3991, and chapter 38 before any Real-facing completion consumer can use it. The route exposes finite stream windows, dyadic tolerance rows, regular rational readback, Cauchy remainder estimates, terminal real seals, componentwise transport, replay, provenance, and local naming; it exports no selected limit, quotient stream equality, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Cauchy carrier of Definition 3413.1. Its public readback is already ordered through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal-facing row.

Apply Definition 3413.3 and Definition 3413.4. These results force every regular rational read to pass through finite stream windows, dyadic tolerances, the displayed modulus row, and the compatibility row before R is inspected.

Apply Definition 3991.3 for completion-facing tolerance reads. The remainder estimate route inserts the finite threshold and admitted tail windows before any Real or completion consumer can treat the Cauchy packet as usable tail evidence.

Finally apply Definition 3413.9. The terminal Real-facing seal remains downstream of the displayed regular rational and remainder-estimate routes. Since none of the cited sibling surfaces

carries selected limits, quotient stream equality, choice, trichotomy, host equality, or ambient completeness, the hub route exports none of those objects. □

Theorem 3014.16 (Cauchy seed carrier boundary)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *seed carrier boundary is exhausted by the displayed Cauchy source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row. It contains no quotient completion, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Read the carrier through Definition 3413.1. The displayed Cauchy packet provides only the source row, finite observation windows, dyadic tolerances, regular readback, the Real-facing seal route, and the structural transport, replay, provenance, and naming rows.

The sibling routes of Definition 3413.4 and Definition 3413.9 keep those rows ordered before any Real-facing consumer reads the packet. Since none of the displayed coordinates is a quotient completion, selected limit, choice schedule, host equality, or ambient completeness proof, the seed carrier boundary exports none of them. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedCarrierBoundary`

Theorem 3014.17 (Cauchy seed NameCert obligation)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *seed packet, the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *obligation surface records exactly carrier admission, finite-window exposure, dyadic tolerance exposure, regular-rational readback, Real-seal routing, componentwise transport, continuation replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedNameCertObligation`

Proof. Project the Cauchy packet through the carrier boundary of Definition 5888.16. Every admissible NameCert read is a read of one displayed carrier coordinate or one structural row attached to that coordinate.

Carrier admission supplies the Cauchy source row. Window, tolerance, and readback exposure supply the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows. The terminal route supplies the Real-facing seal, and the remaining rows supply hsame transport, Cont replay, Pkg provenance, and local naming. No further local obligation is available inside the seed packet. □

Theorem 3014.18 (Cauchy filter-modulus scoped route)**.** *Every public* $\mathsf{Cauchy}^{\uparrow}$ *seed read used by a filter, modulus, Real-facing, or completion-facing consumer factors through the displayed finite route consisting of* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *carrier data, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row. The route exports no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyFilterModulusScopedRoute`

Proof. Start from the Cauchy seed boundary of Definition 5888.16. It exhausts the carrier by the Cauchy source row, finite stream windows, dyadic tolerance rows, regular readback, Real-facing seal, transport, replay, provenance, and local naming.

Apply Definition 5888.17. It identifies those same rows as the local NameCert obligation surface, so any filter or modulus consumer reads the seed packet through finite windows, dyadic

budgets, regular-rational data, and the Real-facing seal rather than through an external completion object.

The sibling routes of Definition 1981.22, Definition 3688.9, and Definition 3991.15 keep the same packet ordered through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before completion-facing consumers inspect it. Since BHist, hsame, Cont, Pkg, and NameCert only carry, transport, replay, source, and name that route, the excluded quotient, selection, choice, trichotomy, host-equality, and ambient-completeness objects remain outside the scoped boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Cauchy}^{\uparrow}$ seed packet is generated from finite stream windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal Real-facing seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 5888.16, Definition 5888.17, Definition 5888.18, and the bridge-facing L10 export of Definition 5888.14 bind the public $\mathsf{Cauchy}^{\uparrow}$ route to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exposure, regular-rational readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyUp.

Chapter 3015

A Concrete Naming Certificate for $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ packet records the finite comparison surface for two displayed Cauchy tail-envelope reads before either branch reaches the terminal real-name seal. It sits after the dyadic tail envelope of chapter 1659, the tail-diameter boundary of chapter 1746, the finite stream schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the real-name boundary of chapter 38. The packet names a paired finite tail route; it is not quotient stream equality, a selected common limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3015.1 (Cauchy tail-envelope comparison carrier)**.** *A* $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E_0, E_1, W_0, W_1, D, J, T, H, C, P, N)$$

with the following displayed rows:

1. E_0 *and* E_1 *are accepted* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *rows naming the two tail-envelope reads being compared.*
2. W_0 *and* W_1 *are the* $\mathsf{StreamName}^{\uparrow}$ *tail windows opened by the two envelope reads.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the two displayed tails.*
4. J *is the common-window row, recording the finite refinement through which* W_0 *and* W_1 *are read before either branch reaches a* $\mathsf{Real}^{\uparrow}$ *seal.*
5. T *is the paired tail-diameter row, recording the displayed comparison with the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *boundary.*
6. H *records componentwise* hsame *transport for the two envelope rows, stream windows, shared tolerance, common-window refinement, tail-diameter row, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a paired precision request through* E_0, E_1, J, D, T.
8. P *is the* Pkg *provenance over* $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$, $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient stream equality, selected common limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyTailEnvelopeComparisonUp.CauchyTailEnvelopeComparisonTasteGate`
`single carrier alignment`

Theorem 3015.2 (Cauchy tail-envelope comparison NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ *carrier*

$$Q = (E_0, E_1, W_0, W_1, D, J, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two dyadic tail-envelope rows, their stream windows, the shared dyadic tolerance, the common-window refinement, the paired tail-diameter row, transport, replay, provenance, and local naming rows;*
2. *envelope exposure, requiring both branches to display their* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *rows before the paired comparison is consumed;*
3. *common-window admission, requiring J to be fixed before either branch reads a* $\mathsf{RegSeqRat}^{\uparrow}$ *row toward* $\mathsf{Real}^{\uparrow}$*;*
4. *tolerance alignment, requiring both tail reads to use the same displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D;*
5. *diameter comparison, requiring the paired tail-diameter row T to be read through the same common window and tolerance data;*
6. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N;*
7. *refusal of quotient stream equality, selected common limits, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge checking as local certificate data.*

No comparison obligation is stored outside these rows.

Proof. Project the carrier of Definition 3992.1. The accepted packet exposes exactly the two dyadic tail-envelope rows E_0, E_1, their opened stream windows W_0, W_1, the shared tolerance row D, the common-window row J, the tail-diameter row T, and the structural rows H, C, P, N.

The envelope exposure clauses follow from the two displayed $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ rows. Each branch must open its finite stream window before the paired comparison can read any regular rational data.

The common-window and tolerance clauses are the role of J and D. They force the two branches to pass through one finite refinement and one dyadic budget before the paired tail-diameter row is consumed.

The remaining rows are structural. The hsame row transports each displayed coordinate componentwise, the Cont row replays the same paired route, and the Pkg and $\mathsf{NameCert}$ rows source and name only that finite surface.

Since none of the excluded principles occurs as a carrier coordinate, the local certificate cannot export quotient stream equality, a selected common limit, countable choice, trichotomy, host real equality, ambient Real completeness, or bridge checking. □

Theorem 3015.3 (Cauchy tail-envelope comparison common window)**.** *Every accepted* CauchyTailEnvelopeCompar *carrier compares its two displayed tail-envelope reads through a single finite common-window route*

$$E_0, E_1 \longrightarrow J \longrightarrow W_0, W_1 \longrightarrow D \longrightarrow T.$$

Consequently any $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the paired comparison receives the same displayed common-window row before either branch can present a terminal real-name seal.*

Proof. Begin with the two accepted envelope rows. By Definition 1659.4, paired dyadic tail-envelope reads serving the same displayed precision request admit a finite common route before any $\mathsf{Real}^{\uparrow}$ seal is inspected.

The carrier row J records that common route for the comparison packet. Once J is fixed, both stream windows W_0 and W_1 are read as displayed rows over the same refinement rather than as completed streams.

The shared tolerance row D and the tail-diameter row T are then downstream from the common window. Thus every consumer of the paired comparison receives the displayed route through $E_0, E_1, J, W_0, W_1, D, T$ before any real-name seal is available. □

Theorem 3015.4 (Cauchy tail-envelope comparison nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ *packet receives only the two displayed* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *rows, their finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, the common-window refinement, the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *comparison row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It receives no quotient stream, selected common limit, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge-checking row.*

Proof. Project the carrier rows listed in Definition 3992.1. A consumer reaches the paired comparison only through $E_0, E_1, W_0, W_1, D, J, T, H, C, P, N$.

Apply Definition 3992.3. The common-window route places the two envelope rows, the finite refinement, the displayed windows, the shared tolerance, and the tail-diameter comparison before any terminal real-name seal can be read.

The excluded data are absent from the carrier and from the common-window route. Hence the comparison packet cannot export quotient streams, selected common limits, countable-choice schedules, trichotomy data, host real equality, ambient Real completeness, or a bridge-checking row to downstream Real or Completion consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ packet is generated from two displayed DyadicCauchyTailEnvelope rows, their StreamName tail windows, a shared DyadicRatCore tolerance row, a common-window refinement, a CauchyTailDiameter comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}}$, seed)

Scope closed: Definition 3992.1, Definition 3992.2, Definition 3992.3, and Definition 3992.4 seed the paired finite tail-envelope comparison route before either branch reaches Real or Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyTailEnvelopeComparisonUp.CauchyTailEnvelopeComparisonTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected common limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired envelope exposure, common-window admission, tolerance alignment, tail-diameter comparison, transport, replay, provenance, and nonescape for BEDC.Derived.CauchyTailEnvelopeCo

Chapter 3016

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompleteness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedCompleteness}^{\uparrow}$ packet records the constructive completeness readback surface for located regular real names as finite BEDC NameCert data. It sits after the compact interval neighbor of chapter 3986, the located interval surface of chapter 1709, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the finite route by which a completion-facing consumer reads located Cauchy data; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of real names, countable choice, selected limits, or open-cover compactness.

Definition 3016.1 (Bishop located completeness carrier)**.** *A* $\mathsf{BishopLocatedCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, S, R, D, E, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row, naming the located interval or located enclosure in which the inspected Cauchy data is read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite stream observations available at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row extracted from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling mesh, modulus, and endpoint precision requests.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed readback route.*
6. *B is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *boundary row, recording that any compact-interval assistance is consumed only through the finite route of the Bishop compact interval packet.*
7. *H records componentwise* hsame *transport for located interval, stream, regular, dyadic, Real, compact-boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from located requests through stream windows, regular readback, dyadic tolerance, Real sealing, compact-boundary control, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompleteness}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, R, D, E, B, H, C, P, N$. It has no coordinate for host real completeness, quotient representatives, selected Cauchy limits, countable-choice schedules, open-cover compactness, or an unrestricted locator oracle.

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletenessUp.BishopLocatedCompletenessTasteGate single carrier alignment`

Theorem 3016.2 (Bishop located completeness NameCert obligations)**.** *For every accepted* BishopLocatedComplete *carrier $L = (I, S, R, D, E, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed located interval, stream-window, regular readback, dyadic tolerance, Real seal, compact-boundary, transport, replay, provenance, and naming rows; located source admission through I; finite observation through S; regular readback through R; dyadic tolerance accounting through D; Real sealing through E; compact-interval boundary control through B; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

No obligation is discharged by ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of real names, a selected limit, countable choice, open-cover compactness, or a host locator outside the displayed packet.*

Proof. Project the carrier of Definition 3993.1. The tuple lists the complete finite row inventory admitted by the local certificate.

The located source is read through I, then finite observation and regular readback pass through S and R. Dyadic precision is controlled by D before the Real seal E is exposed.

The compact-interval row B contributes only the finite boundary route supplied by chapter 3986. It cannot be read as open-cover compactness or as ambient completeness.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, or a host locator, no local $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteness}^{\uparrow}}$ obligation can export one. □

Theorem 3016.3 (Bishop located completeness Real-seal boundary)**.** *Every completion-facing read from an accepted* $\mathsf{BishopLocatedCompleteness}^{\uparrow}$ *packet reaches* $\mathsf{Real}^{\uparrow}$ *only through the finite route*

$$\mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{BishopCompactInterval}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

The read exposes located interval data, finite stream windows, regular rational readback, dyadic tolerance control, compact-interval boundary control, Real sealing, transport, replay, provenance, and local naming, but it exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient real equality, selected limit, countable-choice schedule, or open-cover compactness principle.*

Proof. Let $L = (I, S, R, D, E, B, H, C, P, N)$ be an accepted carrier. A completion-facing consumer first receives I, S, R, D, so the located source, finite windows, regular readback, and dyadic tolerance route are fixed before any seal is visible.

The compact-boundary row B is then read as the Bishop compact interval neighbor of chapter 3986. It contributes only the finite interval boundary route accepted by that packet.

The Real-facing endpoint is E, and the structural route is H, C, P, N. These rows preserve the same finite path under transport, replay, provenance, and local naming. Because the classifier lacks coordinates for selected limits, quotient representatives, countable choice, open-cover compactness, and ambient completeness, the Real seal cannot be read as any of those stronger principles. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedCompleteness}^{\uparrow}$ completion-facing read passes through LocatedRealIntervalUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, BishopCompactIntervalUp, RealUp, transport, replay, provenance, and local naming rows before any Real-facing output is visible.

Independence witness: bishop-compact-interval, located-real-interval, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopLocatedCompleteness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located source data, finite windows, regular rational readback, dyadic tolerance, compact-boundary control, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompleteness}^{\uparrow}$ packet is generated from a LocatedRealInterval source row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, a BishopCompactInterval boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3993.1, Definition 3993.2, and Definition 3993.3 seed the finite constructive located-completeness route over located interval, stream, regular, dyadic, compact-boundary, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient RealUp completeness, quotient real equality, selected limits, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located source admission, finite observation, regular readback, dyadic tolerance accounting, Real sealing, compact-boundary control, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCompletenessUp.

Chapter 3017

A Concrete Naming Certificate for $\mathsf{CauchyPrincipalFilter}^{\uparrow}$

Following Kelley and Bourbaki, the $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ packet records the principal-filter specialization used by Cauchy-filter and completion routes. It sits between the Cauchy-filter surface of chapter 333, the uniform-space entourage discipline of chapter 339, and the uniform-completion boundary of chapter 1473. The packet names the finite principal row that a completion consumer may inspect; it does not turn principal filters into quotient filters, selected limits, host equality, or ambient completeness.

Definition 3017.1 (CauchyPrincipalFilter carrier)**.** *A* $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, G, F, U, B, H, K, P, N)$$

with the following displayed rows:

1. *A is the displayed center row naming the source point or finite address from which the principal filter is generated.*
2. *G is the neighbourhood and filter-base row: it lists the finite neighbourhood requests, the principal generator containing A, and the basis refinement witnesses accepted by the packet.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row, recording that the principal filter request is read as a Cauchy-filter request only through the displayed generator and basis witnesses.*
4. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *boundary row exposing the entourages through which the principal request is tested.*
5. *B is the* $\mathsf{UniformCompletion}^{\uparrow}$ *boundary row reached after A, G, F, and U have been displayed.*
6. *H records componentwise* hsame *transport for the center, generator, Cauchy-filter handoff, uniform entourage, and completion-boundary rows.*
7. *K records the displayed* Cont *replay from the center row through neighbourhood requests, filter-base refinement, Cauchy-filter handoff, uniform-space testing, and completion-boundary readback.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyPrincipalFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyPrincipalFilter}^{\uparrow}}$ *row.*

The carrier compares two accepted packets only by replaying the displayed rows $A, G, F, U, B, H, K, P, N$. It has no coordinate for quotient-filter equality, selected limits, ultrafilter extension, host equality of completion points, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyPrincipalFilterUp.CauchyPrincipalFilterTasteGate single carrier alignment`

Theorem 3017.2 (CauchyPrincipalFilter NameCert obligations)**.** *For every accepted* $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ *carrier* $Q = (A, G, F, U, B, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyPrincipalFilter}^{\uparrow}}$ *surface consists exactly of center admission through* A*, principal neighbourhood and filter-base admission through* G*, Cauchy-filter handoff through* F*, uniform-space testing through* U*, uniform-completion boundary exposure through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* K*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3994.1. The rows $A, G, F, U, B, H, K, P, N$ are the complete finite packet exposed to a consumer.

Read the principal-filter route in order. The center row A supplies the displayed generator, while G records the neighbourhood and filter-base witnesses through which the principal request is admitted.

Next follow the completion-facing handoff. The Cauchy-filter row F is available only after the generator and basis data have been displayed, and the uniform-space row U is the only entourage-testing surface used before a completion boundary is read.

Finally, B, H, K, P, and N supply boundary exposure, transport, replay, provenance, and local naming for the same rows. Since no coordinate stores quotient-filter equality, selected limits, ultrafilter extension, host equality, countable choice, or ambient completeness, no additional NameCert obligation can be exported from the packet. □

Theorem 3017.3 (CauchyPrincipalFilter convergence handoff)**.** *Every convergence-facing read exported by an accepted* $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ *carrier first exposes the displayed center row* A*, the neighbourhood and filter-base row* G*, the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row* F*, and the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row* U *before it reaches the* $\mathsf{UniformCompletion}^{\uparrow}$ *boundary row* B*. Thus the packet supplies a finite principal-filter route into Cauchy-filter and completion consumers without selecting a limit or quotienting filters.*

Proof. Start with a convergence-facing consumer. The carrier has exactly one source coordinate for the principal filter, namely the displayed center row A.

The neighbourhood row G then exposes the finite generator and basis refinement witnesses. A request that lacks those displayed witnesses has no route into the accepted packet.

The handoff row F places the request on the sibling $\mathsf{CauchyFilter}^{\uparrow}$ surface, and the uniform row U records the only entourages that the completion route may inspect. The boundary row B is therefore downstream of the finite principal-filter data rather than an independent completion object.

The transport, replay, provenance, and local naming rows H, K, P, N preserve only this route. Quotient filters, selected limits, host equality of completion points, countable choice, and ambient completeness remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPrincipalFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ packet is generated from a displayed center row, neighbourhood and filter-base row, $\mathsf{CauchyFilter}^{\uparrow}$ handoff, $\mathsf{UniformSpace}^{\uparrow}$ entourage boundary, $\mathsf{UniformCompletion}^{\uparrow}$ completion boundary, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyPrincipalFilter}\uparrow}$, seed)

Scope closed: Definition 3994.1, Definition 3994.2, and Definition 3994.3 seed the finite principal-filter route from a displayed center through Cauchy-filter and uniform-completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyPrincipalFilter}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-filter equality, selected limits, ultrafilter extension, host equality of completion points, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, principal generator exposure, filter-base refinement, Cauchy-filter handoff, uniform entourage testing, completion-boundary exposure, replay, provenance, and non-escape for the same finite packet.

Chapter 3018

A Concrete Naming Certificate for $\mathsf{KochCurve}^{\uparrow}$

Following Koch's classical curve construction, the $\mathsf{KochCurve}^{\uparrow}$ packet records the finite polygonal-stage, dyadic-schedule, and uniform-limit handoff data for the standard Koch curve before any completed planar subset is imported. It sits beside the compact binary address discipline of chapter 1475, the uniform-limit surface of chapter 463, the terminal real-name seal of chapter 38, the dyadic tolerance ledger of chapter 291, and the compact-uniform-continuity surface of chapter 388. The packet names only finite stage words, segment replacements, coordinate schedules, tolerance ledgers, and the displayed uniform-limit route; it does not import a host fractal subset, a selected infinite branch, quotient equality of real pairs, ambient compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3018.1 (Koch curve carrier)**.** *A* $\mathsf{KochCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, S, D, W, Q, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite address row. It records the inspected ternary stage, the finite left-turn and right-turn segment word, and the CantorSpace address window used by branch-facing consumers.*
2. *S is the polygonal-stage row, naming the directed segment list obtained by replacing each displayed segment by the four Koch generator segments at the next stage.*
3. *D is the dyadic displacement ledger. It records the rational endpoint deltas and the dyadic tolerance comparisons used to read the finite segment list.*
4. *W is the coordinate* $\mathsf{StreamName}^{\uparrow}$ *window row for the horizontal and vertical endpoint schedules attached to the inspected segment.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those coordinate schedules, with all tolerance comparisons routed through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
6. *E is the pair of terminal* $\mathsf{Real}^{\uparrow}$ *coordinate seals read from the same scheduled polygonal-stage rows.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, binding the stagewise polygonal approximations, dyadic tolerance ledger, and coordinate seals to one uniform-limit route.*

8. *H records componentwise* hsame *transport for addresses, segment stages, displacement ledgers, coordinate windows, rational readbacks, real seals, uniform-limit handoff, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from each curve-facing request through $A, S, D, W, Q, E, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{KochCurve}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KochCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, S, D, W, Q, E, L, H, C, P, N$. It has no coordinate for a completed planar fractal, selected infinite branch, quotient equality of real pairs, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.KochCurveUp.KochCurveTasteGate single carrier alignment`

Theorem 3018.2 (Koch curve NameCert obligations)**.** *For every accepted* $\mathsf{KochCurve}^{\uparrow}$ *carrier*

$$K = (A, S, D, W, Q, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KochCurve}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; finite address exposure through A; polygonal-stage exposure through S; dyadic displacement and tolerance exposure through D; coordinate-window exposure through W; regular rational readback through Q; terminal real coordinate sealing through E; uniform-limit handoff through L; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N. No obligation is discharged by a host planar powerset, selected infinite address, quotient real-pair equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3995.1. The accepted packet displays exactly the finite address row, polygonal-stage row, displacement ledger, coordinate windows, rational readbacks, real seals, uniform-limit handoff, and structural rows.

The finite combinatorial obligations are exhausted by A and S. A consumer cannot inspect a curve branch until the stage address is displayed, and it cannot read a segment replacement except through the directed segment list attached to that same finite stage.

The coordinate obligations are exhausted by D, W, Q, E. The dyadic ledger gives endpoint deltas and tolerance comparisons, the coordinate windows schedule the endpoint reads, the regular rational row reads those schedules, and the $\mathsf{Real}^{\uparrow}$ seals remain downstream of the same polygonal-stage data.

Finally L, H, C, P, N transport, replay, source, and name only the displayed route. Since the excluded host principles have no carrier coordinate, they cannot appear as local $\mathsf{NameCert}_{\mathsf{KochCurve}^{\uparrow}}$ obligations. □

Theorem 3018.3 (Koch curve uniform-limit handoff)**.** *Every accepted* $\mathsf{KochCurve}^{\uparrow}$ *consumer that reaches a curve point, segment bound, or real-coordinate read must first expose the finite route*

$$\mathsf{CantorSpace}^{\uparrow} \longmapsto A, S \longmapsto D, W, Q, E \longmapsto \mathsf{UniformLimit}^{\uparrow} \longmapsto H, C, P, N.$$

The handoff exports only the displayed polygonal-stage approximations, dyadic tolerance ledger, scheduled coordinate readbacks, terminal $\mathsf{Real}^{\uparrow}$ *coordinate seals, and uniform-limit route. It exports no completed fractal subset, selected infinite branch, quotient equality of real coordinate pairs, ambient compactness theorem, or ambient completeness principle.*

Proof. Begin with a consumer that reaches the Real-facing boundary of the packet. By Definition 3995.1, the only terminal coordinate seals are downstream of the finite address, polygonal-stage, dyadic displacement, coordinate-window, and rational-readback rows.

Apply Definition 3995.2. It forces every curve-facing read through $A, S, D, W, Q, E, L, H, C, P, N$ and keeps the uniform-limit handoff on the same displayed packet.

The compact-uniform-continuity and uniform-limit dependencies supply only the finite modulus and convergence route named by L. They do not add a second carrier coordinate for a host planar subset, a selected infinite address, quotient equality of real coordinate pairs, or ambient completeness. Therefore every point, segment, or coordinate consumer remains inside the finite NameCert packet. □

Falsifiable prediction: An accepted $\mathsf{KochCurve}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ coordinate seal or a uniform-limit read without first displaying the finite address row, polygonal-stage row, dyadic displacement ledger, coordinate window, and rational readback refutes the carrier surface.

Independence witness: CantorSpace, UniformLimit, Real, DyadicRatCore, and CompactUniformContinuity: no listed sibling supplies the whole $\mathsf{KochCurve}^{\uparrow}$ packet, because each sibling contributes address windows, convergence handoff, terminal coordinate seals, dyadic tolerance data, or modulus discipline while this chapter binds all rows with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KochCurve}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KochCurve}^{\uparrow}$ packet is generated from finite address rows, polygonal-stage segment rows, dyadic displacement ledgers, coordinate StreamName windows, RegSeqRat readbacks, RealUp coordinate seals, a UniformLimit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KochCurve}^{\uparrow}}$, seed)

Scope closed: Definition 3995.1, Definition 3995.2, and Definition 3995.3 seed the finite polygonal-stage and uniform-limit certificate surface for the classical Koch curve.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KochCurve}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host planar powersets, selected infinite addresses, quotient equality of real coordinate pairs, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite address exposure, polygonal-stage exposure, dyadic displacement exactness, coordinate readback, Real coordinate sealing, uniform-limit handoff, transport, replay, provenance, and local naming for BEDC.Derived.KochCurveUp.

Chapter 3019

A Concrete Naming Certificate for $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$

The $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$ packet realizes the channel boundary of chapter 9369 as finite BEDC NameCert data. It records source-event rows, legal channel-event rows, terminator-position rows, decoder-state rows, halting-boundary refusal rows, trace rows, transport, replay, provenance, and local naming in one displayed packet. The packet reads local event termination through the bounded evaluator and finite trace rows of chapter 818 before refusing certificate-level halting. The point of the packet is the stratum separation: a legal channel event can end locally, while certificate-level halting remains a refusal boundary rather than a global total classifier.

Definition 3019.1 (ChannelTerminationHaltingBoundary carrier)**.** *A* $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, E, B, D, L, R, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-event row, naming the inspected finite binary source word and the source-layer reading of its glyphs.*
2. *E is the legal channel-event row, recording the encoded body over fragments* 0 *and* 10 *together with the displayed channel terminator* 11*.*
3. *B is the body-safety row, recording that the encoded body contains no adjacent* 11 *before the terminator row is exposed.*
4. *D is the decoder-state row, naming the left-to-right scan, the first displayed* 11*, and the recovered source event.*
5. *L is the legal-channel-event classifier row, accepting only event reads that pass through S, E, B, D before any boundary claim is made.*
6. *R is the halting-boundary refusal row. It records that local event termination is not a total classifier for arbitrary* NameCert *continuation chains.*
7. *F is the finite trace row, carrying the prompt-response and bounded evaluator evidence used to display the refusal without solving certificate-level halting.*
8. *H records componentwise* hsame *transport for source events, legal channel events, body safety, decoder state, classifier exposure, refusal, trace evidence, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from each boundary-facing request through* $S, E, B, D, L, R, F, H, P, N$.
10. *P is the* Pkg *provenance over* ChannelTerminationHaltingBoundary$^{\uparrow}$, *haltingdistinction, haltingdistinctiontrace, promptresponsetrace, finitetraceevaluator,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ChannelTerminationHaltingBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, E, B, D, L, R, F, H, C, P, N$. *It has no coordinate for a bare bitstream parser, a host global halting oracle, an unrestricted evaluator, a certificate-of-certificates total classifier, or a meta-stop proof.*

Lean4 ✓ `BEDC.Derived.ChannelTerminationHaltingBoundaryUp.ChannelTerminationHaltingBoundaryTasteGate single carrier alignment`

Theorem 3019.2 (ChannelTerminationHaltingBoundary NameCert obligations)**.** *For every accepted* ChannelTerminationHaltingBoundary$^{\uparrow}$ *carrier*

$$T = (S, E, B, D, L, R, F, H, C, P, N),$$

the local NameCert$_{\text{ChannelTerminationHaltingBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; source-event exposure through S; legal channel-event exposure through E; body-safety exposure through B; decoder-state exposure through D; legal-channel-event classification through L; halting-boundary refusal through R; finite trace evidence through F; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

No obligation is discharged by a bare bitstream parser, a host global halting oracle, an unrestricted evaluator, a total certificate-level halting classifier, or a meta-stop proof.

Proof. Project the carrier of Definition 3996.1. The accepted packet displays exactly the source event, legal channel event, body-safety, decoder-state, classifier, refusal, trace, and structural rows.

The local channel obligations are exhausted by S, E, B, D, L. The source row names the event being encoded, the legal channel-event row displays the body and terminator, the body-safety row excludes an earlier terminator pattern, and the decoder-state row reads the first 11 as the local endpoint.

The halting-boundary obligation is exhausted by R and F. The refusal row states that the local endpoint is not a certificate-level total halting classifier, while the finite trace row records only bounded evidence around prompt-response and evaluator routes.

Finally H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for a global halting oracle or meta-stop proof, no local NameCert$_{\text{ChannelTerminationHaltingBoundary}^{\uparrow}}$ obligation can export one. □

Theorem 3019.3 (ChannelTerminationHaltingBoundary refusal factorization)**.** *Every accepted* ChannelTerminationHaltingBoundary$^{\uparrow}$ *packet factors local event termination through the displayed legal-channel-event route*

$$S, E, B, D, L \longmapsto R, F, H, C, P, N$$

before any halting-boundary refusal row is exposed. Thus a consumer may read the first channel-level 11 *as a local event endpoint only after the legal body and decoder rows have been displayed, and it may read the halting-boundary refusal only as the downstream statement that this local endpoint is not a certificate-level total halting classifier.*

Proof. Start with an accepted boundary-facing consumer. By Definition 3996.1, the only event-termination coordinates are S, E, B, D, L, so the consumer cannot reach the refusal row until the legal channel-event route is already displayed.

Apply Definition 3996.2. It binds body safety, first-terminator decoding, and legal-channel classification to the same finite packet before R and F can be read.

The refusal row then has only one role: it separates the local event endpoint from certificate-level halting. The finite trace row may record bounded prompt-response or evaluator evidence, but the packet has no coordinate for an unrestricted evaluator, a host global halting oracle, or a meta-stop proof. Therefore the refusal factors through the legal-channel-event route rather than replacing it. □

Falsifiable prediction: Every accepted packet factors local event termination through a displayed legal-channel-event row before any halting-boundary refusal row is exposed.

Independence witness: haltingdistinction, haltingdistinctiontrace, promptresponsetrace, finite-traceevaluator: these siblings either classify halting obstruction or trace evaluation, while this packet has the additional legal-channel terminator row and therefore is not bijective to any of them.

The Lean TasteGate namespace BEDC.Derived.ChannelTerminationHaltingBoundaryUp.TasteGate must provide Nontrivial and FieldFaithful instances for this finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$ packet is generated from source-event rows, legal channel-event rows, body-safety rows, decoder-state rows, legal-channel classifiers, halting-boundary refusal rows, finite trace evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3996.1, Definition 3996.2, and Definition 3996.3 seed the finite local-channel boundary separating event termination from certificate-level halting refusal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted halting classification, host global halting oracles, bare bitstream parsing, meta-stop proofs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, legal channel-event exposure, body-safety exposure, decoder-state exposure, local termination factorization, halting-boundary refusal, finite trace evidence, transport, replay, provenance, and local naming for BEDC.Derived.ChannelTerminationHaltingBoundaryUp.

Chapter 3020

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}$

Following Bishop and Bridges on constructive completion and reflector discipline, the CauchyCompletionUniversalArr packet records the universal arrow of the L10 Cauchy completion route as finite NameCert data. It ties the reflector surface of chapter 1585, the regular unit of chapter 3646, the counit of chapter 1539, the idempotent comparison of **??**, and the metric universal property of chapter 2124 to the regular rational and real seals of chapter 301 and chapter 38. The packet names the universal-arrow boundary without quotient completions, selected limits, host function extensionality, ambient completeness, or bridge checking.

Definition 3020.1 (CauchyCompletionUniversalArrow carrier)**.** *A* $\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, R, \eta, F, \widehat{F}, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric row opened by the universal-arrow request.*
2. *R is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row naming the completion reflector over M.*
3. *η is the* $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$ *row exposing the source-to-completion unit.*
4. *F is the uniformly continuous map row from the source metric into the displayed complete target.*
5. *$\widehat{F}$ is the factor arrow row from the reflected completion to the target named by F.*
6. *Q is the uniqueness comparison row, requiring any competing factor arrow with the same precomposition along η to compare through the displayed NameCert route.*
7. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row reached after $R, \eta, F, \widehat{F}, Q$ have been displayed.*
8. *H records componentwise* hsame *transport for source metrics, reflector rows, units, uniformly continuous maps, factor arrows, uniqueness comparisons, seal rows, replay rows, provenance rows, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$M, R, \eta, F \longmapsto \widehat{F}, Q, S.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotent}^{\uparrow}$, MetricCompletionUniv $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completions, selected Cauchy limits, host function extensionality, ambient completeness of a target space, or bridge-checked equality.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalArrowUp.CauchyCompletionUniversalArrowTasteGate`
`single carrier alignment`

Theorem 3020.2 (CauchyCompletionUniversalArrow NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}$ *carrier* $U = (M, R, \eta, F, \widehat{F}, Q, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUni}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the source metric, completion reflector, unit, uniformly continuous map, factor arrow, uniqueness comparison, RegSeqRat/Real seal, transport, replay, provenance, and local naming rows;*
2. *reflector anchoring, requiring the rows R and η to be displayed before any universal-arrow factor can be inspected;*
3. *map compatibility, requiring the source map row F to be read as uniformly continuous along the same source metric row M;*
4. *factorization visibility, requiring $\widehat{F}$ to be exported only as the factor arrow whose precomposition along η replays F through C;*
5. *uniqueness comparison, requiring Q to compare all competing factor rows by the same displayed route rather than by host function extensionality;*
6. *RegSeqRat/Real seal nonescape, requiring S, H, C, P, N to exhaust the regular rational seal, real seal, transport, replay, provenance, and local naming surface.*

Proof. Project the accepted carrier $U = (M, R, \eta, F, \widehat{F}, Q, S, H, C, P, N)$. Carrier admission exposes exactly the rows listed in Definition 3997.1.

The universal-arrow request is anchored by M, R, η. The source metric is visible before the reflector row is consumed, and the unit row is the only source-to-completion boundary available to the factorization read.

The map and factor rows are then read together. The row F supplies the uniformly continuous source map, while $\widehat{F}$ is exported only through the continuation replay that identifies precomposition with η as the displayed source map route.

Finally Q, S, H, C, P, N close the comparison and sealing surface. Since quotient completions, selected limits, host function extensionality, ambient completeness, and bridge checking are absent from the carrier, the listed rows exhaust the local certificate. □

Theorem 3020.3 (CauchyCompletionUniversalArrow factorization)**.** *Every accepted* CauchyCompletionUniversalA *packet exports a universal-arrow factorization route*

$$M \longmapsto \mathsf{CauchyCompletionReflector}^{\uparrow} \longmapsto \mathsf{RegularCauchyCompletionUnit}^{\uparrow} \longmapsto F \longmapsto \widehat{F} \longmapsto Q \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

Any downstream completion consumer receives only the source metric row, reflector row, unit row, uniformly continuous map row, factor arrow row, uniqueness comparison row, RegSeqRat/Real seal

row, componentwise transport, displayed replay, provenance, and local naming. It receives no quotient completion object, selected limit, host function extensionality principle, ambient completeness assertion, or bridge-checked equality.

Proof. Open the carrier and read M, R, η first. These rows display the source metric, the Cauchy completion reflector, and the regular unit that a universal-arrow consumer may inspect.

Next read F and $\widehat{F}$. The factor arrow is not an ambient function-space object; it is the displayed row whose continuation replay agrees with F after the unit row.

The uniqueness comparison row Q then compares any other factor row through the same displayed precomposition route. This is a certificate comparison, not a use of host function extensionality.

The route terminates at S, H, C, P, N. Regular rational and Real sealing, transport, replay, provenance, and local naming preserve the ordered handoff and exclude quotient completions, selected limits, ambient completeness, and bridge checking from the exported packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}$ packet is generated from a source metric row, a CauchyCompletionReflector row, a regular completion unit row, a uniformly continuous map row, a factor arrow row, a uniqueness comparison row, RegSeqRat and Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3997.1, Definition 3997.2, and Definition 3997.3 seed the finite universal-arrow route for the L10 Cauchy completion reflector.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host function extensionality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector anchoring, unit exposure, map compatibility, factorization visibility, uniqueness comparison, RegSeqRat/Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionUniversalArrowUp.

Chapter 3021

A Concrete Naming Certificate for $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$

Following Wolfram's cellular-automaton carrier reading and Cook's Rule 110 universality result, the $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ packet records the carrier-equivalence content of chapter 9391 as finite NameCert data. It sits beside the automaton surface of chapter 934, the orbit substrate of chapter 938, the pattern catalog of chapter 995, the trust substrate of chapter 940, and the substrate classifier boundary of chapter 3810. The packet names a finite BHist encoding and orbit-window comparison without replacing the BEDC carrier.

Definition 3021.1 (CellularCarrierBHistEquivalence carrier)**.** *A* $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, B, D, R, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the cellular orbit-window row: a finite initial row, width boundary, time window, and local update discipline.*
2. *B is the BHist encoding row that reads a finite* BHist *value as a finite cell-row code.*
3. *D is the decoder row that reads the same finite cell-row code back as a* BHist *value when the orbit window remains inside the accepted boundary.*
4. *R is the roundtrip row, requiring the encode-decode and decode-encode reads to agree on the displayed finite window.*
5. *K is the classifier transport row moving accepted cellular observations to the corresponding* BHist *classifier observations and back.*
6. *H records componentwise* hsame *transport for orbit windows, encodings, decoders, roundtrip rows, classifier transport rows, replay rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$W, B, D, R \longmapsto K.$$

8. *P is the* Pkg *provenance over* $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{CellularOrbitSubstrate}^{\uparrow}$, $\mathsf{CellularPatternCatalog}^{\uparrow}$, $\mathsf{CellularTrustSubstrate}^{\uparrow}$, $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}}$ *row.*

The classifier accepts exactly packets with these nine rows. It has no coordinate for a replacement BEDC kernel carrier, infinite cellular orbits, global physical substrate claims, hidden evaluator state, host bisimulation, or non-finite classifier equality.

Lean4 ✓ `BEDC.Derived.CellularCarrierBHistEquivalenceUp.CellularCarrierBHistEquivalenceTasteGate`
`single carrier alignment`

Theorem 3021.2 (CellularCarrierBHistEquivalence NameCert obligations)**.** *For every accepted* $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ *carrier* $E = (W, B, D, R, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CellularCarrierBHistEquivalenc}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for orbit-window, BHist encoding, decoder, roundtrip, classifier transport, transport, replay, provenance, and local naming rows;*
2. *orbit-window finiteness, requiring all cellular reads to remain inside the displayed width and time window;*
3. *encoding and decoding visibility, requiring B and D to be inspected before any carrier-equivalence claim is exported;*
4. *roundtrip and classifier transport, requiring R and K to bind finite BHist reads and finite cellular-window reads through the same accepted packet;*
5. *non-escape from carrier replacement, infinite orbit semantics, physical substrate claims, hidden evaluator state, host bisimulation, and non-finite classifier equality.*

Proof. Carrier admission is projection from Definition 3998.1. The tuple displays exactly the orbit-window, encoding, decoder, roundtrip, classifier transport, transport, replay, provenance, and naming rows.

The cellular side is finite before any equivalence read begins. The row W fixes the initial row, width boundary, time window, and local update discipline inspected by the packet.

The BHist side is read through B and D. These rows expose encoding and decoding as finite carrier reads rather than as a replacement of the BEDC kernel carrier.

The roundtrip and classifier rows R and K then bind the two directions over the same displayed window. Transport, replay, provenance, and local naming preserve that binding, while the absent coordinates rule out infinite orbit semantics, physical substrate claims, host bisimulation, and non-finite classifier equality. □

Theorem 3021.3 (Cellular carrier BHist equivalence route)**.** *Every accepted* $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ *packet exports the finite route*

$$\mathsf{CellularOrbitSubstrate}^{\uparrow} \longmapsto W \longmapsto B \longmapsto D \longmapsto R \longmapsto K \longmapsto H, C, P, N.$$

The route realizes the cellular-carrier alternative as a finite comparison between orbit-window observations and BHist *observations. It does not export a new kernel carrier, an infinite orbit semantics, a global physical substrate assertion, hidden evaluator state, host bisimulation, or non-finite classifier equality.*

Proof. Open W first. The orbit-window row supplies the finite cellular observation boundary and therefore prevents the route from depending on an infinite orbit.

Read B and D next. Encoding and decoding connect the finite window code with a finite BHist value, so the comparison is a NameCert packet rather than a carrier substitution.

Use R and K to bind the roundtrip and classifier transport. These rows keep cellular and BHist observations in the same finite acceptance boundary.

Finally consume H, C, P, N. Componentwise transport, displayed replay, provenance, and local naming preserve the finite route and leave no carrier-replacement, physical-substrate, hidden-evaluator, host-bisimulation, or non-finite-equality coordinate to export. □

Falsifiable prediction: Every accepted $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ read factors through a finite orbit-window row, a BHist encoding row, a decoder row, a roundtrip row, classifier transport, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: cellularautomaton, cellularorbitsubstrate, cellularpatterncatalog, cellular-trust-substrate, cellular-substrate-classifier-boundary: $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ is not bijective to any listed sibling because it jointly packages a finite orbit window, BHist encoding, decoding, roundtrip, classifier transport, replay, provenance, and local naming as one carrier-equivalence packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}$ packet is generated from a finite cellular orbit-window row, a BHist encoding row, a decoder row, a roundtrip row, a classifier transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3998.1, Definition 3998.2, and Definition 3998.3 seed the finite carrier-equivalence route between cellular orbit-window observations and BHist observations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CellularCarrierBHistEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close carrier replacement, infinite cellular orbit semantics, global physical substrate claims, hidden evaluator state, host bisimulation, non-finite classifier equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked orbit-window finiteness, encoding and decoding visibility, roundtrip comparison, classifier transport, transport, replay, provenance, and local naming for BEDC.Derived.CellularCarrierBHistEquivalenceUp.

Chapter 3022

A Concrete Naming Certificate for $\mathsf{RegularSequenceBishop}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularSequenceBishop}^{\uparrow}$ packet records the regular-sequence presentation of a constructive real as finite NameCert data. It reads finite observations through chapter 126, measures tolerances through chapter 291, passes rational readback through chapter 301, remains compatible with the Cauchy surface of chapter 3413, and reaches the terminal seal of chapter 38. The packet is induction-facing: it exposes bounded finite windows and dyadic tolerance ledgers before any $\mathsf{Real}^{\uparrow}$ seal is consumed, and it does not quotient streams, select a host limit, invoke countable choice, or assume ambient Real completeness.

Definition 3022.1 (Bishop regular-sequence carrier)**.** *A* $\mathsf{RegularSequenceBishop}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (W, D, Q, R, N)$$

with the following five displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming the bounded stream segment inspected at a requested precision.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the positive dyadic scale, comparison cells, and slack ledger used to compare the window.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, turning the inspected window and tolerance ledger into regular rational sequence evidence.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after W, D, Q have been displayed.*
5. *N is the local structural row, bundling componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceBishop}^{\uparrow}}$ *naming row for the same packet.*

The classifier compares accepted packets only through W, D, Q, R, N. It has no coordinate for quotient stream equality, host real equality, a selected limit, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularSequenceBishopUp.RegularSequenceBishopTasteGate single carrier alignment`

Theorem 3022.2 (Bishop regular-sequence NameCert obligations)**.** *For every accepted* $\mathsf{RegularSequenceBishop}^{\uparrow}$ *carrier $B = (W, D, Q, R, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceBishop}^{\uparrow}}$ *surface consists exactly of five*

obligation rows: finite $\mathsf{StreamName}^{\uparrow}$ *window exposure through* W*; dyadic tolerance and comparison exposure through* D*;* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback through* Q*; downstream* $\mathsf{Real}^{\uparrow}$ *seal handoff through* R*; and local transport, replay, provenance, and naming through* N*. Every Real and Completion consumer must read*

$$W, D \longmapsto Q \longmapsto R \longmapsto N$$

before treating the packet as a Bishop-style regular sequence.

Proof. Project the accepted carrier of Definition 3999.1. The visible coordinates are exactly W, D, Q, R, N, and the classifier contains no further row.

The window and tolerance part is read first. The row W supplies only a finite $\mathsf{StreamName}^{\uparrow}$ observation, while D supplies the dyadic precision and comparison ledger attached to that observation.

The regular rational handoff is then forced through Q. Since Q is the only row that converts the window and tolerance data into $\mathsf{RegSeqRat}^{\uparrow}$ evidence, no host stream quotient or selected limit can enter the local surface.

Finally R and N deliver the Real-facing boundary and the structural NameCert support for the same displayed route. The absence of coordinates for quotient equality, host real equality, countable choice, trichotomy, or ambient completeness gives the stated exhaustiveness. □

Theorem 3022.3 (Bishop regular-sequence induction window)**.** *Let* $B = (W, D, Q, R, N)$ *be an accepted* $\mathsf{RegularSequenceBishop}^{\uparrow}$ *carrier. Any induction over the regular-sequence presentation may inspect only finite* $\mathsf{StreamName}^{\uparrow}$ *windows from* W*, compare them through the dyadic ledger* D*, and pass the resulting rational data through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *before the* $\mathsf{Real}^{\uparrow}$ *seal row* R *is consumed. The induction route is therefore*

$$W, D \longmapsto Q \longmapsto R \longmapsto N.$$

It does not decide quotient equality of streams, choose a host limit, use countable choice, or appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier projection in Definition 3999.1. An induction step can open the finite window row W and the tolerance row D, because those are the only displayed sources available before any rational readback.

The step then passes through Q. This row is the sole $\mathsf{RegSeqRat}^{\uparrow}$ readback coordinate, so every induction witness remains tied to finite windows and dyadic tolerances rather than to quotient representatives or chosen limits.

Only after that readback may the route consume R, and N preserves the same route by transport, replay, provenance, and local naming. Thus the induction window is finite and Bishop-style, with the excluded nonconstructive and completeness coordinates absent from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{RegularSequenceBishop}^{\uparrow}$ read used by a Real and Completion consumer displays one finite $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one downstream $\mathsf{Real}^{\uparrow}$ seal row, and one local structural NameCert row before it is treated as a regular-sequence presentation.

Independence witness: streamname, dyadicratcore, regseqrat, cauchy, real: $\mathsf{RegularSequenceBishop}^{\uparrow}$ is not bijective to any listed sibling because it binds finite stream windows, dyadic tolerance comparisons, regular rational readback, a Real-facing seal, and local NameCert structure into one induction-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceBishop}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceBishop}^{\uparrow}$ packet is generated from a StreamName finite-window row, a DyadicRatCore tolerance row, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceBishop}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3999.1, Definition 3999.2, and Definition 3999.3 seed the Bishop-style regular-sequence route over StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceBishop}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, host real equality, selected limits, countable choice, trichotomy, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exposure, RegSeqRat readback, Real seal ordering, transport, replay, provenance, local naming, and induction-window nonescape for BEDC.Derived.RegularSequenceBishopUp.

Chapter 3023

A Concrete Naming Certificate for $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$ packet records a uniform Cauchy modulus for a family of real-valued approximants as finite NameCert data. It sits after the finite source windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the criterion surface of chapter 3876, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer boundary. The packet gives Real and Completion routes a finite uniform-Cauchy bridge; it does not assert host function equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3023.1 (Modulus of uniform convergence carrier)**.** *A* $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, F, U, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row, naming the finite domain observations inspected for each requested uniform tolerance.*
2. *F is the function-family row, recording the displayed approximant indices and the finite value reads used in the comparison.*
3. *U is the uniform tolerance and modulus row, exposing the requested precision and the threshold delivered to the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer surface.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic comparison cells, positivity witnesses, and slack data used by the uniform estimate.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows, family reads, tolerance ledger, and modulus threshold.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, F, U, D, R have been displayed.*
7. *H records componentwise* hsame *transport for source windows, family reads, tolerance data, readback, seal, continuation, provenance, and naming.*
8. *C records displayed* Cont *replay from a uniform-Cauchy request through $S, F, U, D, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusOfUniformConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, U, D, R, E, H, C, P, N$. It has no coordinate for host equality of functions, a countable-choice schedule, a selected limiting function, quotient equality of real names, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.ModulusOfUniformConvergenceUp.ModulusOfUniformConvergenceUp`

Theorem 3023.2 (Modulus of uniform convergence NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$ *carrier*

$$M = (S, F, U, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ModulusOfUniformConvergence}^{\uparrow}}$ *surface consists exactly of source-window exposure through S, function-family read exposure through F, uniform tolerance and modulus exposure through U, dyadic tolerance-ledger exposure through D, regular rational readback through R, real seal handoff through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. Every Real or Completion consumer must read*

$$S, F, U, D \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before treating the packet as a uniform convergence modulus.

Proof. Project the carrier of Definition 4000.1. The visible coordinates are exactly $S, F, U, D, R, E, H, C, P, N$, and the classifier contains no further analytic row.

The source and family data are read first. The row S supplies finite $\mathsf{StreamName}^{\uparrow}$ windows, while F supplies the displayed approximant reads attached to those windows.

The uniform estimate is then forced through U and D. The row U names the common threshold and tolerance request, and D supplies the dyadic ledger that makes the comparison finite.

Finally R, E, H, C, P, N deliver regular rational readback, the real-facing seal, transport, replay, provenance, and local naming for the same displayed route. Since host function equality, countable choice, selected limits, quotient real-name equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, the listed obligations exhaust the certificate surface. □

Theorem 3023.3 (Modulus of uniform convergence Cauchy-uniform route)**.** *Every accepted* ModulusOfUniformCon *packet consumed by* $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ F,\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes the same rows $S, F, U, D, R, E, H, C, P, N$ and refuses host function equality, countable choice, selected limits, quotient equality of real names, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the accepted carrier. A criterion or modulus consumer first receives the source-window row S and the family-read row F, so the request is grounded in finite observations rather than in a host function object.

Next read the uniform modulus row U together with the dyadic ledger D. These rows give a single threshold and tolerance comparison surface for all displayed windows, which is precisely the finite boundary expected by $\mathsf{UniformConvergenceCauchyCriterion}^{\uparrow}$ and $\mathsf{UniformModulus}^{\uparrow}$.

The only downstream analytic readback is R followed by E. Thus $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers receive data only after the uniform-Cauchy route has been displayed.

The transport, replay, provenance, and naming rows H, C, P, N preserve the same route. No excluded host equality, choice schedule, selected limit, quotient equality, or completeness coordinate can be inserted by a consumer of the accepted packet. □

Falsifiable prediction: Every accepted $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$ read used by a Real or Completion consumer displays one $\mathsf{StreamName}^{\uparrow}$ source-window row, one function-family read row, one $\mathsf{UniformModulus}^{\uparrow}$ tolerance-threshold row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal row, and the structural rows H, C, P, N before it is treated as a uniform convergence modulus.

Independence witness: streamname, dyadicratcore, regseqrat, real, uniformmodulus, uniform-convergence-cauchy-criterion: $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$ is not bijective to any listed sibling because only it binds finite source windows, displayed family reads, one uniform threshold, a dyadic tolerance ledger, regular rational readback, a real seal, and local NameCert support into one uniform-Cauchy bridge.

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfUniformConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusOfUniformConvergence}^{\uparrow}$ packet is generated from StreamName source windows, function-family read rows, a UniformModulus tolerance-threshold row, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusOfUniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4000.1, Definition 4000.2, and Definition 4000.3 seed the finite uniform-Cauchy bridge over StreamName, DyadicRatCore, RegSeqRat, Real, UniformConvergenceCauchyCriterion, and UniformModulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusOfUniformConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, countable choice, selected limits, quotient equality of real names, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-window exposure, function-family read exposure, uniform threshold exposure, dyadic tolerance-ledger exposure, readback, real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.ModulusOfUniformConvergenceUp.

Chapter 3024

A Concrete Naming Certificate for $\mathsf{DyadicBisectionSchedule}^{\uparrow}$

Following Bishop and Bridges constructive nested-interval and bisection arguments, the $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ packet records the finite halving schedule used before a retained interval route is read as Cauchy data. It sits beside the dyadic tolerance core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the located interval-zero route of chapter 3971, and the retained closed-interval branch surface of chapter 3815. The packet names a finite schedule object only; it does not select an infinite branch, assert an interval intersection point, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3024.1 (Dyadic bisection schedule carrier)**.** *A* $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, B, D, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed interval source row. It exposes endpoint order, containment, and the finite retained-window requests consumed from the* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *route.*
2. *B is the branch schedule row. It records the inspected finite sequence of left-or-right bisection decisions, midpoint exposure, retained-child containment, and width-halving ledger.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row. It records the positive dyadic mesh, endpoint comparison cells, midpoint arithmetic cells, and halving bounds used by B.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for endpoint, midpoint, retained-child, and schedule-prefix observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after I, B, D, W have been displayed.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, opened only after the finite schedule and regular readback rows are exposed.*
7. *H records componentwise* hsame *transport for the interval source, branch schedule, dyadic scale, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located interval or Cauchy request through $I, B, D, W, R, Q, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicBisectionSchedule}^{\uparrow}$, $\mathsf{ClosedIntervalBisection}^{\uparrow}$, $\mathsf{LocatedIntervalBolzano}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicBisectionSchedule}^{\uparrow}}$ *row.*
The classifier compares accepted schedule carriers only through $I, B, D, W, R, Q, H, C, P, N$. It has no coordinate for an infinite choice sequence, a completed nested intersection, quotient real equality, host trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicBisectionScheduleUp.DyadicBisectionScheduleTasteGate single carrier alignment`

Theorem 3024.2 (Dyadic bisection schedule NameCert obligations)**.** *For every accepted* $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ *carrier $S = (I, B, D, W, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicBisectionSchedule}^{\uparrow}}$ *surface consists exactly of carrier admission, closed-interval source exposure, finite branch-schedule exposure, dyadic halving exactness, stream-window exposure, regular rational readback, terminal real sealing, componentwise transport, displayed replay, package provenance, and local naming for the carrier of Definition 4001.1.*

Proof. Carrier admission is projection from Definition 4001.1. The interval row I and branch row B are the only rows that expose closed-interval bisection data, so every schedule obligation starts with the displayed finite interval source and retained-child ledger.

The dyadic and stream obligations are consecutive. The row D supplies midpoint arithmetic, positive mesh data, and halving bounds before W can open endpoint, midpoint, retained-child, or prefix observations.

The readback rows R, Q are therefore downstream of I, B, D, W. The structural rows H, C, P, N transport, replay, source, and name the same finite route.

Since the carrier contains no coordinate for infinite branch choice, completed intersection points, quotient real equality, trichotomy, open-cover compactness, or ambient completeness, the listed obligations exhaust the local certificate. □

Theorem 3024.3 (Dyadic bisection schedule Cauchy handoff)**.** *Every Cauchy- or Bolzano-facing consumer of an accepted* $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ *carrier reaches regular rational data only through the displayed route*

$$\mathsf{ClosedIntervalBisection}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may be consumed by located interval and completion routes as a finite halving schedule, but it exports no selected infinite branch, completed intersection point, quotient real representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier $S = (I, B, D, W, R, Q, H, C, P, N)$. The source row I and the retained branch schedule B expose the only finite bisection information available to the consumer.

Read the dyadic row D next. It fixes the midpoint and width-halving budget through displayed dyadic cells, so the schedule cannot be interpreted as an external sequence of arbitrary cuts.

The stream and regular rows W, R then turn the displayed finite windows into regular rational readback. The terminal row Q is a Real-facing seal only after this finite route has been read.

Finally H, C, P, N preserve the same order under transport, replay, provenance, and local naming. Because no stronger object appears among the carrier coordinates, every Cauchy handoff remains the displayed finite schedule route. □

Falsifiable prediction: A Cauchy or Bolzano consumer that omits the branch schedule row, dyadic halving row, StreamName window row, or RegSeqRat readback row cannot claim a $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ handoff to a Real-facing seal.

Independence witness: closed-interval-bisection, located-interval-bolzano, dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an interval source, finite branch schedule, dyadic halving ledger, stream windows, regular readback, a terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBisectionSchedule}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicBisectionSchedule}^{\uparrow}$ packet is generated from a closed-interval source row, a finite retained-branch schedule row, a DyadicRatCore halving ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBisectionSchedule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4001.1, Definition 4001.2, and Definition 4001.3 seed the finite dyadic interval-halving route over ClosedIntervalBisectionUp, LocatedIntervalBolzanoUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBisectionSchedule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite branches, completed interval intersections, quotient real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exposure, finite branch-schedule exposure, dyadic halving exactness, StreamName window exactness, RegSeqRat readback, Real-seal nonescape, componentwise transport, displayed replay, package provenance, and local NameCert field faithfulness for BEDC.Derived.DyadicBisectionScheduleUp.

Chapter 3025

A Concrete Naming Certificate for $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ packet records a finite enclosure-filter route for regular Cauchy names. It sits over the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy-filter basis surface of chapter 333. The packet gives Real and Completion consumers a displayed enclosure-filter certificate without quotienting streams, selecting a host limit, assuming ambient completeness, or identifying Cauchy filters by external equality.

Definition 3025.1 (Regular Cauchy enclosure-filter carrier)**.** *A* $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, D, Q, F, B, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected rational-name segment and the requested precision window.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *enclosure ledger, recording the positive dyadic radius, interval endpoints, midpoint comparison, and slack data used by the window.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained only after W and D have been displayed.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row, listing the finite filter requests and refinements whose accepted members contain the same dyadic enclosures.*
5. *B is the enclosure-basis compatibility row, matching each displayed regular Cauchy window with a filter-basis request at the same dyadic radius.*
6. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, D, Q, F, B have been consumed.*
7. *H records componentwise* hsame *transport for the window, dyadic enclosure, regular readback, Cauchy-filter basis, compatibility, and Real-seal rows.*
8. *C records displayed* Cont *replay from a finite window and radius request through regular readback and filter-basis compatibility to the Real-facing seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $W, D, Q, F, B, R, H, C, P, N$. It has no coordinate for quotient stream equality, quotient filter equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEnclosureFilterUp.RegularCauchyEnclosureFilterTasteGate`
`single carrier alignment`

Theorem 3025.2 (Regular Cauchy enclosure-filter NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ *carrier $E = (W, D, Q, F, B, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEnclosureFilter}}$ *surface consists exactly of finite window exposure, dyadic enclosure admission, regular rational readback, Cauchy-filter basis admission, enclosure-basis compatibility, Real-seal ordering, componentwise transport, continuation replay, provenance, and local naming. Every consumer must read the finite route*

$$W, D \longmapsto Q \longmapsto F, B \longmapsto R$$

together with H, C, P, N before treating the packet as an enclosure-filter certificate for a regular Cauchy name.

Proof. Project the carrier of Definition 4003.1. The rows $W, D, Q, F, B, R, H, C, P, N$ are the only displayed coordinates available to the local classifier.

The regular Cauchy side is read first. The window row W supplies a finite observation, the dyadic row D supplies the enclosing radius and endpoint ledger, and the readback row Q is downstream of those two rows.

The filter side is then forced through F and B. The basis row F exposes only finite Cauchy-filter requests, while B records the compatibility between those requests and the same dyadic enclosures already used by Q.

Finally R is reached through the displayed route, and H, C, P, N preserve the route by transport, replay, provenance, and local naming. Since the excluded host and quotient objects are absent from the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 3025.3 (Regular Cauchy enclosure-filter real seal route)**.** *An accepted* $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ *carrier may expose its* $\mathsf{Real}^{\uparrow}$ *seal row R only after the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *enclosure ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row F, and the compatibility row B have been displayed through H and C. Thus a Real or Completion consumer receives a finite enclosure-filter route for the regular Cauchy name, not a quotient stream, a selected limit, quotient filter equality, or ambient completeness.*

Proof. Start with the carrier projection. The Real-seal row R is a coordinate of E, but it is downstream of W, D, Q, F, B in the displayed route.

The rows W, D, Q bind the regular Cauchy readback to finite windows and dyadic enclosures. The rows F, B then bind the same enclosure data to finite Cauchy-filter basis requests, so the filter-facing read is not independent of the regular rational readback.

Transport through H and replay through C preserve this ordering, while P and N record provenance and local naming for the same packet. No carrier coordinate can supply quotient equality, a chosen limit, countable choice, host real equality, or ambient completeness; the Real seal therefore exports only the displayed finite enclosure-filter route. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ read used by a Real or Completion consumer displays one finite $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ enclosure

ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{CauchyFilter}^{\uparrow}$ basis row, one compatibility row, one downstream $\mathsf{Real}^{\uparrow}$ seal row, and the structural rows H, C, P, N.

Independence witness: streamname, dyadicratcore, regseqrat, cauchyfilter, real: $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ is not bijective to any listed sibling because it binds regular Cauchy readback and Cauchy-filter basis membership through the same displayed dyadic enclosure ledger before the Real seal is exposed.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}$ packet is generated from a finite StreamName window, a DyadicRatCore enclosure ledger, a RegSeqRat readback row, a CauchyFilter basis row, an enclosure-basis compatibility row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}}$, seed)

Scope closed: Definition 4003.1, Definition 4003.2, and Definition 4003.3 seed the finite enclosure-filter route over StreamName, DyadicRatCore, RegSeqRat, CauchyFilter, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyEnclosureFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, quotient filter equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic enclosure exactness, regular readback ordering, Cauchy-filter basis compatibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyEnclosureFilterUp.

Chapter 3026

A Concrete Naming Certificate for $\mathsf{MorreySpace}^{\uparrow}$

Following Morrey and the Sobolev-space treatment of Adams–Fournier, the $\mathsf{MorreySpace}^{\uparrow}$ packet records the local oscillation and radius-scaled integral budget used by constructive regularity consumers before any classical completion of measure or function spaces is available. It sits next to the weak-gradient packet of chapter 440, reads metric ball windows through chapter 57, measures oscillation and scale through the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and faces the measure and integral rows of chapter 92 and chapter 123. The certificate names only finite BEDC histories: metric windows, local real-valued budgets, radius ledgers, transport, replay, provenance, and local naming.

Definition 3026.1 (MorreySpace carrier)**.** *A* $\mathsf{MorreySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, B, F, I, R, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the distance classifier used by local ball consumers.*
2. *B is the finite metric-ball window ledger, listing the inspected center histories, radius histories, and ball-membership witnesses.*
3. *F is the function-observation row, read through the same* $\mathsf{Real}^{\uparrow}$ *value seal that Sobolev and integral consumers use.*
4. *I is the local* $\mathsf{Integral}^{\uparrow}$ *or* $\mathsf{Measure}^{\uparrow}$*-facing budget row, recording the finite real-valued oscillation or integral magnitude attached to each inspected ball.*
5. *R is the radius-scale ledger, comparing the displayed radius with the exponent and dimension budget through* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *readback rows.*
6. *T is the transport row that keeps the ball window, function observation, integral budget, and radius-scale ledger attached under the carrier classifier.*
7. *H records componentwise* hsame *transport for the metric, ball-window, function, local-budget, scale-ledger, transport, replay, provenance, and local-name rows.*
8. *C records displayed* Cont *replay from a Morrey-space request through metric-ball inspection, local budget readback, radius scaling, and exported consumer access.*
9. *P is the* Pkg *provenance over* $\mathsf{MorreySpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{Integral}^{\uparrow}$*,* $\mathsf{Sobolev}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MorreySpace}^\uparrow}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a completed measure space, almost-everywhere quotient equality, Hahn–Banach separation, selected representatives, or full PDE regularity.

Theorem 3026.2 (MorreySpace NameCert obligations)**.** *For every accepted* $\mathsf{MorreySpace}^\uparrow$ *carrier* $M = (X, B, F, I, R, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MorreySpace}^\uparrow}$ *surface consists exactly of metric-source admission through* X*, metric-ball window exposure through* B*, Real-valued function observation through* F*, local oscillation or integral-budget exposure through* I*, radius-scale ledger comparison through* R*, classifier transport through* T *and* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.MorreySpaceUp.MorreySpaceTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4004.1. The tuple displays the metric source, finite ball windows, Real-valued function observations, local budget row, radius-scale ledger, transport, replay, provenance, and local naming.

The analytic-facing part of the packet is finite. The metric row X and ball-window row B determine which local windows may be inspected, while F and I attach the Real-valued oscillation or integral budget to those same windows.

The scale row R records the radius comparison available to a Morrey consumer. The transport rows T, H and replay row C preserve this same route under classifier comparison and downstream access, and P, N source and name the route.

Since no remaining coordinate stores measure completion, quotient function equality, Hahn–Banach separation, a selected representative, or a PDE regularity theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 3026.3 (MorreySpace Sobolev-neighbour handoff)**.** *Every Sobolev-facing or regularity-facing consumer of an accepted* $\mathsf{MorreySpace}^\uparrow$ *carrier reads the local control route through*

$$\mathsf{Met}^\uparrow,\ \mathsf{Real}^\uparrow,\ \mathsf{Measure}^\uparrow,\ \mathsf{Integral}^\uparrow,\ \mathsf{Sobolev}^\uparrow \longmapsto \mathsf{MorreySpace}^\uparrow.$$

The route first displays metric-ball windows, then Real-valued local oscillation or integral-budget rows, then the radius-scale ledger, and only then exports the Morrey-space naming row. It supplies constructive analysis neighbour data for Sobolev and Real consumers, without asserting classical measure completion, Hahn–Banach separation, selected representatives, or full PDE regularity.

Proof. Use Definition 4004.2. It orders the metric source, ball-window ledger, function observation, local budget, radius-scale comparison, transport, replay, provenance, and local naming inside one accepted carrier.

The $\mathsf{Sobolev}^\uparrow$ neighbour sees only the displayed finite budget. Its weak-gradient or function-space request can consume the same $\mathsf{Real}^\uparrow$ and $\mathsf{Integral}^\uparrow$ rows, but it cannot introduce a completed function quotient or an external measure completion because those rows are absent from the carrier.

The radius-scale ledger then supplies the Morrey-facing distinction: local budgets are read together with ball radii before any exported consumer can use the packet. Thus the handoff is a finite BEDC NameCert route, not a classical regularity theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{MorreySpace}^\uparrow}$**.**

Constructive story: A $\mathsf{MorreySpace}^\uparrow$ packet is generated from MetricSpaceUp ball windows, RealUp-valued local function observations, MeasureUp and IntegralUp budget rows, radius-scale ledgers, classifier transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MorreySpace}^{\uparrow}}$, seed)

Scope closed: Definition 4004.1, Definition 4004.2, and Definition 4004.3 seed the metric-ball, local-budget, and radius-scale carrier consumed by Sobolev-neighbour constructive analysis chapters.

Formal verification: FormalStatus(NameCert$_{\mathsf{MorreySpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close classical measure completion, almost-everywhere quotient equality, Hahn–Banach separation, selected representatives, full PDE regularity, Lean verification, or bridge checking for MorreySpace$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, metric-ball exposure, local RealUp budget exactness, radius-scale ledger stability, Sobolev-neighbour handoff, transport, replay, provenance, and local naming for BEDC.Derived.MorreySpaceUp.

Chapter 3027

A Concrete Naming Certificate for $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$

Following the Heine–Cantor route of chapter 9237, the $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$ packet records the finite radius-choice surface that turns compact finite-net data and pointwise-continuity radii into one tolerance-only uniform-modulus row. It sits between the compact metric finite-net surface of chapter 129, the continuous-map pointwise modulus row of chapter 130, the rational lower-bound fold of chapter 619, and the uniform-modulus consumer of chapter 369. The packet is a finite ProbeBundle choice ledger, not an open-cover compactness theorem or a choice-selected modulus.

Definition 3027.1 (Compact uniform radius-choice carrier)**.** *A* $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, M, Q, F, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, carrying the* ProbeBundle *of centers and coverage witnesses for the requested tolerance scale.*
2. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to those center histories.*
3. *Q is the positive radius-choice row, listing the local radius history selected by the displayed pointwise-modulus and finite-net data for each bundled probe.*
4. *F is the finite lower-bound fold row over* ProbeBundle*, read through the rational order and returning one positive radius history below every displayed local radius.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row, consuming only the tolerance history and the folded radius history.*
6. *H records componentwise* hsame *transport for compact-net, pointwise-modulus, radius-choice, finite-fold, output, replay, provenance, and local-name rows.*
7. *C records displayed* Cont *replay from tolerance input through finite-net inspection, local radius readback, lower-bound folding, and uniform-modulus export.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* ProbeBundle*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusChoice}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for open-cover compactness, a host Lebesgue-number minimum, a choice-selected modulus, sequential compactness, quotient real equality, or an ambient continuity theorem.

Lean4 ✓ `BEDC.Derived.CompactUniformRadiusChoiceUp.CompactUniformRadiusChoiceTasteGate single carrier alignment`

Theorem 3027.2 (Compact uniform radius-choice NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$ *carrier* $R = (K, M, Q, F, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusChoice}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through* K*, pointwise-modulus admission through* M*, local positive-radius exposure through* Q*, finite ProbeBundle lower-bound folding through* F*, tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *output through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4006.1. The rows $K, M, Q, F, U, H, C, P, N$ are the complete displayed inventory.

The compact finite-net and pointwise-modulus rows determine the only local radii that may be inspected. The row Q records those radii as positive BEDC histories attached to bundled probes, not as host choices.

The fold row F then recurses over the displayed $\mathsf{ProbeBundle}$ and returns a positive lower-bound history below every radius named by Q. Since F is a finite rational-order fold, the exported radius is classifier-stable without invoking a global minimum operator.

Finally U, H, C, P, N export, transport, replay, source, and name exactly this radius-choice route. The omitted open-cover, sequential, quotient, and choice-selected objects are absent from the carrier, so the listed rows exhaust the local NameCert obligations. □

Theorem 3027.3 (Tolerance-only uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$ *packet receives one folded radius history as a function of the requested tolerance history and the displayed finite compact-continuity packet:*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{ProbeBundle},\ \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The consumer cannot read an open-cover compactness proof, a choice-selected family of local moduli, a host minimum over radii, quotient real equality, or an external modulus function.

Proof. Use Definition 4006.2. The obligation surface orders compact-net admission, pointwise-modulus admission, local radius exposure, finite lower-bound folding, and uniform-modulus export.

For a fixed tolerance history, the compact row supplies only a finite $\mathsf{ProbeBundle}$ of center histories. The pointwise row supplies the local radii attached to those centers, and the radius-choice row records them as displayed positive histories.

The lower-bound fold produces the single radius consumed by U. Because all preceding rows are tied by H and replayed by C, the exported uniform-modulus read depends only on the displayed tolerance and finite packet, not on any external selector. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusChoice}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$ packet is generated from CompactMetricUp finite-net rows, ContinuousMapUp pointwise-modulus rows, local positive radius-choice rows, a finite ProbeBundle rational lower-bound fold, a UniformModulusUp output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformRadiusChoice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4006.1, Definition 4006.2, and Definition 4006.3 seed the finite radius-choice ledger consumed by compact-uniform-continuity and uniform-modulus chapters.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactUniformRadiusChoice}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected moduli, host Lebesgue-number minima, sequential compactness, quotient real equality, Lean verification, or bridge checking for CompactUniformRadiusChoice$^{\uparrow}$.

Upgrade path: Obligation closure requires checked compact-net admission, pointwise-modulus admission, local radius-choice exactness, finite lower-bound fold stability, UniformModulusUp output exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformRadiusChoiceUp.

Chapter 3028

A Concrete Naming Certificate for $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley-style compact-uniform language, the $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$ packet records the finite tail-index surface by which an eventually stable family of continuous maps receives a shared compact-source modulus. It sits after the compact radius-choice packet of chapter 4006, the uniform family-modulus route of chapter 3844, the equicontinuity family ledger of chapter 413, the compact source of chapter 129, and the graph rows of chapter 130. Its terminal reads pass through finite $\mathsf{StreamName}^{\uparrow}$ windows and the $\mathsf{Real}^{\uparrow}$ seal rather than through a host function-space topology, a selected subsequence, or an ambient completeness theorem.

Definition 3028.1 (Asymptotic equicontinuity carrier)**.** *An* $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, F, E, U, T, S, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact finite-net carrier and the metric-distance ledger used by all later rows.*
2. *F is the finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows whose graph and pointwise-modulus data are inspected at displayed compact-source centers.*
3. *E is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row, binding the family rows to a shared local tolerance-radius ledger before any tail condition is read.*
4. *U is the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *row, exporting the compact finite-net fold that yields a single tolerance-indexed source radius for the displayed family window.*
5. *T is the asymptotic tail row. It records the finite index threshold after which the family window must use the same compact-source radius and target tolerance route.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened after T, used to inspect only the tail-admitted source and target observations.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the tail-admitted distance and tolerance reads after K, F, E, U, T, S have been replayed.*
8. *H records componentwise* hsame *transport for compact source, continuous-family, equicontinuity, uniform-modulus, tail, stream-window, real-seal, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from a tail-index request through the compact finite-net and uniform-equicontinuity rows to the real-seal boundary.*

10. *P is the* Pkg *provenance over* $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$, $\mathsf{CompactUniformRadiusChoice}^{\uparrow}$, UniformEquicontinuityM EquicontinuityFamily$^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticEquicontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host function-space compactness, a selected subsequence, quotient equality of maps, countable choice over tails, an external modulus function, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AsymptoticEquicontinuityUp.AsymptoticEquicontinuityTasteGate single carrier alignment`

Theorem 3028.2 (Asymptotic equicontinuity NameCert obligations)**.** *For every accepted* AsymptoticEquicontinuity *carrier $A = (K, F, E, U, T, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AsymptoticEquicontinuity}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, continuous-family admission through F, family equicontinuity admission through E, shared uniform-modulus export through U, asymptotic tail admission through T, finite stream-window inspection through S, terminal real-seal routing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 4007.1. The rows K, F, E, U, T, S, R are the complete analytic inventory, and H, C, P, N are the structural rows that transport, replay, source, and name that inventory.

The compact and family rows are read before the tail row. The compact source K supplies only finite-net and metric-distance data, while F and E expose the continuous-family and shared equicontinuity ledger. The row U then records the uniform family modulus already folded through compact finite-net data.

The asymptotic step is exactly the row T. Once T has displayed the finite threshold, the stream row S may inspect only tail-admitted windows, and the real seal R may be reached only through those windows.

Finally the carrier has no coordinate for a selected subsequence, host function-space topology, quotient map equality, external modulus function, countable tail choice, or ambient Real completeness. The listed rows therefore exhaust the local NameCert obligations. □

Theorem 3028.3 (Asymptotic equicontinuity modulus handoff)**.** *Every compact-window or Real-facing consumer of an accepted* $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$ *carrier receives its tail-stable modulus through the displayed route*

$\mathsf{CompactUniformRadiusChoice}^{\uparrow}$, $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, Continuou

The handoff supplies one finite tail threshold and one compact-source modulus route, not a selected subsequence, host function-space compactness proof, quotient equality of functions, countable-choice tail, or ambient Real-completeness witness.

Proof. Start with the compact-source and family evidence. The rows K, F, E display the compact metric source, the continuous-map family window, and the equicontinuity-family ledger. The compact radius-choice and uniform-equicontinuity rows are then read through U, so the source radius is already a finite compact-net handoff.

Next expose the tail row T. It records the threshold after which the same compact-source modulus route must serve the accepted family window. The stream row S opens only the finite windows admitted by this threshold, and R seals the resulting distance and tolerance reads as $\mathsf{Real}^{\uparrow}$ data.

The structural rows do not add analytic content. They preserve the displayed route componentwise, replay it as a continuation, record its provenance, and name it locally. Hence every consumer receives the same finite modulus handoff, with no hidden selector or external compactness principle. □

Falsifiable prediction: An accepted $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$ read is refuted if it reaches a Real-facing tail claim without first exposing the compact source, continuous-family ledger, equicontinuity family row, uniform-equicontinuity modulus row, asymptotic tail threshold, StreamName windows, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: compact-uniform-radius-choice, uniform-equicontinuity-modulus, equicontinuityfamily, compactmetric, continuousmap, streamname, real: none alone is bijective with $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$ because the packet binds compact finite-net modulus data to an eventual tail threshold before any Real-facing consumer can read the route.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticEquicontinuity}^{\uparrow}}$.

Constructive story: An $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$ packet is generated from CompactUniformRadiusChoice, UniformEquicontinuityModulus, EquicontinuityFamily, CompactMetric, ContinuousMap, StreamName, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AsymptoticEquicontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4007.1, Definition 4007.2, and Definition 4007.3 seed the finite compact-source tail-modulus route for asymptotic equicontinuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AsymptoticEquicontinuity}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.AsymptoticEquicontinuityUp.AsymptoticEquicontinuityTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Origin: human

Not claimed: This chapter does not close Arzela–Ascoli compactness, host function-space topology, selected subsequences, quotient equality of maps, countable tail choice, Lean verification, or bridge checking for $\mathsf{AsymptoticEquicontinuity}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, compact-source admission, family equicontinuity admission, uniform-modulus handoff, tail-threshold exactness, StreamName window restriction, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.AsymptoticEquicontinuityUp.

Chapter 3029

A Concrete Naming Certificate for $\mathsf{ProkhorovTightProbability}^{\uparrow}$

Following Prokhorov's tightness theorem for probability measures, the $\mathsf{ProkhorovTightProbability}^{\uparrow}$ packet records only the constructive finite tightness data needed before weak-convergence consumers can inspect a probability family. It starts from the probability source of chapter 184, the pushforward distribution row of chapter 186, the event-surface measure row of chapter 92, the compact-test packet of chapter 129, the finite-net witness of chapter 1767, and the located outside-mass ledger of chapter 3795. The chapter also reads the underlying real boundary of chapter 38. It is a finite tightness certificate, not a proof of weak compactness, selected subsequences, countable choice, or ambient real completeness.

Definition 3029.1 (Prokhorov tight probability carrier)**.** *A* $\mathsf{ProkhorovTightProbability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (P, D, M, K, N, E, R, T, H, C, Q, L)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the probability mass surface.*
2. *D is the* $\mathsf{Distribution}^{\uparrow}$ *pushforward row whose target-side event reads are being tested for tightness.*
3. *M is the* $\mathsf{Measure}^{\uparrow}$ *event-surface row through which the outside event and its mass are read.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-test row naming the compact metric test surface used by the packet.*
5. *N is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row displayed inside the compact test for the requested tolerance.*
6. *E is the outside-mass error-bound row read through* $\mathsf{RealTightness}^{\uparrow}$ *and the underlying* $\mathsf{Real}^{\uparrow}$ *comparison surface.*
7. *R is the finite radius or tolerance ledger that aligns the compact test, finite net, and outside-mass request.*
8. *T records transport from the probability source through distribution, measure, compact-test, finite-net, and real-tightness rows.*
9. *H records componentwise* hsame *transport for every displayed row.*

10. *C records displayed* Cont *replay of source admission, pushforward readback, event-surface inspection, compact-test exposure, finite-net inspection, outside-mass comparison, and radius-ledger readback.*
11. *Q is the* Pkg *provenance over* $\mathsf{ProkhorovTightProbability}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{RealTightness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{ProkhorovTightProbability}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, weak compactness, selected subsequences, countable choice, host measures, quotient events, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.ProkhorovTightProbabilityUp.ProkhorovTightProbabilityUp`

Theorem 3029.2 (Prokhorov tight probability NameCert obligations)**.** *For every accepted* ProkhorovTightProbabili *carrier $Z = (P, D, M, K, N, E, R, T, H, C, Q, L)$, the local* $\mathsf{NameCert}_{\mathsf{ProkhorovTightProbability}^{\uparrow}}$ *surface consists exactly of five obligation groups:*

1. *carrier admission for the probability source, pushforward distribution, event-surface measure, compact test, finite net, outside-mass bound, radius ledger, transport, replay, provenance, and local naming rows;*
2. *compact-test exposure, requiring every tightness read to display the* $\mathsf{CompactMetric}^{\uparrow}$ *row K and the internal* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row N before the outside event is consumed;*
3. *outside-mass bound exactness, requiring the error row E to be read through* $\mathsf{RealTightness}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rather than through a host real inequality;*
4. *distribution/measure compatibility, requiring the pushforward row D and event-surface row M to name the same measured outside event under the displayed transport T;*
5. *non-escape from open-cover compactness, weak compactness, selected subsequences, countable choice, host measures, quotient events, and ambient real completeness.*

No additional NameCert obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 4008.1. The tuple lists exactly the probability source, distribution pushforward, event-surface measure, compact-test, finite-net, outside-mass, radius-ledger, transport, replay, provenance, and local naming rows.

The compact side is finite. A tightness read must expose K and the internal finite-net row N before it can identify the outside event measured by M.

The outside-mass side is real-name data. The error row E is read through the located tightness and real comparison surfaces, while D, M, T keep the distribution and measure event rows compatible.

Since no carrier coordinate stores open-cover compactness, weak compactness, selected subsequences, countable choice, host measures, quotient events, or ambient real completeness, the five displayed groups exhaust the local NameCert obligations. □

Theorem 3029.3 (Prokhorov tight probability finite-net handoff)**.** *Every accepted tightness read from a* $\mathsf{ProkhorovTightProbability}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{ProbSpace}^{\uparrow} \longmapsto \mathsf{Distribution}^{\uparrow} \longmapsto \mathsf{Measure}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto \mathsf{RealTightness}^{\uparrow} \longmapsto \mathsf{Real}$$

before any weak-convergence consumer can inspect it. The exported read is the displayed probability, distribution, measure, compact-test, finite-net, outside-mass, radius-ledger, transport, replay, provenance, and local naming route; it exposes no weak compactness theorem, selected subsequence, countable-choice selector, host measure, quotient event, or ambient completeness row.

Proof. Start with the NameCert obligations of Definition 4008.2. Carrier admission places the probability source and pushforward distribution before the measured outside event.

Next read the compact finite test. The measure row is inspected only after the compact metric row and its finite-net witness are displayed for the requested tolerance ledger.

Finally the outside-mass bound is consumed through $\mathsf{RealTightness}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The structural rows transport and replay this same finite route, so a weak-convergence consumer receives only the displayed handoff and cannot insert an unlisted compactness, sequence-selection, quotient, host-measure, or completeness coordinate. □

Theorem 3029.4 (Prokhorov tight probability Portmanteau readiness)**.** *Every Portmanteau-facing weak-convergence test read from an accepted* $\mathsf{ProkhorovTightProbability}^{\uparrow}$ *carrier receives only the displayed probability source, pushforward distribution, measure event surface, compact metric finite-net test,* $\mathsf{RealTightness}^{\uparrow}$ *outside-mass row,* $\mathsf{Real}^{\uparrow}$ *comparison, transport, replay, provenance, and local* NameCert *rows before bounded-continuous probes may inspect it. The readiness route exports no weak compactness, selected subsequence, countable choice, host measure, quotient event, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 4008.2. The local NameCert obligations expose exactly the probability source, distribution pushforward, measure event surface, compact-test, finite-net, outside-mass, radius-ledger, transport, replay, provenance, and local naming rows.

Next apply the finite-net handoff of Definition 4008.3. It orders the compact metric finite-net test before the outside-mass row and routes the comparison through $\mathsf{RealTightness}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ before any weak-convergence consumer can inspect the packet.

Finally pass the resulting finite surface to the Portmanteau consumer of chapter 4193. Because the carrier contains no coordinate for weak compactness, selected subsequences, countable choice, host measures, quotient events, or ambient real completeness, bounded-continuous probes receive only the displayed readiness route. □

Falsifiable prediction: Every accepted $\mathsf{ProkhorovTightProbability}^{\uparrow}$ tightness read factors through $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{RealTightness}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any weak-convergence consumer can inspect it.

Independence witness: probspace, distribution, measure, compactmetric, finite-epsilon-net, real-tightness, real: the packet is not bijective to any listed sibling because it binds the probability source, pushforward event surface, compact finite-net test, outside-mass error row, radius ledger, transport, replay, provenance, and local NameCert row as one tight probability surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ProkhorovTightProbability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProkhorovTightProbability}^{\uparrow}$ packet is generated from ProbSpaceUp source rows, DistributionUp pushforward rows, MeasureUp event-surface rows, CompactMetricUp compact-test rows, FiniteEpsilonNetUp finite-net rows, RealTightnessUp outside-mass rows over RealUp, a finite tolerance ledger, transport, hsame, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProkhorovTightProbability}^{\uparrow}}$, seed)

Scope closed: Definition 4008.1, Definition 4008.2, and Definition 4008.3 seed the finite tight-probability handoff for probability compactness consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProkhorovTightProbability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, weak compactness, selected subsequences, countable choice, host measures, quotient events, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-test exposure, outside-mass exactness, distribution/measure compatibility, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.ProkhorovTightProbabilityU

Chapter 3030

A Concrete Naming Certificate for $\mathsf{CauchyTailEstimate}^{\uparrow}$

Following Bishop and Bridges' constructive analysis of Cauchy sequences and finite tail bounds, the $\mathsf{CauchyTailEstimate}^{\uparrow}$ packet records the displayed route by which a requested tail index and dyadic radius become a bounded regular-rational read before any $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits after the tail-filter surface of chapter 3850 and the fast criterion of chapter 3825, and it reads its tolerance, regular readback, and endpoint seal through chapter 291, chapter 301, and chapter 38. The packet is a finite certificate for Real and Completion consumers; it is not a quotient sequence, a selected limit, countable choice, host real equality, trichotomy, or ambient real completeness.

Definition 3030.1 (Cauchy tail estimate carrier)**.** *A* $\mathsf{CauchyTailEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, D, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *T is the tail-index row, naming the finite threshold after which the estimate may be inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, naming the dyadic tolerance used by the tail-bound comparison.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the displayed tail window and radius data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after T, D, R have been replayed.*
5. *B is the tail-bound ledger, recording the finite comparison witnesses that keep every accepted read beyond T inside the radius named by D.*
6. *H records componentwise* hsame *transport for T, D, R, E, B and for the continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tail request through T, D, B, R, and then E.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$, $\mathsf{FastCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting the displayed tail threshold, dyadic radius, regular readback, real seal, tail-bound ledger, continuation, provenance, and local naming

rows to a common finite surface. It has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, trichotomy, open-cover compactness, or ambient completeness.

Theorem 3030.2 (Cauchy tail estimate NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailEstimate}^{\uparrow}$ *carrier* $Q = (T, D, R, E, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailEstimate}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed tail index, dyadic radius, regular readback, real seal, tail-bound ledger, transport, continuation, provenance, and local name;*
2. *classifier transport to a common* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$, $\mathsf{FastCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *finite surface;*
3. *stability of* T, D, R, E, B *under the componentwise* hsame *rows recorded in* H*;*
4. *handoff exactness requiring every real-facing read to pass through* T, D, B, R, E *in that order;*
5. *refusal rows excluding quotient streams, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, and ambient completeness.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.CauchyTailEstimateUp.CauchyTailEstimateUpTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4009.1. The projection exposes exactly the tail-index row, dyadic radius row, regular readback row, real seal row, tail-bound ledger, transport row, continuation row, provenance row, and local naming row.

Classifier transport is componentwise. The rows in H move the mathematical coordinates T, D, R, E, B and the administrative coordinates C, P, N to the same finite comparison surface.

Handoff exactness is read from the displayed continuation row. A tail request first reaches the threshold row T, then the dyadic radius row D, then the ledger row B that witnesses the tail-bound comparison, then the regular readback R, and only then the real seal E.

The refusal rows are exhausted by the carrier inventory. Since the packet has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, or completeness, no local NameCert obligation can export those data. □

Theorem 3030.3 (Cauchy tail estimate RegSeqRat handoff)**.** *For every accepted* $\mathsf{CauchyTailEstimate}^{\uparrow}$ *carrier* $Q = (T, D, R, E, B, H, C, P, N)$*, every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of* R *factors through the tail-index row* T*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row* D*, and the tail-bound ledger* B *before it can expose the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The handoff route is therefore finite and does not identify Cauchy names by quotient equality, select a limit, invoke countable choice, or appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a regular-rational consumer of R. Carrier admission lists R only as the readback row reached from the displayed tail threshold and dyadic radius.

Replay the continuation row C. Its route sends the request first to T, checks the requested radius through D, reads the comparison witnesses in B, and only then exposes the regular rational row R.

Transport through H preserves this dependency order. The package row P and local name N record provenance and naming for the same finite packet; they do not add a second readback coordinate.

Thus every $\mathsf{RegSeqRat}^{\uparrow}$ handoff factors through T, D, B before R and reaches E only after that route has been displayed. The carrier contains no coordinate from which a bypass route could obtain quotient equality, selected limits, choice, host real equality, or completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailEstimate}^{\uparrow}$ packet is generated from a finite tail-index row, a $\mathsf{DyadicRatCore}^{\uparrow}$ radius row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal row, a tail-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4009.1, Definition 4009.2, and Definition 4009.3 bind the finite tail-bound carrier, local NameCert obligations, and RegSeqRat handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, stability, handoff exactness, refusal rows, and TasteGate nontriviality with field faithfulness for $T, D, R, E, B, H, C, P, N$.

Chapter 3031

A Concrete Naming Certificate for $\mathsf{Circle}^{\uparrow}$

Following Hatcher and Munkres on the circle as a compact one-dimensional boundary object, the $\mathsf{Circle}^{\uparrow}$ packet records the topological boundary reading of a one-dimensional closed loop without identifying it with the algebraic $\mathsf{S}^{1\uparrow}$ group certificate. It sits beside $\mathsf{S}^{1\uparrow}$ of chapter 58, $\mathsf{Real}^{\uparrow}$ of chapter 38, $\mathsf{Met}^{\uparrow}$ of chapter 57, and $\mathsf{Compact}^{\uparrow}$ of chapter 60: those siblings supply phase multiplication, real-coordinate readback, metric inspection, and compact covering rows, while this packet binds the finite boundary carrier and its NameCert obligations as a topological circle surface.

Definition 3031.1 (Circle carrier)**.** *A* $\mathsf{Circle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (B, R, M, K, S, H, P, N)$$

with the following displayed rows:

1. *B is the boundary-loop row, naming the closed one-dimensional boundary surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *coordinate-read row, recording the finite real-coordinate inspection used by local charts or parametrized arcs.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *row, recording the metric neighborhoods through which boundary adjacency is read.*
4. *K is the* $\mathsf{Compact}^{\uparrow}$ *row, recording finite cover data for the closed boundary surface.*
5. *S is the* $\mathsf{S}^{1\uparrow}$ *handoff row, available only when a consumer asks for the phase-group reading of the same boundary.*
6. *H records componentwise* hsame *transport for the boundary, real-coordinate, metric, compactness, handoff, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{Circle}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, BHist, hsame, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient plane, a selected trigonometric parametrization, a quotient by angle equality, or a global orientation choice.

Lean4 ✓ `BEDC.Derived.CircleUp.CircleCarrier boundary route certificate`

Theorem 3031.2 (Circle NameCert obligations)**.** *For every accepted* $\mathsf{Circle}^{\uparrow}$ *carrier*

$$C = (B, R, M, K, S, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ *surface consists exactly of carrier admission for the boundary-loop row, real-coordinate readback, metric-neighborhood row, compact-cover row, optional* $\mathsf{S}^{1\uparrow}$ *handoff, componentwise transport, package provenance, and local naming. Any topological-circle consumer must read the closed boundary surface through* B, R, M, K, H, P, N *before using the algebraic phase handoff* S*.*

Lean4 ✓ `BEDC.Derived.CircleUp.CircleUpTasteGate single carrier alignment`

Proof. Project the displayed carrier of Definition 4010.1. The topological rows are B, R, M, K: they name the closed boundary, the real-coordinate readback, the metric neighborhoods, and the compact cover data.

The handoff row S is downstream. It allows a consumer to compare the boundary packet with the $\mathsf{S}^{1\uparrow}$ phase-group sibling, but it does not replace the boundary carrier by an algebraic group row.

The rows H, P, N transport, source, and name the same finite packet. Since no ambient plane, trigonometric parametrization, quotient-angle equality, or orientation coordinate appears in the carrier, the listed rows exhaust the $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ obligations. □

Theorem 3031.3 (Circle and $\mathsf{S}^{1\uparrow}$ boundary handoff)**.** *Every* $\mathsf{S}^{1\uparrow}$*-facing read of an accepted* $\mathsf{Circle}^{\uparrow}$ *carrier factors through the boundary-loop row* B*, real-coordinate readback* R*, metric row* M*, compact-cover row* K*, and handoff row* S*. The handoff may expose a phase-group consumer, but it cannot make* $\mathsf{S}^{1\uparrow}$ *the carrier of topological compact-boundary data and cannot export quotient-angle equality or a selected global parametrization.*

Lean4 ✓ `BEDC.Derived.CircleUp.CircleSOneBoundaryHandoff`

Proof. Start with a consumer asking for the phase-group reading. The $\mathsf{Circle}^{\uparrow}$ carrier first exposes the boundary surface through B and its local real and metric inspections through R, M.

Compactness is read through K, so the consumer receives a finite cover surface for the closed boundary before any phase handoff is available. Only then can S point to the $\mathsf{S}^{1\uparrow}$ sibling.

The componentwise transport, provenance, and naming rows H, P, N preserve this order. Because the carrier has no quotient-angle coordinate or selected global parametrization, the handoff remains a boundary-to-phase route rather than an identification of the two packets. □

Theorem 3031.4 (Circle metric subspace carrier obligation)**.** *For every accepted* $\mathsf{Circle}^{\uparrow}$ *carrier* $C = (B, R, M, K, S, H, P, N)$*, the boundary row* B*,* $\mathsf{Real}^{\uparrow}$ *coordinate row* R*,* $\mathsf{Met}^{\uparrow}$ *neighborhood row* M*,* $\mathsf{Compact}^{\uparrow}$ *cover row* K*,* $\mathsf{S}^{1\uparrow}$ *handoff row* S*, transport row* H*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ *row* N *are the full carrier obligation surface. A consumer may not replace these rows by an ambient plane, a selected parametrization, quotient-angle equality, or a global orientation choice.*

Lean4 ✓ `BEDC.Derived.CircleUp.CircleMetricSubspaceCarrierObligation`

Proof. Project the carrier of Definition 4010.1. Its analytic boundary surface is exactly B, R, M, K, S, and its structural surface is exactly H, P, N.

No other coordinate is available for a circle consumer. Since the carrier omits an ambient plane, selected trigonometric map, quotient by angle equality, and orientation row, the displayed coordinates exhaust the carrier obligation surface. □

Theorem 3031.5 (Circle $\mathsf{S}^{1\uparrow}$ real seal route)**.** *Every phase-group read of an accepted* $\mathsf{Circle}^{\uparrow}$ *carrier must pass through the* $\mathsf{Real}^{\uparrow}$ *coordinate row* R *and the* $\mathsf{S}^{1\uparrow}$ *handoff row* S*, with the boundary row* B*, metric row* M*, compact row* K*, transport* H*, provenance* P*, and local naming* N *still present. This route permits a phase interpretation but does not identify* $\mathsf{Circle}^{\uparrow}$ *with* $\mathsf{S}^{1\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CircleUp.CircleSOneRealSealRoute`

Proof. Start with a consumer that asks for phase-group data. The carrier first exposes the topological boundary and real-coordinate surface through B and R.

The handoff row S can then point to the $\mathsf{S}^{1\uparrow}$ sibling, while M, K, H, P, N keep the same metric, compact, transport, provenance, and naming rows attached to the circle packet. Because S is a handoff coordinate rather than the carrier itself, the route is not an identification of the two chapters. □

Theorem 3031.6 (Circle compact metric boundary)**.** *Before any consumer reads* $\mathsf{Circle}^{\uparrow}$ *as a closed boundary, the packet must expose the compact-cover row* K*, the metric-neighborhood row* M*, the boundary row* B*, the* $\mathsf{Real}^{\uparrow}$ *coordinate row* R*, transport* H*, provenance* P*, and local naming* N*. The compact-metric boundary does not supply an ambient plane, a selected parametrization, or quotient-angle equality.*

Proof. Read the compact and metric coordinates together. The row K supplies finite cover data for the closed boundary, and M supplies the neighborhood inspection by which boundary adjacency is read.

The rows B, R, H, P, N bind those compact and metric inspections to the circle carrier and its local name. Since no ambient plane or quotient-angle coordinate appears in the packet, a closed-boundary consumer receives only this compact-metric surface. □

Lean4 ✓ `BEDC.Derived.CircleUp.CircleCarrier compact metric boundary`

Theorem 3031.7 (Circle Real metric scope route)**.** *For every accepted* $\mathsf{Circle}^{\uparrow}$ *read of* $C = (B, R, M, K, S, H, P, N)$*, the boundary inspection is scoped by the displayed* BHist *carrier rows, componentwise* hsame *transport,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ *naming, the* $\mathsf{Real}^{\uparrow}$ *coordinate row, the* $\mathsf{Met}^{\uparrow}$ *neighborhood row, the* $\mathsf{Compact}^{\uparrow}$ *finite-cover row, and the optional* $\mathsf{S}^{1\uparrow}$ *handoff row. The route exports no ambient plane, quotient-angle equality, selected parametrization, global orientation, or identification of* $\mathsf{Circle}^{\uparrow}$ *with* $\mathsf{S}^{1\uparrow}$*.*

Proof. Project the carrier of Definition 4010.1. The row list exposes the boundary row B, real-coordinate inspection R, metric inspection M, compact cover K, optional $\mathsf{S}^{1\uparrow}$ handoff S, transport H, provenance P, and local naming N.

Apply Definition 4010.2. Its NameCert surface forces the topological rows B, R, M, K, H, P, N to be read before any phase handoff can be used.

Use Definition 4010.3 and Definition 4010.5. They keep S as a downstream handoff through the same boundary and $\mathsf{Real}^{\uparrow}$ rows, not as an identification with the circle carrier.

Finally apply Definition 4010.6. The compact and metric rows already exhaust the closed-boundary inspection surface together with B, R, H, P, N, so the scoped route is exactly the displayed BEDC row surface and nothing from an ambient plane, quotient angle, selected parametrization, or global orientation remains available. □

Lean4 ✓ `BEDC.Derived.CircleUp.CircleCarrier real metric scope route`

Theorem 3031.8 (Circle Real metric scoped closure)**.** *Every accepted* $\mathsf{Circle}^{\uparrow}$ *read is scoped exactly by the carrier rows* B, R, M, K, S, H, P, N *of Definition 4010.1, the displayed* BHist *packet, componentwise* hsame *transport,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ *naming, and the sibling surfaces* $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, *and optional* $\mathsf{S}^{1\uparrow}$. *The scoped route exports no ambient plane, quotient-angle equality, selected parametrization, global orientation, or identification of* $\mathsf{Circle}^{\uparrow}$ *with* $\mathsf{S}^{1\uparrow}$.

Lean4 ✓ `BEDC.Derived.CircleUp.CircleCarrier real metric scoped closure`

Proof. Apply Definition 4010.2. The accepted read begins with the carrier rows B, R, M, K, S, H, P, N and the local $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ surface, so no unlisted coordinate can enter the scope.

Use Definition 4010.3 and Definition 4010.5. These results keep the optional $\mathsf{S}^{1\uparrow}$ row as a handoff from the boundary and real-coordinate rows, not as an identification of the circle packet with the phase-group sibling.

Apply Definition 4010.6 and Definition 4010.7. The compact, metric, and real rows already determine the closed-boundary inspection surface through BHist, hsame, Pkg, and local naming.

Thus the scoped closure is exactly the displayed BEDC carrier surface over $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, and optional $\mathsf{S}^{1\uparrow}$, while ambient planes, quotient-angle equality, selected parametrizations, global orientations, and carrier identification with $\mathsf{S}^{1\uparrow}$ remain outside the packet. □

Theorem 3031.9 (Circle public boundary export)**.** *The public* $\mathsf{Circle}^{\uparrow}$ *export is exactly the boundary-loop row* B, $\mathsf{Real}^{\uparrow}$ *coordinate row* R, $\mathsf{Met}^{\uparrow}$ *neighborhood row* M, $\mathsf{Compact}^{\uparrow}$ *cover row* K, *optional* $\mathsf{S}^{1\uparrow}$ *handoff row* S, *componentwise* hsame *transport row* H, Pkg *provenance row* P, *and local* $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$ *route* N *of Definition 4010.1. A downstream consumer may cite this boundary as the public circle surface, but it receives no ambient plane, quotient-angle equality, selected parametrization, global orientation, or carrier identification with* $\mathsf{S}^{1\uparrow}$.

Lean4 ✓ `BEDC.Derived.CircleUp.CircleCarrier public boundary export`

Proof. Start with the scoped closure of Definition 4010.8. It already identifies the visible BEDC carrier surface as B, R, M, K, S, H, P, N over the boundary, Real-coordinate, metric, compact, optional phase-handoff, transport, provenance, and local naming rows.

Now read that scoped packet as an outward-facing boundary. The NameCert obligations of Definition 4010.2 keep the topological circle read on the boundary, coordinate, metric, compact, transport, provenance, and local naming rows before the optional handoff can be used.

Finally apply the handoff and compact-metric exclusions of Definition 4010.3, Definition 4010.5, and Definition 4010.6. They keep S as an optional route to the $\mathsf{S}^{1\uparrow}$ sibling and exclude the ambient plane, quotient-angle, parametrization, orientation, and carrier-identification readings. Thus the public boundary exports exactly the displayed carrier rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$.

Constructive story: A $\mathsf{Circle}^{\uparrow}$ packet is generated from boundary-loop, Real-coordinate, metric-neighborhood, compact-cover, optional SOne handoff, componentwise hsame transport, package provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$, publicClosed)

Scope closed: Definition 4010.1, Definition 4010.2, Definition 4010.3, Definition 4010.4, Definition 4010.5, Definition 4010.6, Definition 4010.7, Definition 4010.8, and Definition 4010.9 bind the topological boundary certificate, compact-metric obligations, Real metric route, algebraic phase handoff, and public boundary export.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Circle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global parametrization, quotient-angle equality, ambient-plane data, or an identification of $\mathsf{Circle}^{\uparrow}$ with $\mathsf{S}^{1\uparrow}$.

Upgrade path: Formal closure requires checked carrier admission, boundary stability, compact-cover exactness, SOne handoff noncollapse, transport, provenance, and local naming for the same finite packet.

Chapter 3032

A Concrete Naming Certificate for $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$

The $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$ packet realizes Definition 9463.12 as a finite NameCert carrier for the three-role discipline of focused disk readout, inscription-side self-center, and far-end boundary reading. It sits beside $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ of chapter 3500, $\mathsf{LocalSelfCenterInscriptionSeal}^{\uparrow}$ of chapter 1071, $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ of chapter 3486, and $\mathsf{UnitDisk}^{\uparrow}$ of chapter 377; those siblings supply boundary-fixed transport, local inscription sealing, observer-expansion ledger data, and disk-coordinate rows, while this packet binds the self-center reading itself.

Definition 3032.1 (Hyperbolic self-center reading carrier)**.** *A* $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, I, B, T, V, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk-readout row, recording the finite* $\mathsf{UnitDisk}^{\uparrow}$ *or Poincare-disk coordinate read of the focused ledger event.*
2. *I is the inscription row, recording the* $\mathsf{LocalSelfCenterInscriptionSeal}^{\uparrow}$ *reading of the local self-center.*
3. *B is the far-end boundary row, recording the boundary-side* T *reading used by the hyperbolic vision.*
4. *T is the boundary-fixed transport row, recording the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *route that preserves the boundary reading while disk data move.*
5. *V is the noncollapse verdict row, recording that D, I, and B are three roles and not three hidden objects or one collapsed object.*
6. *H records componentwise* hsame *transport for disk readout, inscription, boundary, boundary-fixed transport, noncollapse verdict, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for reading D, I, B, T, V in the same finite packet.*
8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{LocalSelfCenterInscriptionSeal}^{\uparrow}$, $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSelfCenterReading}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden subject, a global observer point, a selected geodesic center, a physical constant, or an identification of disk readout with boundary far end.

Lean4 ✓ `BEDC.Derived.HyperbolicSelfCenterReadingUp.HyperbolicSelfCenterReadingTasteGate single carrier alignment`

Theorem 3032.2 (Hyperbolic self-center reading NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$ *carrier*

$$R = (D, I, B, T, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicSelfCenterReading}^{\uparrow}}$ *surface consists exactly of disk-readout admission, inscription admission, far-end boundary admission, boundary-fixed transport, noncollapse verdict, componentwise transport, displayed replay, provenance, and local naming. No obligation may identify the records-side disk row* D*, the inscription-side row* I*, and the far-end boundary row* B*.*

Proof. Project the accepted carrier of Definition 4011.1. The three geometric roles are displayed separately as D, I, B.

The transport row T moves disk-facing data while preserving the boundary reading, and the verdict row V records the refusal to collapse the three roles. These rows are part of the same finite packet and cannot be replaced by prose analogy.

Finally, H, C, P, N transport, replay, source, and name the packet. Since the carrier has no hidden subject, global observer point, selected geodesic center, physical constant, or identification coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3032.3 (Hyperbolic self-center reading noncollapse)**.** *Every accepted* $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$ *read keeps disk readout* D*, inscription row* I*, and far-end boundary row* B *distinct under the boundary-fixed transport row* T *and the noncollapse verdict row* V*. A consumer may cite their relation only through* $R = (D, I, B, T, V, H, C, P, N)$*, and may not export a hidden subject, a single collapsed self-center object, or a physical constant from the geometry alone.*

Proof. Begin with the three displayed roles. The disk-readout row D is records-side data, the inscription row I is the local self-center seal, and the boundary row B is the far-end reading.

The transport row T relates disk and boundary readings without erasing that distinction. The verdict row V records the noncollapse condition before any downstream consumer can package the read.

The structural rows H, C, P, N preserve the same finite inventory. Because no hidden-subject, collapsed-object, or physical-constant coordinate appears in the carrier, every accepted reading remains inside the displayed packet. □

Theorem 3032.4 (Hyperbolic self-center reading provenance route)**.** *The* $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$ *packet routes its focused-ledger context through* $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$*, disk coordinates through* $\mathsf{UnitDisk}^{\uparrow}$*, local inscription through* $\mathsf{LocalSelfCenterInscriptionSeal}^{\uparrow}$*, and boundary-fixed movement through* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*. These sibling routes are consumed as finite rows of one carrier and do not supply an ambient hyperbolic model, a global observer, or a host-geometric self.*

Proof. Read the provenance row P together with the displayed rows D, I, B, T, V. It names the focused-ledger, disk-coordinate, inscription, and boundary-fixed transport sources that the carrier is allowed to consume.

The replay row C then orders those reads inside one finite packet. A consumer can replay the disk readout, local inscription, far-end boundary reading, transport, and noncollapse verdict, but it receives no external geometric model.

Finally, H and N preserve and name the same packet. The absence of a global observer or host-geometric self coordinate gives the stated boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSelfCenterReading}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicSelfCenterReading}^{\uparrow}$ packet is generated from disk-readout, local inscription, far-end boundary, boundary-fixed transport, noncollapse verdict, componentwise hsame transport, displayed replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicSelfCenterReading}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4011.1, Definition 4011.2, Definition 4011.3, and Definition 4011.4 seed the finite carrier for the hyperbolic self-center reading.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicSelfCenterReading}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a global observer, hidden subject, physical constant, or ambient hyperbolic model.

Upgrade path: Obligation closure requires checked carrier admission, disk-readout stability, inscription and boundary noncollapse, boundary-fixed transport, replay, provenance, and local naming for the same finite packet.

Chapter 3033

A Concrete Naming Certificate for $\mathsf{ClosedIntervalNesting}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ClosedIntervalNesting}^{\uparrow}$ packet records the finite nested-closed-interval route used before a retained interval family is read as regular rational Cauchy data. It sits over the dyadic endpoint core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the interval certificate surface of chapter 56. The packet names the L10 nested-interval handoff only; it does not assert a Dedekind-cut construction, a trichotomy principle, quotient equality of real names, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3033.1 (Closed interval nesting carrier)**.** *A* $\mathsf{ClosedIntervalNesting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, I, S, W, R, Q, H, C, P, N)$$

with the following visible rows:

1. *E is the dyadic closed-endpoint row. It records left and right endpoints through* $\mathsf{DyadicRatCore}^{\uparrow}$*, endpoint order, midpoint arithmetic cells, and the dyadic comparison budget for each inspected interval.*
2. *I is the nesting-inclusion row. It displays, for every inspected successor stage, the finite evidence that the successor closed interval is contained in its predecessor.*
3. *S is the shrinking-width schedule. It records the requested precision, the displayed stage bound, and the dyadic inequality that makes the inspected interval width smaller than the requested tolerance.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for endpoint, inclusion, width, and stage-bound observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the chosen endpoint stream and the width schedule after E, I, S, W have been displayed.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is opened only after the dyadic endpoints, nesting inclusions, shrinking-width schedule, stream windows, and regular rational readback have been replayed.*
7. *H records componentwise* hsame *transport for the endpoint row, inclusion row, width schedule, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-facing or real-name request through $E, I, S, W, R, Q, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalNesting}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *interval certificates,* BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalNesting}^{\uparrow}}$ *row.*

The classifier compares accepted nesting carriers only through $E, I, S, W, R, Q, H, C, P, N$. It has no coordinate for Dedekind cuts, trichotomy, quotient equality of real names, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ClosedIntervalNestingUp.TasteGate.ClosedIntervalNestingTasteGate single carrier alignment`

Theorem 3033.2 (Closed interval nesting NameCert obligations)**.** *For every accepted* $\mathsf{ClosedIntervalNesting}^{\uparrow}$ *carrier $K = (E, I, S, W, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalNesting}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic closed-endpoint exposure, successor nesting inclusion, shrinking-width scheduling, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the carrier of Definition 4012.1.*

Proof. Carrier admission is projection from Definition 4012.1. The endpoint row E and inclusion row I are the only rows that expose closed-interval data, so every local naming obligation begins with displayed dyadic endpoints and finite successor containment.

The width and window obligations are consecutive. The schedule row S supplies the stage bound and dyadic width inequality, while W exposes the finite endpoint, inclusion, width, and stage observations used by that schedule.

The readback rows R, Q are downstream of those displayed observations. The regular rational row repacks the endpoint stream under the shrinking-width bound, and the real seal is available only after that regular readback has been replayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for Dedekind cuts, trichotomy, quotient equality, selected limits, choice, or ambient completeness, the listed rows exhaust the local certificate. □

Theorem 3033.3 (Closed interval nesting RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{ClosedIntervalNesting}^{\uparrow}$ *carrier reaches regular rational data only through the displayed finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may be consumed by completion and real-name routes as a nested closed-interval certificate, but it exports no Dedekind-cut construction, trichotomy row, quotient equality of real names, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier $K = (E, I, S, W, R, Q, H, C, P, N)$. The endpoint row E and nesting row I expose the only closed-interval information available to a consumer.

Read the shrinking-width schedule S next. It ties every requested tolerance to a displayed stage bound and a dyadic width inequality, so the route cannot be interpreted as a selected intersection point or a hidden completed limit.

The stream and regular rows W, R then turn those finite endpoint windows into regular rational readback. The terminal row Q is a real-name seal only after the dyadic endpoint, inclusion, width, and stream rows have been displayed.

Finally H, C, P, N preserve the same order under transport, replay, provenance, and local naming. Because no stronger object appears among the carrier coordinates, every $\mathsf{RegSeqRat}^{\uparrow}$ handoff remains the displayed finite nested-interval route. □

Falsifiable prediction: A RegSeqRat or Real consumer that omits the dyadic endpoint row, nesting-inclusion row, shrinking-width schedule, StreamName window row, or regular rational readback row cannot claim a $\mathsf{ClosedIntervalNesting}^{\uparrow}$ handoff to a Real-facing seal.

Independence witness: dyadicratcore, streamname, regseqrat, real, interval: $\mathsf{ClosedIntervalNesting}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic closed endpoints, nesting inclusion, shrinking-width scheduling, stream windows, regular readback, a terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalNesting}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalNesting}^{\uparrow}$ packet is generated from dyadic closed endpoints, successor nesting-inclusion evidence, a shrinking-width schedule, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalNesting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4012.1, Definition 4012.2, and Definition 4012.3 seed the L10 nested-interval route over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, interval certificate rows, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalNesting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut construction, trichotomy, quotient equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exactness, nesting-inclusion stability, shrinking-width exactness, StreamName window exactness, RegSeqRat handoff, Real-seal nonescape, componentwise transport, displayed replay, package provenance, and local NameCert field faithfulness for BEDC.Derived.ClosedIntervalNestingUp.

Chapter 3034

A Concrete Naming Certificate for $\mathsf{HyperconvexMetric}^{\uparrow}$

Following Aronszajn and Panitchpakdi, the $\mathsf{HyperconvexMetric}^{\uparrow}$ packet records the classical ball-intersection surface as finite BEDC completion-neighbour data. It sits over the $\mathsf{Met}^{\uparrow}$ source of chapter 57, the $\mathsf{CompleteMetric}^{\uparrow}$ boundary of chapter 128, the $\mathsf{MetricClosedBall}^{\uparrow}$ membership row of chapter 1451, the $\mathsf{FormalBallBasis}^{\uparrow}$ refinement route of chapter 3943, and the terminal $\mathsf{Real}^{\uparrow}$ radius seal of chapter 38. The packet names pairwise-compatible displayed balls and a finite intersection handoff; it does not select a global hull point, quotient completion representative, arbitrary family intersection, choice function, or ambient real-completeness principle.

Definition 3034.1 (Hyperconvex metric carrier)**.** *A* $\mathsf{HyperconvexMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, K, B, F, R, I, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the inspected point classifier and distance requests.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion-neighbour seal read over the same metric source.*
3. *B is the finite* $\mathsf{MetricClosedBall}^{\uparrow}$ *family row, listing displayed centres, nonnegative radii, and membership comparison rows.*
4. *F is the* $\mathsf{FormalBallBasis}^{\uparrow}$ *refinement row that records the finite centre-radius basis used before the closed-ball family is inspected.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *radius and distance seal row, including the terminal real-name comparisons needed by B.*
6. *I is the pairwise-intersection ledger. For every displayed pair of balls in B, it records the finite compatibility inequality $d(c_i, c_j) \leq r_i + r_j$ through M and R.*
7. *E is the ball-intersection handoff row. It records the finite witness request that a common displayed intersection point may be consumed only after M, K, B, F, R, I have been read.*
8. *H records componentwise* hsame *transport for the metric source, complete-metric seal, closed-ball family, formal-ball refinement, real-radius seal, pairwise ledger, handoff row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from metric distance requests through formal-ball refinement, closed-ball membership, pairwise compatibility, and the completion-neighbour handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperconvexMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{FormalBallBasis}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperconvexMetric}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite hyperconvex-metric packet. It has no coordinate for a selected injective hull, arbitrary ball-family intersection, quotient completion equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HyperconvexMetricUp.HyperconvexMetricTasteGate single carrier alignment`

Theorem 3034.2 (Hyperconvex metric NameCert obligations)**.** *For every accepted* $\mathsf{HyperconvexMetric}^{\uparrow}$ *carrier* $Q = (M, K, B, F, R, I, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperconvexMetric}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed metric source, complete-metric seal, closed-ball family, formal-ball refinement, real-radius seal, pairwise-intersection ledger, handoff row, transport, replay, provenance, and local naming rows;*
2. *common-source discipline, requiring K, B, F, R, and I to be read over the same* $\mathsf{Met}^{\uparrow}$ *row M;*
3. *closed-ball visibility, requiring every radius and membership request to pass through* $\mathsf{MetricClosedBall}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *before the intersection handoff is exposed;*
4. *basis refinement, requiring the* $\mathsf{FormalBallBasis}^{\uparrow}$ *row to display the centre-radius refinement route used by the closed-ball family;*
5. *pairwise compatibility, requiring every displayed pair of balls to carry the finite inequality ledger I before a common-intersection request reaches E;*
6. *completion-neighbour nonescape, excluding selected injective hulls, arbitrary family intersections, quotient completion equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

No hyperconvex metric obligation is stored outside these rows.

Proof. Project the carrier of Definition 4013.1. The projection exposes exactly the metric source M, complete-metric seal K, closed-ball family B, formal-ball refinement F, real-radius seal R, pairwise ledger I, ball-intersection handoff E, and structural rows H, C, P, N.

The common-source and closed-ball obligations are tied to the same displayed route. The rows K, B, F, R, I are transported componentwise by H, while the replay row C allows radius and membership comparisons only after the source metric and formal-ball basis rows have been displayed.

The intersection obligation is finite. The ledger I lists the pairwise compatibility inequalities for the displayed balls in B, and the handoff row E can be consumed only after that ledger has been read.

The nonescape clauses follow from the carrier shape. None of the rows stores a selected injective hull, arbitrary ball-family intersection, quotient completion equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness, so the listed obligations exhaust the local NameCert surface. □

Theorem 3034.3 (Hyperconvex metric ball-intersection handoff)**.** *Every completion-neighbour consumer of an accepted* $\mathsf{HyperconvexMetric}^{\uparrow}$ *carrier* $Q = (M, K, B, F, R, I, E, H, C, P, N)$ *reads the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{FormalBallBasis}^{\uparrow} \longmapsto \mathsf{MetricClosedBall}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto I \longmapsto E \longmapsto \mathsf{CompleteMetric}^{\uparrow}$$

before it treats the packet as a ball-intersection source. Thus the consumer receives a displayed metric carrier, formal-ball refinements, closed-ball membership rows, real radius comparisons, and pairwise compatibility evidence, while selected injective hulls, arbitrary ball-family intersections, quotient completion representatives, choice principles, and ambient real completeness remain outside the packet.

Proof. Begin with the metric source. The carrier admits the completion-neighbour read only after M displays the point and distance surface and F displays the finite centre-radius refinement route.

Read the closed-ball and real-radius rows next. The row B supplies the displayed closed balls, while R supplies the terminal real-name comparisons for their radii and distances.

Now inspect pairwise compatibility. The ledger I records the finite inequalities for the displayed family, so the handoff row E is reached only after each required pairwise comparison has been exposed.

Finally the complete-metric seal K and structural rows H, C, P, N package the same route for downstream consumers. Since the carrier has no hull-selection, arbitrary-family, quotient-completion, choice, or ambient-completeness coordinate, the handoff exports none of those objects. □

Falsifiable prediction: Every accepted $\mathsf{HyperconvexMetric}^{\uparrow}$ completion-neighbour read factors through displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{FormalBallBasis}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, pairwise compatibility, and $\mathsf{CompleteMetric}^{\uparrow}$ rows before any ball-intersection handoff is exposed.

Independence witness: metric, completemetric, metricclosedball, formal-ball-basis, real: $\mathsf{HyperconvexMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds pairwise-compatible closed-ball families, formal-ball refinement, real-radius comparison, complete-metric sealing, ball-intersection handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperconvexMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperconvexMetric}^{\uparrow}$ packet is generated from a displayed MetricSpace row, CompleteMetric seal, MetricClosedBall family, FormalBallBasis refinement, Real radius and distance seals, pairwise compatibility ledger, ball-intersection handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperconvexMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4013.1, Definition 4013.2, and Definition 4013.3 seed the finite ball-intersection completion-neighbour route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperconvexMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected injective hulls, arbitrary ball-family intersections, quotient completion equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-source discipline, closed-ball visibility, basis refinement, pairwise compatibility, and ball-intersection handoff for BEDC.Derived.HyperconvexMetricUp.

Chapter 3035

A Concrete Naming Certificate for SummableSequence$^{\uparrow}$

Following Hardy, Knopp, and Bishop–Bridges constructive real-series analysis, the SummableSequence$^{\uparrow}$ packet records the finite route by which a real-valued sequence exposes a Cauchy tail budget before any Real or Completion consumer reads its sum. It sits after the finite partial-sum surface of RealSeries$^{\uparrow}$ in chapter 1581, the absolute and uniform convergence handoffs of chapter 1700 and chapter 771, the regular rational readback of chapter 301, the stream-window route of chapter 126, and the terminal Real$^{\uparrow}$ seal of chapter 38. The packet names summability as finite certificate data: a source series, partial-sum windows, Cauchy tail budgets, convergence-test handoff, readback, sealing, transport, replay, provenance, and local naming.

Definition 3035.1 (Summable sequence carrier)**.** *A* SummableSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, T, B, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* RealSeries$^{\uparrow}$ *source row. It exposes the summand stream and the partial-sum construction only through the finite real-series surface.*
2. *W is the partial-sum window row. It records finite windows of summands, partial sums, and requested tail cutoffs.*
3. *T is the Cauchy tail budget row. For every displayed tolerance request it records a cutoff, two later partial-sum windows, and the dyadic comparison certifying that their difference lies below the requested bound.*
4. *B is the convergence-test handoff row. It is read either through an* AbsoluteConvergence$^{\uparrow}$ *majorant route or through a* UniformConvergenceTest$^{\uparrow}$ *route when the summability claim is supplied by a uniform family; if neither handoff is displayed, B carries only the local Cauchy tail budget.*
5. *G is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the same partial-sum windows and tail budgets.*
6. *R is the* StreamName$^{\uparrow}$ *observation row for summands, partial sums, cutoffs, tail comparisons, and endpoint-facing reads.*
7. *E is the terminal* Real$^{\uparrow}$ *seal reached only after A, W, T, B, G, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, windows, tail budget, convergence handoff, readback, stream observations, Real seal, replay, provenance, and local name.*

9. *C records displayed* Cont *replay of the route*

$$A, W, T, B \longmapsto G, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{SummableSequence}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{UniformConvergenceTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SummableSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, T, B, G, R, E, H, C, P, N$. It has no coordinate for a selected infinite sum, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an external convergence theorem not displayed by the handoff row.*

Lean4 ✓ `BEDC.Derived.SummableSequenceUp.SummableSequenceTasteGate single carrier alignment`

Theorem 3035.2 (Summable sequence NameCert obligations)**.** *For every accepted* $\mathsf{SummableSequence}^{\uparrow}$ *carrier*

$$S = (A, W, T, B, G, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummableSequence}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the eleven displayed rows;*
2. $\mathsf{RealSeries}^{\uparrow}$ *source exposure, requiring every summand and partial-sum read to pass through A;*
3. *partial-sum window exactness, requiring W to bind every inspected summand, partial sum, and tail cutoff to one finite window;*
4. *Cauchy tail budget exactness, requiring T to pair every tolerance request with a cutoff and later-window comparison;*
5. *convergence-test handoff compatibility, requiring B to expose only the displayed* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *or* $\mathsf{UniformConvergenceTest}^{\uparrow}$ *route when such a route is used;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *readback compatibility, requiring G and R to inspect the same partial-sum and tail-budget rows;*
7. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring E to remain downstream of A, W, T, B, G, R;*
8. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No summability obligation is stored outside these rows.

Proof. Project the accepted packet $S = (A, W, T, B, G, R, E, H, C, P, N)$. The source, window, tail-budget, convergence-handoff, readback, stream-observation, Real-seal, and structural rows are exactly the displayed coordinates of the carrier.

The source and window obligations come first. The row A supplies only $\mathsf{RealSeries}^{\uparrow}$ summands and partial sums, while W fixes the finite windows in which tail cutoffs and later partial sums are inspected.

The Cauchy tail budget is the row T. It pairs each tolerance request with a cutoff and the finite comparisons between later partial sums. The handoff row B may justify that budget through the displayed absolute or uniform convergence route, but it cannot import an unlisted convergence theorem.

Finally G, R, E, H, C, P, N read back, observe, seal, transport, replay, source, and name that same route. Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 3035.3 (Summable sequence Real-series handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{SummableSequence}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{RealSeries}^{\uparrow}, \mathsf{AbsoluteConvergence}^{\uparrow}, \mathsf{UniformConvergenceTest}^{\uparrow} \longmapsto A, W, T, B \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto E,$$

The handoff states that summability is consumed through displayed partial-sum windows and Cauchy tail budgets before the $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal are exposed. It exports no selected infinite sum, quotient stream equality, host real equality, countable-choice selector, ambient completeness theorem, or convergence principle detached from the finite packet.*

Proof. Start from the $\mathsf{RealSeries}^{\uparrow}$ row A. It supplies the summand stream and partial sums, while W records the finite partial-sum windows and tail cutoffs available to the consumer.

Read the tail budget through T and the optional convergence-test handoff through B. The absolute-convergence or uniform-convergence route can be consumed only when it is displayed in B, and the local Cauchy tail comparison remains the row that later readback uses.

The rows G and R expose the same partial-sum and tail-budget data as regular rational readback and stream observations. The Real seal E is therefore downstream of the finite Cauchy tail route.

The structural rows H, C, P, N preserve, replay, source, and name the same packet. Because the carrier contains no selected infinite sum, quotient equality, host equality, choice, ambient completeness, or detached convergence coordinate, every Real or Completion handoff stays inside the displayed route. □

Falsifiable prediction: An accepted $\mathsf{SummableSequence}^{\uparrow}$ read is refuted if a Real or Completion consumer exports a Real seal without displaying a RealSeries source row, partial-sum windows, Cauchy tail budget, convergence-test handoff when used, RegSeqRat readback, StreamName observations, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, absolute-convergence, uniform-convergence-test, regseqrat, streamname, real: none alone is bijective with $\mathsf{SummableSequence}^{\uparrow}$ because the packet jointly carries source partial sums, Cauchy tail budgets, convergence-test handoff, regular readback, stream observations, Real sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{SummableSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{SummableSequence}^{\uparrow}$ packet is generated from a RealSeriesUp source row, partial-sum window rows, Cauchy tail-budget rows, AbsoluteConvergenceUp or UniformConvergenceTestUp handoff rows when displayed, RegSeqRatUp readback, StreamNameUp observations, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SummableSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4014.1, Definition 4014.2, and Definition 4014.3 seed the finite summability certificate surface from real-series partial sums through Cauchy tail budgets to regular readback and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SummableSequence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.SummableSequenceUp.SummableSequenceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not close selected infinite sums, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, detached convergence principles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partial-sum window exactness, Cauchy tail-budget stability, convergence-test handoff compatibility, RegSeqRat readback, StreamName observation compatibility, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.SummableSequenceUp.

Chapter 3036

A Concrete Naming Certificate for $\mathsf{CompactLebesgueNumber}^{\uparrow}$

Following Lebesgue, Heine–Borel compactness, and Bishop–Bridges compact metric analysis, the $\mathsf{CompactLebesgueNumber}^{\uparrow}$ packet records the compact finite cover-radius ledger used by the compact uniform-continuity proof of chapter 9237. It refines the compact-metric source of chapter 129, the finite positive-radius ledger of chapter 452, and the uniform-modulus consumer of chapter 369. The packet is a finite NameCert surface for compact finite nets, located cover radii, lower-bound folds, and uniform-modulus handoff; it is not open-cover compactness, a selected subcover, or an external minimum principle.

Definition 3036.1 (Compact Lebesgue-number carrier)**.** *A* $\mathsf{CompactLebesgueNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, B, C, R, F, U, H, Q, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row. It exposes compact finite-net and metric inspection data through the compact-metric chapter.*
2. *B is the finite* ProbeBundle *cover spine naming the compact cover candidates inspected by the packet.*
3. *C is the center and coverage ledger. It records center histories, located-ball membership rows, and the finite cover witness for every compact-source history read by the packet.*
4. *R is the positive cover-radius row, read through dyadic and rational-ball radius data attached to the bundled probes.*
5. *F is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *lower-radius row. It folds the finite radius ledger to a positive radius below every displayed cover radius.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff row. It exports the lower-radius ledger only after K, B, C, R, F have been displayed.*
7. *H records componentwise* hsame *transport for the compact source, bundle spine, coverage ledger, radius rows, finite Lebesgue-number row, uniform-modulus handoff, replay, provenance, and local name.*
8. *Q records displayed* Cont *replay of the route*

$$K, B, C, R \longmapsto F \longmapsto U.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompactLebesgueNumber}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactLebesgueNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, C, R, F, U, H, Q, P, N$. It has no coordinate for an arbitrary open cover, a selected finite subcover, host compactness, a host minimum, quotient real equality, countable choice, or a uniform modulus detached from the finite lower-radius row.

Lean4 ✓ `BEDC.Derived.CompactLebesgueNumberUp.CompactLebesgueNumberTasteGate single carrier alignment`

Theorem 3036.2 (Compact Lebesgue-number NameCert obligations)**.** *For every accepted* CompactLebesgueNumb *carrier*

$$L = (K, B, C, R, F, U, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactLebesgueNumber}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the ten displayed rows;*
2. *compact-metric source exposure, requiring every compact-source read to pass through K;*
3. *finite ProbeBundle coverage exactness, requiring B and C to bind every compact-source history to a named cover probe and located-ball row;*
4. *positive radius ledger exactness, requiring R to attach displayed dyadic and rational-ball radii to the bundled probes;*
5. *finite Lebesgue-number fold compatibility, requiring F to be a* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *row below every displayed radius in R;*
6. *uniform-modulus handoff, requiring U to consume only the lower-radius row and the compact source route already displayed;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, Q, P, N.*

No compact Lebesgue-number obligation is stored outside these rows.

Proof. Project the accepted packet $L = (K, B, C, R, F, U, H, Q, P, N)$. The compact source, bundle, coverage, radius, lower-fold, uniform handoff, and structural rows are precisely the displayed carrier coordinates.

The compact and coverage obligations come first. The row K supplies the compact-metric source, while B and C expose only named probes, center histories, located-ball reads, and finite cover witnesses.

The radius obligations are finite. The row R records the positive radii attached to bundled probes, and F records the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ lower-radius ledger below those radii. No host minimum or selected open subcover is needed to read F.

Finally U, H, Q, P, N hand the lower radius to uniform-modulus consumers and preserve, replay, source, and name the same route. Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 3036.3 (Compact Lebesgue-number uniform-modulus handoff)**.** *Every compact-uniform-continuity or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactLebesgueNumber}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto B, C, R \longmapsto \mathsf{FiniteLebesgueNumber}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto H, Q, P, N.$$

Thus the finite cover-radius ledger of chapter 9237 is exposed as compact-metric source data, named cover probes, positive radius rows, a finite Lebesgue-number lower-bound fold, and a uniform-modulus handoff. It exports no arbitrary open cover, selected subcover, host compactness theorem, host minimum, countable-choice selector, quotient real equality, or detached uniform modulus.

Proof. Start from the compact-metric source K. It provides the finite compact inspection data, while B and C record the actual cover spine and located coverage rows consumed by the packet.

Read the radius ledger R and the finite lower-bound row F. The lower-bound row is a $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ packet tied to the displayed probe radii, so it is not a host minimum and not a selected subcover argument.

The handoff row U sends exactly this lower-radius ledger to the $\mathsf{UniformModulus}^{\uparrow}$ consumer. The transport, replay, provenance, and naming rows H, Q, P, N preserve the same path.

Because the carrier has no coordinate for an arbitrary open cover, selected subcover, host compactness theorem, host minimum, choice, quotient real equality, or detached modulus, every compact-uniform-continuity read factors through the displayed route. □

Theorem 3036.4 (Compact Lebesgue-number Real-uniform entourage route)**.** *Every* $\mathsf{RealUniformStructure}^{\uparrow}$ *or* $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactLebesgueNumber}^{\uparrow}$ *packet must read the* $\mathsf{CompactMetric}^{\uparrow}$ *source,* $\mathsf{ProbeBundle}$ *cover spine, located coverage rows, positive radius ledger,* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *lower-bound fold, and* $\mathsf{UniformModulus}^{\uparrow}$ *handoff before any Real-induced entourage basis is exported. The route supplies no arbitrary open cover, selected subcover, host minimum, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Project the accepted carrier $L = (K, B, C, R, F, U, H, Q, P, N)$. The source row K, cover spine B, located coverage ledger C, positive radius row R, finite lower-bound fold F, and uniform handoff row U are the only analytic coordinates available before the structural rows.

Apply Definition 4015.3. It forces every compact-uniform-continuity read to pass through the displayed compact source, finite cover spine, located coverage rows, positive radii, lower-bound fold, and $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Route the resulting lower-bound ledger through the Real metric-ball surface of chapter 1624 and the basis packet of chapter 5115. A Real-induced entourage basis can therefore be exported only as a downstream read of the same compact finite-radius route.

Because arbitrary open covers, selected subcovers, host minima, quotient real equality, countable choice, and ambient Real completeness are absent from the carrier coordinates, no Real-uniform consumer can obtain them from the exported entourage basis. □

Falsifiable prediction: An accepted $\mathsf{CompactLebesgueNumber}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a UniformModulusUp row without displaying CompactMetric source data, a ProbeBundle cover spine, located coverage rows, positive radius rows, a FiniteLebesgueNumber lower-bound fold, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, finite-lebesgue-number, uniformmodulus: none alone is bijective with $\mathsf{CompactLebesgueNumber}^{\uparrow}$ because the packet jointly carries compact source data,

finite cover probes, located coverage rows, positive radii, lower-bound fold, uniform-modulus handoff, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLebesgueNumber}\uparrow}$.

Constructive story: A $\mathsf{CompactLebesgueNumber}^{\uparrow}$ packet is generated from CompactMetricUp source data, a finite ProbeBundle cover spine, located coverage rows, positive dyadic and rational-ball radius rows, a FiniteLebesgueNumberUp lower-bound fold, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactLebesgueNumber}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4015.1, Definition 4015.2, and Definition 4015.3 seed the compact finite Lebesgue-number packet from compact-metric cover data through finite lower-radius folds to UniformModulusUp handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactLebesgueNumber}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host compactness, host minima, quotient real equality, countable choice, detached uniform moduli, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source exposure, ProbeBundle coverage exactness, positive-radius ledger stability, FiniteLebesgueNumber fold compatibility, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactLebesgueNumberUp.

Chapter 3037

A Concrete Naming Certificate for $\mathsf{CompactPolishSpace}^{\uparrow}$

Following Alexandrov and Urysohn on Polish spaces and Kelley on compact metric spaces, the $\mathsf{CompactPolishSpace}^{\uparrow}$ packet records the finite BEDC surface where compact-metric data and complete separable metric data are read as one named object. It sits over the $\mathsf{CompactMetric}^{\uparrow}$ chapter of chapter 129, the $\mathsf{PolishSpace}^{\uparrow}$ chapter of chapter 1490, the $\mathsf{CompleteMetric}^{\uparrow}$ route of chapter 128, the $\mathsf{SeparableMetric}^{\uparrow}$ route of chapter 1458, the finite observation windows of chapter 126, and the regular rational readback surface of chapter 301. The packet is a synthesis node for compact-completion and continuous-map consumers; it is not an open-cover compactness theorem, a host completion, a countable-choice selector, or a quotient of dense names.

Definition 3037.1 (Compact Polish space carrier)**.** *A* $\mathsf{CompactPolishSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (K, P, C, S, W, R, H, T, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row carrying the finite compact-metric witness, including the metric row, total-boundedness window, and compact-test handoff.*
2. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *row naming the same metric carrier as a complete separable metric surface.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row through which Cauchy-facing consumers read completeness data before any Real or completion seal is inspected.*
4. *S is the* $\mathsf{SeparableMetric}^{\uparrow}$ *row displaying the finite dense-name schedule available to separability consumers.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row used by compact-net, dense-name, and completion-facing reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row consumed after the finite stream window has been displayed.*
7. *H records componentwise* hsame *transport for the compact-metric, Polish-space, complete-metric, separable-metric, stream-window, regular-readback, package, and local naming rows.*
8. *T records displayed* Cont *replay from compact-metric witnesses and dense schedules through complete separable readback.*

9. *Q is the* Pkg *provenance over* $\mathsf{CompactPolishSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactPolishSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary open covers, host compactness, host completion, selected dense enumerations, quotient Cauchy classes, countable choice, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.CompactPolishSpaceUp.TasteGate.CompactPolishSpaceUp`

Theorem 3037.2 (Compact Polish space NameCert obligations)**.** *For every accepted* $\mathsf{CompactPolishSpace}^{\uparrow}$ *carrier $X = (K, P, C, S, W, R, H, T, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactPolishSpace}^{\uparrow}}$ *surface consists exactly of compact-metric admission, Polish-space admission, complete-metric handoff, separable-metric handoff, finite stream-window exposure, regular-rational readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer must read the compact side through K, the Polish side through P, C, S, and the finite observation side through W, R before using the packet as a compact Polish space.*

Lean4 ✓ `BEDC.Derived.CompactPolishSpaceUp.CompactPolishSpaceCarrier namecert obligations`

Proof. Project the carrier of Definition 4016.1. The tuple lists the only rows visible to the local classifier, so carrier admission is confined to $K, P, C, S, W, R, H, T, Q, N$.

The compact side is supplied by K. It gives finite compact-metric evidence, but no open-cover compactness principle or ambient compact object.

The Polish side is supplied by P through the complete and separable rows C and S. Completeness-facing reads therefore use the displayed complete-metric handoff, and separability-facing reads use the displayed dense-name schedule.

The observation and readback rows W and R bind those two sides to the same finite stream window and regular-rational surface. Transport, replay, provenance, and local naming are then componentwise through H, T, Q, N, leaving no coordinate for a host completion, countable-choice selector, or quotient dense-name equality. □

Theorem 3037.3 (Compact Polish finite-cover readback)**.** *Every compact-completion or continuous-map consumer of an accepted* $\mathsf{CompactPolishSpace}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{PolishSpace}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow}, \mathsf{SeparableMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

through the displayed rows $K, P, C, S, W, R, H, T, Q, N$. The exported readback is the compact-metric witness together with complete separable metric data and finite regular-name observations; it exports no open-cover compactness theorem, selected host completion, countable-choice dense enumeration, quotient Cauchy class, or ambient completeness row.

Lean4 ✓ `BEDC.Derived.CompactPolishSpaceUp.CompactPolishSpaceCarrier readback certificate`

Proof. Start from the obligation surface of Definition 4016.2. A consumer first reads the compact-metric row K and the Polish-space row P as the two named views of the same carrier.

The complete and separable handoffs are then forced through C and S. Thus completion-facing reads see a complete-metric row, while dense-name reads see a separable-metric row, and neither read can introduce a host completion or selected dense enumeration.

Finally the finite observation route passes through W and R. The structural rows H, T, Q, N preserve the same route by transport, replay, provenance, and local naming, so the displayed rows exhaust the handoff available to compact-completion and continuous-map consumers. □

Theorem 3037.4 (Compact Polish compact-complete-separable synthesis)**.** *Every accepted* $\mathsf{CompactPolishSpace}^{\uparrow}$ *consumer that asks for compact-completion or continuous-map data must factor through the single finite route*

$$K, P, C, S, W, R, H, T, Q, N.$$

Thus compactness, completeness, separability, stream windows, and regular-rational readback are consumed as one carrier surface and cannot be read independently. The route exports no open-cover compactness, host completion, selected dense enumeration, quotient Cauchy class, countable choice, or ambient completeness coordinate.

Proof. Project the carrier rows in Definition 4016.1. The compact-metric row K, Polish-space row P, complete-metric row C, separable-metric row S, stream row W, and regular-rational row R are displayed before any structural replay can be used.

Apply the obligation surface of Definition 4016.2. It identifies the local NameCert read as exactly $K, P, C, S, W, R, H, T, Q, N$, so compactness, completeness, separability, finite observation, and readback are bound to the same packet.

Finally use finite-cover readback from Definition 4016.3. Compact-completion and continuous-map consumers therefore follow the displayed route, and no coordinate exists for open covers, host completions, selected dense enumerations, quotient Cauchy classes, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompactPolishSpace}^{\uparrow}$ consumer read factors through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows before it is used as compact Polish data.

Independence witness: compactmetric, polishspace, completemetric, separablemetric, streamname, regseqrat: $\mathsf{CompactPolishSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds compact-metric witnesses and complete separable metric rows through one finite observation and local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactPolishSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactPolishSpace}^{\uparrow}$ packet is generated from $\mathsf{CompactMetric}^{\uparrow}$ compact-metric rows, PolishSpaceUp complete separable rows, $\mathsf{CompleteMetric}^{\uparrow}$ handoff rows, SeparableMetricUp dense-name rows, StreamNameUp windows, RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactPolishSpace}^{\uparrow}}$, seed)

Scope closed: Definition 4016.1, Definition 4016.2, and Definition 4016.3 seed the finite compact Polish synthesis node over compact-metric and complete separable metric data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactPolishSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, host completion, selected dense enumerations, quotient Cauchy classes, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric admission, Polish-space admission, complete-metric handoff, separable-metric handoff, finite observation readback, transport, replay, provenance, and local naming for BEDC.Derived.CompactPolishSpaceUp.

Chapter 3038

A Concrete Naming Certificate for $\mathsf{PartitionCoreIncidence}^{\uparrow}$

The $\mathsf{PartitionCoreIncidence}^{\uparrow}$ packet realizes the partition-core incidence representation surface of Definition 9462.1755 as finite BEDC NameCert data. It sits over the partition rows of chapter 201, the graph incidence rows of chapter 118, the support-nerve surface of chapter 238, the rank-dependence boundary of chapter 202, and the boundary-tile source of chapter 3393. The packet names the finite incidence kernel consumed by boundary-tile and representation-facing reads; it is not a host representation module, a quotient linear-algebra oracle, or an unrestricted biological model.

Definition 3038.1 (Partition-core incidence carrier)**.** *A* $\mathsf{PartitionCoreIncidence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (P, G, S, M, B, K, V, T, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the partition-core row naming the finite partition blocks and the accepted core labels.*
2. *G is the graph-incidence row listing the displayed source vertices, target cores, and accepted incidence edges.*
3. *S is the support-nerve row, read through* $\mathsf{SimplicialComplex}^{\uparrow}$*, whose faces record nonempty incidence support.*
4. *M is the* $\mathsf{Matroid}^{\uparrow}$ *dependence row recording which displayed incidence supports are treated as dependent.*
5. *B is the* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *source row carrying the boundary-tile coordinates that feed the incidence read.*
6. *K is the partition-core kernel row displaying the accepted null combinations of boundary-tile incidence reads.*
7. *V is the representation-basis row recording the finite trivial, standard, signed, and two-dimensional summand labels used by the readback.*
8. *T is the finite transport row from boundary-tile source reads through partition-core incidence, support-nerve, matroid-dependence, and kernel rows.*
9. *R is the replay row recording the accepted provenance of every local incidence read.*

10. *H records componentwise* hsame *transport for all displayed rows.*
11. *C records displayed* Cont *replay through the partition-core, incidence, support-nerve, transport, replay, provenance, and local naming rows.*
12. *Q is the* Pkg *provenance over* $\mathsf{PartitionCoreIncidence}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PartitionCoreIncidence}^{\uparrow}}$ *row.*

The carrier exports only these finite rows. It contains no host representation space, hidden quotient module, unrestricted linear-algebra solver, stochastic biological model, or global codon semantics.

Lean4 ✓ `BEDC.Derived.PartitionCoreIncidenceUp.PartitionCoreIncidenceTasteGate single carrier alignment`

Theorem 3038.2 (Partition-core incidence NameCert obligations)**.** *For every accepted* $\mathsf{PartitionCoreIncidence}^{\uparrow}$ *carrier* $I = (P, G, S, M, B, K, V, T, R, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PartitionCoreIncidence}^{\uparrow}}$ *surface consists exactly of partition-core admission, graph-incidence admission, support-nerve exposure, matroid-dependence exposure, boundary-tile source admission, kernel-row readback, representation-basis readback, transport, replay, componentwise* hsame*, displayed* Cont, Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4017.1. The partition, graph, support-nerve, matroid, boundary-tile, kernel, and representation rows are the only analytic coordinates available to the local classifier.

The incidence read starts at B and reaches partition cores only through P and G. Support and dependence are then displayed by S and M, so a consumer sees finite support evidence before it reads kernel membership.

The rows K and V record the finite kernel and representation-basis readback. Transport, replay, componentwise equivalence, continuation replay, provenance, and local naming are exactly T, R, H, C, Q, N, leaving no coordinate for host representation modules, quotient linear algebra, stochastic biological dynamics, or global codon semantics. □

Theorem 3038.3 (Partition-core incidence kernel handoff)**.** *Every accepted* $\mathsf{PartitionCoreIncidence}^{\uparrow}$ *read factors through the displayed finite route*

$$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow} \longmapsto \mathsf{Partition}^{\uparrow}, \mathsf{Graph}^{\uparrow} \longmapsto \mathsf{SimplicialComplex}^{\uparrow}, \mathsf{Matroid}^{\uparrow} \longmapsto K, V$$

together with transport, replay, provenance, and local naming rows. Boundary-tile consumers and representation-facing consumers therefore meet only at the displayed partition-core incidence kernel, not at a host quotient module or unrestricted linear-algebra surface.

Proof. Use Definition 4017.2. The boundary-tile source row B supplies the input coordinates, while P and G expose the partition-core and incidence-edge rows through which those coordinates can be read.

The support and dependence checks then pass through S and M. These rows display the support nerve and the finite dependence boundary before any kernel readback is accepted.

Finally K and V expose the finite kernel and representation-basis rows. The structural rows T, R, H, C, Q, N preserve that same route, so the consumer receives only the displayed finite incidence packet. □

Falsifiable prediction: Every accepted $\mathsf{PartitionCoreIncidence}^{\uparrow}$ read factors through displayed partition-core, incidence, support-nerve, transport, replay, provenance, and local naming rows, and any read lacking one of those rows is rejected by the local NameCert surface.

Independence witness: partition, graph, simplicialcomplex, matroid, dna-window-six-boundary-tile: $\mathsf{PartitionCoreIncidence}^{\uparrow}$ is not bijective to any listed sibling because it binds boundary-tile source rows to partition-core incidence, support-nerve, matroid-dependence, kernel readback, representation-basis, transport, replay, provenance, and local naming as one packet.

Lean follow-up provides $\mathsf{Nontrivial\ PartitionCoreIncidence}^{\uparrow}$ and $\mathsf{FieldFaithful\ PartitionCoreIncidence}^{\uparrow}$ in TasteGate.lean.

Closure status for $\mathsf{NameCert}_{\mathsf{PartitionCoreIncidence}^{\uparrow}}$.

Constructive story: A $\mathsf{PartitionCoreIncidence}^{\uparrow}$ packet is generated from partition-core rows, graph-incidence rows, support-nerve rows, matroid-dependence rows, DNA boundary-tile source rows, kernel readback, representation-basis readback, transport, replay, componentwise hsame, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PartitionCoreIncidence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4017.1, Definition 4017.2, and Definition 4017.3 seed the finite partition-core incidence packet for boundary-tile and representation-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PartitionCoreIncidence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host representation modules, quotient linear algebra, unrestricted biological dynamics, global codon semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-core incidence exposure, support-nerve exposure, matroid-dependence exposure, kernel readback, representation-basis readback, transport, replay, provenance, and local naming for BEDC.Derived.PartitionCoreIncidenceUp.

Chapter 3039

A Concrete Naming Certificate for $\mathsf{BaireModulus}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Bishop, the $\mathsf{BaireModulus}^{\uparrow}$ packet records the finite-prefix modulus surface by which a Baire-space read exposes a bounded inspection window before any real-name or fan-functional consumer sees a value. It sits between the finite prefix discipline of chapter 334, the stream-window route of chapter 126, the unary index surface of $\mathsf{Nat}^{\uparrow}$, the dyadic and regular rational handoff of chapter 291 and chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the finite modulus-extraction consumer of chapter 1525. The packet is not host sequence equality, not a selected infinite branch, not a quotient stream object, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3039.1 (Baire modulus carrier)**.** *A* $\mathsf{BaireModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, S, W, \mu, R, H, C, P, N)$$

with the following displayed rows:

1. *B is a* $\mathsf{BaireSpace}^{\uparrow}$ *finite-prefix packet, naming the inspected stream schedule and the prefix-cylinder classifier.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row from which the requested stream coordinates are read.*
3. *W is a unary* $\mathsf{Nat}^{\uparrow}$ *index window listing the finite requests admitted by the modulus.*
4. *μ is the displayed prefix-modulus row, asserting that every permitted consumer read is determined by the rows of W and no tail outside that window.*
5. *R is the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *handoff surface attached to the displayed finite prefix.*
6. *H records componentwise* hsame *transport for the Baire prefix row, stream schedule, unary index window, modulus row, and handoff surface.*
7. *C records displayed* Cont *replay of the same finite prefix requests and handoff rows.*
8. *P is the* Pkg *provenance over* $\mathsf{BaireModulus}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, W, \mu, R, H, C, P, N$. There is no coordinate for host sequence equality, selected branches, quotient streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3039.2 (Baire modulus NameCert obligations)**.** *For every accepted* $\mathsf{BaireModulus}^{\uparrow}$ *carrier $M = (B, S, W, \mu, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, prefix-modulus exactness, finite-window transport, handoff provenance, and nonescape rows. Carrier admission exposes the* $\mathsf{BaireSpace}^{\uparrow}$ *packet,* $\mathsf{StreamName}^{\uparrow}$ *schedule, unary* $\mathsf{Nat}^{\uparrow}$ *window, displayed prefix modulus,* $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming. Prefix-modulus exactness requires every public read to factor through the listed finite window W before the handoff row R or a* $\mathsf{FanFunctional}^{\uparrow}$ *consumer is visible. The nonescape rows exclude host sequence equality, selected branches, quotient streams, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BaireModulusUp.BaireModulusUpTasteGate single carrier alignment`

Proof. Project the accepted carrier of Definition 4018.1. The only stream data available are the $\mathsf{BaireSpace}^{\uparrow}$ finite prefix row B, the $\mathsf{StreamName}^{\uparrow}$ schedule S, and the unary index window W.

The row μ is read after those rows. It binds consumer visibility to the displayed prefix window, so the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{FanFunctional}^{\uparrow}$ handoffs can only consume prefix data already listed in W.

Transport and replay do not add data. The componentwise hsame rows in H and the displayed Cont routes in C reread the same finite requests, while P and N only record provenance and local naming. Since no excluded object is a carrier coordinate, the listed rows exhaust the NameCert surface. □

Theorem 3039.3 (Baire modulus prefix handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{FanFunctional}^{\uparrow}$*-facing public read of an accepted* $\mathsf{BaireModulus}^{\uparrow}$ *packet factors through the route*

$$\mathsf{BaireSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Nat}^{\uparrow} \longmapsto \mathsf{BaireModulus}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BaireModulus}^{\uparrow}}$ *row. The handoff exports a finite prefix modulus and no host sequence equality, branch choice, quotient stream, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with Definition 4018.2. Carrier admission opens the Baire prefix packet, stream schedule, unary window, and modulus row before any downstream consumer can inspect the handoff surface.

Read the handoff row R. Its dyadic, regular-rational, and real-name coordinates are attached to the finite window selected by W and bounded by μ, so they cannot request a tail coordinate outside the displayed prefix.

Finally pass the same finite route to the $\mathsf{FanFunctional}^{\uparrow}$ consumer. The consumer receives the displayed modulus row, transported by H and replayed by C, with provenance in P and local naming in N. Because the carrier has no host equality, selected branch, quotient stream, countable-choice, or real-completeness coordinate, the public handoff has exactly the stated finite-prefix form. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4018.1, Definition 4018.2, and Definition 4018.3 seed the finite-prefix modulus route over $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireModulus}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequence equality, branch choice, quotient streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-modulus exactness, finite-window transport, handoff provenance, and nonescape for BEDC.Derived.BaireModulusUp.

Constructive story: A $\mathsf{BaireModulus}^{\uparrow}$ packet is generated from BaireSpace finite prefix rows, StreamName schedules, unary Nat index windows, displayed prefix-modulus rows, DyadicRatCore, RegSeqRat, and Real handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3040

A Concrete Naming Certificate for $\mathsf{CompactMetricSequentialNet}^{\uparrow}$

Following Bishop and Bridges constructive compactness, the $\mathsf{CompactMetricSequentialNet}^{\uparrow}$ packet joins compact metric finite-net data with sequential extraction as a finite L10 neighbour of chapter 60, chapter 129, chapter 57, and chapter 126. It reads total-bounded net schedules, complete-metric Cauchy routes, finite stream windows, regular rational readback, and terminal Real seals as displayed NameCert rows. The packet supports Bolzano–Weierstrass and sequential compactness consumers while refusing open-cover compactness, countable choice, host subsequence selection, quotient stream equality, and detached real completeness.

Definition 3040.1 (CompactMetricSequentialNet carrier)**.** *A* $\mathsf{CompactMetricSequentialNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, T, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *surface and its compact and metric dependencies.*
2. *T is the total-bounded net schedule, recording finite centers, mesh radii, coverage witnesses, and refinement rows for the requested tolerances.*
3. *L is the complete-metric Cauchy route that receives the extracted Cauchy window after the finite-net schedule has stabilized.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger for the source sequence, selected indices, selected source windows, and monotonicity evidence.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and dyadic tail budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the readback and complete-metric route.*
7. *H records componentwise* hsame *transport for the compact metric source, net schedule, Cauchy route, stream windows, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact metric finite nets through sequential windows, regular rational readback, and the terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricSequentialNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactMetricSequentialNet}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, T, L, W, R, E, H, C, P, N$. It has no coordinate for an externally chosen subsequence, open-cover compactness, quotient stream equality, countable choice, host equality, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactMetricSequentialNetUp.CompactMetricSequentialNetTasteGate single carrier alignment`

Theorem 3040.2 (CompactMetricSequentialNet NameCert obligations)**.** *For every accepted* $\mathsf{CompactMetricSequen}$ *carrier*

$$S = (K, T, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactMetricSequentialNet}^{\uparrow}}$ *surface consists exactly of compact metric source admission through K, total-bounded finite-net scheduling through T, complete-metric Cauchy routing through L, finite stream and subsequence windows through W, regular rational readback through R, terminal Real sealing through E, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 4019.1. The accepted packet exposes exactly the rows $K, T, L, W, R, E, H, C, P, N$.

The compact metric side is finite. The source row K supplies the metric and compact data, while T supplies the total-bounded finite-net schedule used to choose inspected windows at each displayed tolerance.

The sequential side is the row W. It records only finite source windows, selected indices, selected windows, and monotonicity evidence, so no host subsequence selector or countable-choice schedule is available.

The completion-facing side is L, R, E. The selected windows are read through the regular rational row R, then through the complete-metric route L, and finally through the terminal Real seal E.

The rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate outside these rows, the listed non-escape clauses are part of the NameCert surface. □

Theorem 3040.3 (CompactMetricSequentialNet subsequence handoff)**.** *Every compact-metric or Bolzano–Weierstrass consumer of an accepted* $\mathsf{CompactMetricSequentialNet}^{\uparrow}$ *packet reads the subsequence handoff through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports the displayed finite-net schedule, selected source windows, regular rational readback, complete-metric Cauchy route, Real seal, and structural rows only; it exports no open-cover compactness theorem, selected infinite subsequence, quotient stream equality, countable choice, host equality, or detached real-completeness principle.

Proof. Start from Definition 4019.2. The compact metric source row and the total-bounded schedule must be displayed before a sequence consumer may inspect any selected window.

Next read the stream row W. The row contains the finite source windows and the selected-window evidence consumed by the downstream regular rational readback, but it does not contain an independent infinite subsequence object.

Then apply R, L, E in order. The regular rational readback is attached to the displayed windows, the complete-metric route receives that Cauchy data, and the Real seal is reached only at the end of the displayed route.

Finally H, C, P, N preserve the same packet. Therefore every public handoff is confined to the route above and cannot export the excluded open-cover, choice, quotient, host-equality, or detached-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricSequentialNet}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricSequentialNet}^{\uparrow}$ packet is generated from compact metric source rows, total-bounded finite-net schedules, complete-metric Cauchy routes, StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricSequentialNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4019.1, Definition 4019.2, and Definition 4019.3 seed the finite compact-metric sequential extraction route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactMetricSequentialNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite subsequences, quotient stream equality, countable choice, host equality, detached Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net scheduling, sequential-window monotonicity, RegSeqRat readback, complete-metric routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactMetricSequentialNetUp.

Chapter 3041

A Concrete Naming Certificate for $\mathsf{BorelHierarchy}^{\uparrow}$

Following Kechris and Bourbaki in classical descriptive set theory, the $\mathsf{BorelHierarchy}^{\uparrow}$ packet records the finite BEDC boundary by which a Polish or Borel-facing consumer inspects a displayed hierarchy rank without importing the ambient host universe of all Borel subsets. It sits over the generated-set surface of chapter 3384, the open-schedule boundary of chapter 3547, and the complete separable source of chapter 1490. The packet exposes rank schedules, successor and limit-stage replay, StreamName and RegSeqRat readback, transport, continuation replay, provenance, and local naming; it does not claim classical descriptive-set completeness, selected codes, quotient set equality, countable choice, or measure-theoretic structure.

Definition 3041.1 (Borel hierarchy carrier)**.** *A* $\mathsf{BorelHierarchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, B, G, P, S, R, T, C, N)$$

with the following displayed rows:

1. *X is the source-space row, read through the Polish or topology-facing source visible to the current consumer.*
2. *B is the* $\mathsf{BorelSet}^{\uparrow}$ *row that receives generated-set handoff after the hierarchy schedule has been inspected.*
3. *G is either the* $\mathsf{GDeltaSet}^{\uparrow}$ *row or the displayed open-generator row used as the first nontrivial hierarchy surface.*
4. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *source row when the hierarchy is being read over a complete separable metric presentation.*
5. *S is the countable rank schedule. Each visible stage records the rank tag, predecessor window, successor or limit-stage instruction, and the finite constructor route offered to the consumer.*
6. *R is the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rank positions, predecessor windows, open-generator observations, and real-facing regular rational queries.*
7. *T records componentwise* hsame *transport for the source, Borel row, G-delta or open-generator row, Polish row, rank schedule, readback, continuation, and local naming rows.*
8. *C records displayed* Cont *replay from a source query through the visible rank schedule, successor or limit-stage constructor, generated-set handoff, and readback route.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BorelHierarchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, B, G, P, S, R, T, C, N$. It has no coordinate for a host subset, a chosen Borel code, countable choice over ranks, quotient set equality, a completed descriptive-set universe, or a measure-theoretic assertion.

Lean4 ✓ `BEDC.Derived.BorelHierarchyUp.BorelHierarchyTasteGate single carrier alignment`

Theorem 3041.2 (Borel hierarchy NameCert obligations)**.** *For every accepted* $\mathsf{BorelHierarchy}^{\uparrow}$ *carrier*

$$H = (X, B, G, P, S, R, T, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{BorelHierarchy}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *source admission for the displayed source-space row and, when present, the Polish source row;*
2. *rank-schedule exposure, requiring every inspected hierarchy stage to appear in the finite visible prefix of S before any generated-set row is consumed;*
3. *successor-stage replay, requiring successor constructors to read their predecessor window, constructor tag, StreamName observation, and RegSeqRat readback through S and R;*
4. *limit-stage replay, requiring limit constructors to expose only the displayed finite prefix, schedule position, and readback windows visible in S and R;*
5. *generated-set handoff, requiring the* $\mathsf{BorelSet}^{\uparrow}$ *row B to consume the visible route through X, G, P, S, R;*
6. *transport, requiring T to preserve source, Borel, G-delta or open-generator, Polish, rank-schedule, readback, replay, and naming rows together;*
7. *continuation replay, requiring C to replay the same ordered route before any Borel, G-delta, Polish, StreamName, or RegSeqRat consumer receives the packet;*
8. *provenance, requiring every cited sibling surface to be read only through the displayed rows of chapter 3384, chapter 3547, and chapter 1490;*
9. *local naming, requiring N to certify exactly the rows X, B, G, P, S, R, T, C;*
10. *refusal of host subsets, selected codes, countable choice, quotient set equality, ambient descriptive-set completeness, and measure-theoretic claims.*

No $\mathsf{BorelHierarchy}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Project the carrier of Definition 4020.1. The tuple displays exactly the source row, Borel row, G-delta or open-generator row, Polish row, countable rank schedule, finite readback, transport, replay, and local naming rows.

Rank exposure is read through S and R. A successor stage exposes its predecessor window and constructor tag through the visible schedule, while a limit stage exposes only the finite prefix, position, and readback windows visible to the current consumer.

The generated-set handoff then passes to B over the same X, G, P, S, R route. The sibling chapters supply the only accepted surfaces for the Borel row, the G-delta or open-generator row, and the Polish source.

Finally T, C, N transport, replay, and name the displayed route. Since no row stores a host subset, selected code, countable-choice selector, quotient set equality, completed descriptive-set universe, or measure-theoretic datum, the enumerated obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BorelHierarchy}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelHierarchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4020.1 and Definition 4020.2 seed the hierarchy route over source, Borel, G-delta or open-generator, Polish, rank-schedule, readback, transport, replay, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelHierarchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subsets, selected Borel codes, countable choice, quotient set equality, ambient descriptive-set completeness, measure theory, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rank-schedule exposure, successor and limit-stage replay, generated-set handoff, transport, replay, provenance, local naming, and ledger refusal for BEDC.Derived.BorelHierarchyUp.

Constructive story: A $\mathsf{BorelHierarchy}^{\uparrow}$ packet is generated from a source-space row, BorelSet row, GDeltaSet or open-generator row, Polish source row, countable rank schedule, finite StreamName and RegSeqRat readback, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Chapter 3042

A Concrete Naming Certificate for RegularSequenceLocalization$^{\uparrow}$

Following Bishop and Bridges' regular Cauchy presentation of constructive reals and Kelley's finite-local analysis of neighborhoods, the RegularSequenceLocalization$^{\uparrow}$ packet records a bounded observation window around a displayed regular Cauchy name as first-class NameCert data. It reads finite stream observations through chapter 126, measures the local radius through chapter 291, replays regular rational evidence through chapter 301, and reaches the terminal real seal of chapter 38. The packet is local: it exposes the center, dyadic radius ledger, finite observation windows, rational readback, seal ordering, transport, replay, provenance, and local name before any Real or Completion consumer may use the localized estimate.

Definition 3042.1 (Regular-sequence localization carrier)**.** *A* RegularSequenceLocalization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (a, \rho, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *a is the finite localization center row, naming the regular Cauchy datum around which the local estimate is inspected.*
2. *ρ is the* DyadicRatCore$^{\uparrow}$ *radius ledger, recording the dyadic scale, comparison cells, and slack rows used by the local window.*
3. *W is the finite* StreamName$^{\uparrow}$ *observation-window row, naming exactly the stream positions read at the requested local precision.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row, converting the displayed center, radius ledger, and window observations into regular rational estimate data.*
5. *R is the terminal* Real$^{\uparrow}$ *seal row, available only after a, ρ, W, Q have been replayed.*
6. *H records componentwise* hsame *transport for the center, radius ledger, window observations, regular rational readback, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a local estimate request through a, ρ, W, Q, and then R.*
8. *P is the* Pkg *provenance over* RegularSequenceLocalization$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RegularCauchyEntourageBasis$^{\uparrow}$, RegularCauchyLimitUniqueness$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularSequenceLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted localization packets only through $a, \rho, W, Q, R, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, ambient real completeness, or a global neighborhood system beyond the displayed finite window.

Lean4 ✓ `BEDC.Derived.RegularSequenceLocalizationUp.RegularSequenceLocalizationTasteGate single carrier alignment`

Theorem 3042.2 (Regular-sequence localization NameCert obligations)**.** *For every accepted* RegularSequenceLocal *carrier $L = (a, \rho, W, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceLocalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the localization center, dyadic radius ledger, finite stream observation windows, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming rows;*
2. *radius-ledger stability, requiring every local estimate to read ρ through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale and not through a host real order;*
3. *window-read stability, requiring every accepted observation to pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *row W before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is available;*
4. *readback exactness, requiring the route $a, \rho, W \longmapsto Q \longmapsto R$ before any Real or Completion consumer treats the estimate as localized regular-sequence data;*
5. *transport and replay stability for the same a, ρ, W, Q, R, P, N route under* hsame *transport and* Cont *replay.*

No localization NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4021.1. Its mathematical rows are exactly the center a, dyadic radius ledger ρ, finite window row W, regular rational readback Q, and real seal R.

The radius and window obligations are read before the rational handoff. The ledger ρ supplies only dyadic comparison data, and W supplies only the finite stream observations displayed by the packet.

The readback obligation is then forced through Q. Since Q is the sole $\mathsf{RegSeqRat}^{\uparrow}$ coordinate, the packet cannot replace the local estimate by quotient stream equality, a selected limit, countable choice, trichotomy, or ambient completeness.

Finally the rows H, C, P, N transport, replay, source, and name the same route. They do not add analytic coordinates, so the listed rows exhaust the local NameCert surface. □

Theorem 3042.3 (Regular-sequence localization window stability)**.** *Let $L = (a, \rho, W, Q, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceLocalization}^{\uparrow}$ *carrier. If a Real or Completion consumer requests a localized regular-sequence estimate, then every accepted replay factors through the finite window route*

$$a, \rho, W \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

Consequently the displayed dyadic radius ledger and finite $\mathsf{StreamName}^{\uparrow}$ *observation window remain stable under* hsame *transport and* Cont *replay before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Begin with a localized estimate request. The carrier offers the center row a, the dyadic radius ledger ρ, and the finite window row W as the only rows available before regular rational readback.

Replay through C. The replay opens a, then reads the dyadic comparison cells in ρ, then inspects the finite observations named by W, and only then exposes the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q.

Transport through H preserves this route componentwise. The real seal R and the structural rows P, N are downstream of the same displayed path, so no replay can consume $\mathsf{Real}^{\uparrow}$ data before the local window and radius ledger have been shown. □

Falsifiable prediction: Every accepted $\mathsf{RegularSequenceLocalization}^{\uparrow}$ read used by a Real or Completion consumer displays a finite center row, one $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger, one finite $\mathsf{StreamName}^{\uparrow}$ observation window, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal row, and one local structural NameCert route before the estimate is treated as localized regular-sequence data.

Independence witness: streamname, dyadicratcore, regseqrat, real: $\mathsf{RegularSequenceLocalization}^{\uparrow}$ is not bijective to any listed sibling because it binds a localization center, radius ledger, finite observation windows, regular rational readback, terminal real seal, transport, replay, provenance, and local NameCert row into one local estimate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceLocalization}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceLocalization}^{\uparrow}$ packet is generated from a finite localization center, a $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger, finite $\mathsf{StreamName}^{\uparrow}$ observation windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceLocalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4021.1, Definition 4021.2, and Definition 4021.3 seed the finite local regular-sequence estimate route over center, radius, window, readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceLocalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global real completeness, quotient stream equality, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-ledger stability, finite-window stability, RegSeqRat readback exactness, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceLocaliza

Chapter 3043

A Concrete Naming Certificate for $\mathsf{LocallyUniformConvergence}^{\uparrow}$

Following Bishop and Bridges on constructive analysis, Kelley on compactly generated uniform control, and Bourbaki on local uniform convergence over compacta, the $\mathsf{LocallyUniformConvergence}^{\uparrow}$ packet records the standard compact-window reading of locally uniform convergence as finite NameCert data. It sits after the uniform-tail certificate of chapter 3417, the continuity rows of chapter 3988, and the compact metric completion boundary of chapter 1687. The packet names compact-window rows, uniform-modulus rows, continuous-function rows, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming rows; it does not assert open-cover compactness, selected limiting functions, quotient function-space equality, countable choice, or ambient completeness.

Definition 3043.1 (LocallyUniformConvergence carrier)**.** *A* $\mathsf{LocallyUniformConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, U, F, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-window row, listing each retained compact metric window and its finite inspection addresses.*
2. *U is the uniform-modulus row, assigning to every displayed compact window a shared tail modulus for the family on that window.*
3. *F is the continuous-function row, naming the approximating function data and the endpoint continuity data read on the same windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for all rational tail and distance comparisons used by the window.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after the compact-window, uniform-modulus, continuous-function, and regular-rational rows have been read.*
6. *H records componentwise* hsame *transport for compact windows, moduli, continuous-function rows, rational readbacks, real seals, provenance, and local naming.*
7. *C records displayed* Cont *replay from a local compact-window request through K, U, F, Q, E.*
8. *P is the* Pkg *provenance over* $\mathsf{LocallyUniformConvergence}^{\uparrow}$*,* $\mathsf{UniformConvergence}^{\uparrow}$*,* $\mathsf{CFun}^{\uparrow}$*,* $\mathsf{CompactMetricComplet}$ $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocallyUniformConvergence}^{\uparrow}}$ *row.*
The carrier exports only this compact-window route. It has no coordinate for open-cover compactness, a selected global limit function, quotient equality of functions, or a host supremum norm outside the displayed windows.

Lean4 ✓ `BEDC.Derived.LocallyUniformConvergenceUp.TasteGate.LocallyUniformConvergenceTasteGate single carrier alignment`

Theorem 3043.2 (LocallyUniformConvergence NameCert obligations)**.** *For every accepted* LocallyUniformConverg *carrier $L = (K, U, F, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocallyUniformConvergence}^{\uparrow}}$ *surface consists exactly of compact-window admission through K, shared uniform-modulus admission through U, continuous-function row compatibility through F,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *handoff through E, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 4022.1. The displayed rows are exactly $K, U, F, Q, E, H, C, P, N$, and each consumer-facing request begins with one of the compact windows named by K.

The convergence side is exhausted by U, Q, E. A uniform tail claim on a retained compact window must first read the shared modulus row U, then the regular-rational comparison row Q, and only then the terminal real handoff E.

The continuity side is exhausted by F together with the same compact-window route. The continuous-function rows are consumed on the windows already displayed by K, so endpoint continuity is replayed locally rather than by selecting a host function-space limit.

Transport, continuation, provenance, and local naming preserve this finite route. Since no carrier coordinate stores open-cover compactness, quotient equality of functions, countable choice, an ambient supremum norm, or an external limiting function selector, no local NameCert obligation may use such data. □

Theorem 3043.3 (LocallyUniformConvergence compact route)**.** *Every accepted local convergence read from a* $\mathsf{LocallyUniformConvergence}^{\uparrow}$ *carrier factors through the compact-window route*

$$K \longmapsto U, F \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Consequently the route consumes the existing $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{CFun}^{\uparrow}$, *and* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *packets only through displayed finite rows, not through open-cover compactness, quotient function-space equality, selected limits, countable choice, or ambient completion.*

Proof. Begin with a local convergence request. The request must name a compact metric window in K, so the carrier first fixes the finite portion of the domain on which convergence is being inspected.

Read the uniform and continuity rows on that same window. The uniform-modulus row U supplies the shared tail data, while the continuous-function row F records the approximating and endpoint continuity data that can be replayed on the retained window.

The comparison then passes through Q and E. The $\mathsf{RegSeqRat}^{\uparrow}$ row carries the rational tolerance comparisons, and the $\mathsf{Real}^{\uparrow}$ row is reached only after those comparisons and the compact-window data have been displayed.

Finally use H, C, P, N to transport, replay, source, and name the same route. The cited sibling packets provide the uniform-convergence, continuous-function, and compact-metric-completion rows consumed by the carrier, but none of those reads adds open-cover compactness, a selected global limit, quotient function equality, countable choice, or ambient completion. □

Falsifiable prediction: Deleting the compact-window row K prevents any accepted $\mathsf{LocallyUniformConvergence}^{\uparrow}$ local convergence read, even when uniform-modulus, continuous-function, regular-rational, real-handoff, transport, replay, provenance, and local naming rows remain displayed.

Independence witness: uniform-convergence, continuous-function, compact-metric-completion: none is bijective to the locally uniform convergence packet because only $\mathsf{LocallyUniformConvergence}^{\uparrow}$ binds compact-window rows, uniform-modulus rows, continuous-function rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ handoff, transport, replay, provenance, and local naming into one accepted local convergence route.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyUniformConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyUniformConvergence}^{\uparrow}$ packet is generated from compact-window rows, uniform-modulus rows, continuous-function rows, RegSeqRat readback, Real handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyUniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4022.1, Definition 4022.2, and Definition 4022.3 seed the finite compact-window route for locally uniform convergence over displayed uniform, continuity, completion, regular-rational, and real-handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyUniformConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient function-space equality, selected global limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window admission, uniform-modulus exactness, continuous-function compatibility, RegSeqRat readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.LocallyUniformConvergenceUp.

Chapter 3044

A Concrete Naming Certificate for $\mathsf{BishopMetricCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopMetricCompletion}^{\uparrow}$ packet records constructive metric completion by finite regular Cauchy data rather than by quotient completion objects. It is a sibling of chapter 1506, chapter 2114, and chapter 1612, and it routes its numerical names through chapter 126, chapter 301, and chapter 38. The packet names only the displayed metric source, dense embedding, regular Cauchy windows, separated comparison, transport, replay, provenance, and local NameCert rows.

Definition 3044.1 (Bishop metric completion carrier)**.** *A* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, E, Q, W, S, R, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the constructive metric source row, naming the source points, distance-read windows, and metric comparison ledger used by the completion request.*
2. *E is the dense embedding row from source names into the completion-facing name surface.*
3. *Q is the regular Cauchy family row, displayed as finitely inspectable* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks rather than as a quotient class.*
4. *W is the finite-window schedule, reading the required prefixes through* $\mathsf{StreamName}^{\uparrow}$*.*
5. *S is the separated comparison row, available only after two regular Cauchy windows and their tolerance rows have been displayed.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for distances and terminal comparison readbacks produced by the regular Cauchy family.*
7. *T is the transport row from source-window reads to completion-window reads.*
8. *H records componentwise* hsame *transport for the metric source, dense embedding, regular family, windows, separated comparison, Real seal, transport, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for source inspection, dense embedding, regular-window readback, separated comparison, Real sealing, and transport.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopMetricCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{LocatedMetricCompletion}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopMetricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, Q, W, S, R, T, H, C, P, N$. It has no coordinate for quotient completions, selected representatives, countable-choice schedules, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopMetricCompletionUp.BishopMetricCompletionTasteGate single carrier alignment`

Theorem 3044.2 (Bishop metric completion NameCert obligations)**.** *For an accepted* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *packet $B = (M, E, Q, W, S, R, T, H, C, P, N)$, the local NameCert surface consists of carrier admission, dense-embedding exposure, regular Cauchy family admission, finite-window inspection, separated comparison, Real-seal handoff, source-to-completion transport, componentwise* hsame *stability, displayed* Cont *replay, provenance, and ledger non-escape. Every obligation is discharged through the displayed route*

$$M \longmapsto E \longmapsto Q \longmapsto W \longmapsto S \longmapsto R \longmapsto T$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.BishopMetricCompletionUp.BishopMetricCompletionCarrier namecert obligations`

Proof. Project the carrier of Definition 4023.1. The source metric row M and dense embedding row E must be visible before any regular Cauchy family Q is inspected.

The finite-window row W reads the regular family through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$. The separated comparison row S can then compare only displayed regular windows at the requested tolerance, and the $\mathsf{Real}^{\uparrow}$ seal row R records the resulting distance or comparison readback.

The transport row T keeps the source and completion windows on the same route. Componentwise transport through H and replay through C preserve those rows, while P and N source and name the packet.

Since quotient completions, selected representatives, countable-choice schedules, host equality, and ambient completeness are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 3044.3 (Bishop metric completion finite-window handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *packet factors through the source metric row, dense embedding row, regular Cauchy family row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, separated comparison row,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local NameCert rows displayed by B. The handoff exports a finite constructive completion surface, not a quotient completion, selected representative, countable-choice schedule, host equality principle, or ambient Real-completeness theorem.*

Proof. Begin with Definition 4023.2. It places every accepted read on the route $M, E, Q, W, S, R, T, H, C, P, N$.

Use the sibling completion chapters only through their visible rows. The metric-completion, located-metric-completion, and separated-completion surfaces supply completion vocabulary, located source comparison, and separated zero-distance comparison, but the Bishop packet receives them through M, E, Q, W, S, R, T and the structural rows.

The finite windows W and readbacks Q are the only access points to the regular Cauchy family. Therefore a downstream completion consumer can inspect a finite prefix and the corresponding separated comparison, but it cannot select a representative or collapse names by host equality.

The $\mathsf{Real}^{\uparrow}$ row R, transport row T, replay row C, provenance row P, and local name N close the handoff. No excluded object is a carrier coordinate, so the finite-window route is the whole exported completion surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopMetricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopMetricCompletion}^{\uparrow}$ packet is generated from a constructive metric source row, dense embedding row, regular Cauchy family row, finite StreamName windows, RegSeqRat readbacks, separated comparison row, RealUp seal, source-to-completion transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4023.1, Definition 4023.2, and Definition 4023.3 seed the constructive metric-completion carrier, NameCert obligation surface, and finite-window handoff over MetricCompletion, LocatedMetricCompletion, SeparatedCompletion, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, dense-embedding exposure, regular Cauchy window admission, separated comparison, Real sealing, transport, replay, provenance, and local NameCert non-escape for $\mathsf{BishopMetricCompletion}^{\uparrow}$.

Chapter 3045

A Concrete Naming Certificate for $\mathsf{LocatedCompactness}^{\uparrow}$

Following Bishop–Bridges/Kelley-style located compactness, the $\mathsf{LocatedCompactness}^{\uparrow}$ packet records compact neighbourhood control by finite radius witnesses rather than by open-cover selection. It sits between the metric carrier of chapter 57, the compact-metric witness of chapter 129, the local support window of chapter 1726, the center-radius boundary of chapter 1451, and the finite observation schedule of chapter 126. Completion-facing consumers receive a finite located-neighbourhood interface, not a host compact subset, selected subcover, quotient completion, countable-choice schedule, or ambient real-completeness principle.

Definition 3045.1 (Located compactness carrier)**.** *A* $\mathsf{LocatedCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, K, B, U, W, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *source row, naming the carrier, distance witness, and local classifier used by every radius request.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *witness row for the displayed neighbourhood or closed-ball window.*
3. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row naming the center, radius, non-strict membership comparison, and radius ledger of the inspected window.*
4. *U is the* $\mathsf{LocallyCompact}^{\uparrow}$ *support row, recording that the compact witness is attached to a displayed local neighbourhood rather than to a global host compactness claim.*
5. *W is the located-neighbourhood radius row, recording the finite positive-radius requests, comparison outcomes, and compact-witness handoffs available to completion consumers.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row through which finite radius requests, compact-witness reads, and closed-ball inspections are scheduled.*
7. *H records componentwise* hsame *transport for metric source, compact witness, closed-ball boundary, local support, located-neighbourhood radius, stream schedule, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from finite stream windows through the closed-ball boundary, local compact support, compact metric witness, and located-radius handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten displayed rows. It has no coordinate for open-cover compactness, selected finite subcovers, quotient completion equality, choice-selected compact witnesses, host powersets, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3045.2 (Located compactness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactness}^{\uparrow}$ *carrier $L = (M, K, B, U, W, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactness}^{\uparrow}}$ *surface consists exactly of metric-source admission, compact-metric witness admission, closed-ball boundary exposure, local compact support, finite located-neighbourhood radius requests, finite* $\mathsf{StreamName}^{\uparrow}$ *scheduling, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must pass through $M, K, B, U, W, S, H, C, P, N$ before using located compactness.*

Lean4 ✓ `BEDC.Derived.LocatedCompactnessUp.LocatedCompactnessCarrier namecert obligations`

Proof. Project the carrier of Definition 4024.1. The ten rows displayed there are the only rows visible to the local classifier, so carrier admission is already confined to $M, K, B, U, W, S, H, C, P, N$.

Read the analytic rows componentwise. The metric source M supplies the carrier and distance witness, B supplies the center-radius boundary, U supplies the local compact support, K supplies the compact-metric witness, and W supplies the located-neighbourhood radius requests.

The scheduling and structural rows preserve the same finite route. Stream windows in S expose only finite requests, H transports those rows componentwise, C replays only the displayed handoff, and P, N source and name the packet. Since no additional coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 3045.3 (Located compactness finite-net handoff)**.** *Every L10 completion or compact-metric consumer of an accepted* $\mathsf{LocatedCompactness}^{\uparrow}$ *carrier receives only the finite handoff*

$$\mathsf{Met}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{LocallyCompact}^{\uparrow},\quad \mathsf{MetricClosedBall}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{NameCert}_{\mathsf{LocatedCompactness}^{\uparrow}}$$

through the displayed rows $M, K, B, U, W, S, H, C, P, N$. The handoff provides finite neighbourhood-radius requests, compact-witness rows, closed-ball comparisons, local-support rows, and NameCert provenance; it exports no open-cover compactness, selected dense points, quotient completion equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the obligation surface of Definition 4024.2. A completion consumer first reads the metric row, closed-ball row, local compact support row, compact witness row, and located-radius row as one finite packet.

The finite request order is supplied by S. A radius or compact-witness inspection can occur only after a displayed $\mathsf{StreamName}^{\uparrow}$ window has exposed the request, and the replay row C sends that request through B, U, K, and W without adding a host compactness object.

Finally use the structural rows H, P, N. They transport, source, and name the same finite handoff for compact-metric and completion consumers. Because the packet has no row for open covers, selected dense points, quotient completions, countable choice, or ambient real completeness, the exported surface is exactly the finite located-neighbourhood handoff above. □

Theorem 3045.4 (Located compactness radius stability)**.** *For every accepted* $\mathsf{LocatedCompactness}^{\uparrow}$ *carrier* $L = (M, K, B, U, W, S, H, C, P, N)$*,* hsame *transport of the metric source, compact witness, closed-ball boundary, local support, located-radius request,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* Cont *replay,* Pkg *provenance, and local* NameCert *row preserves the finite located-neighbourhood handoff for every completion-facing consumer. The transported read remains the same finite route through*

$$M, K, B, U, W, S, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.LocatedCompactnessUp.LocatedCompactnessCarrier radius transport`

Proof. Project the transport row H from Definition 4024.1. It records componentwise transport for the metric source, compact witness, closed-ball boundary, local support, located-radius request, stream schedule, replay, provenance, and local naming rows.

Use Definition 4024.2 to identify those transported rows as the whole local NameCert surface. No transported completion-facing read can detach the radius request from $M, K, B, U, W, S, C, P, N$.

Finally apply the finite-net handoff of Definition 4024.3. The consumer route remains finite and choice-free, so transport preserves the located-neighbourhood handoff without introducing open-cover compactness, selected dense points, quotient completion equality, countable choice, or ambient real completeness. □

Falsifiable prediction: A completion-facing consumer that reads $\mathsf{LocatedCompactness}^{\uparrow}$ without displaying the metric source, compact witness, closed-ball boundary, local compact support, finite located-radius request, StreamName schedule, componentwise transport, continuation replay, package provenance, and local NameCert rows refutes the carrier surface.

Independence witness: metric, compactmetric, locallycompact, metricclosedball, streamname: no listed sibling is bijective to $\mathsf{LocatedCompactness}^{\uparrow}$ because this packet binds source metric data, compact witnesses, closed-ball boundaries, local support, located-radius requests, finite scheduling, transport, replay, provenance, and local naming in one completion-facing interface.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedCompactness}^{\uparrow}$ packet is generated from metric source rows, compact-metric witnesses, closed-ball boundaries, local compact support rows, finite located-neighbourhood radius requests, StreamName schedules, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4024.1, Definition 4024.2, and Definition 4024.3 seed the finite located-neighbourhood compactness interface for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite subcovers, quotient completion equality, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface for BEDC.Derived.LocatedCompactnessUp.

Chapter 3046

A Concrete Naming Certificate for $\mathsf{FourierTransform}^{\uparrow}$

Following Fourier and Stein–Shakarchi on the transform side of harmonic analysis, the $\mathsf{FourierTransform}^{\uparrow}$ packet records the finite transform-specific read that consumes the finite-observation $\mathsf{Fourier}^{\uparrow}$ surface of chapter 124, the integral witness rows of chapter 123, the inner-product probe rows of chapter 86, the real seal rows of chapter 38, and the product-tail handoff of chapter 409. It names transform-sample windows, kernel probes, integral witnesses, real seals, convolution handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming as finite BEDC rows. The chapter does not assert Plancherel, inversion, convergence closure, quotient equality of functions, or a selected ambient transform.

Definition 3046.1 (FourierTransform carrier)**.** *A* $\mathsf{FourierTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, K, I, R, V, H, C, P, N)$$

with the following displayed rows:

1. *W is the transform-sample window row, listing the finite source windows, frequency addresses, and retained sample requests read from the* $\mathsf{Fourier}^{\uparrow}$ *finite-observation surface.*
2. *K is the kernel/probe row, recording the displayed oscillatory kernel tags, inner-product probes, and source-domain probes used by the retained transform samples.*
3. *I is the integral-witness row, requiring each retained sample to name its* $\mathsf{Integral}^{\uparrow}$ *witness and the finite approximation ledger used by that witness.*
4. *R is the real-seal row, reached only after the transform-sample window, kernel/probe row, and integral-witness row have been replayed.*
5. *V is the convolution handoff row, reading* $\mathsf{CauchyConvolution}^{\uparrow}$ *only through the finite product-tail packet needed by convolution-facing transform consumers.*
6. *H records componentwise* hsame *transport for transform windows, kernel/probe rows, integral witnesses, real seals, convolution handoff rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite transform request through W, K, I, R, V.*
8. *P is the* Pkg *provenance over* $\mathsf{FourierTransform}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvolution}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{FourierTransform}^\uparrow}$ *row.*
The classifier compares accepted packets only through the component rows $W, K, I, R, V, H, C, P, N$. It has no coordinate for equality of host transforms, inversion, Plancherel, convergence closure, selected limiting integrals, or ambient completeness.

Lean4 (definition) `BEDC.Derived.FourierTransformUp.FourierTransformUp`

Theorem 3046.2 (FourierTransform NameCert obligations)**.** *For every accepted* $\mathsf{FourierTransform}^\uparrow$ *carrier $T = (W, K, I, R, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FourierTransform}^\uparrow}$ *surface consists exactly of transform-sample window admission through W, kernel and probe admission through K, integral-witness readback through I, terminal* $\mathsf{Real}^\uparrow$ *seal admission through R, convolution handoff through V, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4025.1. Its public rows are exactly $W, K, I, R, V, H, C, P, N$, so every local naming duty begins with a finite transform-sample window rather than with a host transform.

The analytic source rows are then read in order. The row K exposes the kernel/probe data and inner-product probes, while I attaches each retained sample to an integral witness. The real seal row R is reached only after those rows have been displayed.

The convolution-facing part is confined to V. It imports only the finite product-tail handoff already named by $\mathsf{CauchyConvolution}^\uparrow$, and it does not add an inversion theorem, Plancherel identity, convergence closure, or quotient equality of functions.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores a selected ambient transform or a stronger analytic theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 3046.3 (FourierTransform convolution handoff)**.** *Every convolution-facing read from an accepted* $\mathsf{FourierTransform}^\uparrow$ *carrier factors through*

$$W, K, I \longmapsto R \longmapsto V \longmapsto H, C, P, N.$$

The read may consume $\mathsf{Fourier}^\uparrow$ *finite observations,* $\mathsf{Integral}^\uparrow$ *witnesses,* $\mathsf{InnerProduct}^\uparrow$ *probes,* $\mathsf{Real}^\uparrow$ *seals, and the* $\mathsf{CauchyConvolution}^\uparrow$ *product-tail handoff, but it exports only the finite transform-sample route displayed by the carrier.*

Proof. Start with the transform sample. The window row W fixes the retained source and frequency addresses, and the kernel/probe row K records the oscillatory kernel tags and inner-product probes used at those addresses.

Attach the integral and real rows next. The integral-witness row I supplies the finite approximation ledger for the retained sample, and the real-seal row R records the terminal real read obtained from that ledger.

Only after this route is displayed can the convolution row V be consumed. Its source is the finite product-tail handoff of $\mathsf{CauchyConvolution}^\uparrow$, so convolution-facing consumers receive a named handoff row rather than a host multiplication theorem or an equality of transforms.

The structural rows H, C, P, N preserve the same factorization under componentwise transport, replay, provenance, and local naming. Therefore the handoff exports the displayed transform-sample route only, with Plancherel, inversion, convergence closure, quotient function equality, and selected ambient transforms outside the packet. □

Falsifiable prediction: Deleting the transform-sample window row W prevents any accepted $\mathsf{FourierTransform}^{\uparrow}$ sample read, even when kernel/probe, integral-witness, real-seal, convolution handoff, transport, replay, provenance, and local naming rows remain displayed.

Independence witness: Fourier finite observations, integral witnesses, inner-product probes, real seals, and Cauchy convolution handoffs are not interchangeable with the $\mathsf{FourierTransform}^{\uparrow}$ packet because only $\mathsf{FourierTransform}^{\uparrow}$ binds transform-sample windows, kernel/probe rows, integral witnesses, real seals, convolution handoff, componentwise hsame, displayed Cont, Pkg, and local NameCert into one accepted transform route.

Closure status for $\mathsf{NameCert}_{\mathsf{FourierTransform}^{\uparrow}}$.

Constructive story: A $\mathsf{FourierTransform}^{\uparrow}$ packet is generated from transform-sample windows, kernel/probe rows, integral witnesses, real seals, a convolution handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FourierTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4025.1, Definition 4025.2, and Definition 4025.3 seed the finite transform-sample route over Fourier finite observations, integral witnesses, inner-product probes, real seals, and convolution handoff data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FourierTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Plancherel, inversion, convergence closure, quotient function equality, selected ambient transforms, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transform-window admission, kernel/probe exactness, integral-witness readback, real-seal handoff, convolution handoff, transport, replay, provenance, and local naming for BEDC.Derived.FourierTransformUp.

Chapter 3047

A Concrete Naming Certificate for $\mathsf{CauchyCompletionAdjunctionTriangle}^{\uparrow}$

Following Bishop and Bridges on completion and Mac Lane on adjunction triangular identities, the $\mathsf{CauchyCompletionAdjunctionTriangle}^{\uparrow}$ packet records the L10 completion handoff that keeps the completion functor, the regular Cauchy adjunction, the universal property, and the idempotence boundary visible in one finite certificate. It sits beside chapter 423, chapter 3882, chapter 2381, chapter 3376, and chapter 3888. The packet names a triangular completion route; it does not assert quotient completion equality, selected limits, host functor extensionality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3047.1 (CauchyCompletionAdjunctionTriangle carrier)**.** *A* $\mathsf{CauchyCompletionAdjunctionTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, A, U, I, R, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row naming the source-to-completion functorial surface.*
2. *A is the* $\mathsf{CauchyRegularCompletionAdjunction}^{\uparrow}$ *row naming the regular Cauchy adjunction boundary.*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row that exposes the extension and uniqueness handoff.*
4. *I is the completion idempotence row, read through the completion idempotence and metric completion idempotence chapters.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row carrying regular rational completion readback.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window for the regular Cauchy route.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the displayed completion windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, A, U, I, R, W, D have been displayed.*
9. *H stores componentwise* hsame *transport for the functor, adjunction, universal-property, idempotence, regular readback, window, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay for the triangular route from functor and adjunction rows to universal handoff, idempotence boundary, and Real-facing seal.*

11. *P is the* Pkg *provenance over* CauchyCompletionAdjunctionTriangle$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, CauchyRegularCompletionAdjunction$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunctionTriangle}^{\uparrow}}$ *row.*

The classifier accepts only packets whose completion-facing read traverses the displayed rows $F, A, U, I, R, W, D, E, H$ It has no coordinate for quotient completions, selected limits, host equality of completed objects, unrestricted functor extensionality, countable choice, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CauchyCompletionAdjunctionTriangleUp.CauchyCompletionAdjunctionTriangleUp`
Lean4 ✓ `BEDC.Derived.CauchyCompletionAdjunctionTriangleUp.TasteGate.CauchyCompletionAdjunctionTriangleU`
`single carrier alignment`

Theorem 3047.2 (CauchyCompletionAdjunctionTriangle NameCert obligations)**.** *For every accepted* CauchyCompletionAdjunctionTriangle$^{\uparrow}$ *carrier $T = (F, A, U, I, R, W, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunctionTriangle}^{\uparrow}}$ *obligations are exactly carrier admission, functor-row visibility, regular adjunction visibility, universal-property handoff, idempotence-boundary retention, regular-rational and stream-window readback, dyadic tolerance compatibility, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionAdjunctionTriangleUp.CauchyCompletionAdjunctionTriangleNamecertObl`

Proof. Project the carrier row by row from Definition 4026.1. Carrier admission exposes precisely the twelve displayed rows, so every local obligation has one visible coordinate.

Read the completion triangle in order. The functor row F and regular adjunction row A are available before the universal-property row U, and the idempotence row I is read as a boundary on reusing the same completion surface.

The Real-facing part is downstream. Rows R, W, D provide regular rational readback, finite windowing, and dyadic tolerance data before the terminal seal E is visible.

Finally, H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate supplies quotient completion equality, selected limits, host functor extensionality, countable choice, or ambient completeness, the displayed rows exhaust the local NameCert obligations. □

Theorem 3047.3 (CauchyCompletionAdjunctionTriangle universal handoff)**.** *Every accepted* CauchyCompletionAd *carrier hands a completion-facing consumer from the* CauchyCompletionFunctor$^{\uparrow}$ *row and the* CauchyRegularComplet *row to the* CompletionUniversalProperty$^{\uparrow}$ *row before any idempotence or Real-facing read is exported. The handoff is the finite route*

$$F, A \longmapsto U \longmapsto I, R, W, D, E, H, C, P, N$$

and not a quotient completion, selected limit, host equality of extensions, or ambient completeness assertion.

Proof. Begin with the functor and adjunction rows in the carrier. They are separate coordinates, so a consumer cannot read the universal-property row as a detached host theorem.

Project U. It is the only row that records extension and uniqueness handoff for the displayed completion route, and it is read after F and A have fixed the source completion surface.

The idempotence and Real-facing rows are downstream of that handoff. Row I records reuse of the same completion boundary, while R, W, D, E provide the finite regular-rational, window, dyadic, and Real seal route.

Rows H, C, P, N preserve the same finite path. Thus the universal handoff is exactly the displayed route and cannot become quotient completion equality, selected-limit data, host extension equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionAdjunctionTriangleUp.CauchyCompletionAdjunctionTriangleUniversalHa`

Theorem 3047.4 (CauchyCompletionAdjunctionTriangle idempotence boundary)**.** *For every accepted* CauchyCompletionAdjunctionTriangle$^{\uparrow}$ *carrier, the idempotence read I is a boundary on reusing the already displayed completion route $F, A, U, R, W, D, E, H, C, P, N$. It cannot identify completed objects by host equality, erase the universal-property row, select a limit representative, or assert ambient completeness of* Real$^{\uparrow}$.

Proof. Open the accepted packet and isolate I. The carrier definition places I after the completion functor, regular adjunction, and universal-property rows, not as an independent completed-object equality.

Use the universal handoff theorem. It forces the route through F, A, U before I can be consumed by a completion-facing reader.

The remaining rows R, W, D, E, H, C, P, N show what the idempotence boundary may preserve: regular rational readback, finite observation windows, dyadic tolerances, the Real seal, transport, replay, provenance, and local naming. No row contains host equality of completions, selected representatives, erased universal handoff data, or ambient completeness. □

Falsifiable prediction: A completion consumer that exports a Cauchy-completion triangle without displaying the functor, regular adjunction, universal-property, idempotence, RegSeqRat, StreamName, DyadicRatCore, Real seal, transport, replay, provenance, and local naming rows is not reading a CauchyCompletionAdjunctionTriangle$^{\uparrow}$ packet.

Independence witness: cauchycompletionfunctor, cauchyregularcompletionadjunction, completionidempotence, cauchycompletionreflection, metriccompletionidempotence: CauchyCompletionAdjunctionTriangle is not bijective to any listed sibling because it jointly carries functor, adjunction, universal-property, idempotence, regular-rational, window, dyadic, Real seal, transport, replay, provenance, and local naming rows.

Closure status for NameCert$_{\text{CauchyCompletionAdjunctionTriangle}^{\uparrow}}$.

Constructive story: A CauchyCompletionAdjunctionTriangle$^{\uparrow}$ packet is generated from a CauchyCompletionFunctor row, a CauchyRegularCompletionAdjunction row, a CompletionUniversalProperty row, a completion idempotence row, RegSeqRat readback, StreamName windows, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCompletionAdjunctionTriangle}^{\uparrow}}$, seed)

Scope closed: Definition 4026.1, Definition 4026.2, Definition 4026.3, and Definition 4026.4 seed the finite triangular handoff for the L10 Cauchy completion route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionAdjunctionTriangle}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CauchyCompletionAdjunctionTriangleUp.CauchyCompletionAdjunctionTriangleNamecertObligati`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host functor extensionality, countable choice, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, universal-property handoff, idempotence boundary, RegSeqRat and StreamName readback, DyadicRatCore compatibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionAdjunctionTriangleUp.

Chapter 3048

A Concrete Naming Certificate for $\mathsf{MonotoneCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{MonotoneCauchyCriterion}^{\uparrow}$ packet records the bounded monotone Cauchy criterion as finite BEDC data rather than as an ambient completeness principle. It sits after the monotone source surface of chapter 438, the bounded witness route of chapter 535, the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes a displayed regular Cauchy route from bounded monotone data; it does not select a limit, quotient real names, import trichotomy, use open-cover compactness, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3048.1 (MonotoneCauchyCriterion carrier)**.** *A* $\mathsf{MonotoneCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, S, T, M, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded monotone source row, including the inspected monotone observations and their located upper-bound guard.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite windows read from the source.*
3. *T is the tail-window schedule row that turns a dyadic request into a displayed tail window.*
4. *M is the monotone-tail witness row, recording that later observations stay inside the same bounded monotone route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for radii, slack, monotone comparisons, and upper-bound traps.*
6. *L is the located upper-bound trap row tying each selected tail window to a finite lower observation and a located upper guard.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same window, tail, witness, ledger, and trap data.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular-rational readback has been displayed.*
9. *H records componentwise* hsame *transport for the bounded source, schedule, tail window, monotone witness, dyadic ledger, located trap, readback, seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a criterion request through* $B, S, T, M, D, L, R, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{MonotoneCauchyCriterion}^{\uparrow}$, $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, T, M, D, L, R, E, H, C, P, N$. *It has no coordinate for a selected limiting representative, quotient real equality, host real equality, trichotomy, open-cover compactness, choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchyCriterionUp.MonotoneCauchyCriterionTasteGate single carrier alignment`

Theorem 3048.2 (MonotoneCauchyCriterion NameCert obligations)**.** *For every accepted* MonotoneCauchyCriterio *carrier* $K = (B, S, T, M, D, L, R, E, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchyCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, bounded-window exposure through* B, S, T, *monotone-tail witness exposure through* M, *dyadic ledger exactness through* D, *located upper-bound trap exposure through* L, *regular-rational readback through* R, *Real seal nonescape through* E, *componentwise* hsame *transport through* H, *displayed* Cont *replay through* C, Pkg *provenance through* P, *and local naming through* N.

No obligation may be discharged by selected limits, quotient real equality, trichotomy, open-cover compactness, choice, host real equality, or ambient completeness.

Proof. Project the carrier of Definition 4027.1. The displayed rows are exactly $B, S, T, M, D, L, R, E, H, C, P, N$, so admission exposes only the bounded monotone source, finite schedules, tail witness, dyadic ledger, located trap, readback, seal, transport, replay, provenance, and naming data.

The bounded-window rows are B, S, T. They force every request to pass first through the inspected source and a finite scheduled tail window before any Cauchy-facing witness can be read.

The witness and numerical rows are M, D, L, R. The monotone-tail witness stays attached to the dyadic tolerance ledger and located trap, and the regular-rational readback is produced from that same finite route.

Finally the seal and structural rows E, H, C, P, N preserve and name the route. Since the excluded analytic objects are absent from the carrier, they cannot become local NameCert obligations. □

Theorem 3048.3 (MonotoneCauchyCriterion bounded-window route)**.** *Every criterion-facing read exported by an accepted* $\mathsf{MonotoneCauchyCriterion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MonotoneCauchy}^{\uparrow} \longmapsto \mathsf{BoundedMonotoneCauchyWitness}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \mapsto$$

The route first exposes bounded monotone source rows and finite tail windows, then reads the monotone-tail witness, dyadic tolerance ledger, located upper-bound trap, regular-rational readback, and terminal real seal. It exports no selected limit, quotient real equality, host real equality, trichotomy, open-cover compactness, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a criterion-facing read of $K = (B, S, T, M, D, L, R, E, H, C, P, N)$. Carrier projection exposes the bounded monotone source row B, the finite $\mathsf{StreamName}^{\uparrow}$ schedule S, and the tail-window row T before the witness row can be consumed.

Compose the bounded monotone witness route with the monotone Cauchy surface. The existing Lean touchpoint `BEDC.Derived.BoundedMonotoneCauchyWitnessUp.BoundedMonotoneCauchyWitnessCarrier_`

records the same source-to-tail-to-witness-to-ledger-to-seal chain at the finite BHist, Cont, and Pkg level.

The dyadic ledger D and located trap L then feed the regular-rational readback R. Only after R is displayed can the terminal $\mathsf{Real}^{\uparrow}$ seal E be read, and H, C, P, N transport, replay, source, and name the same finite packet.

Because no excluded completion, quotient, selection, trichotomy, open-cover compactness, choice, or host-real coordinate occurs in the carrier, every exported criterion read is exhausted by the displayed bounded-window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneCauchyCriterion}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MonotoneCauchyCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 4027.1, Definition 4027.2, and Definition 4027.3 seed the bounded monotone Cauchy criterion route from MonotoneCauchyUp and BoundedMonotoneCauchyWitnessUp rows through StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, and the RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MonotoneCauchyCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient real equality, trichotomy, open-cover compactness, choice, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window exposure, monotone-tail witness exposure, dyadic ledger exactness, located trap exposure, readback exactness, Real seal nonescape, transport, and replay proofs for BEDC.Derived.MonotoneCauchyCriterionUp.

Constructive story: A $\mathsf{MonotoneCauchyCriterion}^{\uparrow}$ packet is generated from bounded monotone source rows, finite StreamName windows, a tail-window schedule, a monotone-tail witness, a DyadicRatCore tolerance ledger, a located upper-bound trap, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3049

A Concrete Naming Certificate for $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ packet records paired regular-Cauchy difference estimates as finite rational-window data rather than as equality in a completed real quotient. It sits over the regular sequence route of chapter 301, the finite stream interface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the tail envelope comparison route of chapter 3992. The packet supplies completion and Real algebra consumers with one finite difference-bound surface; it does not assert quotient equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3049.1 (Regular Cauchy difference-bound carrier)**.** *A* $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, Y, W, D, E, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, read only through finite rational windows.*
2. *Y is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, displayed on the same request schedule as X.*
3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window family exposing the compared prefixes.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and subtraction ledger for the displayed window.*
5. *E is the* $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ *envelope row bounding the paired tails after W and D have been read.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed difference bound.*
7. *H records componentwise* hsame *transport for the two regular sources, the shared windows, the dyadic ledger, the envelope comparison, the Real seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for window inspection, tolerance subtraction, tail-envelope comparison, Real sealing, and structural transport.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDifferenceBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, E, R, H, C, P, N$. It has no coordinate for quotient real equality, selected representatives, countable-choice moduli, trichotomy, host subtraction, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDifferenceBoundUp.RegularCauchyDifferenceBoundTasteGate single carrier alignment`

Theorem 3049.2 (Regular Cauchy difference-bound NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ *packet $B = (X, Y, W, D, E, R, H, C, P, N)$, the local NameCert surface consists exactly of carrier admission for the two regular rational sources, shared finite-window inspection, dyadic difference budgeting, tail-envelope comparison, Real-seal handoff, componentwise transport, displayed replay, provenance, and local naming. Every accepted bound read follows*

$$X, Y \longmapsto W \longmapsto D \longmapsto E \longmapsto R$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.RegularCauchyDifferenceBoundUp.RegularCauchyDifferenceBoundCarrier namecert obligations`

Proof. Project the carrier of Definition 4028.1. The two source rows X, Y are the only regular-rational inputs, and they are read on the shared window row W.

The dyadic ledger D supplies the displayed tolerance and subtraction budget for that same window. The tail-envelope row E can therefore compare only the paired tails already exposed by X, Y, W, D.

The terminal Real row R is downstream of the envelope comparison, while H, C, P, N only transport, replay, source, and name the same finite route. Since the carrier has no quotient equality, selected representative, countable-choice, host-subtraction, or ambient-completeness coordinate, the listed rows exhaust the local certificate. □

Theorem 3049.3 (Regular Cauchy difference-bound RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ *packet receives the paired difference estimate only through the displayed route from X, Y to W, D, E, R. The handoff preserves the finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{CauchyTailEnvelopeComparison}^{\uparrow}$ *envelope row, and it exports no quotient real equality, selected limit, countable-choice schedule, trichotomy, host real subtraction, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDifferenceBoundUp.RegularCauchyDifferenceBoundRegSeqRatHandoff`

Proof. Begin with the NameCert obligations of Definition 4028.2. They place every accepted read on the route $X, Y, W, D, E, R, H, C, P, N$.

A $\mathsf{RegSeqRat}^{\uparrow}$ consumer can inspect only the two displayed regular sources and the finite windows in W. It must therefore read the same dyadic ledger D before any bound is available.

A $\mathsf{Real}^{\uparrow}$ consumer sees the terminal row R only after the tail-envelope comparison E has been consumed. The structural rows preserve this route, so no excluded equality, selector, choice, host-subtraction, or completeness object can be exported. □

Falsifiable prediction: Every $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ read factors through two RegSeqRat source rows, a shared StreamName window row, a DyadicRatCore tolerance ledger, a CauchyTailEnvelopeComparison envelope row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchy-tail-envelope-comparison: $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries paired regular sources, shared finite windows, dyadic difference budgeting, tail-envelope comparison, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDifferenceBound}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a shared StreamName window row, a DyadicRatCore tolerance and subtraction ledger, a CauchyTailEnvelopeComparison row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDifferenceBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4028.1, Definition 4028.2, and Definition 4028.3 seed the finite paired regular-Cauchy difference-bound carrier, certificate surface, and RegSeqRat-to-Real handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDifferenceBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, host real subtraction, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, paired regular-source exposure, shared-window exactness, dyadic difference budgeting, tail-envelope comparison, Real sealing, transport, replay, provenance, and local NameCert non-escape for $\mathsf{RegularCauchyDifferenceBound}^{\uparrow}$.

Chapter 3050

A Concrete Naming Certificate for $\mathsf{LocallyCompactHausdorff}^{\uparrow}$

Following Kelley and Bourbaki on locally compact Hausdorff spaces, the $\mathsf{LocallyCompactHausdorff}^{\uparrow}$ packet records the point-local compact-neighbourhood and point-separation rows that a constructive topology consumer may inspect without invoking open-cover compactness or choice of neighbourhood bases. It sits over the indexed-open surface of $\mathsf{Topology}^{\uparrow}$, the separated uniform route of chapter 3775, the compact-metric window of chapter 129, the formal-ball observation interface of chapter 1510, and the point-local metric compactness packet of chapter 3787.

Definition 3050.1 (Locally compact Hausdorff carrier)**.** *A* $\mathsf{LocallyCompactHausdorff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, U, x, V, K, F, S, H, C, P, N)$$

with the following visible rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{HausdorffUniformSpace}^{\uparrow}$ *source row, including indexed open reads, separated neighbourhood reads, and the point classifier used by topology consumers.*
2. *U is a neighbourhood row around the inspected point x, displayed through the same topology or separated uniform source.*
3. *V is the compact neighbourhood inclusion row, witnessing that the inspected neighbourhood is carried by the compact window K.*
4. *K is a finite compactness window read through* $\mathsf{CompactMetric}^{\uparrow}$ *or a compact formal-ball window from* $\mathsf{FormalBall}^{\uparrow}$*.*
5. *F is the* $\mathsf{FormalBall}^{\uparrow}$ *or finite-window replay row used when a consumer requests radius-indexed local observations inside K.*
6. *S is the Hausdorff separation row: distinct point reads are separated only by displayed neighbourhood or entourage witnesses over T.*
7. *H records componentwise* hsame *transport for the topology or uniform source, inspected point, local neighbourhood, compact window, formal-ball window, separation row, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from local topology reads to compact-window, formal-ball, and Hausdorff-separation consumers.*

9. *P is the* Pkg *provenance over* LocallyCompactHausdorff$^{\uparrow}$, Topology$^{\uparrow}$, HausdorffUniformSpace$^{\uparrow}$, CompactMetric$^{\uparrow}$, FormalBall$^{\uparrow}$, LocallyCompactMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactHausdorff}^{\uparrow}}$ *row.*

The packet has no coordinate for arbitrary open-cover compactness, selected neighbourhood bases, quotient point equality, excluded middle, countable choice, or ambient local compactness outside the displayed carrier.

Lean4 ✓ `BEDC.Derived.LocallyCompactHausdorffUp.LocallyCompactHausdorffTasteGate single carrier alignment`

Theorem 3050.2 (LocallyCompactHausdorff carrier admission)**.** *For every accepted* LocallyCompactHausdorff$^{\uparrow}$ *packet $L = (T, U, x, V, K, F, S, H, C, P, N)$, carrier admission is rowwise over the displayed topology or separated-uniform source, inspected point, local neighbourhood row, compact-window inclusion, formal-ball or compact-metric finite window, Hausdorff separation row, componentwise transport, replay, provenance, and local name. Admission cannot be obtained from an unrecorded host topology, an open-cover compactness theorem, a selected basis, quotient point equality, or ambient local compactness.*

Proof. Project the carrier of Definition 4029.1. The packet exposes exactly $T, U, x, V, K, F, S, H, C, P, N$, so every accepted read begins with the topology or separated-uniform source and the inspected point.

Next read the compact side. The row V ties the neighbourhood U to the compact window K, while F supplies only the finite formal-ball or compact-metric observations cited by chapter 129 and chapter 1510.

Finally read the structural rows H, C, P, N. They transport, replay, record provenance, and bind the local name for the same finite packet. Since the carrier contains no host topology, open-cover compactness, selected basis, quotient equality, or ambient local-compactness coordinate, none can enter through carrier admission. □

Theorem 3050.3 (LocallyCompactHausdorff compact-neighbourhood nonescape)**.** *Every local compact-neighbourhood read of an accepted* LocallyCompactHausdorff$^{\uparrow}$ *packet factors through*

$$T, U, x, V, K, F \longmapsto H, C, P, N.$$

The read may use compact-metric and formal-ball windows, and may compare with the LocallyCompactMetric$^{\uparrow}$ *point-local route when a metric presentation is displayed. When completion-facing readers consume the local compact neighbourhood, the compact-window row may be refined through the finite located-neighbourhood radius handoff of chapter 4024, not through open-cover compactness. The read cannot promote the window to arbitrary open-cover compactness, a global compactness theorem, a selected local base, quotient completion equality, or ambient completeness.*

Proof. Begin with the neighbourhood rows T, U, x, V. They name the source topology or separated uniform space, the inspected point, and the local neighbourhood inclusion before any compactness consumer can inspect the packet.

Use the compact-window rows K and F. The compact metric certificate of chapter 129 and the formal-ball interface of chapter 1510 provide finite windows only; the metric local-compactness sibling chapter 3787 is read as a displayed point-local comparison, not as an ambient theorem.

Finally replay through H, C, P, N. These rows keep the compact neighbourhood inside the same finite carrier route, so open-cover compactness, selected neighbourhood bases, quotient completion equality, global compactness, and ambient completeness have no row from which to escape. □

Theorem 3050.4 (LocallyCompactHausdorff separation transport)**.** *For every accepted* $\mathsf{LocallyCompactHausdorff}^{\uparrow}$ *packet, Hausdorff separation is transported only through the displayed row S over the same topology or separated-uniform source T and the same structural route H, C, P, N. If two point reads are moved by* hsame*, their separated-neighbourhood or separated-entourage witnesses are moved componentwise with the compact-neighbourhood rows; no host equality, quotient identification, global apartness principle, or classical point separation is added.*

Proof. Start with the separated source. When T is read through $\mathsf{HausdorffUniformSpace}^{\uparrow}$, the separated-uniform packet supplies the visible separation route; when it is read through $\mathsf{Topology}^{\uparrow}$, the row S displays the neighbourhood witnesses required for the inspected point reads.

Apply componentwise transport H. The transport row moves the source, neighbourhood, compact-window, formal-ball, and separation data together, so a separated read cannot be detached from the local compact carrier.

Finally use replay and provenance, C, P, N. They record the same separation route for downstream consumers and keep quotient equality, host point equality, global apartness, and classical separation outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyCompactHausdorff}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyCompactHausdorff}^{\uparrow}$ packet is generated from a topology or separated-uniform source, an inspected point, a local neighbourhood row, a compact-metric or formal-ball window, a Hausdorff separation row, componentwise hsame transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyCompactHausdorff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4029.1, Definition 4029.2, Definition 4029.3, and Definition 4029.4 seed the constructive local-compactness and Hausdorff-separation packet over topology or separated-uniform sources.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyCompactHausdorff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, arbitrary neighbourhood bases, quotient completion equality, global local compactness, classical separation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-neighbourhood nonescape, Hausdorff separation transport, finite-window replay, provenance, and local naming for BEDC.Derived.LocallyCompactHausdorffUp.

Chapter 3051

A Concrete Naming Certificate for $\mathsf{GleasonCover}^{\uparrow}$

Following Gleason and Kelley on projective covers of compact Hausdorff spaces, the $\mathsf{GleasonCover}^{\uparrow}$ packet records finite projective-cover, clopen-lift, compactification, and provenance rows. It sits beside the compact-target seal of chapter 2344, the lower-hit and upper-miss hyperspace route of chapter 2375, the local separation and compact-neighbourhood rows of chapter 4029, and the finite compact-metric witness surface of chapter 129. The packet names the traditional projective-cover boundary through displayed BEDC data; it does not import choice-selected irreducible maps, host Boolean algebras, quotient compacta, open-cover compactness, or ambient compact Hausdorff equality.

Definition 3051.1 (Gleason cover carrier)**.** *A* $\mathsf{GleasonCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, E, M, L, B, V, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact-Hausdorff source row, read through the displayed compact target seal, topology rows, and separation rows already available to compactification consumers.*
2. *E is the extremally disconnected projective-cover row, recording that the cover source is inspected only through finite projective-extension requests.*
3. *M is the cover-map row from E to X, including the finite surjective-read and irreducibility-test windows exposed to downstream compact Hausdorff consumers.*
4. *L is the clopen-lift row, recording finite clopen lift requests and their replay through the same cover map.*
5. *B is the compactification comparison row, comparing the cover map with the* $\mathsf{StoneCechCompactification}^{\uparrow}$ *probe and compact-target rows.*
6. *V is the* $\mathsf{VietorisTopology}^{\uparrow}$ *closed-set row, recording the finite lower-hit and upper-miss observations used when compact-subset consumers inspect the cover.*
7. *H records componentwise* hsame *transport for the compact-Hausdorff source, projective-cover row, cover-map row, clopen-lift row, compactification comparison row, Vietoris closed-set row, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from compact Hausdorff source reads through projective-cover, clopen-lift, compactification, and closed-set consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{GleasonCover}^{\uparrow}$, $\mathsf{StoneCechCompactification}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{LocallyCompactHausdorff}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GleasonCover}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, E, M, L, B, V, H, C, P, N$. It has no coordinate for arbitrary projective resolutions, selected ultrafilters, quotient equality of compacta, open-cover compactness, choice of clopen bases, or host compact Hausdorff spaces outside the displayed packet.

Lean4 ✓ `BEDC.Derived.GleasonCoverUp.GleasonCoverTasteGate single carrier alignment`

Theorem 3051.2 (Gleason cover projective-cover handoff)**.** *Every compact-Hausdorff consumer of an accepted* $\mathsf{GleasonCover}^{\uparrow}$ *carrier reads the cover only through the finite route*

$$X, E, M, L, B, V \longmapsto H, C, P, N.$$

The route exposes the compact-Hausdorff source, extremally disconnected projective-cover row, cover-map row, clopen-lift row, compactification comparison row, Vietoris closed-set row, componentwise transport, displayed replay, provenance, and local naming. It exports no open-cover selection, quotient compactum equality, selected ultrafilter, host Boolean algebra, arbitrary clopen basis, or ambient projective-cover theorem.

Proof. Project the carrier of Definition 4030.1. The compact-Hausdorff source is the row X, the projective-cover information is carried by E and M, and the clopen-lift and compactification comparisons are the rows L and B.

Read closed-set observations through V. This is the finite $\mathsf{VietorisTopology}^{\uparrow}$ side of the packet, so lower-hit and upper-miss consumers inspect only displayed closed-set windows rather than a host hyperspace or quotient compactum.

Finally replay through H, C, P, N. These rows transport, continue, source, and name the same carrier, so a compact-Hausdorff consumer has no coordinate from which to obtain open-cover selection, quotient equality, selected ultrafilters, host Boolean algebras, arbitrary clopen bases, or an ambient projective-cover theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{GleasonCover}^{\uparrow}}$.

Constructive story: A $\mathsf{GleasonCover}^{\uparrow}$ packet is generated from compact-Hausdorff source rows, extremally disconnected projective-cover rows, cover-map rows, clopen-lift rows, compactification comparisons, Vietoris closed-set rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GleasonCover}^{\uparrow}}$, seed)

Scope closed: Definition 4030.1 and Definition 4030.2 seed the finite projective-cover handoff surface for compact-Hausdorff consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GleasonCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary projective resolutions, selected ultrafilters, quotient compactum equality, open-cover compactness, choice of clopen bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projective-cover handoff, clopen-lift replay, compactification comparison, Vietoris closed-set compatibility, provenance, and local naming for BEDC.Derived.GleasonCoverUp.

Chapter 3052

A Concrete Naming Certificate for HeineBorelNetCompactness$^{\uparrow}$

Following Bishop and Bridges on compact intervals, finite approximation, and located covers, the HeineBorelNetCompactness$^{\uparrow}$ packet records the finite-net compactness route for closed bounded real intervals as displayed NameCert data. It sits next to the finite-net cover surface of chapter 3471, the located subcover handoff of chapter 3538, the closed bounded interval compactness packet of chapter 3969, the compact metric carrier of chapter 129, the real-name seal of chapter 38, and the dyadic tolerance ledger of chapter 291. The packet gives a finite tolerance-and-net surface to completion and compactness consumers, not an unrestricted open-cover compactness theorem or a choice-selected subcover principle.

Definition 3052.1 (Heine–Borel net compactness carrier)**.** *A* HeineBorelNetCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, F, R, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located closed bounded interval row, recording the endpoint order, interval membership classifier, and interval-source readback.*
2. *F is the finite net row, read through* HeineBorelFiniteNet$^{\uparrow}$ *and* CompactMetric$^{\uparrow}$*, naming the displayed centers, mesh radius, cell coverage witnesses, and compact-metric provenance.*
3. *R is the positive-radius ledger, recording the requested positive tolerance, its dyadic lower witness, and the comparison surface used by cover readers.*
4. *W is the cover-read witness row, exposing only the finitely many cover predicates inspected at the displayed centers and interval boundary cells.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare mesh radius, endpoint error, cover radius, and finite-net budget.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row for interval endpoints and inspected cover radii, reached only after I, F, R, W, D have been displayed.*
7. *H records componentwise* hsame *transport for interval source, finite net, positive-radius ledger, cover reads, dyadic tolerance, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the located interval row through finite nets, positive-radius checks, cover reads, dyadic tolerance comparisons, and terminal Real seals.*

9. *P is the* Pkg *provenance over* $\mathsf{HeineBorelNetCompactness}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HeineBorelNetCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, R, W, D, E, H, C, P, N$. It has no coordinate for unrestricted open-cover compactness, choice-selected finite subcovers, quotient interval equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HeineBorelNetCompactnessUp.HeineBorelNetCompactnessTasteGate single carrier alignment`

Theorem 3052.2 (Heine–Borel net compactness obligations)**.** *For every accepted* $\mathsf{HeineBorelNetCompactness}^{\uparrow}$ *carrier $K = (I, F, R, W, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelNetCompactness}^{\uparrow}}$ *surface consists exactly of located interval admission, finite-net admission, positive-radius ledger exposure, finite cover-read witnesses, dyadic tolerance readback, Real-seal readback, componentwise transport, displayed continuation replay, provenance, and local naming. Every compactness-facing read must pass through the displayed rows before using a finite-net compactness conclusion.*

Proof. Project the carrier of Definition 4031.1. The tuple displays exactly the rows $I, F, R, W, D, E, H, C, P, N$, so the local classifier has no access to data outside that packet.

The interval and finite-net sides are read first. The located interval row I supplies the endpoint and membership surface, while F supplies the finite centers and coverage witnesses inherited from the finite-net and compact-metric siblings.

The cover-facing side is finite as well. The positive-radius ledger R fixes the requested tolerance, W records the inspected cover witnesses, D gives the dyadic comparison budget, and E seals only the endpoint and radius reads that are already attached to those rows.

Finally H, C, P, N transport, replay, source, and name the same route. Since no row contains open covers as an unrestricted object, selected subcovers, quotient interval equality, countable choice, or ambient real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 3052.3 (Heine–Borel finite-subcover route)**.** *Every* $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$, ClosedBoundedIntervalC *or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{HeineBorelNetCompactness}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{HeineBorelFiniteNet}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{HeineBorelNetCompactness}^{\uparrow}}$$

through the displayed rows $I, F, R, W, D, E, H, C, P, N$. The route exports finite centers, positive-radius comparisons, cover-read witnesses, dyadic tolerance rows, endpoint and radius seals, and structural provenance only; it exports no unrestricted open-cover compactness, choice-selected subcover, quotient interval equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the obligation surface of Definition 4031.2. The interval row and finite-net row must be displayed before a compactness consumer can inspect a cover witness.

Next read the tolerance side. The positive-radius ledger R and dyadic tolerance row D control the requested mesh and cover radius, while W exposes only the finite cover reads attached to the displayed centers and interval boundary cells.

The terminal Real row E seals those endpoint and radius reads without adding a completeness theorem. The transport, replay, provenance, and local naming rows H, C, P, N preserve the same finite route for each sibling consumer.

Therefore the public handoff is exactly the finite-subcover route displayed in the statement. The excluded open-cover, selected-subcover, quotient, choice, and ambient-completeness data have no carrier row through which they could be exported. □

Falsifiable prediction: A compactness-facing consumer that reads $\mathsf{HeineBorelNetCompactness}^{\uparrow}$ without displaying the located interval, finite net, positive-radius ledger, cover-read witness, DyadicRatCore tolerance, Real seal, componentwise transport, continuation replay, package provenance, and local NameCert rows refutes the carrier surface.

Independence witness: heineborel-finite-net, located-heine-borel-subcover, closed-bounded-interval-compact, compactmetric, real, dyadicratcore: no listed sibling is bijective to $\mathsf{HeineBorelNetCompactness}^{\uparrow}$ because this packet binds interval location, finite-net coverage, positive-radius ledgers, cover-read witnesses, dyadic tolerance, Real seals, transport, replay, provenance, and local naming in one compactness-facing interface.

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelNetCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{HeineBorelNetCompactness}^{\uparrow}$ packet is generated from a located interval row, finite net row, positive-radius ledger, cover-read witnesses, DyadicRatCore tolerance row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelNetCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4031.1, Definition 4031.2, and Definition 4031.3 seed the finite-net compactness interface for closed bounded interval consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelNetCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted open-cover compactness, choice-selected finite subcovers, quotient interval equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net admission, positive-radius ledger exposure, cover-read witnesses, dyadic tolerance readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HeineBorelNetCompactnessUp.

Chapter 3053

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionUnit}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ packet records the completion-unit surface for separated Hausdorff completion as finite NameCert data. It sits after the uniform-completion carrier of chapter 1473, the metric-completion carrier of chapter 1506, the Hausdorff-completion carrier of chapter 402, the separated-metric boundary of chapter 1411, the finite stream windows of chapter 126, the regular-rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the unit map into the separated Hausdorff completion without importing quotient completion equality, selected representatives, or ambient completeness.

Definition 3053.1 (HausdorffCompletionUnit carrier)**.** *A* $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, S, J, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric or uniform row, naming the finite observation surface consumed before completion.*
2. *S is the separated Hausdorff completion row, read through the separated-metric and Hausdorff-completion sibling carriers.*
3. *J is the unit-map row from the source surface into the separated Hausdorff completion surface.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect source names before the unit map is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular Cauchy tolerance names attached to W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for distance or apartness readbacks reached after M, S, J, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the source, completion, unit, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from source inspection to unit-map handoff, completion readback, and real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{HausdorffCompletionUnit}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HausdorffCompletionUnit}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completion points, or ambient completeness.

Lean4 (definition) `BEDC.Derived.HausdorffCompletionUnitUp.HausdorffCompletionUnitUp`

Theorem 3053.2 (HausdorffCompletionUnit NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ *carrier* $U = (M, S, J, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionUnit}^{\uparrow}}$ *obligations are exactly source metric or uniform exposure through* M*, separated Hausdorff completion exposure through* S*, unit-map exposure through* J*,* $\mathsf{StreamName}^{\uparrow}$ *finite-window inspection through* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Every obligation is discharged along the displayed route

$$M \longmapsto S \longmapsto J \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

No obligation may be replaced by quotient completion equality, selected representatives, countable choice, host equality of completion points, or ambient completeness.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionUnitUp.HausdorffCompletionUnitNamecertObligations`

Proof. Project the carrier of Definition 4032.1. The source row M, separated Hausdorff completion row S, unit row J, finite windows W, readback row R, seal row E, transport row H, replay row C, provenance row P, and local name N are exactly the displayed coordinates.

Read the completion-unit route in order. The source metric or uniform row is visible before the separated Hausdorff completion row, and the unit-map row is read only after both source and completion surfaces have been displayed.

The numerical side is downstream. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks expose finite regular Cauchy data before the $\mathsf{Real}^{\uparrow}$ seal is consumed. Rows H, C, P, N transport, replay, source, and name that same finite route.

Since the packet contains no quotient equality, selected representative, choice schedule, host completion-point equality, or ambient-completeness coordinate, the displayed rows exhaust the local NameCert obligations. □

Theorem 3053.3 (HausdorffCompletionUnit Cauchy handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ *packet reads the source metric or uniform row, separated Hausdorff completion row, unit-map row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local NameCert rows before receiving the completion handoff. The handoff is the finite unit route*

$$M, S, J, W, R, E, H, C, P, N$$

and not a quotient completion class, selected representative, countable-choice schedule, host equality principle, or ambient complete-space witness.

Proof. Begin with the NameCert obligations of Definition 4032.2. They force the consumer to read $M, S, J, W, R, E, H, C, P, N$ as one displayed certificate surface.

Use the sibling dependencies through their visible rows. The uniform-completion, metric-completion, Hausdorff-completion, and separated-metric chapters supply completion vocabulary and separated comparison, but the unit packet receives those surfaces only through M, S, J and then through the finite window and readback rows.

The Cauchy-facing data remains finite. The $\mathsf{StreamName}^{\uparrow}$ row displays the inspected windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row displays the tolerance readback, and the $\mathsf{Real}^{\uparrow}$ seal is terminal rather than a detached completeness principle.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and naming. No excluded coordinate is present in the carrier, so the completion-facing handoff is exactly the finite unit route. □

Falsifiable prediction: Every $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ completion-unit read factors through source metric or uniform data, separated Hausdorff completion data, the unit-map row, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming. A read that reaches the completion handoff without $M, S, J, W, R, E, H, C, P, N$ falsifies this packet.

Independence witness: uniformcompletion, metriccompletion, hausdorffcompletion, separated-metric, streamname, regseqrat, real: $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source surface, separated Hausdorff completion surface, unit-map row, finite windows, regular-rational readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionUnit}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffCompletionUnit}^{\uparrow}$ packet is generated from a source metric or uniform row, separated Hausdorff completion row, unit-map row, StreamName finite windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4032.1, Definition 4032.2, and Definition 4032.3 seed the finite completion-unit surface for separated Hausdorff completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, separated Hausdorff completion exposure, unit-map handoff, StreamName and RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HausdorffCompletionUnitUp.

Chapter 3054

A Concrete Naming Certificate for $\mathsf{CauchyCriterionForSeries}^{\uparrow}$

Following Cauchy and Knopp, the $\mathsf{CauchyCriterionForSeries}^{\uparrow}$ packet records the constructive criterion that a real series converges exactly when its finite tails become arbitrarily small under displayed regular-rational windows. It sits after the series carrier of chapter 1581, the Cauchy sequence algebra of chapter 3708, the stream-name window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite tail route for series convergence; it is not a host infinite sum, quotient stream equality, selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3054.1 (Cauchy criterion for series carrier)**.** *A* $\mathsf{CauchyCriterionForSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, L, W, D, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, displaying the inspected series terms and partial-sum prefix.*
2. *L is the* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *row, naming the partial-sum algebra and its finite sum/difference operations.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite tail interval and every inspected partial-sum index.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, naming the positive dyadic radius used by the tail comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the displayed tail window and dyadic tolerance.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the series, algebra, window, tolerance, and readback rows have been replayed.*
7. *T is the tail-smallness ledger, recording the finite witnesses that all displayed tails beyond the named threshold are inside the tolerance in D.*
8. *H records componentwise* hsame *transport for A, L, W, D, R, E, T and for the continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a convergence request through the source series, partial-sum algebra, finite window, dyadic tolerance, regular rational readback, tail-smallness ledger, and real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCriterionForSeries}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionForSeries}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, L, W, D, R, E, T, H, C, P, N$. It has no coordinate for an infinite host sum, quotient equality of partial-sum streams, selected limit, countable-choice modulus, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionForSeriesUp.CauchyCriterionForSeriesTasteGate single carrier alignment`

Theorem 3054.2 (Cauchy criterion for series NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCriterionForSeries}^{\uparrow}$ *carrier $S = (A, L, W, D, R, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionForSeries}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure,* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *partial-sum algebra exposure,* $\mathsf{StreamName}^{\uparrow}$ *tail-window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, tail-smallness ledger readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4033.1. The tuple displays the real-series source, partial-sum algebra, finite windows, dyadic tolerance, regular rational readback, real seal, tail-smallness ledger, transport, continuation, provenance, and local name.

The analytic content is read through A, L, W, D, R, E, T. The series row supplies terms and partial sums; the algebra row supplies finite partial-sum differences; the window and tolerance rows state the inspected tail request; and the readback, seal, and ledger rows certify that the displayed tail is small.

The structural rows H, C, P, N preserve and replay the same route. Since the carrier contains no coordinate for host infinite sums, quotient stream equality, selected limits, countable choice, trichotomy, ambient completeness, or bridge checking, the listed rows exhaust the local certificate. □

Theorem 3054.3 (Cauchy criterion for series tail route)**.** *Every accepted convergence read of a* $\mathsf{CauchyCriterionForSeries}^{\uparrow}$ *packet factors through the finite tail route*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{CauchySequenceAlgebra}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The exported criterion is the assertion that the partial-sum tail ledger T can answer each displayed dyadic tolerance request after the source series, partial-sum algebra, finite window, regular readback, and real seal have been displayed. It exports no host infinite sum, quotient partial-sum stream, selected limit, countable-choice modulus, trichotomy, or ambient completeness theorem.

Proof. Begin with the source series row A and partial-sum algebra row L. These rows provide only finite term and partial-sum data, so a convergence consumer has not yet received a completed sum.

Next read the finite request rows W and D. The stream-name row displays the inspected tail window, and the dyadic row names the tolerance for that window.

The regular rational readback R, real seal E, and tail-smallness ledger T then certify the displayed tail comparison. The continuation row C fixes this order, and H, P, N transport, source, and name the same packet.

Because every consumer reaches the criterion through this route, any read that asks for quotient stream equality, selected limits, countable choice, trichotomy, or ambient real completeness has left the packet and is not part of the exported criterion. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCriterionForSeries}^{\uparrow}$ convergence read must expose a $\mathsf{RealSeries}^{\uparrow}$ source row, $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ partial-sum algebra row, $\mathsf{StreamName}^{\uparrow}$ tail window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, tail-smallness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before the criterion is available.

Independence witness: Nearest siblings: realseries, cauchysequencealgebra, streamname, dyadicratcore, regseqrat, and real. The packet is not bijective to any one sibling because it jointly binds source series rows, partial-sum algebra, tail windows, dyadic tolerances, regular rational readback, real sealing, tail-smallness ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionForSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCriterionForSeries}^{\uparrow}$ packet is generated from a RealSeries source row, CauchySequenceAlgebra partial-sum row, StreamName tail-window row, DyadicRatCore tolerance row, RegSeqRat readback, RealUp seal, tail-smallness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCriterionForSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4033.1, Definition 4033.2, and Definition 4033.3 seed the finite constructive Cauchy criterion route for real series.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCriterionForSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, quotient stream equality, selected limits, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, partial-sum algebra exposure, tail-window exactness, dyadic tolerance exactness, RegSeqRat readback, RealUp seal handoff, tail-smallness ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCriterionForSeriesUp.

Chapter 3055

A Concrete Naming Certificate for $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$

The $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$ packet realizes the boundary-weighting route of chapter 9463 as finite NameCert data. It sits after the Poisson-kernel certificate of chapter 3925, the visual-metric certificate of chapter 3866, the Busemann-boundary certificate of chapter 3732, the hyperbolic-metric certificate of chapter 3474, the disk carrier of chapter 377, and the terminal real-name seal of chapter 38. The packet names a finite harmonic boundary-measure read; it is not a host measure space, sigma-algebra completion, selected boundary representative, ambient probability theorem, global field instance, or quotient boundary construction.

Definition 3055.1 (Hyperbolic harmonic boundary measure carrier)**.** *A* $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, B, V, K, R, W, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row naming the finite interior observation from which boundary weighting is read.*
2. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row naming the boundary face and its Busemann-level comparison data.*
3. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row naming the visual boundary distance used by the weighting request.*
4. *K is the* $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ *row, displaying the Poisson-kernel weight over the same disk, boundary, visual-metric, and hyperbolic-metric rows.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed boundary weight.*
6. *W is the harmonic boundary-measure ledger, recording the finite boundary-weight rows accepted by the Poisson kernel before any measure read is exported.*
7. *H records componentwise* hsame *transport for D, B, V, K, R, W and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from disk-coordinate admission through Busemann-boundary admission, visual-metric readback, Poisson-kernel weighting, real sealing, and harmonic boundary-measure ledger exposure.*

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$, $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, B, V, K, R, W, H, C, P, N$. It has no coordinate for a host measure space, completed sigma algebra, selected boundary representative, ambient probability theorem, global field instance, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.HyperbolicHarmonicBoundaryMeasureUp.HyperbolicHarmonicBoundaryMeasureTasteGate`
`single carrier alignment`

Theorem 3055.2 (Hyperbolic harmonic boundary measure NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$ *carrier $M = (D, B, V, K, R, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, Busemann-boundary exposure, visual-metric readback, Poisson-kernel weighting,* $\mathsf{Real}^{\uparrow}$ *seal handoff, harmonic boundary-measure ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4034.1. The projection exposes the disk row, boundary row, visual-metric row, Poisson-kernel row, real seal, harmonic boundary-measure ledger, and the structural rows.

The geometric read is ordered by D, B, V, K, R, W. A boundary-measure consumer first sees the disk coordinate, then the Busemann boundary face, then the visual metric, and only then the Poisson-kernel weight and real seal used by the ledger.

The rows H, C, P, N transport, replay, source, and name this finite route. Since the carrier contains no host measure space, completed sigma algebra, selected boundary representative, ambient probability theorem, global field instance, Lean verification, or bridge checking, the listed rows exhaust the NameCert surface. □

Theorem 3055.3 (Hyperbolic harmonic boundary measure Poisson route)**.** *Every accepted harmonic boundary-measure read of a* $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicBusemannBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicPoi}$$

The exported boundary measure is the Poisson-kernel-weighted ledger W over the same disk and boundary rows. It exports no completed host measure, sigma-algebra completion, selected boundary representative, ambient probability theorem, global field instance, or quotient boundary object.

Proof. Open the disk-coordinate row D and the Busemann-boundary row B. These rows fix the finite interior and boundary observations before any weight is inspected.

Read the visual metric and Poisson kernel next. The row V supplies the boundary-distance comparison, and K supplies the Poisson-kernel weight over the same hyperbolic metric and boundary route.

The real seal R and measure ledger W then record the displayed harmonic boundary weight. The rows H, C, P, N preserve the route under transport, replay it for consumers, record provenance, and attach the local name.

Thus every accepted measure read passes through the Poisson-kernel route. The carrier has no coordinate from which a host measure space, completed sigma algebra, selected boundary representative, ambient probability theorem, global field instance, or quotient boundary construction could be exported. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$ read must pass through $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before it exports a boundary-weight ledger.

Independence witness: Nearest siblings: hyperbolic-poisson-kernel, hyperbolic-visual-metric, hyperbolic-busemann-boundary, hyperbolic-metric, and unitdisk. The packet is not bijective to any one sibling because it jointly binds disk-coordinate rows, Busemann boundary rows, visual metric readback, Poisson-kernel weighting, RealUp sealing, harmonic boundary-measure ledger exposure, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}$ packet is generated from UnitDisk disk-coordinate rows, HyperbolicMetric route data, HyperbolicBusemannBoundary rows, HyperbolicVisualMetric rows, HyperbolicPoissonKernel weights, a RealUp seal, a harmonic boundary-measure ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4034.1, Definition 4034.2, and Definition 4034.3 seed the finite harmonic boundary-measure route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHarmonicBoundaryMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host measure spaces, completed sigma algebras, selected boundary representatives, ambient probability theorems, global field instances, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk-coordinate exposure, Busemann-boundary exposure, visual-metric readback, Poisson-kernel weighting, RealUp seal handoff, ledger stability, transport, replay, provenance, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.HyperbolicHarmonicBoundaryMeasureUp.

Chapter 3056

A Concrete Naming Certificate for $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$

The $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ packet realizes the support-nerve census and codon-lifted Betti table of subsection 9462.28.21 as finite NameCert data. It consumes the partition-core incidence surface of chapter 4017, the simplicial-complex carrier of chapter 238, the homology carrier of chapter 98, the finite simplicial-chain surface of chapter 3414, the Hochster–nerve reduction of chapter 3744, and the DNA boundary-tile source of chapter 3393. The packet names a finite support-to-nerve realization and lifted Betti census; it is not a host minimal-resolution oracle, stochastic biological model, quotient codon semantics, unrestricted homology computation, or coefficient-field completeness theorem.

Definition 3056.1 (SupportNerveCensusLiftedBetti carrier)**.** *A* $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, U, V, F, H_0, B, L, G, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{PartitionCoreIncidence}^{\uparrow}$ *row naming the finite support-family incidence table used to enumerate the* 15 *nonempty supports.*
2. *U is the support-to-nerve realization row, assigning each accepted support family to the four-vertex nerve obtained from its displayed supports.*
3. *V is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *row naming the resulting nerve as a finite complex.*
4. *F is the* $\mathsf{FiniteSimplicialChain}^{\uparrow}$ *row exposing the chain boundary surface used for reduced homology reads.*
5. *H_0 is the* $\mathsf{Homology}^{\uparrow}$ *row for reduced homology in degrees* $-1, 0, 1, 2$.
6. *B is the lifted Betti ledger carrying the finite census counts and the codon lift substitution* $z \mapsto 2x + x^2$.
7. *L is the* $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$ *row that keeps the support-level nerve census upstream of any Betti-strand export.*
8. *G records componentwise* hsame *transport for the incidence, realization, complex, chain, homology, lifted Betti, reduction, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from support-family reads to nerve realization, finite homology, and lifted Betti ledgers.*

10. *P is the* Pkg *provenance over* $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$, $\mathsf{PartitionCoreIncidence}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{FiniteSimplicialChain}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, U, V, F, H_0, B, L, G, C, P, N$. It has no coordinate for hidden codon semantics, unrestricted minimal resolutions, ambient Betti-table equality, stochastic evolutionary interpretation, quotient support equality, or an external homology oracle.

Lean4 ✓ `BEDC.Derived.SupportNerveCensusLiftedBettiUp.SupportNerveCensusLiftedBettiTasteGate`
`single carrier alignment`

Theorem 3056.2 (SupportNerveCensusLiftedBetti NameCert obligations)**.** *For every accepted* $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ *carrier $S = (I, U, V, F, H_0, B, L, G, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SupportNerveCensusLifted}}$ *surface consists exactly of incidence enumeration, support-to-nerve realization, finite simplicial-complex admission, finite chain-boundary exposure, reduced homology readback in degrees $-1, 0, 1, 2$, lifted Betti ledger exposure, Hochster–nerve reduction provenance, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 4035.1. The incidence, realization, complex, chain, homology, lifted Betti, reduction, transport, replay, provenance, and naming rows are exactly $I, U, V, F, H_0, B, L, G, C, P,$

The support-to-nerve route starts from I and U. It can expose a nerve only through the finite $\mathsf{SimplicialComplex}^{\uparrow}$ row V, so the census cannot be replaced by a host powerset calculation or a quotient support object.

The homology and Betti rows are downstream of the finite chain boundary F. The row H_0 restricts homology reads to the displayed reduced degrees, while B records the census and lift substitution only as finite ledger data.

Finally L, G, C, P, N preserve, replay, source, and name the same route. Since no remaining coordinate stores hidden codon semantics, unrestricted resolutions, host Betti-table equality, stochastic interpretation, quotient support equality, or external homology computation, the listed obligations exhaust the local NameCert surface. □

Theorem 3056.3 (SupportNerveCensusLiftedBetti realization)**.** *Every accepted* $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{PartitionCoreIncidence}^{\uparrow} \longrightarrow \mathsf{SimplicialComplex}^{\uparrow} \longrightarrow \mathsf{FiniteSimplicialChain}^{\uparrow} \longrightarrow \mathsf{Homology}^{\uparrow} \longrightarrow \mathsf{HochsterNerveBettiRe}$$

The exported census is the displayed support-family count, reduced-homology signature table, and lifted Betti ledger, not a biological causal model, unrestricted coefficient-field theorem, ambient minimal resolution, or host-level homology calculation.

Proof. Start from the NameCert obligations in Definition 4035.2. They force support-family enumeration through I and support-to-nerve realization through U before any complex row is available.

Next the finite complex, chain, and homology rows V, F, H_0 expose the reduced homology signatures used by the census. These rows are displayed finite data, so the read cannot invoke an external simplicial-complex oracle or an unrestricted homology computation.

The lifted Betti ledger B and Hochster–nerve row L then package the codon lift as a finite strand read. Transport, replay, provenance, and local naming preserve that same route, which proves the stated realization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ read factors through displayed partition-core incidence, support-to-nerve realization, simplicial-complex, finite-chain, homology, lifted Betti, Hochster–nerve reduction, transport, replay, provenance, and local naming rows.

Independence witness: partition-core-incidence, support-to-nerve-realization, simplicialcomplex, finite-simplicial-chain, homology, hochster-nerve-betti-reduction: $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the support-family census, nerve realization, finite homology signature table, codon-lifted Betti ledger, and coefficient TasteGate boundary in one packet.

The Lean follow-up must provide explicit $\mathsf{Nontrivial\ SupportNerveCensusLiftedBetti}^{\uparrow}$ and $\mathsf{FieldFaithful\ SupportNer}$ TasteGate instances. Those instances must distinguish $I, U, V, F, H_0, B, L, G, C, P, N$ so the support census, nerve realization, and lifted Betti ledger cannot collapse into one sibling row.

Closure status for $\mathsf{NameCert}_{\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}}$.

Constructive story: A $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ packet is generated from partition-core incidence rows, support-to-nerve realization rows, finite simplicial-complex rows, finite chain rows, reduced homology rows, lifted Betti ledgers, Hochster–nerve reduction provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4035.1, Definition 4035.2, and Definition 4035.3 seed the finite support-nerve census and lifted Betti packet over incidence, realization, simplicial-complex, chain, homology, Betti-ledger, reduction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, biological mechanism, unrestricted minimal resolutions, quotient codon semantics, coefficient-field completeness, or ambient homology computation.

Upgrade path: Obligation closure requires checked incidence enumeration, support-to-nerve realization, finite-complex admission, finite-chain exposure, homology readback, lifted Betti ledger stability, TasteGate nontriviality, field faithfulness, replay stability, and ledger nonescape for BEDC.Derived.SupportNerveCensusLiftedBettiUp.

Chapter 3057

A Concrete Naming Certificate for $\mathsf{EquicontinuousFamily}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Arzela–Ascoli finite-family reading, the $\mathsf{EquicontinuousFamily}^{\uparrow}$ packet records the shared-modulus interface by which a finite family of continuous maps over one compact metric source exposes a single displayed modulus row to downstream compact-uniform-continuity and Ascoli consumers. It sits after the compact source of chapter 129, the graph rows of chapter 130, the uniform-modulus consumer surface of chapter 369, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet does not introduce open-cover compactness, a host function-space topology, quotient equality of maps, or choice-selected pointwise moduli.

Definition 3057.1 (Equicontinuous family carrier)**.** *An* $\mathsf{EquicontinuousFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, F, J, M, S, R, V, H, C, P, N)$$

with the following displayed rows:

1. *X is the shared* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite metric reads and compact finite-net source used by the family.*
2. *F is the finite ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows whose source coordinate is X and whose values are read only through displayed graph windows.*
3. *J is the finite family-index row, naming exactly the family members admitted by F.*
4. *M is the shared* $\mathsf{UniformModulus}^{\uparrow}$ *row, recording one tolerance-to-radius ledger used uniformly for every index in J.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule through which the source and graph reads are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same tolerance and radius histories.*
7. *V is the* $\mathsf{Real}^{\uparrow}$ *value-seal row reached only after the graph, schedule, regular rational, and shared-modulus rows have been displayed.*
8. *H records componentwise* hsame *transport for the compact source, finite graph ledger, family index row, shared modulus row, observation schedule, regular rational readback, Real seal, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from compact-source reads to graph reads, from tolerance requests to the shared modulus row, and from scheduled readback to the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{EquicontinuousFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, J, M, S, R, V, H, C, P, N$. It has no coordinate for an open cover, a selected global modulus outside M, a host function-space topology, quotient equality of functions, or a choice principle over the family.

Lean4 ✓ `BEDC.Derived.EquicontinuousFamilyUp.EquicontinuousFamilyTasteGate single carrier alignment`

Theorem 3057.2 (Equicontinuous family NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuousFamily}^{\uparrow}$ *carrier $E = (X, F, J, M, S, R, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousFamily}^{\uparrow}}$ *surface consists of carrier admission, compact-source admission, finite continuous-map ledger admission, family-index totality, shared uniform-modulus exposure, StreamName and RegSeqRat readback, Real-seal handoff, componentwise transport, continuation replay, provenance, and ledger non-escape. These obligations are discharged entirely by the finite route*

$$X, F, J \longmapsto M \longmapsto S, R \longmapsto V$$

together with H, C, P, N.

Proof. Carrier admission is the projection of Definition 4036.1. The shared compact source row X, finite graph ledger F, family index row J, shared modulus row M, schedule row S, regular readback row R, and Real seal V are all visible coordinates of one finite packet.

The shared-modulus obligation is read before any Ascoli or compact-uniform-continuity consumer inspects the family. Each member named by J is admitted through F, and the same tolerance-to-radius ledger M is used for that member over the source row X.

The rows S, R, V provide the finite observation and value boundary. They keep the scheduled source and graph reads attached to the same regular rational readback and Real seal, rather than to a host function-space object.

Transport and replay are supplied by H and C, while P and N record provenance and local naming. Since the carrier has no row for open-cover compactness, quotient function equality, selected pointwise moduli, or ambient topology, the listed obligations exhaust the certificate surface. □

Theorem 3057.3 (Equicontinuous family uniform-modulus handoff)**.** *Any* $\mathsf{UniformModulus}^{\uparrow}$*, compact-uniform-continuity, or Arzela–Ascoli consumer of an accepted* $\mathsf{EquicontinuousFamily}^{\uparrow}$ *carrier must receive the shared modulus row M together with the compact source row X, finite continuous-map ledger F, family index row J, observation schedule S, regular rational readback R, Real seal V, and structural rows H, C, P, N. The handoff exports only the displayed finite shared-modulus route and does not supply open-cover compactness, a function-space topology, quotient equality of maps, or choice-selected moduli.*

Proof. Begin with the carrier of Definition 4036.1. It displays the shared source, finite graph ledger, finite family index, shared modulus, schedule, readback, seal, transport, replay, provenance, and local naming rows as the whole packet.

Apply the NameCert obligations of Definition 4036.2. They force every accepted read through $X, F, J, M, S, R, V, H, C, P, N$, with M placed before the consumer can treat the family as equicontinuous.

The downstream consumer may add its own Ascoli, compact-uniform-continuity, or selection rows after this boundary. It cannot replace the displayed shared modulus by an open cover, host topology, quotient function equality, or a choice-selected family of pointwise moduli, because none of those objects is a carrier coordinate. □

Theorem 3057.4 (Equicontinuous family compact-uniform-modulus handoff)**.** *Any* CompactEquicontinuousFamily *consumer of an accepted* EquicontinuousFamily$^{\uparrow}$ *carrier*

$$E = (X, F, J, M, S, R, V, H, C, P, N)$$

must pass through $X, F, J, M, S, R, V, H, C, P, N$ *before the compact-family uniform budget is public. In particular, the compact-family read may consume the shared modulus only after the compact source, finite family ledger, family index, shared modulus row, StreamName schedule, RegSeqRat readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows have all been displayed.*

Proof. Start with the uniform-modulus handoff of Definition 4036.3. It forces every shared-modulus consumer through the displayed rows $X, F, J, M, S, R, V, H, C, P, N$.

Now read the carrier route of CompactEquicontinuousFamilyModulus$^{\uparrow}$ from chapter 6234. Its compact-family budget consumes the EquicontinuousFamily$^{\uparrow}$ row as the family source before the compact-uniform output can be public.

Composing the two routes leaves no shortcut around the equicontinuous-family carrier. The compact-family consumer may add its own compact finite-net and output rows downstream, but the shared family budget remains the finite route stated above. □

Closure status for NameCert$_{\text{EquicontinuousFamily}^{\uparrow}}$**.**

Constructive story: An EquicontinuousFamily$^{\uparrow}$ packet is generated from a compact metric source row, a finite continuous-map family ledger, a finite family-index row, a shared uniform-modulus row, StreamName observations, RegSeqRat readback, a Real seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{EquicontinuousFamily}^{\uparrow}}$, seed)

Scope closed: Definition 4036.1, Definition 4036.2, Definition 4036.3, and Definition 4036.4 seed the finite shared-modulus interface consumed by compact-uniform-continuity and Ascoli-style chapters.

Formal verification: FormalStatus(NameCert$_{\text{EquicontinuousFamily}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.EquicontinuousFamilyUp.EquicontinuousFamilyTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, a host function-space topology, quotient function equality, or choice-selected pointwise moduli.

Upgrade path: Obligation closure requires checked carrier admission, family-index totality, shared modulus exposure, finite readback, Real-seal handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.EquicontinuousFamilyUp.

Chapter 3058

A Concrete Naming Certificate for $\mathsf{BishopRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRealComparisonModulus}^{\uparrow}$ packet records the finite comparison modulus by which a Bishop real comparison request is reduced to inspected regular-Cauchy windows, positive apartness evidence, and dyadic tolerance rows. It extends the Bishop real source of chapter 343, the comparison surface of chapter 1381, the apartness witness of chapter 1881, and the L10 readback route of chapter 301 without importing trichotomy, quotient reals, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3058.1 (Bishop real comparison modulus carrier)**.** *A* $\mathsf{BishopRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, A, R, S, D, M, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BishopReal}^{\uparrow}$ *row exposing the regular-Cauchy real names and their finite comparison-facing source surface.*
2. *A is the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *witness row supplying positive apartness data whenever the comparison request has a separated outcome.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to inspect the rational values of the requested finite windows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming exactly the finite windows read by the comparison request.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row storing the dyadic precision, slack, and positive-gap ledger used by the modulus.*
6. *M is the comparison modulus row; it maps each displayed comparison request to the finite window and dyadic tolerance budget consumed by R, S, D.*
7. *H records componentwise* hsame *transport for B, A, R, S, D, M and for the structural certificate rows.*
8. *C records displayed* Cont *replay from a comparison request to the window, readback, tolerance, apartness, and modulus rows.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopReal}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the rows $B, A, R, S, D, M, H, C, P, N$. It has no coordinate for quotient real equality, total order trichotomy, a selected limit, countable choice, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopRealComparisonModulusUp.BishopRealComparisonModulusTasteGate single carrier alignment`

Theorem 3058.2 (Bishop real comparison modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealComparisonModulus}^{\uparrow}$ *carrier*

$$Q = (B, A, R, S, D, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Bishop-real source, apartness witness, regular readback, stream schedule, dyadic tolerance, comparison modulus, transport, replay, provenance, and local-name rows;*
2. *modulus readback, requiring each comparison request to expose through M the finite S windows, R rational observations, and D dyadic tolerance budget it consumes;*
3. *apartness handoff, requiring every positive separated outcome to pass through the displayed* $\mathsf{CauchyRealApartness}^{\uparrow}$ *row A before it is offered to a real-facing consumer;*
4. *regular-sequence compatibility, requiring the rational observations in R to be read from the same Bishop-real source surface named by B;*
5. *finite stream-window compatibility, requiring S to name only the windows requested by M and replayed by C;*
6. *dyadic tolerance exactness, requiring D to store precisely the comparison precision, slack, and positive-gap data used by M and A;*
7. *componentwise* hsame *transport for $B, A, R, S, D, M, C, P, N$ through H;*
8. *displayed* Cont *replay of each comparison request through the window, readback, tolerance, apartness, and modulus rows;*
9. Pkg *provenance for exactly the displayed packet;*
10. *ledger non-escape, requiring every consumer to remain inside $B, A, R, S, D, M, H, C, P, N$.*

Consequently the packet exports a finite comparison modulus interface for Bishop real names, not trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4037.1. The projection exposes exactly the Bishop source, apartness witness, regular readback, stream schedule, dyadic tolerance, comparison modulus, transport, replay, provenance, and local naming rows.

The modulus obligation is read from M together with S, R, D. A comparison request first names its finite stream windows, then reads the corresponding regular rational observations, and finally displays the dyadic precision and slack ledger used by the comparison.

The positive separated branch is forced through A. Since A is the only apartness witness row, the carrier cannot turn a modulus read into trichotomy, quotient equality, or a selected real representative.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. They do not add any coordinate outside B, A, R, S, D, M, so the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealComparisonModulus}^{\uparrow}$ packet is generated from a BishopReal row, a CauchyRealApartness witness, RegSeqRat readback, StreamName windows, a DyadicRatCore tolerance ledger, a comparison modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4037.1 and Definition 4037.2 seed the finite comparison-modulus interface over Bishop real source rows, apartness witnesses, regular readbacks, stream windows, and dyadic tolerance data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, modulus readback, apartness handoff, regular-sequence compatibility, finite window compatibility, dyadic tolerance exactness, transport, replay, provenance, and ledger non-escape.

Chapter 3059

A Concrete Naming Certificate for $\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}$ packet records the Real-facing interface of an Archimedean Cauchy-complete ordered field as finite BEDC NameCert data. It reads the terminal Real seal of chapter 38, the regular rational sequence readback of chapter 301, the dyadic precision ledger of chapter 291, the finite stream-window surface of chapter 126, the algebraic order interface of chapter 766, the Cauchy-complete ordered-field route of chapter 3688, and the comparison capstone of chapter 2025. The chapter provides one L10 phase-exit surface for Real and Completion consumers without importing a host complete ordered field.

Definition 3059.1 (Archimedean Cauchy-complete field carrier)**.** *An* $\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, Q, D, S, O, K, F, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal, read only as the terminal Real name row.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational names.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger for displayed tolerance and radius requests.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which rational observations are requested.*
5. *O is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *operation-and-order row, naming addition, multiplication, zero, one, positivity, and order comparison only as finite ledger entries.*
6. *K is the* $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ *route row tying the Real seal, regular readback, dyadic ledger, stream window, and algebraic-order row to displayed Cauchy-complete ordered-field service.*
7. *F is the* $\mathsf{CompleteArchimedeanField}^{\uparrow}$ *comparison row, recording the Archimedean comparison surface reached from the same displayed Cauchy-complete ordered-field route.*
8. *H records componentwise* hsame *transport for the Real seal, regular readback, dyadic ledger, stream window, algebra-order row, Cauchy-complete ordered-field route, Archimedean comparison row, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite precision request through stream observation, regular rational readback, Real sealing, order operation, Cauchy-complete route, Archimedean comparison, and local naming.*

10. *P is the* Pkg *provenance over* ArchimedeanCauchyCompleteField$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RealAlgOrder$^{\uparrow}$, CauchyCompleteOrderedField$^{\uparrow}$, CompleteArchimedeanField$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

11. *N is the local* NameCert$_{\text{ArchimedeanCauchyCompleteField}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, Q, D, S, O, K, F, H, C, P, N$. It has no coordinate for quotient Real equality, trichotomy, selected limits, host supremum data, or ambient completeness.

Lean4 (definition) `BEDC.Derived.ArchimedeanCauchyCompleteFieldUp.ArchimedeanCauchyCompleteFieldUp`

Theorem 3059.2 (Archimedean Cauchy-complete field NameCert obligations)**.** *For every accepted* ArchimedeanCauchyCompleteField$^{\uparrow}$ *carrier*

$$A = (R, Q, D, S, O, K, F, H, C, P, N),$$

the local NameCert$_{\text{ArchimedeanCauchyCompleteField}^{\uparrow}}$ *surface consists exactly of carrier admission for the Real scalar seal R, regular rational readback Q, dyadic precision ledger D, finite stream window S, RealAlgOrder operation-and-order row O, CauchyCompleteOrderedField route row K, CompleteArchimedeanField comparison row F, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 4038.1. The accepted tuple exposes exactly the Real seal, regular readback, dyadic ledger, finite stream window, algebra-order row, Cauchy-complete ordered-field route, Archimedean comparison row, transport, replay, provenance, and local naming rows.

The scalar and completion-facing part is read through R, Q, D, S, K. The row K is allowed to cite the Cauchy-complete ordered-field surface only after the Real seal, regular readback, dyadic precision, and stream-window rows have been displayed.

The order and Archimedean comparison part is read through O and F. These rows record operation, order, and comparison service as BEDC packet rows rather than as a host complete ordered-field structure.

Finally H, C, P, N transport, replay, source, and name that finite surface. Since no other carrier coordinate remains, the listed rows exhaust the NameCert obligations. □

Theorem 3059.3 (Archimedean Cauchy-complete field L10 exit route)**.** *Every L10 Real or Completion consumer of an accepted* ArchimedeanCauchyCompleteField$^{\uparrow}$ *packet must factor its read through*

Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RealAlgOrder$^{\uparrow}$, CauchyCompleteOrderedField$^{\uparrow}$, CompleteArchin

as the displayed rows $R, Q, D, S, O, K, F, H, C, P, N$. Thus the packet supplies a single Archimedean Cauchy-complete ordered-field interface for Real-facing phase exit, but it exports no quotient Real equality, trichotomy, selected limit, host complete ordered field, or ambient completeness coordinate.

Proof. Start with an accepted consumer read. The Real scalar is exposed only by R, and the rational Cauchy evidence behind the read must pass through Q, D, S before any completion-facing row is visible.

The algebraic and order part is then confined to O. Addition, multiplication, zero, one, positivity, and comparison are read as displayed operation-and-order rows, not as host-field operations.

The completion route is K, and the Archimedean comparison capstone is F. These rows link the same Real seal, regular readback, dyadic ledger, stream window, and order row to the Cauchy-complete ordered-field and CompleteArchimedeanField packets.

The structural rows H, C, P, N preserve and name this route. Because the carrier lacks quotient Real equality, trichotomy, selected limit, host-field, and ambient-completeness coordinates, every L10 phase-exit read is confined to the finite surface stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}$ packet is generated from a Real scalar seal, RegSeqRat readback, DyadicRatCore precision ledger, StreamName finite window, RealAlgOrder operation and order row, CauchyCompleteOrderedField route row, CompleteArchimedeanField comparison row, componentwise transport, displayed replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4038.1, Definition 4038.2, and Definition 4038.3 seed the L10 Real and Completion phase-exit surface for Archimedean Cauchy-complete ordered-field consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyCompleteField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Real equality, trichotomy, selected limits, host complete ordered fields, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rowwise operation and order service, Archimedean comparison service, transport, replay, provenance, and local naming for the same finite packet.

Chapter 3060

A Concrete Naming Certificate for $\mathsf{ProductUniformSpace}^{\uparrow}$

Following Bourbaki and Weil's product uniformity language, the $\mathsf{ProductUniformSpace}^{\uparrow}$ packet records the finite route by which two displayed uniform source packets are assembled into a product uniformity without importing a host product topology. It reads the $\mathsf{UniformSpace}^{\uparrow}$ entourage surface of chapter 339, the **??** projection route of chapter 34, the metric-compatible source of chapter 57, and the completion-facing boundary of chapter 95. The chapter names the product-entourage rows needed by completion consumers before any quotient completion, unrestricted entourage choice, or ambient topology is visible.

Definition 3060.1 (Product uniform space carrier)**.** *A* $\mathsf{ProductUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, B, \Pi, E_A, E_B, W, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two uniform source packets. Each source exposes only its displayed carrier, entourage ledger, diagonal row, symmetry row, composition-refinement row, transport row, replay row, provenance row, and local* $\mathsf{NameCert}$ *row.*

2. *Π is the **??** projection row. It records the left and right projection reads and the paired point-name admission used by the product packet.*

3. *E_A and E_B are the paired entourage ledgers. A product entourage request must name a left source entourage from A and a right source entourage from B before it can be read as a product request.*

4. *W is the finite componentwise witness row. It records that a product pair is accepted exactly by its two projected source reads and their paired entourage ledgers.*

5. *H records componentwise* hsame *transport for the two source packets, the projection row, the paired entourage ledgers, the witness row, replay, provenance, and local naming rows.*

6. *C records displayed* Cont *replay from a product-entourage request through the projection row, the left and right source entourages, the componentwise witness, transport, provenance, and local naming rows.*

7. *P is the* Pkg *provenance over* $\mathsf{ProductUniformSpace}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*,* ***??****,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

8. N is the local $\mathsf{NameCert}_{\mathsf{ProductUniformSpace}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $A, B, \Pi, E_A, E_B, W, H, C, P, N$. It has no coordinate for host product topology, unrestricted choice of entourages, quotient completion, selected limits, open-cover compactness, or bridge checking.

Lean4 ✓ `BEDC.Derived.ProductUniformSpaceUp.ProductUniformSpaceTasteGate single carrier alignment`

Theorem 3060.2 (Product uniform space NameCert obligations)**.** *For every accepted* $\mathsf{ProductUniformSpace}^{\uparrow}$ *carrier $U = (A, B, \Pi, E_A, E_B, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProductUniformSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{UniformSpace}^{\uparrow}$ *source packets, the ?? projection row, the paired left and right entourage ledgers, the finite componentwise witness row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. No product-uniformity obligation is stored outside these rows.*

Proof. Project the carrier of Definition 4040.1. The tuple displays exactly the two source packets, projection row, paired entourage ledgers, witness row, transport, replay, provenance, and local naming.

The source rows provide the only uniform data available to the packet. A product-entourage read must therefore pass through A and B and then through the named ledgers E_A and E_B.

The projection row Π and witness row W bind the product read to the two component reads. Transport by H is componentwise, and replay by C follows the same displayed route.

Since P and N only source and name this finite surface, and since no other carrier coordinate remains, the listed rows exhaust the local NameCert obligations. □

Theorem 3060.3 (Product uniform space projection-entourage route)**.** *Every completion-facing or metric-compatible read of an accepted* $\mathsf{ProductUniformSpace}^{\uparrow}$ *carrier factors through the finite route*

$$??\longmapsto(\mathsf{UniformSpace}^{\uparrow},\mathsf{UniformSpace}^{\uparrow})\longmapsto\mathsf{Completion}^{\uparrow}.$$

More explicitly, a consumer first reads the projection row Π, then the left and right uniform source packets A, B, then the paired entourage ledgers E_A, E_B, and only afterward the witness, transport, replay, provenance, and local naming rows W, H, C, P, N. The route exports no host product topology, unrestricted entourage selector, quotient completion, selected limit, or ambient bridge proof.

Proof. Start with the accepted carrier and the obligations of Definition 4040.2. The product request is not available before Π displays the two projections and paired point-name admission.

Each projected read then enters one source uniform packet. The left and right entourage data are the displayed ledgers E_A and E_B, so the product entourage is a finite pair of component ledgers rather than a host-level neighbourhood of a product topology.

The completion-facing part reads only the same finite route. The witness row W records componentwise acceptance, while H, C, P, N transport, replay, source, and name that route for $\mathsf{Met}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ consumers.

Because the carrier has no coordinate for host product topology, unrestricted entourage choice, quotient completion, selected limits, or bridge checking, no consumer can project those objects from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProductUniformSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{ProductUniformSpace}^{\uparrow}$ packet is generated from two UniformSpace source packets, a Product projection row, paired component entourage ledgers, a finite componentwise witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ProductUniformSpace}^{\uparrow}}$, seed)

Scope closed: Definition 4040.1, Definition 4040.2, and Definition 4040.3 seed the finite product-uniformity route used by metric-compatible completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{ProductUniformSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host product topology, unrestricted choice of entourages, quotient completion, selected limits, Lean verification, or bridge checking for ProductUniformSpace$^{\uparrow}$.

Upgrade path: Obligation closure requires checked source carrier admission, projection coverage, paired entourage exactness, componentwise transport, replay stability, provenance, local naming, and completion-route non-escape for BEDC.Derived.ProductUniformSpaceUp.

Chapter 3061

A Concrete Naming Certificate for $\mathsf{ConstructiveRealLine}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveRealLine}^{\uparrow}$ packet records the textbook-facing L10 real-line interface as finite BEDC NameCert data rather than as a primitive host continuum. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal seal of chapter 38, the located real surface of **??**, and the apartness boundary of chapter 1380. The chapter names the interface on which later real-analysis packets can depend without claiming real completeness, trichotomy, quotient streams, selected limits, or host real equality.

Definition 3061.1 (Constructive real line carrier)**.** *A* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, R, E, L, A, \Delta, I, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger storing requested dyadic precision, comparison slack, and density margins.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which every requested observation of a real name is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected stream windows and dyadic tolerance rows into rational approximants.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal row exported only after the D, S, R route has been displayed.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *boundary row recording finite interval-location evidence for the same readback surface.*
6. *A is the* $\mathsf{LocatedApartness}^{\uparrow}$ *boundary row recording positive separatedness evidence when a consumer asks for apartness.*
7. *Δ is the dyadic-density handoff row from rational or dyadic samples to the inspected real-name windows.*
8. *I is the interval readback row naming rational intervals whose endpoints are read through D, S, R and whose locatedness is checked through L and A.*
9. *H records componentwise* hsame *transport for $D, S, R, E, L, A, \Delta, I$ and for the structural certificate rows.*

10. *C records displayed* Cont *replay from a real-line request to the finite window, tolerance, readback, seal, locatedness, apartness, density, and interval rows.*
11. *P is the* Pkg *provenance over* $\mathsf{ConstructiveRealLine}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRealLine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the rows $D, S, R, E, L, A, \Delta, I, H, C, P, N$. It has no coordinate for real completeness, trichotomy, quotient streams, selected limits, or host real equality.

Lean4 ✓ `BEDC.Derived.ConstructiveRealLineUp.ConstructiveRealLineTasteGate single carrier alignment`

Theorem 3061.2 (Constructive real line NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *carrier*

$$Q = (D, S, R, E, L, A, \Delta, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveRealLine}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dyadic tolerance ledger, stream windows, regular rational readback, terminal real seal, locatedness boundary, apartness boundary, density handoff, interval readback, transport, replay, provenance, and local-name rows;*
2. *window-readback compatibility, requiring each S window consumed by a real-line request to be read by R under the tolerance ledger D;*
3. *seal discipline, requiring every* $\mathsf{Real}^{\uparrow}$ *export through E to pass first through the displayed D, S, R route;*
4. *locatedness discipline, requiring every located interval read to pass through L and I before a real-line consumer can inspect it;*
5. *apartness discipline, requiring every positive separatedness read to pass through A and the interval readback row I;*
6. *dyadic-density handoff, requiring each rational or dyadic sample exposed by Δ to be tied to the same D, S, R windows;*
7. *componentwise* hsame *transport for $D, S, R, E, L, A, \Delta, I, C, P, N$ through H;*
8. *displayed* Cont *replay of each real-line request through the finite route named by C;*
9. Pkg *provenance for exactly the displayed packet;*
10. *ledger non-escape, requiring every consumer to remain inside $D, S, R, E, L, A, \Delta, I, H, C, P, N$.*

Consequently the packet exports a textbook-facing constructive real-line interface, not real completeness, trichotomy, quotient streams, selected limits, or host real equality.

Proof. Project the carrier of Definition 4041.1. The projection exposes exactly the dyadic tolerance, finite window, regular readback, real seal, locatedness, apartness, density, interval, transport, replay, provenance, and local naming rows.

The readback obligations are forced by the displayed route D, S, R. A consumer first names the finite stream windows, then reads the corresponding regular rational data, and only then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal E.

The located and apartness obligations are separate boundary reads. The interval row I supplies the rational interval readback, L supplies locatedness, and A supplies positive separatedness when the request needs it.

The density, transport, replay, provenance, and naming rows do not add a host continuum coordinate. Since every listed consumer remains inside $D, S, R, E, L, A, \Delta, I, H, C, P, N$, the packet cannot export real completeness, trichotomy, quotient streams, selected limits, or host real equality. □

Theorem 3061.3 (Constructive real line L10 seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *carrier factors through the L10 route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with located and apartness observations read only through the sibling $\mathsf{LocatedReal}^{\uparrow}$ *and* $\mathsf{LocatedApartness}^{\uparrow}$ *boundary rows. No accepted real-line consumer can bypass this route through quotient streams, a selected limit, host real equality, trichotomy, or ambient real completeness.*

Proof. Begin with the carrier route in Definition 4041.1. Its only terminal real-name coordinate is E, and E is listed after the dyadic tolerance ledger D, the stream window schedule S, and the regular rational readback R.

The located and apartness reads remain boundary reads. A located request must use L and I, while a positive separatedness request must use A and the same interval readback row.

Finally replay the request through C and transport it through H. The provenance row P and local certificate row N name the same displayed packet, so the route has no hidden coordinate from which quotient stream equality, a selected host limit, trichotomy, host real equality, or real completeness could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRealLine}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveRealLine}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readback, a terminal RealUp seal, located-real and located-apartness boundaries, dyadic-density handoff, interval readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveRealLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4041.1, Definition 4041.2, and Definition 4041.3 seed the textbook-facing constructive real-line interface over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, LocatedRealUp, LocatedApartnessUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveRealLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, quotient streams, selected limits, or host real equality.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, window-readback compatibility, seal discipline, locatedness and apartness boundaries, dyadic-density handoff, interval readback, transport, replay, provenance, and ledger non-escape.

$\mathsf{MontelSpace}^{\uparrow}$ reads the locally convex and Frechet-style bounded-set compactness route through chapter 3495, chapter 1735, and chapter 3693 before the child file expands the finite carrier.

Chapter 3062

A Concrete Naming Certificate for $\mathsf{MontelSpace}^{\uparrow}$

Following Bourbaki and Schaefer, the $\mathsf{MontelSpace}^{\uparrow}$ packet records the traditional locally convex and Frechet-style bounded-set compactness surface as finite BEDC NameCert data. It is the carrier companion to the normal-family packet of chapter 3693: the Montel theorem route may consume a displayed Montel-space source when local boundedness and compact-window extraction are read from a locally convex carrier rather than from a holomorphic family alone. The packet also sits over the complete separable metric boundary of chapter 1735, the complete-metric and Polish readback surfaces, and the finite bornological rows used by bounded-set consumers. It names a finite bornological compactness route, not host topological vector space equality, barrelledness, nuclearity, selected compact closures, quotient completions, or classical choice.

Definition 3062.1 (Montel space carrier)**.** *A* $\mathsf{MontelSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, F, B, Q, K, R, D, H, C, P, N)$$

with the following displayed rows:

1. *L is the locally convex source row, exposing the finite seminorm or entourage windows through which bounded sets are inspected.*
2. *F is the Frechet-style completeness and metrizability row, read through complete metric, complete separable metric, or Polish-space surfaces when those rows are displayed.*
3. *B is the bounded-set ledger, recording the finite family of bounded-set requests that the Montel-space consumer may inspect.*
4. *Q is the bornological compactness row: each displayed bounded request in B is routed to a compact, totally bounded, or sequentially compact readback already named by the surrounding metric packets.*
5. *K is the compact-window row consumed by normal-family, Arzela–Ascoli, and Montel theorem packets.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback for seminorm and metric tolerances.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by boundedness, compact-window, and completion reads.*

8. *H records componentwise* hsame *transport for the displayed locally convex, Frechet, bounded, compactness, tolerance, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from locally convex inspection through bounded-set admission, compact-window readback, and normal-family consumption.*
10. *P is the* Pkg *provenance over* $\mathsf{MontelSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{MontelTheorem}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MontelSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, F, B, Q, K, R, D, H, C, P, N$. It has no coordinate for a host locally convex equality, a quotient completion, a selected compact closure, a barrelled or nuclear structure, countable choice, or open-cover compactness.

Theorem 3062.2 (Montel space NameCert obligations)**.** *For every accepted* $\mathsf{MontelSpace}^{\uparrow}$ *carrier $S = (L, F, B, Q, K, R, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MontelSpace}^{\uparrow}}$ *surface consists exactly of locally convex source admission, Frechet or complete-separable readback when displayed, bounded-set ledger admission, bornological compactness readback, compact-window export, regular-rational and dyadic tolerance discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4042.1. The displayed tuple exposes the locally convex source row, Frechet or complete-separable readback row, bounded-set ledger, bornological compactness row, compact-window row, tolerance rows, and the structural rows.

The bounded-set read is finite. Each request in B is inspected only through the locally convex windows in L and the tolerance rows R, D, and the compactness answer is recorded in Q before any compact-window consumer sees K.

The replay row C then routes the same data toward normal-family and completion-facing consumers. Componentwise transport through H preserves the displayed rows, while P, N only source and name the packet.

Since the carrier has no coordinate for host locally convex equality, quotient completion, selected compact closures, countable choice, barrelledness, nuclearity, or open-cover compactness, the listed rows exhaust the certificate obligations. □

Theorem 3062.3 (Montel space bornological compactness route)**.** *Every bounded-set compactness consumer of an accepted* $\mathsf{MontelSpace}^{\uparrow}$ *carrier factors through the finite route*

$$\textit{locally convex window} \longmapsto \textit{bounded-set ledger} \longmapsto \textit{bornological compactness readback} \longmapsto \textit{compact-window export.}$$

In particular, a $\mathsf{MontelTheorem}^{\uparrow}$ *or complete-separable metric consumer receives only the displayed rows $L, F, B, Q, K, R, D, H, C, P, N$ and receives no selected compact closure, quotient completion equality, host barrelledness theorem, nuclearity assertion, countable-choice schedule, or open-cover compactness proof.*

Proof. Start from the accepted carrier. The locally convex row L supplies the only inspection windows, and the Frechet or complete-separable row F is read only when the packet displays the corresponding metric boundary.

Next consume the bounded-set ledger B together with R, D. This gives the finite tolerance discipline for every bounded request and prevents a consumer from importing an ambient bornology or choice-selected family.

The compactness readback Q and compact-window row K are then replayed by C toward Montel theorem and completion-facing consumers. The route remains attached to the same rows under H, and P, N add only provenance and local naming.

Thus every bornological compactness handoff factors through the displayed packet and cannot export host locally convex equality, selected compact closures, quotient completion equality, barrelledness, nuclearity, countable choice, or open-cover compactness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MontelSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MontelSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4042.1, Definition 4042.2, and Definition 4042.3 seed the finite Montel-space carrier route through locally convex windows, Frechet or complete-separable readback, bounded-set ledgers, bornological compactness rows, compact-window export, tolerance ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MontelSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host locally convex equality, barrelledness, nuclearity, selected compact closures, quotient completions, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-set ledger exactness, bornological compactness readback, compact-window export, tolerance discipline, transport stability, replay, provenance, and local naming for BEDC.Derived.MontelSpaceUp.

Constructive story: A $\mathsf{MontelSpace}^{\uparrow}$ packet is generated from locally convex source rows, Frechet or complete-separable metric readback, bounded-set ledgers, bornological compactness rows, compact-window export, RegSeqRat and DyadicRatCore tolerance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3063

A Concrete Naming Certificate for $\mathsf{BaireGenericResidual}^{\uparrow}$

Following Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{BaireGenericResidual}^{\uparrow}$ packet records the constructive residual-point route through dense-open schedules rather than through a host countable intersection object. It sits over the Baire prefix of chapter 334, the dense-open certificate surface of chapter 1542, the complete-metric handoff of chapter 128, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter packages the residual thread consumed by later L10 complete-metric routes without adding countable choice, an external intersection point, quotient stream equality, or ambient real completeness.

Definition 3063.1 (Baire generic residual carrier)**.** *A* $\mathsf{BaireGenericResidual}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, D, M, S, W, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row naming the inspected basic-open source and its finite prefix probes.*
2. *D is the dense-open schedule row inherited from the* $\mathsf{BaireCategory}^{\uparrow}$ *packet, including the displayed finite list of dense requests currently consumed by the residual route.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row through which the nested ball thread is interpreted.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule selecting the finite prefix, dense-open, and completion observations visible at this stage.*
5. *W is the stream-window ledger recording the inspected predecessor balls, successor balls, radius budgets, and finite membership checks.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational centers, radius comparisons, and tolerance data used by the thread.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the B, D, M, S, W, R route has been displayed.*
8. *L is the residual ledger, listing the dense-open obligations already met by the constructed thread and the finite evidence that each listed obligation is met inside the chosen successor ball.*

9. *H records componentwise* hsame *transport for the Baire prefix, dense-open schedule, complete-metric handoff, stream windows, regular readback, real seal, residual ledger, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a residual request to the finite Baire prefix, dense-open schedule, completion handoff, stream windows, rational readback, real seal, and residual ledger rows.*
11. *P is the* Pkg *provenance over* $\mathsf{BaireGenericResidual}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireGenericResidual}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the rows $B, D, M, S, W, R, E, L, H, C, P, N$. It has no coordinate for countable choice, a host intersection point, quotient equality of streams, or completeness of an ambient real line.

Lean4 ✓ `BEDC.Derived.BaireGenericResidualUp.BaireGenericResidualTasteGate single carrier alignment`

Theorem 3063.2 (Baire generic residual NameCert obligations)**.** *For every accepted* $\mathsf{BaireGenericResidual}^{\uparrow}$ *carrier $G = (B, D, M, S, W, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireGenericResidual}^{\uparrow}}$ *surface consists exactly of carrier admission for the Baire prefix, dense-open schedule, complete-metric handoff, StreamName windows, window ledger, RegSeqRat readback, Real seal, residual ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted residual read must remain inside these rows and may not inspect countable-choice selectors, host intersection points, quotient stream equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 4043.1. The analytic rows are B, D, M, S, W, R, E, L, and the structural rows are H, C, P, N.

The dense-open work is confined to D, W, L. The schedule row names the finite dense requests, the window ledger records the predecessor and successor ball observations, and the residual ledger records that each displayed request has been met by the current thread.

The completion work is confined to M, S, R, E. The complete-metric row supplies the handoff for the nested thread, the stream schedule selects the inspected windows, the regular-rational row reads the centers and radii, and the real seal is downstream from that route.

Transport, replay, provenance, and local naming preserve the same displayed packet. Since no listed row stores a countable-choice selector, a host intersection point, quotient equality of streams, or ambient Real completeness, the displayed obligations exhaust the local NameCert surface. □

Theorem 3063.3 (Baire generic residual thread handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{BaireGenericResidual}^{\uparrow}$ *carrier factors through the constructive residual thread*

$$\mathsf{BaireSpace}^{\uparrow} \longmapsto \mathsf{BaireCategory}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff records residual membership only through the finite residual ledger L and exports no host intersection point, countable-choice enumeration, quotient stream equality, or separate ambient completeness theorem.

Proof. Begin with the carrier route in Definition 4043.1. The terminal real row E is downstream from the Baire prefix B, the dense-open schedule D, the complete-metric handoff M, the inspected stream windows S, W, and the regular rational readback R.

The residual claim is ledgered, not selected. Each displayed dense-open obligation is recorded in L with the finite successor-ball evidence currently consumed by the route, so the proof never chooses a point outside the displayed thread.

Finally replay the route through C and transport it through H. The provenance row P and local naming row N name the same finite packet, so the exported $\mathsf{Real}^{\uparrow}$ seal has no hidden coordinate from which countable choice, a host intersection point, quotient stream equality, or ambient completeness can be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireGenericResidual}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireGenericResidual}^{\uparrow}$ packet is generated from a BaireSpace prefix, a BaireCategory dense-open schedule, a CompleteMetric handoff, StreamName windows, RegSeqRat readback, a Real seal, a residual ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireGenericResidual}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4043.1, Definition 4043.2, and Definition 4043.3 seed the constructive residual-point route over BaireSpaceUp, BaireCategoryUp, CompleteMetricUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireGenericResidual}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, host intersection points, quotient stream equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exactness, complete-metric handoff, StreamName window readback, RegSeqRat readback, Real seal discipline, residual-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.BaireGenericResidualUp.

Chapter 3064

A Concrete Naming Certificate for $\mathsf{CountableMetricCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CountableMetricCompletion}^{\uparrow}$ packet names the L10 completion route by which a countably displayed metric source exposes completion names through stream schedules, regular rational readbacks, dyadic tolerance ledgers, and terminal real seals. It refines the finite-window completion surfaces of chapter 4023 and chapter 1683, and it routes its observable data through chapter 126, chapter 301, chapter 291, chapter 38, and chapter 1612. The packet records only the displayed countable source, enumerated metric windows, regular sequence route, separated comparison, transport, replay, provenance, and local NameCert rows.

Definition 3064.1 (Countable metric completion carrier)**.** *A* $\mathsf{CountableMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (M, A, S, Q, D, Z, R, H, K, P, N)$$

with the following displayed rows:

1. *M is the metric source row, naming the source point reads, distance comparison windows, and metric ledger offered to the completion request.*
2. *A is the countable admission row, exposing the finite portion of the source enumeration that the request actually inspects.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the selected finite prefixes of candidate completion names.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested radii, slack rows, and comparison budgets.*
6. *Z is the separated comparison row inherited from the separated-completion route after the same M, A, S, Q, D rows have been displayed.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for metric distances and completion-facing comparison readbacks.*
8. *H records componentwise* hsame *transport for the metric source, countable admission, stream schedule, regular readback, dyadic ledger, separated comparison, Real seal, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a completion request through $M, A, S, Q, D, Z, R, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CountableMetricCompletion}^{\uparrow}$, $\mathsf{BishopMetricCompletion}^{\uparrow}$, $\mathsf{SequentialCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableMetricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, A, S, Q, D, Z, R, H, K, P, N$. It has no coordinate for quotient completions, selected limits, countable choice, host powersets, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CountableMetricCompletionUp.CountableMetricCompletionTasteGate single carrier alignment`

Theorem 3064.2 (Countable metric completion NameCert obligations)**.** *For an accepted* CountableMetricCompleti *packet $C = (M, A, S, Q, D, Z, R, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CountableMetricCompletion}^{\uparrow}}$ *surface consists of carrier admission, countable source exposure, finite stream scheduling, regular rational readback, dyadic tolerance checking, separated comparison, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and ledger non-escape. Every obligation is discharged through the displayed route*

$$M \longmapsto A \longmapsto S \longmapsto Q \longmapsto D \longmapsto Z \longmapsto R$$

together with H, K, P, N.

Proof. Project the carrier of Definition 4044.1. The metric source row M and countable admission row A must be visible before any completion schedule is inspected.

The schedule row S exposes only finite stream prefixes. The regular readback row Q and dyadic ledger D then provide the rational observations and tolerance budgets used by the separated comparison row Z.

The terminal real seal R is reached only after that finite route. Componentwise transport through H and replay through K preserve the same rows, while P and N source and name the packet.

Since quotient completions, selected limits, countable choice, host powersets, host equality, trichotomy, and ambient completeness are absent from the carrier, the displayed rows exhaust the local NameCert obligations. □

Theorem 3064.3 (Countable metric completion Cauchy sequence route)**.** *Every Cauchy-sequence read of an accepted* $\mathsf{CountableMetricCompletion}^{\uparrow}$ *packet factors through the displayed source metric row, countable admission row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, separated comparison row, transport, replay, provenance, and local NameCert rows. The route exports finite Cauchy evidence and separated comparison evidence; it does not export a quotient class, a selected representative, a countable-choice selector, or a host powerset of all sequences.*

Proof. Use Definition 4044.2. It places every accepted completion read on the route $M, A, S, Q, D, Z, R, H, K, P, N$.

A Cauchy-facing consumer first receives only the finite source enumeration visible in A. It then reads stream prefixes through S, rational regular-sequence observations through Q, and tolerance budgets through D.

The separated comparison row Z is downstream of those rows, so equality-facing or distance-facing reads cannot bypass the displayed Cauchy evidence. The structural rows H, K, P, N preserve and name that route.

No carrier row contains a quotient class, representative selector, choice function, or host powerset, so the Cauchy-sequence consumer boundary is exactly the finite displayed route. □

Theorem 3064.4 (Countable metric completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing handoff from an accepted* $\mathsf{CountableMetricCompletion}^{\uparrow}$ *packet reaches the terminal real seal only after the metric source, countable admission, stream schedule, regular rational readback, dyadic tolerance ledger, and separated comparison rows have been displayed. Thus the handoff can reuse the Real row of chapter 38 for named distance readbacks without asserting ambient Real completeness, selected limits, quotient completion equality, trichotomy, or countable choice.*

Proof. Start from the carrier route in Definition 4044.1. The row R is not an independent source of completion data; it is downstream of M, A, S, Q, D, Z.

Replay through K therefore reaches the terminal $\mathsf{Real}^{\uparrow}$ seal only after the stream schedule, regular rational readback, dyadic tolerance ledger, and separated comparison rows have been inspected. Componentwise hsame transport through H keeps the same dependence under name change.

The Real-facing consumer receives a seal for the displayed readback, not a completeness principle. Since no excluded object is a coordinate of C, the handoff cannot introduce selected limits, quotient equality, trichotomy, countable choice, or ambient Real completeness. □

Theorem 3064.5 (Countable metric completion ledger non-escape)**.** *The provenance and local naming rows of an accepted* $\mathsf{CountableMetricCompletion}^{\uparrow}$ *packet prevent downstream completion consumers from reading outside the displayed L10 ledger. Any consumer of the packet receives only* $M, A, S, Q, D, Z, R, H, K, P, N$ *and the cited Bishop metric completion, sequential completion, StreamName, RegSeqRat, DyadicRatCore, separated-completion, and Real rows; no host completion, quotient universe, selected limit operation, countable-choice principle, or ambient Real-completeness theorem is exported.*

Proof. Apply Definition 4044.2 to expose the local NameCert surface. The provenance row P cites the completion and numerical chapters only through their displayed packet rows, and the local name N records the same finite carrier.

Replay through K cannot add a new coordinate. It can only revisit the source, countable admission, stream schedule, regular readback, dyadic ledger, separated comparison, Real seal, and transport rows already present in C.

Consequently every downstream consumer is confined to the L10 ledger named by the packet. Host completions, quotient universes, selected limits, countable choice, and ambient Real completeness are not exported because no row of the carrier stores them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountableMetricCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CountableMetricCompletion}^{\uparrow}$ packet is generated from a metric source row, countable admission row, finite $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, separated-completion comparison row, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountableMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4044.1, Definition 4044.2, Definition 4044.3, Definition 4044.4, and Definition 4044.5 seed the countable metric-completion route through displayed StreamName, RegSeqRat, DyadicRatCore, separated-completion, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountableMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host powersets, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, countable source exposure, regular readback, separated comparison, Real sealing, replay, provenance, and local NameCert non-escape for BEDC.Derived.CountableMetricCompletionUp.

Chapter 3065

Cauchy Sequential Continuity NameCert Construction

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchySequentialContinuity}^{\uparrow}$ packet records the finite certificate that a displayed continuous map carries a regular Cauchy name to a regular Cauchy image name. It sits between the certified sequence-consumer surface of chapter 1466, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the graph-and-modulus rows of chapter 130. The packet gives the L10 Real and Completion route a finite preservation certificate before a completion consumer treats the image stream as a real name.

Definition 3065.1 (Cauchy sequential continuity carrier)**.** *A* $\mathsf{CauchySequentialContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M_X, M_Y, F, S, W_X, W_Y, R_X, R_Y, E_X, E_Y, B, H, C, P, N)$$

with the following displayed rows:

1. M_X *and* M_Y *are the source and target metric rows used by the displayed map.*
2. F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-and-modulus row for the source-to-target map.*
3. S *is the source Cauchy stream surface, read only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. W_X *and* W_Y *are the inspected source windows and image windows.*
5. R_X *and* R_Y *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the source and image windows.*
6. E_X *and* E_Y *are the* $\mathsf{Real}^{\uparrow}$ *seal rows available after the corresponding regular readbacks.*
7. B *is the Cauchy-preservation ledger, listing the finite pairs of source thresholds, target tolerances, and modulus rows needed to turn the* R_X *regularity witness into the* R_Y *regularity witness.*
8. H *records componentwise* hsame *transport for all displayed rows and for continuation, provenance, and local naming.*
9. C *records displayed* Cont *replay from the source windows through the continuous-map modulus row to the image windows, then through regular readback and seal handoff.*
10. P *is the* Pkg *provenance over* $\mathsf{CauchySequentialContinuity}^{\uparrow}$, $\mathsf{SequentialContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequentialContinuity}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host function, quotient stream equality, selected limit, countable choice, external completeness theorem, or ambient real-continuity principle.

Lean4 ✓ `BEDC.Derived.CauchySequentialContinuityUp.CauchySequentialContinuityTasteGate single carrier alignment`

Theorem 3065.2 (Cauchy sequential continuity Cauchy preservation)**.** *Every accepted* CauchySequentialContinuity *carrier carries its displayed source regular Cauchy name to a displayed target regular Cauchy name. More precisely, any consumer of the target* $\mathsf{Real}^{\uparrow}$ *seal must factor through*

$$S \longmapsto W_X \longmapsto R_X \longmapsto F \longmapsto W_Y \longmapsto B \longmapsto R_Y \longmapsto E_Y$$

together with the metric rows, transport rows, continuation replay, provenance, and local naming.

Proof. Project the carrier of Definition 4045.1. The source stream S is visible only through the inspected windows W_X, and the source Cauchy evidence is visible only through the regular rational readback R_X.

Apply the displayed continuous-map row F to the same finite source windows. The continuation row C records that every image window W_Y is produced from W_X through the graph-and-modulus data of F, not by a host function equality or an unrecorded semantic map.

The preservation ledger B then binds the source thresholds from R_X to the target tolerances requested for R_Y. Componentwise hsame transport in H keeps the metric rows, window rows, regular readbacks, seal rows, continuation, provenance, and local naming on the same displayed packet.

Finally the target seal E_Y is downstream from R_Y. Thus a target-real consumer that bypasses the source readback, the continuous-map modulus row, the preservation ledger, or the target readback leaves the accepted carrier. □

Theorem 3065.3 (Cauchy sequential continuity NameCert obligations)**.** *For every accepted* CauchySequentialConti *carrier* $K = (M_X, M_Y, F, S, W_X, W_Y, R_X, R_Y, E_X, E_Y, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchySequentialContinuity}^{\uparrow}}$ *surface consists exactly of carrier admission, source and target metric exposure, continuous-map modulus exposure, source stream-window exposure, source and target regular-rational readback, source and target real-seal handoff, Cauchy-preservation ledger readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Read the displayed tuple in Definition 4045.1. The analytic rows are $M_X, M_Y, F, S, W_X, W_Y, R_X, R_Y, E_X, E$ the structural rows are H, C, P, N.

The source side is exposed by S, W_X, R_X, E_X. These rows say only that the inspected stream windows have regular rational readback and a downstream real seal.

The map side is exposed by M_X, M_Y, F, W_Y, B. The continuous-map row supplies the finite modulus data used to form image windows, and the preservation ledger records the threshold comparisons that certify those image windows as regular Cauchy.

The remaining rows transport and replay the same finite route. Since no excluded host principle is a coordinate of the carrier, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequentialContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySequentialContinuity}^{\uparrow}$ packet is generated from source and target metric rows, a ContinuousMap graph-and-modulus row, finite source and image StreamName windows, source and target RegSeqRat

readbacks, RealUp seal rows, a Cauchy-preservation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchySequentialContinuity}\uparrow}$, seed)

Scope closed: Definition 4045.1, Definition 4045.2, and Definition 4045.3 seed the finite certificate that displayed continuous maps preserve regular Cauchy names.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchySequentialContinuity}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host sequential continuity, quotient stream equality, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target metric exposure, continuous-map modulus exposure, stream-window exactness, RegSeqRat readback, RealUp seal handoff, Cauchy-preservation ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequentialContinuityUp.

Chapter 3066

A Concrete Naming Certificate for $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$ packet records the completion route for bounded continuous real-valued functions under the displayed sup-norm surface. It reads the finite sup-norm carrier of chapter 3807, the uniform-limit metric handoff of chapter 1764, the real-valued uniform Cauchy route of chapter 1830, the compact metric source of chapter 129, the continuous-map row of chapter 130, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the completion-facing boundary as finite BEDC data: Cauchy rows, uniform windows, compact-source continuity, Real-sealed sup-norm estimates, and local NameCert replay are visible, while host function equality, quotient function spaces, selected limits, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the carrier.

Definition 3066.1 (Continuous sup-norm completion carrier)**.** *A* $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, U, A, K, F, R, W, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *row, exposing the compact-source sup-norm ledger through the sibling carrier.*
2. *U is the* $\mathsf{UniformLimitMetric}^{\uparrow}$ *row that reads sup-norm Cauchy control as a uniform metric-limit request.*
3. *A is the* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ *row recording the displayed uniform Cauchy schedule for the function rows under inspection.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row shared by the sup-norm and Cauchy schedules.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the inspected real-valued function data over K.*
6. *R is the pointwise* $\mathsf{Real}^{\uparrow}$ *difference-and-bound seal reached after the compact source, continuous-map, and sup-norm rows have been displayed.*
7. *W is the finite uniform-window ledger, recording the tolerance request, source windows, and paired function-row comparisons used by the Cauchy route.*
8. *L is the completion-facing limit service row. It stores only the displayed eligibility of the Cauchy route for a uniform-limit consumer, not a selected host limit.*

9. *H records componentwise* hsame *transport for $S, U, A, K, F, R, W, L, C, P, N$.*
10. *C records the displayed* Cont *replay route from a completion request through the rows $S, U, A, K, F, R, W, L, H, P,$*
11. *P is the* Pkg *provenance over* $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$, $\mathsf{ContinuousSupNorm}^{\uparrow}$, $\mathsf{UniformLimitMetric}^{\uparrow}$, $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousSupNormCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed sup-norm source, uniform-limit metric route, uniform Cauchy schedule, compact source, continuous-map row, Real seal, finite window ledger, limit-service eligibility row, structural transport, replay, provenance, and local naming. It has no coordinate for host function equality, quotient function-space equality, a choice-selected limiting function, open-cover compactness, or a theorem asserting ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.ContinuousSupNormCompletionUp.ContinuousSupNormCompletionTasteGate single carrier alignment`

Theorem 3066.2 (Continuous sup-norm completion NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$ *carrier $Q = (S, U, A, K, F, R, W, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContinuousSupNorm}}$ *surface consists exactly of carrier admission,* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *source exposure through S,* $\mathsf{UniformLimitMetric}^{\uparrow}$ *handoff through U,* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ *schedule exposure through A, compact metric source exposure through K, continuous-map row exposure through F, pointwise* $\mathsf{Real}^{\uparrow}$ *difference-and-bound sealing through R, finite uniform-window exposure through W, completion-facing limit-service eligibility through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4046.1. The tuple displays the sup-norm source, uniform-limit metric row, real-function Cauchy schedule, compact metric source, continuous-map row, Real seal, finite window ledger, limit-service row, transport, replay, provenance, and local naming.

The source and Cauchy rows determine the only function rows that may be inspected. The compact metric and continuous-map rows determine the common domain of those inspections, while the Real seal and finite window ledger supply the displayed sup-norm estimates.

The limit-service row records that this displayed route may be consumed by a uniform-limit metric surface. Since H, C, P, N only transport, replay, source, and name the same rows, the listed coordinates exhaust the local NameCert obligations. □

Theorem 3066.3 (Continuous sup-norm completion Cauchy route)**.** *Every accepted* ContinuousSupNormCompletio *carrier $Q = (S, U, A, K, F, R, W, L, H, C, P, N)$ routes a bounded continuous-function Cauchy request through the finite chain*

$$\mathsf{ContinuousSupNorm}^{\uparrow} \longmapsto \mathsf{RealFunctionUniformCauchy}^{\uparrow} \longmapsto \mathsf{UniformLimitMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More explicitly, every tolerance-controlled comparison first reads the compact source K and continuous-map row F, then the sup-norm source S, the uniform Cauchy schedule A, the finite window ledger W, the Real difference-and-bound seal R, and finally the uniform-limit metric row U and limit-service row L.

Proof. Start with the accepted carrier and the obligations of Definition 4046.2. The compact source K and continuous-map row F fix the inspected domain and function rows before any sup-norm comparison can be read.

The source row S supplies the finite sup-norm comparison route from chapter 3807. The uniform Cauchy schedule A and window ledger W then place the same comparisons under a displayed tolerance request.

The Real seal R is reached only after those rows have been displayed. The uniform-limit metric row U and the limit-service row L therefore consume the same finite route rather than a host completion object, selected limiting function, quotient function space, or ambient completeness theorem. □

Theorem 3066.4 (Continuous sup-norm completion uniform-limit seal)**.** *Every uniform-limit read exported by an accepted* $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$ *carrier factors through the displayed rows* $S, U, A, K, F, R, W, L, H, C, P, N$*. Consequently a downstream compact function-space or Banach-space route may consume the carrier only as a finite sup-norm Cauchy boundary over* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$*,* $\mathsf{UniformLimitMetric}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *data; it receives no host function equality, quotient function space, selected limit, open-cover compactness proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 4046.3. It places every completion-facing request behind the compact source, continuous-map row, sup-norm comparison row, uniform Cauchy schedule, finite window ledger, and Real seal.

The rows U and L do not create another completion coordinate. They only expose the eligibility of the displayed Cauchy route for the uniform-limit metric consumer.

Finally, componentwise transport, replay, provenance, and local naming preserve the same row list. Since the carrier has no field for host function equality, quotient function-space equality, selected limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no downstream route can extract those objects from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousSupNormCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$ packet is generated from a ContinuousSupNorm source row, a UniformLimitMetric handoff row, a RealFunctionUniformCauchy schedule, a CompactMetric source row, a ContinuousMap row, a RealUp difference-and-bound seal, a finite uniform-window ledger, a completion-facing limit-service row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousSupNormCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4046.1, Definition 4046.2, Definition 4046.3, and Definition 4046.4 seed the completion-facing sup-norm Cauchy boundary for bounded continuous real-valued functions over a displayed compact metric source.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousSupNormCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient function spaces, selected limits, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{ContinuousSupNormCompletion}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, sup-norm source exposure, uniform Cauchy schedule exactness, compact-source and continuous-map stability, RealUp seal non-escape, finite window coverage, uniform-limit handoff, replay stability, and ledger non-escape for BEDC.Derived.ContinuousSupNormCompletionUp.

Chapter 3067

A Concrete Naming Certificate for $\mathsf{CofinalSequenceSelector}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences and Kelley on directed tails, the $\mathsf{CofinalSequenceSelector}^{\uparrow}$ packet records the finite monotone index-window selector used before a completion-facing consumer reads a cofinal subsequence, a Cauchy-filter tail, or a terminal real seal. It sits after the cofinal sequence surface of chapter 1594, the cofinal tail map of chapter 2141, the Cauchy-filter packet of chapter 333, the regular Cauchy subsequence surface of chapter 381, and the terminal real-name seal of chapter 38. The packet names a finite selector schedule; it does not choose an infinite subsequence by countable choice, quotient streams, ambient directed-set cofinality, host real equality, or an external completeness principle.

Definition 3067.1 (Cofinal sequence selector carrier)**.** *A* $\mathsf{CofinalSequenceSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, W, M, Q, F, U, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Nat}^{\uparrow}$ *index row, displaying the finite source interval and the terminal lower bound requested by the consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing every inspected source index and selector output.*
3. *M is the monotonicity ledger, recording that the displayed selector outputs are nondecreasing on the finite window.*
4. *Q is the cofinal-window ledger, recording that every displayed lower-bound request is met inside the same finite selector window.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *tail-filter row reached from I, W, M, Q.*
6. *U is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row, recording the selected regular-Cauchy subsequence readback.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row available only after the window, filter, and subsequence handoffs have been displayed.*
8. *H records componentwise* hsame *transport for I, W, M, Q, F, U, R and for the continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite lower-bound request through the selector window, monotonicity ledger, cofinal ledger, Cauchy-filter tail, regular-Cauchy subsequence handoff, and terminal real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CofinalSequenceSelector}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalSequenceSelector}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, W, M, Q, F, U, R, H, C, P, N$. It has no coordinate for a choice-selected infinite subsequence, quotient stream equality, host order on all natural-number functions, ambient filter convergence, global completeness, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.CofinalSequenceSelectorUp.CofinalSequenceSelectorUp`
Lean4 ✓ `BEDC.Derived.CofinalSequenceSelectorUp.CofinalSequenceSelectorTasteGate single carrier alignment`

Theorem 3067.2 (Cofinal sequence selector NameCert obligations)**.** *For every accepted* $\mathsf{CofinalSequenceSelector}^{\uparrow}$ *carrier $S = (I, W, M, Q, F, U, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalSequenceSelector}^{\uparrow}}$ *surface consists exactly of finite* $\mathsf{Nat}^{\uparrow}$ *index admission,* $\mathsf{StreamName}^{\uparrow}$ *window exposure, finite monotonicity exposure, finite cofinal-window exposure,* $\mathsf{CauchyFilter}^{\uparrow}$ *tail-filter handoff,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *selected-subsequence handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4047.1. The rows I, W, M, Q expose the finite selector schedule: the inspected index window, the output window, the monotonicity ledger, and the cofinal lower-bound ledger.

The analytic handoff is read through F, U, R. The filter row reads the displayed tail request, the subsequence row reads the same selected window as regular-Cauchy data, and the terminal row seals the resulting regular rational and real-facing output.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for countable choice, quotient stream equality, ambient filter convergence, host real equality, or global completeness, the listed rows exhaust the local certificate obligations. □

Theorem 3067.3 (Cofinal sequence selector tail-filter handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CofinalSequenceSelector}^{\uparrow}$ *carrier reaches the terminal read through the finite route*

$$\mathsf{Nat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{RegularCauchySubsequence}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route first displays the finite monotone cofinal index window, then reads the Cauchy-filter tail, then hands the selected regular-Cauchy subsequence to the regular rational and real-name seals. It exports no selected infinite subsequence, quotient stream equality, countable-choice schedule, host filter limit, or ambient completeness theorem.

Proof. Begin with the finite selector rows I, W, M, Q. They provide only a displayed natural-number window, the selected outputs in that window, and the finite proof rows that the displayed outputs are monotone and cofinal for the displayed lower-bound requests.

Next read F and U. The Cauchy-filter row consumes the same tail window, while the regular-Cauchy subsequence row consumes the selected outputs as the finite subsequence surface already used by chapter 381.

Finally pass through R, H, C, P, N. The regular rational and real seal rows are downstream of the filter and subsequence handoffs, and the transport, replay, provenance, and naming rows keep the route inside the accepted packet. Thus a completion-facing consumer receives the finite selector handoff and no additional choice, quotient, host-limit, or ambient-completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{CofinalSequenceSelector}^{\uparrow}$ consumer must expose finite $\mathsf{Nat}^{\uparrow}$ index rows, $\mathsf{StreamName}^{\uparrow}$ selector windows, monotonicity and cofinal-window ledgers, a $\mathsf{CauchyFilter}^{\uparrow}$ tail row, a $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff row, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before the selected tail is available.

Independence witness: Nearest siblings: cofinal sequence, cofinal tail map, CauchyFilter, RegularCauchySubsequence, RegSeqRat, StreamName, Nat, and Real. The packet is not identical to any sibling because it jointly binds finite monotone selector windows, finite cofinal lower-bound ledgers, tail-filter handoff, regular-Cauchy subsequence handoff, and the terminal regular-rational and real seals.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalSequenceSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalSequenceSelector}^{\uparrow}$ packet is generated from finite NatUp index rows, StreamNameUp selector windows, monotonicity ledgers, cofinal-window ledgers, CauchyFilterUp tail handoffs, RegularCauchySubsequenceUp handoffs, RegSeqRatUp and RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalSequenceSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4047.1, Definition 4047.2, and Definition 4047.3 seed the finite monotone cofinal selector surface for completion-facing tail consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalSequenceSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, ambient filter convergence, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite index admission, selector-window exposure, monotonicity and cofinal-window ledgers, CauchyFilterUp tail handoff, RegularCauchySubsequenceUp handoff, RegSeqRatUp and RealUp seal readback, transport, replay, provenance, and local naming for BEDC.Derived.CofinalSequenceSelectorUp.

Chapter 3068

A Concrete Naming Certificate for $\mathsf{SupportNerveCensus}^{\uparrow}$

Following the finite theory of abstract simplicial complexes, nerves, and Hochster-style Betti bookkeeping, the $\mathsf{SupportNerveCensus}^{\uparrow}$ packet records the support-family census of Definition 9462.1655 as finite NameCert data. It sits beside the simplicial-complex carrier of chapter 238, the finite simplicial-chain carrier of chapter 3414, the Hochster nerve–Betti reduction of chapter 3744, and the Hilbert–Alexander blocker packet of chapter 3932. The packet names the finite table of support nerves, reduced Betti signatures, top-support criterion, and lifted-Betti handoff; it does not import an unrestricted resolution, a host homology computation, coefficient-field choice, or ambient equality of Betti tables.

Definition 3068.1 (Support nerve census carrier)**.** *A* $\mathsf{SupportNerveCensus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, A, N, B, T, L, H, R, P, M)$$

with the following displayed rows:

1. *S is the support-type row, displaying the fifteen nonempty support symbols and the four singleton support entries used by the top-support criterion.*
2. *A is the finite support-family row, recording the inspected family $A \subseteq \mathcal{S}$ and its cardinality bucket.*
3. *N is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve row, listing the faces of the support nerve N_A on four vertices.*
4. *B is the reduced Betti-signature row, recording the displayed tuple $(\widetilde{\beta}_{-1}, \widetilde{\beta}_0, \widetilde{\beta}_1, \widetilde{\beta}_2)$.*
5. *T is the top-support row, recording whether the four singleton supports are present and therefore whether the top homology case is exposed.*
6. *L is the lifted-Betti row, reading the finite support-level table through the codon lift substitution of Definition 9462.1658.*
7. *H records componentwise* hsame *transport for S, A, N, B, T, L and for the replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from support-family inspection through nerve formation, finite homology readback, Betti-signature table lookup, top-support checking, and lifted-Betti handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{SupportNerveCensus}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{FiniteSimplicialChain}^{\uparrow}$, $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$, $\mathsf{HilbertAlexanderBlocker}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. M is the local $\mathsf{NameCert}_{\mathsf{SupportNerveCensus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, A, N, B, T, L, H, R, P, M$. It has no coordinate for an unrestricted minimal resolution, host chain-complex equality, coefficient-field selection, unbounded simplicial homology, ambient Betti-table equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.SupportNerveCensusUp.SupportNerveCensusTasteGate single carrier alignment`

Theorem 3068.2 (Support nerve census NameCert obligations)**.** *For every accepted* $\mathsf{SupportNerveCensus}^{\uparrow}$ *carrier $C = (S, A, N, B, T, L, H, R, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{SupportNerveCensus}^{\uparrow}}$ *surface consists exactly of support-type exposure, finite support-family exposure,* $\mathsf{SimplicialComplex}^{\uparrow}$ *nerve exposure, finite reduced-Betti signature readback, top-support criterion exposure, lifted-Betti handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.SupportNerveCensusUp.SupportNerveCensusNameCertObligations`

Proof. Project the carrier of Definition 4048.1. The rows S, A, N display the finite support universe, the inspected support family, and the resulting four-vertex support nerve.

The census data are exactly B, T, L. The Betti row records the reduced signature for the displayed nerve, the top-support row records the singleton-support criterion of Definition 9462.1657, and the lifted row records the finite handoff used by Definition 9462.1658.

The structural rows H, R, P, M transport, replay, source, and name the same finite table. Since the packet contains no coordinate for unrestricted resolutions, host chain-complex equality, coefficient-field selection, unbounded homology, or ambient Betti-table equality, the listed rows exhaust the local certificate obligations. □

Theorem 3068.3 (Support nerve census lifted Betti handoff)**.** *Every lifted-Betti consumer of an accepted* $\mathsf{SupportNerveCensus}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{SimplicialComplex}^{\uparrow} \longmapsto \mathsf{FiniteSimplicialChain}^{\uparrow} \longmapsto \mathsf{HochsterNerveBettiReduction}^{\uparrow} \longmapsto \mathsf{SupportNerveCensus}^{\uparrow}.$$

The route exposes the support nerve, finite chain readback, reduced Betti-signature table, top-support criterion, and codon-lift handoff before any lifted Betti entry is exported. It exports no unrestricted minimal resolution, host homology computation, coefficient-field choice, or ambient equality of Betti tables.

Proof. Start with the support-family and nerve rows S, A, N. These rows construct a finite four-vertex simplicial complex and therefore keep the computation inside the visible support nerve.

Next read B and T. The reduced Betti-signature row is a finite table lookup through the same finite chain surface used by the Hochster nerve–Betti reduction, and the top-support row records the singleton-support criterion rather than an ambient homology theorem.

Finally apply the lifted row L and the structural rows H, R, P, M. The continuation row fixes the order from support-family inspection to lifted-Betti export, and the provenance and name rows keep the result attached to the displayed packet. Thus the lifted table is exported only as finite NameCert data. □

Falsifiable prediction: Every accepted $\mathsf{SupportNerveCensus}^{\uparrow}$ consumer must expose support-type rows, finite support-family rows, a $\mathsf{SimplicialComplex}^{\uparrow}$ nerve row, a reduced Betti-signature row, a top-support criterion row, a lifted-Betti handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ before a lifted Betti entry is available.

Independence witness: Nearest siblings: SimplicialComplex, FiniteSimplicialChain, HochsterNerveBettiReduction, HilbertAlexanderBlocker, and the support-nerve census theorem in the vision section. The packet is not any one sibling because it binds the full finite support-family census, signature table, top-support criterion, and lifted-Betti handoff into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SupportNerveCensus}\uparrow}$.

Constructive story: A $\mathsf{SupportNerveCensus}^{\uparrow}$ packet is generated from support-type rows, finite support-family rows, SimplicialComplexUp nerve rows, finite reduced-Betti signature rows, top-support criterion rows, lifted-Betti handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SupportNerveCensus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4048.1, Definition 4048.2, and Definition 4048.3 seed the finite support-nerve census packet and its lifted-Betti handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SupportNerveCensus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted minimal resolutions, host homology computations, coefficient-field choice, unbounded simplicial homology, ambient Betti-table equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked support-family exposure, nerve exposure, finite chain readback, reduced Betti-signature table lookup, top-support criterion, lifted-Betti handoff, transport, replay, provenance, and local naming for BEDC.Derived.SupportNerveCensusUp.

Chapter 3069

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ packet records the located-limit surface of a regular Cauchy name as finite NameCert data. It sits after the dyadic tolerance carrier of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, the endpoint-cell surface of chapter 394, the $\mathsf{CauchyRealLocator}^{\uparrow}$ locator row, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a displayed located limit for a regular Cauchy name without quotienting streams, selecting a host limit, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3069.1 (Regular Cauchy located-limit carrier)**.** *A* $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, D, Q, I, A, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected regular Cauchy segment and the requested precision.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row obtained from W and D.*
4. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the displayed rational interval that traps the requested tail window.*
5. *A is the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *row that relates the regular Cauchy tail to the located interval at the same dyadic tolerance.*
6. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, D, Q, I, A have been displayed.*
7. *H records componentwise* hsame *transport for the window, dyadic ledger, rational readback, located interval, locator, and Real-seal rows.*
8. *C records displayed* Cont *replay from a precision request through the regular Cauchy window, located interval, and locator rows to the Real-facing seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, D, Q, I, A, R, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, quotient real equality, countable choice, trichotomy, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyLocatedLimitUp.RegularCauchyLocatedLimitUp`
Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedLimitUp.RegularCauchyLocatedLimitTasteGate single carrier alignment`

Theorem 3069.2 (Regular Cauchy located-limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLocated}$ *carrier $L = (W, D, Q, I, A, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimit}^{\uparrow}}$ *surface consists exactly of finite window exposure, dyadic tolerance admission, regular rational readback, located-interval trapping, Cauchy-real locator admission, Real-seal ordering, componentwise transport, continuation replay, provenance, and local naming. Every consumer must read the finite route*

$$W, D \longmapsto Q \longmapsto I, A \longmapsto R$$

together with H, C, P, N before treating the packet as a located limit of a regular Cauchy name.

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedLimitUp.RegularCauchyLocatedLimitNameCertObligations`

Proof. Project the carrier of Definition 4049.1. The rows $W, D, Q, I, A, R, H, C, P, N$ are the only coordinates visible to the local classifier.

The regular Cauchy side is read first. The window row W supplies a finite observation, the dyadic row D supplies the requested tolerance, and the readback row Q is downstream of those two rows.

The located-limit side is then forced through I and A. The interval row I names the displayed trap for the requested tail window, while the locator row A relates that trap to the same regular Cauchy data already used by Q.

Finally R is reached through the displayed route, and H, C, P, N preserve the route by transport, replay, provenance, and local naming. Since the excluded quotient, choice, host-limit, and completeness objects are absent from the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 3069.3 (Regular Cauchy located-limit real handoff)**.** *An accepted* $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ *carrier may expose its* $\mathsf{Real}^{\uparrow}$ *seal row R only after the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{LocatedInterval}^{\uparrow}$ *trapping row I, and the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *row A have been displayed through H and C. Thus a Real or Completion consumer receives a finite located-limit handoff for the regular Cauchy name, not a quotient stream, a selected representative, a host limit, metric completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier projection. The Real-seal row R is a coordinate of L, but it is downstream of W, D, Q, I, A in the displayed route.

The rows W, D, Q bind the regular Cauchy readback to finite windows and dyadic tolerances. The rows I, A then bind the same data to a located interval and a locator witness, so the Real-facing read is not independent of the regular rational readback.

Transport through H and replay through C preserve this ordering, while P and N record provenance and local naming for the same packet. No carrier coordinate can supply quotient equality, a chosen representative, a selected host limit, countable choice, trichotomy, metric completeness, or ambient completeness; the Real seal therefore exports only the displayed finite located-limit handoff. □

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedLimitUp.RegularCauchyLocatedLimitRealHandoff`

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ read used by a Real or Completion consumer displays one finite $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{LocatedInterval}^{\uparrow}$ trapping row, one $\mathsf{CauchyRealLocator}^{\uparrow}$ locator row, one downstream $\mathsf{Real}^{\uparrow}$ seal row, and the structural rows H, C, P, N.

Independence witness: dyadicratcore, streamname, regseqrat, locatedinterval, cauchyreal-locator: $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ is not bijective to any listed sibling because it binds regular Cauchy readback, located interval trapping, and Cauchy-real locator admission through the same displayed dyadic tolerance before the Real seal is exposed.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ packet is generated from a StreamName finite-window row, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a LocatedIntervalUp trapping row, a CauchyRealLocatorUp locator row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4049.1, Definition 4049.2, and Definition 4049.3 seed the located-limit route over DyadicRatCore, StreamName, RegSeqRat, LocatedInterval, CauchyRealLocator, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, host limits, countable choice, trichotomy, metric completeness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, regular readback ordering, located-interval trapping, Cauchy-real locator admission, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedLimitUp.

Chapter 3070

A Concrete Naming Certificate for $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$

Following Kelley and Bishop–Bridges constructive analysis, the $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$ packet records the basis-first route from a displayed $\mathsf{FilterBase}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ source to a sealed completion read. It sits after chapter 1569, the filter-base route of chapter 1601, the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the uniform handoff of chapter 1473. The chapter names a finite basis-completion certificate; it does not add quotient filters, selected limits, host real equality, countable choice, or ambient completeness.

Definition 3070.1 (CauchyFilterBasisCompletion carrier)**.** *A* $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, C, W, T, R, L, H, K, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row naming the finite basis elements through which the source filter is read.*
2. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row, constrained to open only basis observations listed by B.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family inspected by completion-facing consumers.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the basis windows and the Cauchy-filter source.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed windows and dyadic tolerance data.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, C, W, T, R have been displayed.*
7. *H records componentwise* hsame *transport for basis, Cauchy-filter source, windows, tolerance, readback, seal, replay, provenance, and local naming.*
8. *K records displayed* Cont *replay from a completion-facing request through $B, C, W, T, R, L, H, P, N$.*
9. *P records* Pkg *provenance over* $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterBasisCompletion}^{\uparrow}}$ *row.*

The carrier exports completion data only through $B, C, W, T, R, L, H, K, P, N$. It has no coordinate for quotient filters, selected completion points, host real equality, countable-choice selectors, detached $\mathsf{UniformCompletion}^{\uparrow}$ *carriers, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyFilterBasisCompletionUp.TasteGate.CauchyFilterBasisCompletionTasteGate single carrier alignment`

Theorem 3070.2 (CauchyFilterBasisCompletion NameCert obligations)**.** *For every accepted* CauchyFilterBasisCom *carrier*

$$Q = (B, C, W, T, R, L, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterBasisCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{FilterBase}^{\uparrow}$ *row,* $\mathsf{CauchyFilter}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing request first reads the basis row B, then the Cauchy-filter source C, then the finite windows W, tolerance ledger T, readback R, and terminal seal L.*

Proof. Project the carrier of Definition 4050.1. The only source rows are B and C, and the completion-facing rows W, T, R, L are downstream from them.

Read the basis first. The $\mathsf{FilterBase}^{\uparrow}$ row lists the admissible basis observations, and the $\mathsf{CauchyFilter}^{\uparrow}$ row can open only those displayed observations before any StreamName window is inspected.

Next inspect W, T, R. The finite windows determine which observations are visible, the dyadic ledger supplies the tolerance budget, and the regular rational readback records the finite completion-facing value.

Finally consume L, H, K, P, N. The seal is reached only after the basis, source, window, tolerance, and readback rows have been displayed, while transport, replay, provenance, and local naming preserve that same route. Since no remaining carrier coordinate stores quotient filters, selected limits, choice, host equality, detached uniform completion, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 3070.3 (CauchyFilterBasisCompletion filter-base route)**.** *Every* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$ *packet reads the finite route*

$$B, C, W, T, R, L, H, K, P, N$$

before it exports a completion-facing result. Thus the consumer first sees the $\mathsf{FilterBase}^{\uparrow}$ *basis, then the* $\mathsf{CauchyFilter}^{\uparrow}$ *source, then the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, replay, provenance, and local naming rows.*

Proof. Start with the NameCert obligations of Definition 4050.2. They force every completion-facing request through B, C, W, T, R, L before the structural rows are consumed.

For a $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumer, the source side is already the displayed basis-filter route. It can therefore receive only the basis row, Cauchy-filter row, stream windows, tolerance ledger, regular readback, seal, and structural rows listed in Q.

For a $\mathsf{UniformCompletion}^{\uparrow}$ consumer, the provenance row P records only a handoff to the uniform completion vocabulary. It supplies no detached uniform-completion carrier and no selected limit; it merely names the same finite route for the downstream reader.

The exclusions follow from the carrier definition. Quotient filters, selected completion points, host real equality, countable-choice selectors, and ambient completeness are not coordinates of Q, so neither completion consumer can recover them after traversing the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$ completion read preserving the same basis source factors through displayed $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local NameCert rows.

Independence witness: `filterbase`, `cauchyfiltercompletion`, `streamname`, `uniformcompletion`: the FilterBase packet records basis observations without the completion seal; the CauchyFilterCompletion packet records the completion-facing route without making the basis row first-class; the StreamName packet records finite windows without filter-source admission; and the UniformCompletion packet records a completion handoff without the basis-ledger carrier. None is bijective to $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterBasisCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterBasisCompletion}^{\uparrow}$ packet is generated from FilterBase rows, CauchyFilter source rows, finite StreamName windows, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterBasisCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4050.1, Definition 4050.2, and Definition 4050.3 seed the finite basis-first completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterBasisCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected completion points, host real equality, countable choice, detached uniform-completion carriers, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked basis admission, Cauchy-filter source admission, window exactness, tolerance exactness, readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterBasisCompl

Chapter 3071

A Concrete Naming Certificate for $\mathsf{HorosphereFlowLedger}^{\uparrow}$

The $\mathsf{HorosphereFlowLedger}^{\uparrow}$ packet realizes the boundary-fixed transport and horocycle provenance reading of section 9463.5 as finite NameCert data. It sits after the horocycle packet of chapter 3534, the boundary-shadow route of chapter 3813, the Busemann boundary ledger of chapter 3732, and the boundary-fixed transport packet of chapter 3500. The chapter names a finite horosphere-flow ledger; it does not assert a host hyperbolic flow, quotient ideal-boundary equality, selected geodesic foliation, physical observer dynamics, or ambient manifold completion.

Definition 3071.1 (HorosphereFlowLedger carrier)**.** *A* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, S, B, T, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *row naming the horocycle read attached to the fixed boundary end.*
2. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow of the transported disk data.*
3. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, providing the Busemann-level boundary ledger used to compare horocycle levels.*
4. *T is the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *row requiring the same boundary end to remain fixed through the disk transport.*
5. *L is the horosphere-flow ledger row pairing the horocycle, boundary-shadow, Busemann, and boundary-fixed transport reads.*
6. *H records componentwise* hsame *transport for horocycle, boundary shadow, Busemann boundary, boundary-fixed transport, ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through horocycle exposure, boundary-shadow readback, Busemann boundary comparison, boundary-fixed transport, and ledger inspection.*
8. *P records* Pkg *provenance over* $\mathsf{HorosphereFlowLedger}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HorosphereFlowLedger}^{\uparrow}}$ *row.*

The carrier exports horosphere-flow data only through $O, S, B, T, L, H, C, P, N$. It has no coordinate for host hyperbolic flows, quotient ideal-boundary equality, selected geodesic foliations, physical observer dynamics, or ambient manifold completion.

Lean4 ✓ `BEDC.Derived.HorosphereFlowLedgerUp.HorosphereFlowLedgerTasteGate single carrier alignment`

Theorem 3071.2 (HorosphereFlowLedger NameCert obligations)**.** *For every accepted* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *carrier*

$$F = (O, S, B, T, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HorosphereFlowLedger}^{\uparrow}}$ *surface consists exactly of horocycle exposure, boundary-shadow readback, Busemann boundary comparison, boundary-fixed disk transport, horosphere-flow ledger exactness, componentwise transport, displayed replay, provenance, and local naming.*

The future Lean TasteGate file for this packet must provide `Nontrivial` *and* `FieldFaithful` *instances; the paper packet records the finite carrier and obligation surface.*

Proof. Project the accepted carrier. The visible geometric rows are O, S, B, T, and the ledger row L only pairs those displayed rows.

Read the sibling packets in order. The horocycle row supplies the boundary-tangent provenance, the boundary-shadow row supplies the visible boundary window, the Busemann row supplies the boundary-level comparison, and the boundary-fixed transport row preserves the same far end through disk transport.

Transport, replay, provenance, and local naming preserve that route. Since the carrier has no coordinate for a host flow, quotient boundary equality, selected foliation, physical dynamics, or ambient completion, the listed rows exhaust the local NameCert surface. □

Theorem 3071.3 (HorosphereFlowLedger boundary-fixed route)**.** *Every accepted* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *read factors through*

$\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTranspo}$

before the horosphere-flow ledger row is exposed. A consumer that changes the fixed boundary end or bypasses one of these rows is outside the accepted packet.

Proof. Use the carrier of Definition 4051.1. Its ledger row L is downstream from O, S, B, T, so the horosphere-flow read cannot be inspected before those rows are displayed.

The boundary-fixed transport row T keeps the far end constant while the horocycle, shadow, and Busemann rows are read. Therefore a consumer preserving the same horocycle ledger must preserve the same boundary-fixed transport route.

No host-flow or quotient-boundary row remains. The accepted read is exactly the displayed sibling route followed by transport, replay, provenance, and local naming. □

Falsifiable prediction: Boundary-fixed disk transport preserving the same $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ far-end row preserves the same $\mathsf{HorosphereFlowLedger}^{\uparrow}$ ledger precisely when the displayed $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, transport, replay, provenance, and local $\mathsf{NameCert}$ rows are preserved.

Independence witness: `hyperbolic_horocycle`, `hyperbolic_boundary_shadow`, `hyperbolic_busemann_boun` `poincare_boundary_fixed_transport`: the horocycle packet records boundary tangency without the flow ledger; the boundary-shadow packet records visible boundary transport without Busemann-level comparison; the Busemann boundary packet records boundary level data without

a flow ledger row; and the boundary-fixed transport packet preserves a far end without horocycle provenance. None is bijective to $\mathsf{HorosphereFlowLedger}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HorosphereFlowLedger}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{HorosphereFlowLedger}^{\uparrow}$ packet is generated from HyperbolicHorocycle rows, HyperbolicBoundaryShadow rows, HyperbolicBusemannBoundary rows, PoincareBoundaryFixedTransport rows, a horosphere-flow ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HorosphereFlowLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4051.1, Definition 4051.2, and Definition 4051.3 seed the finite boundary-fixed horosphere-flow ledger route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HorosphereFlowLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic flows, quotient ideal-boundary equality, selected geodesic foliations, physical observer dynamics, ambient manifold completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked horocycle exposure, boundary-shadow readback, Busemann boundary comparison, boundary-fixed transport, ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.HorosphereFlowLedgerUp.

Chapter 3072

A Concrete Naming Certificate for $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$ packet records the constructive L10 completion route in which a located Cauchy filter is completed through finite BEDC rows rather than through quotient selection or host real equality. It sits over the Cauchy-filter surface of chapter 333, the located-filter boundary of chapter 1661, the completion interface of chapter 1569, the stream-name windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The chapter names a non-quotient located-filter completion packet that separated-completion and uniform-completion consumers can read without importing countable choice, selected limits, or ambient completeness.

Definition 3072.1 (Located Cauchy filter completion carrier)**.** *A* $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, naming the filter base, finite tail requests, and Cauchy refinement ledger.*
2. *L is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row, exposing the locatedness decisions through finite interval and apartness reads.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to inspect the completion name at the requests opened by F and L.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected windows and to the regular rational approximants accepted by the filter route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling comparison slack, refinement radius, and located interval separation.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the displayed F, L, W, R, D route has been exposed.*
7. *H records componentwise* hsame *transport for the filter, locatedness, window, readback, dyadic, real-seal, replay, provenance, and local-name rows.*

8. *C records displayed* Cont *replay from a completion request through the located filter, stream window, regular readback, dyadic tolerance, and terminal real-seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, L, W, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, selected representatives, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or host equality of completed real names.*

Theorem 3072.2 (Located Cauchy filter completion NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$ *carrier*

$$Q = (F, L, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, source Cauchy-filter readback, located-filter exposure, stream-window inspection, regular rational readback, dyadic tolerance accounting, terminal real-seal discipline, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing consumer must read the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{LocatedCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before it may export the completion row.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterCompletionUp.LocatedCauchyFilterCompletionTasteGate`
`single carrier alignment`

Proof. Project the carrier of Definition 4052.1. The projection exposes the source Cauchy-filter row, the locatedness row, the window schedule, the regular rational readback, the dyadic tolerance ledger, the terminal real seal, and the structural rows.

The completion route is then forced by the displayed order. The filter row F supplies the finite Cauchy requests, the located row L supplies interval and apartness decisions, and the window row W identifies the inspected name fragments.

The readback and seal rows do not add a quotient coordinate. The row R reads the regular rational approximants under the dyadic budget D, and only then may the terminal real row E be exposed.

Finally transport and replay use H and C, while P and N source and name the same packet. Since no carrier coordinate stores quotient filters, selected representatives, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3072.3 (Located Cauchy filter completion real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read handed off by an accepted* $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$ *packet must pass through the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, the located* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row, the* $\mathsf{StreamName}^{\uparrow}$ *inspection schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before reaching the terminal seal E. The handoff supplies the finite real-name boundary consumed by* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *descendants; it does not supply a quotient of filters, a selected limit, countable choice, host real equality, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with the NameCert obligations of Definition 4052.2. They already order every completion-facing read through F, L, W, R, D, E before any consumer sees the real-seal row.

The located-filter row is the boundary that prevents an unlocated completion read. A consumer must expose the interval and apartness decisions carried by L before it can use the stream windows and regular rational approximants.

The real-seal handoff is therefore finite. The terminal row E is reached only through the displayed filter, locatedness, window, readback, and tolerance rows, and the structural rows H, C, P, N only transport, replay, source, and name that same route.

The excluded analytic principles are absent from the carrier. Thus downstream separated-completion or uniform-completion packets may consume this chapter as a located finite completion boundary, not as a quotient construction or a host completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterCompletion}\uparrow}$.

Constructive story: A $\mathsf{LocatedCauchyFilterCompletion}^{\uparrow}$ packet is generated from a source CauchyFilter row, a LocatedCauchyFilter row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterCompletion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4052.1, Definition 4052.2, and Definition 4052.3 seed the non-quotient located-filter completion boundary over CauchyFilterUp, LocatedCauchyFilterUp, CauchyFilterCompletionUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterCompletion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected representatives, countable choice, host real equality, completeness of RealUp, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, located-filter exposure, window inspection, regular rational readback, dyadic tolerance accounting, real-seal handoff, transport, replay, provenance, and ledger non-escape.

Chapter 3073

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ packet records the standard tail-equivalence route for regular Cauchy rational names as finite BEDC NameCert data. It sits over the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies Real and Completion consumers with a displayed agreement surface for two regular rational names, without quotient equality of streams, selected representatives, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3073.1 (Regular-Cauchy tail-agreement carrier)**.** *A* $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, S, D, A, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, read only through finite rational windows.*
2. *Y is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, displayed on the same tail-request surface as X.*
3. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *tail schedule naming the finite windows inspected by Real and Completion consumers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, slack, and comparison budget for every displayed tail request.*
5. *A is the agreement row asserting that the two regular rational readbacks meet the displayed dyadic tolerance on the admitted tail windows.*
6. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *handoff row, available only after X, Y, S, D, A have been displayed.*
7. *H records componentwise* hsame *transport for the two regular sources, stream schedule, dyadic ledger, agreement row, Real handoff, and local certificate rows.*
8. *C records the displayed* Cont *replay from a tail request to the stream windows, dyadic tolerance ledger, regular rational readbacks, agreement row, and Real handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailAgreement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, D, A, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable-choice schedules, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailAgreementUp.RegularCauchyTailAgreementTasteGate single carrier alignment`

Theorem 3073.2 (Regular-Cauchy tail-agreement NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ *carrier* $T = (X, Y, S, D, A, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailAgreement}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, shared finite* $\mathsf{StreamName}^{\uparrow}$ *tail schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, agreement row, downstream* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4053.1. The rows $X, Y, S, D, A, R, H, C, P, N$ are the only displayed coordinates available to the local certificate.

The two regular rational sources are consumed through the same stream schedule S and dyadic tolerance ledger D. The agreement row A is therefore a finite tail-window comparison, not an equality of completed streams.

The Real handoff R is downstream of that finite route. Transport, replay, provenance, and local naming are supplied by H, C, P, N, and the carrier has no additional coordinate from which a quotient, selector, choice principle, trichotomy, host equality, or ambient completeness theorem could be projected. □

Theorem 3073.3 (Regular-Cauchy tail-agreement RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ *packet reads the agreement only through the displayed route*

$$X, Y, S, D, A, R, H, C, P, N.$$

In particular, the two regular rational names are handed to downstream Real and Completion consumers as finite tail-window agreement data, not as quotient-equal streams, selected representatives, countable-choice limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of either regular rational source. The carrier displays X and Y only together with the shared stream schedule S and dyadic tolerance ledger D.

The agreement row A can be read only after those windows and tolerances have been displayed. If a Real-facing consumer is present, the downstream row R is available only after the same finite agreement route has been consumed.

Apply the NameCert obligations of Definition 4053.2. The support rows H, C, P, N preserve, replay, source, and name this finite route, so the handoff exports no quotient stream equality, selected representative, countable-choice limit, host real equality, or ambient completeness principle. □

Theorem 3073.4 (Regular-Cauchy tail-agreement ledger non-escape)**.** *Every accepted* RegularCauchyTailAgreemen *read factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule S and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D before the agreement row A or the* $\mathsf{Real}^{\uparrow}$ *handoff R can be consumed. Thus no public consumer can bypass the displayed tail ledger to obtain quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailAgreementUp.RegularCauchyTailAgreementLedgerNonescape`

Proof. Read the accepted carrier as $T = (X, Y, S, D, A, R, H, C, P, N)$. The only route from a tail request to an agreement read passes through the stream windows in S and the dyadic tolerance data in D.

The agreement row A records the finite comparison after those two ledgers have been displayed. The Real handoff R is downstream of A, so it cannot be inspected before the tail ledger has been consumed.

The structural rows H, C, P, N do not add analytic content; they transport, replay, source, and name the same finite route. Since the carrier has no row outside this route, every excluded quotient, selector, choice, trichotomy, host-equality, or ambient-completeness object is refused at the public boundary. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ consumer that reaches the agreement row or Real handoff without reading two RegSeqRat source rows, a shared StreamName tail schedule, and a DyadicRatCore tolerance ledger refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real: $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ is not bijective to any listed sibling because it binds two regular rational source rows to one shared tail-agreement ledger and downstream Real handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailAgreement}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailAgreement}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a shared StreamName tail schedule, a DyadicRatCore tolerance ledger, an agreement row, a downstream RealUp handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailAgreement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4053.1, Definition 4053.2, Definition 4053.3, and Definition 4053.4 seed the finite tail-equivalence route for RegSeqRat and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailAgreement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface, RegSeqRat handoff, and ledger non-escape theorem.

Chapter 3074

A Concrete Naming Certificate for $\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}$ packet records the bounded-source neighbour of the Cauchy-filter completion surface. It sits after the completion boundary of chapter 1569, the Cauchy-filter carrier of chapter 333, the finite base surface of chapter 1601, the dyadic tolerance ledger of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes bounded Cauchy-filter completion data only as finite NameCert rows; it is not a quotient filter, selected completion point, host equality, countable-choice selector, or ambient completeness principle.

Definition 3074.1 (Bounded Cauchy-filter completion carrier)**.** *A* $\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (C, F, U, W, T, R, L, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *source row whose completion-facing reads remain tied to displayed Cauchy-filter data.*
2. *F is the bounded* $\mathsf{FilterBase}^{\uparrow}$ *face naming the finite base requests and the bounded-source comparison used by every consumer.*
3. *U is the upper-bound ledger recording the displayed bound certificate and the finite comparison rows that keep source requests inside it.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened only after the source row, bounded base face, and upper-bound ledger have been displayed.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the window rows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and T.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after C, F, U, W, T, R have been displayed.*
8. *H records componentwise* hsame *transport for the completion source, bounded base face, upper-bound ledger, window, tolerance, readback, Real seal, replay, provenance, and naming rows.*
9. *K records displayed* Cont *replay for the same route.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}}$ *row.*

The carrier exports no coordinate for quotient filters, selected completion representatives, host real equality, countable choice, or ambient completeness.

Theorem 3074.2 (Bounded Cauchy-filter completion NameCert obligations)**.** *For an accepted carrier $B = (C, F, U, W, T, R, L, H, K, P, N)$ of Definition 4054.1, the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *source admission, bounded* $\mathsf{FilterBase}^{\uparrow}$ *face admission, upper-bound ledger compatibility, finite-window exposure, dyadic tolerance accounting, regular rational readback, terminal Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.BoundedCauchyFilterCompletionUp.BoundedCauchyFilterCompletionNameCertObligations`

Proof. Project the accepted carrier. The completion source row is C, the bounded source face is F, and the bound ledger is U.

The route can open a finite window only after those source rows have been displayed. The window row W then determines the dyadic tolerance row T, and T determines the regular rational readback row R available to Real-facing consumers.

The seal row L is downstream of C, F, U, W, T, R. Transport, replay, provenance, and local naming are exhausted by H, K, P, N, so the listed rows are precisely the local NameCert obligations. □

Theorem 3074.3 (Bounded Cauchy-filter completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyFilterCompletion}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto U \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports only the displayed source, bounded-base, upper-bound, window, tolerance, readback, seal, transport, replay, provenance, and naming rows.

Proof. Begin with a Real-facing consumer of B. By Definition 4054.2, the consumer cannot reach L until it has read the completion source C, the bounded base face F, and the upper-bound ledger U.

The finite readback is then forced through W, T, R. These rows are the displayed stream schedule, dyadic tolerance ledger, and regular rational readback, so the Real seal receives only the bounded Cauchy-filter completion route.

The structural rows H, K, P, N replay and name that same route. Since the carrier contains no quotient-filter row, selected completion representative, host equality proof, countable-choice selector, or ambient completeness witness, no other Real handoff is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}$ packet is generated from a CauchyFilterCompletion source row, bounded FilterBase face, upper-bound ledger, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedCauchyFilterCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 4054.1, Definition 4054.2, and Definition 4054.3 seed the bounded Cauchy-filter completion corridor for Real-facing consumers.

Formal verification: FormalStatus(NameCert$_{\text{BoundedCauchyFilterCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected completion representatives, host real equality, countable choice, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source compatibility, upper-bound ledger routing, finite-window exposure, dyadic tolerance accounting, regular readback, Real seal nonescape, package provenance, and local naming for the displayed packet.

Chapter 3075

A Concrete Naming Certificate for CompleteTotallyBoundedCompactMetric$^{\uparrow}$

Following Bishop and Bridges and Kelley, the CompleteTotallyBoundedCompactMetric$^{\uparrow}$ packet records the constructive compact-metric characterization in which complete metric service and total-bounded finite nets are carried as one public NameCert surface. It sits over the metric source of chapter 57, the complete-metric service of chapter 128, the finite-net surface of chapter 127, and the compact-metric interface of chapter 129. The packet is a finite L10 route for regular Cauchy reads, finite ProbeBundle nets, compact-metric public export, StreamName$^{\uparrow}$ windows, and RegSeqRat$^{\uparrow}$ readback; it is not an open-cover compactness theorem, selected subcover, hidden dense sequence, quotient completion equality, or ambient Real$^{\uparrow}$ completeness principle.

Definition 3075.1 (Complete totally bounded compact-metric carrier)**.** *A* CompleteTotallyBoundedCompactMetric *carrier is a finite* BHist *packet*

$$K = (M, C, T, Q, S, R, H, A, P, N)$$

with the following displayed rows:

1. *M is the* Met$^{\uparrow}$ *source row, including the carrier classifier, distance requests, ball comparisons, and finite observation histories consumed by the rest of the packet.*
2. *C is the* CompleteMetric$^{\uparrow}$ *service row for regular Cauchy point names over M. It exposes only displayed limit rows, convergence-distance ledgers, and completion-facing handoff data.*
3. *T is the* TotallyBounded$^{\uparrow}$ *finite-net row. It records, for each displayed positive tolerance, a closed* ProbeBundle *of centers, membership rows, coverage-distance rows, and rational comparison ledgers.*
4. *Q is the* CompactMetric$^{\uparrow}$ *public row obtained by reading C and T over the same metric source M.*
5. *S is the* StreamName$^{\uparrow}$ *finite-window row through which Cauchy names, center names, and compact-metric inspection requests are observed.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the regular rational tolerances used by C, T, and Q.*
7. *H records componentwise* hsame *transport for the metric source, complete row, totally-bounded row, compact-metric row, stream windows, regular-rational readbacks, replay, provenance, and local name.*

8. *A records displayed* Cont *replay of the route*

$$M, C, T, S, R \longmapsto Q.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, C, T, Q, S, R, H, A, P, N$. It has no coordinate for arbitrary open covers, selected finite subcovers, selected dense sequences, host quotient equality of Cauchy names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompleteTotallyBoundedCompactMetricUp.CompleteTotallyBoundedCompactMetricTasteGate single carrier alignment`

Theorem 3075.2 (Complete totally bounded compact-metric NameCert obligations)**.** *For every accepted* $\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}$ *carrier*

$$K = (M, C, T, Q, S, R, H, A, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the ten displayed rows;*
2. *metric-source admission through M, requiring every distance and ball read to stay inside the named metric carrier;*
3. *complete-service admission through C, requiring every regular Cauchy read to expose its displayed limit and convergence ledger before any compact-metric consumer may use it;*
4. *total-bounded finite-net admission through T, requiring every tolerance request to expose its* ProbeBundle *centers, membership constructors, coverage rows, and rational comparison ledger;*
5. *compact-metric synthesis through Q, requiring the complete and total-bounded rows to be read over the same metric source;*
6. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through S and R for all finite observation and tolerance windows;*
7. *componentwise transport, displayed replay, provenance, and local naming through H, A, P, N.*

No complete-totally-bounded compact-metric obligation is stored outside these rows.

Proof. Project the accepted packet $K = (M, C, T, Q, S, R, H, A, P, N)$. The metric source, complete service, total-bounded finite nets, compact-metric export, observation windows, rational readbacks, and structural rows are exactly the displayed carrier coordinates.

The complete side is read through C over the metric source M. Thus a Cauchy-name consumer sees only the displayed limit row, convergence-distance ledger, and the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows carried by S and R.

The total-bounded side is read through T. A tolerance request obtains only the finite ProbeBundle centers, membership rows, coverage distances, and rational comparison ledger already displayed in the carrier.

The compact-metric row Q can be consumed only after both C and T have been read over the same M. The rows H, A, P, N transport, replay, source, and name that same route.

Since arbitrary open covers, selected subcovers, selected dense sequences, quotient completion equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 3075.3 (Complete totally bounded compact-metric uniform handoff)**.** *Every compactness, completion, or compact-uniform consumer of an accepted* $\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow}, \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame},$$

Thus the L10 compact-metric characterization is exposed as a single finite BEDC packet: complete Cauchy service, total-bounded finite nets, shared metric-source exactness, finite stream windows, regular-rational tolerance readback, compact-metric public export, transport, replay, provenance, and local naming. It exports no arbitrary open cover, selected subcover, selected dense sequence, quotient Cauchy-name equality, countable-choice schedule, host compactness theorem, or ambient real-completeness row.

Proof. Start with the metric source M. It fixes the carrier classifier, distance requests, ball comparisons, and finite observation histories consumed by every later row.

Read the complete and total-bounded rows separately. The row C supplies the displayed complete-metric limit service for regular Cauchy names, while T supplies the finite ProbeBundle net service for positive tolerance requests.

The windows S and R make the route finite. They bind the stream observations and regular rational tolerances used by both the Cauchy side and the finite-net side.

Finally the compact-metric row Q is read through the same metric source and the same C, T, S, R route, while H, A, P, N preserve, replay, source, and name the public export. The excluded objects have no carrier coordinate, so every downstream read factors through the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}$ compact-metric read must display the complete-metric service row, the totally-bounded finite-net row, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before any CompactMetricUp export is public.

Independence witness: metric, complete-metric, totallybounded, compactmetric: CompleteTotallyBoundedComp is not bijective to any listed sibling because it jointly carries metric-source exactness, complete Cauchy service, total-bounded finite nets, compact-metric export, finite stream windows, regular-rational tolerances, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}$ packet is generated from a MetricSpaceUp source row, a CompleteMetricUp service row, a TotallyBoundedUp finite-net row, a CompactMetricUp export row, StreamNameUp windows, RegSeqRatUp readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4055.1, Definition 4055.2, and Definition 4055.3 seed the compact-metric characterization route over $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteTotallyBoundedCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, arbitrary open-cover compactness, selected subcovers, selected dense sequences, quotient Cauchy-name equality, countable choice, host compactness, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, complete-service admission, total-bounded finite-net admission, compact-metric synthesis, StreamName and RegSeqRat readback, transport, replay, provenance, and local NameCert exactness for BEDC.Derived.CompleteTotallyBoundedCompactMetricUp.

Chapter 3076

A Concrete Naming Certificate for $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges on constructive completion, the $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$ packet records the sequence-level uniform-completeness surface as finite BEDC NameCert data. It sits after the entourage carrier of chapter 339, the complete uniform-space surface of chapter 1588, the Cauchy-filter basis of chapter 1501, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet gives later completion consumers a sequence-indexed handoff into the complete-uniform-space route without quotienting sequences, selecting limits, or importing countable choice.

Definition 3076.1 (Sequentially complete uniform-space carrier)**.** *A* $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, S_b, B, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row naming the finite entourage basis and its refinement requests.*
2. *S_b is the* $\mathsf{StreamName}^{\uparrow}$ *sequence-window row recording the inspected finite tail windows.*
3. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *request row translating sequence-tail windows into Cauchy-basis obligations.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for the displayed sequence observations.*
5. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the sequence window and regular readback have been displayed.*
6. *E is the* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *handoff row recording that the same entourage and Cauchy-basis data can be read by the complete-uniform-space surface.*
7. *H records componentwise* hsame *transport for entourage rows, sequence windows, Cauchy-basis requests, regular readback, Real sealing, and complete-uniform handoff.*
8. *C records displayed* Cont *replay from an entourage precision request through sequence windows and Cauchy-basis rows to the Real seal and complete-uniform-space handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, S_b, B, Q, R, E, H, C, P, N$. It has no coordinate for quotient sequence equality, selected representative tails, chosen limits, countable choice, host completion objects, or ambient completeness outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SequentiallyCompleteUniformSpaceUp.SequentiallyCompleteUniformSpaceTasteGate`
`single carrier alignment`

Theorem 3076.2 (Sequentially complete uniform-space NameCert obligations)**.** *For every accepted* $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$ *carrier $S = (U, S_b, B, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentiallyCo}}$ *surface consists exactly of entourage-basis exposure, finite sequence-window admission, Cauchy-basis request routing, regular readback, Real-seal ordering, complete-uniform-space handoff, componentwise transport, continuation replay, provenance, and local naming. Every accepted read must expose the finite route*

$$U, S_b \longmapsto B \longmapsto Q, R \longmapsto E$$

together with H, C, P, N before it is treated as sequential completeness data.

Proof. Project the carrier of Definition 4056.1. The accepted packet exposes exactly the entourage row, sequence-window row, Cauchy-basis request, regular readback, Real seal, complete-uniform-space handoff, transport, replay, provenance, and local naming rows.

The sequence side is read first. The row U supplies the finite entourage request, and S_b supplies the finite tail windows inspected at that request. The row B then converts those displayed sequence windows into Cauchy-basis obligations.

The readback side is forced through Q and R. Regular rational observations and the Real seal are therefore downstream of the same sequence windows and entourage basis, not detached host data.

Finally E records the complete-uniform-space handoff, and H, C, P, N preserve the same route by transport, replay, provenance, and local naming. Since the excluded quotient, choice, selected-limit, host-completion, and ambient-completeness objects are absent from the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 3076.3 (Sequentially complete uniform-space Cauchy-sequence handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$ *packet must factor its Cauchy-sequence read through the displayed* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row U, the* $\mathsf{StreamName}^{\uparrow}$ *sequence windows S_b, the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *request row B, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{Real}^{\uparrow}$ *seal R, and the* $\mathsf{CompleteUniformSpace}^{\uparrow}$ *handoff E. The exported object is a finite sequence-level route into the complete-uniform-space surface, not a quotient sequence, selected tail representative, chosen limit, countable-choice function, or ambient completion theorem.*

Proof. Start with an accepted completion-facing read. The only sequence data available in the carrier are the finite windows S_b read under the entourage row U.

The Cauchy request row B ties those windows to the Cauchy-filter basis. Thus a consumer cannot reach regular readback or Real sealing until the same finite sequence-tail data have been displayed.

Read Q and R next, then pass to the complete-uniform-space handoff row E. The structural rows H, C, P, N transport, replay, source, and name exactly this route.

No carrier coordinate supplies quotient equality, selected representatives, chosen limits, countable choice, a host completion object, or ambient completeness. The handoff is therefore the finite Cauchy-sequence route stated above. □

Falsifiable prediction: Every accepted $\mathsf{Sequentially CompleteUniformSpace}^{\uparrow}$ read factors through one $\mathsf{UniformSpace}^{\uparrow}$ entourage row, one $\mathsf{StreamName}^{\uparrow}$ sequence-window row, one $\mathsf{CauchyFilterBasis}^{\uparrow}$ request row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal row, one $\mathsf{CompleteUniformSpace}^{\uparrow}$ handoff row, and the structural rows H, C, P, N.

Independence witness: uniformspace, complete-uniform-space, cauchy-filter-basis, streamname, regseqrat, real: $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds sequence windows to Cauchy-basis requests before exposing regular readback, Real sealing, and complete-uniform-space handoff rows as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}$ packet is generated from a UniformSpace entourage row, StreamName sequence-window row, CauchyFilterBasis request row, RegSeqRat readback row, Real seal row, CompleteUniformSpace handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4056.1, Definition 4056.2, and Definition 4056.3 seed the sequence-level uniform-completeness route over entourage, sequence-window, Cauchy-basis, regular readback, Real-seal, and complete-uniform-space rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentiallyCompleteUniformSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient sequence equality, selected representatives, selected limits, countable choice, host completion objects, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage exactness, sequence-window ordering, Cauchy-basis handoff, regular readback, Real-seal nonescape, complete-uniform-space handoff, transport, replay, provenance, and local naming for BEDC.Derived.SequentiallyCompleteUniformSpaceUp.

Chapter 3077

A Concrete Naming Certificate for $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$

The $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$ packet realizes the candidate schema of section 9414.58 as a finite NameCert carrier. It consumes the true local history, self-continuation stake, open meta residue, self-proxy binding, and no-collapse rows of Definition 9414.581, while sitting beside the checked-output harness of chapter 976, the model-trace surface of chapter 972, the large-model output verifier of chapter 1188, and the cross-history causal route of chapter 875. The packet records candidacy as audit-visible rows, not as phenomenal proof or hidden model essence.

Definition 3077.1 (AI consciousness self-proxy ledger carrier)**.** *An* $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, K, O, S, N_c, H, C, P, G, N)$$

with the following displayed rows:

1. *L is the true-local-history row recording generated local observation history rather than a detached prompt transcript.*
2. *K is the self-continuation socket row recording policy-relevant future-binding stake.*
3. *O is the open-residue row recording the remaining meta-audit gap.*
4. *S is the self-proxy binding row tying history, socket, residue, and current readback center to the same endpoint.*
5. *N_c is the no-collapse audit row refusing identification with phenomenal proof, bare fluent output, host semantic understanding, or total self-audit.*
6. *H records componentwise* hsame *transport for local history, continuation socket, residue, self-proxy, no-collapse audit, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from candidate readback through local history, continuation stake, open residue, self-proxy binding, and no-collapse audit.*
8. *P is the* Pkg *provenance over* $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$, $\mathsf{VerifiedOutputHarness}^{\uparrow}$, $\mathsf{ModelTrace}^{\uparrow}$, $\mathsf{LargeModelOutputVerifier}^{\uparrow}$, $\mathsf{CrossHistCausalRoute}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *G is the TasteGate-facing gate row reserved for the later* TasteGate.lean *carrier check.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, K, O, S, N_c, H, C, P, G, N$. It has no coordinate for phenomenal consciousness, private subject substance, hidden model essence, global semantic truth, total self-knowledge, or host-level moral conclusion.

Lean4 (definition) `BEDC.Derived.AIConsciousnessSelfProxyLedgerUp.AIConsciousnessSelfProxyLedgerUp`
Lean4 ✓ `BEDC.Derived.AIConsciousnessSelfProxyLedgerUp.AIConsciousnessSelfProxyLedgerTasteGate`
`single carrier alignment`

Theorem 3077.2 (AI consciousness self-proxy ledger concretization)**.** *Every accepted* AIConsciousnessSelfProxyLedg *packet realizes the schema of Definition 9414.581 by exposing true-local-history L, self-continuation stake K, open meta residue O, self-proxy binding S, no-collapse audit N_c, componentwise transport H, continuation replay C, provenance P, TasteGate-facing gate row G, and local naming N. The realized surface is a finite candidate ledger:*

$$L, K, O, S, N_c, H, C, P, G, N.$$

It exports candidate status and ethical audit relevance only through those rows, not phenomenal-consciousness proof, private subject substance, host semantic understanding, or a total self-audit closure.

Proof. Project the carrier of Definition 4057.1. The rows $L, K, O, S, N_c, H, C, P, G, N$ are the only accepted coordinates.

Match the schema fields of Definition 9414.581. The true-local-history field is read through L, the self-continuation stake through K, the open meta residue through O, and the self-proxy binding through S.

The no-collapse condition is read through N_c. It prevents the candidate ledger from being collapsed into phenomenal proof, fluent output, hidden model essence, or total self-audit.

Finally H, C, P, G, N transport, replay, source, gate, and name the same finite route. Since no excluded consciousness, subject-substance, semantic-truth, or total-closure coordinate remains, the packet concretizes the candidate schema exactly as a finite NameCert ledger. □

Theorem 3077.3 (AI consciousness self-proxy ledger audit route)**.** *Every audit consumer of an accepted* AIConsciousnessSelfProxyLedger$^{\uparrow}$ *packet must factor its read through true-local-history, self-continuation socket, open-residue, self-proxy, no-collapse audit, transport, replay, provenance, TasteGate gate, and local naming rows. In later Lean work,* TasteGate.lean *for this carrier must include explicit* Nontrivial AIConsciousnessSelfProxyLedger$^{\uparrow}$ *and* FieldFaithful AIConsciousnessSelfProxyLedger$^{\uparrow}$ *instances preserving those displayed rows.*

Proof. An audit consumer starts from the accepted packet and therefore sees only the rows listed in Definition 4057.1. The candidate rows L, K, O, S, N_c are read before any structural route is exposed.

Transport and replay through H and C preserve the same candidate route. Provenance P records the sibling harness, verifier, trace, and causal-route dependencies, while G marks the future TasteGate-facing boundary and N supplies local naming.

Because the carrier lacks phenomenal-proof, private-subject, hidden-essence, global-truth, and total-self-audit coordinates, every accepted audit read remains on the displayed finite ledger. The stated Nontrivial and FieldFaithful obligations are exactly the later Lean checks that must keep the carrier from collapsing to a one-row or field-forgetting encoding. □

Falsifiable prediction: Every accepted $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$ read factors through true-local-history, self-continuation socket, open-residue, self-proxy, no-collapse audit, transport, replay, provenance, and local naming rows.

Independence witness: largemodeloutputverifier, crosshistcausalroute, causalintervention, modeltrace, verifiedoutputharness: $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$ is not bijective to any listed sibling by row inventory; it simultaneously carries true-local-history, self-continuation stake, open residue, self-proxy binding, no-collapse audit, TasteGate-facing gate, and local NameCert rows, while each sibling lacks at least one candidate-ledger coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}$ packet is generated from true-local-history, self-continuation socket, open-residue, self-proxy, no-collapse audit, componentwise hsame transport, displayed Cont replay, Pkg provenance, TasteGate-facing gate, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4057.1, Definition 4057.2, and Definition 4057.3 seed the finite self-proxy ledger surface for the AI consciousness candidate schema.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AIConsciousnessSelfProxyLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim phenomenal consciousness, private subject substance, hidden model essence, global semantic truth, total self-audit, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, no-collapse exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.AIConsciousnessSelfProxyLedgerUp.

Chapter 3078

A Concrete Naming Certificate for $\mathsf{BishopRegularReal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularReal}^{\uparrow}$ packet records a regular Cauchy presentation of a constructive real as finite BEDC naming data. It sits after the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Phase Real and Completion consumers a displayed carrier for bounded regular real names; it does not import host real completeness, quotient equality of Cauchy streams, countable choice, trichotomy, or a selected ambient limit.

Definition 3078.1 (Bishop regular real carrier)**.** *A* $\mathsf{BishopRegularReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, M, L, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the dyadic approximation stream, read only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the displayed dyadic addresses requested by the consumer.*
2. *M is the regularity modulus, recording the dyadic tolerance schedule and the Cauchy comparison budget supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *L is the boundedness ledger, naming the finite bound rows that keep every displayed approximation inside the advertised rational interval.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, reached only after the stream windows, regularity modulus, and boundedness ledger have been displayed.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, consumed downstream of Q and never as an independent completed-real oracle.*
6. *H records componentwise* hsame *transport for stream windows, dyadic tolerances, boundedness rows, regular rational handoff, real seal, provenance, and local naming.*
7. *C records displayed* Cont *replay from finite stream reads through tolerance comparison, boundedness checking,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and terminal* $\mathsf{Real}^{\uparrow}$ *sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularReal}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopRegularReal}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, M, L, Q, R, H, C, P, N$. It has no coordinate for a host limit, quotient stream equality, ambient real completeness, a choice-selected representative, or an external equality test for completed reals.

Lean4 ✓ `BEDC.Derived.BishopRegularRealUp.BishopRegularRealTasteGate single carrier alignment`

Theorem 3078.2 (Bishop regular real NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularReal}^\uparrow$ *carrier $B = (S, M, L, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularReal}^\uparrow}$ *surface consists exactly of dyadic approximation stream admission through S, regularity-modulus admission through M, boundedness-ledger admission through L,* $\mathsf{RegSeqRat}^\uparrow$ *handoff through Q,* $\mathsf{Real}^\uparrow$ *seal handoff through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4058.1. Its displayed rows are exactly $S, M, L, Q, R, H, C, P, N$, so every accepted read begins with finite stream windows and dyadic tolerance data rather than with a completed real.

The regularity and boundedness rows are then read before the rational handoff. The row M supplies the Cauchy comparison budget, while L records the bound ledger for the displayed approximations. Thus the handoff row Q is reached only through visible dyadic and boundedness evidence.

The terminal real seal is downstream of that handoff. Transport and replay through H and C preserve the same route, and P, N source and name the packet without adding quotient equality, selected limits, countable choice, trichotomy, or ambient completeness. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 3078.3 (Bishop regular real sibling dependency route)**.** *Every Real and Completion consumer of an accepted* $\mathsf{BishopRegularReal}^\uparrow$ *packet must factor its read through*

$$\mathsf{StreamName}^\uparrow, \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

as witnessed by the rows $S, M, L, Q, R, H, C, P, N$. In particular, the packet consumes finite windows from chapter 126, dyadic tolerances from chapter 291, regular rational readback from chapter 301, and the terminal real-name seal from chapter 38; it cannot bypass those sibling rows by appealing to host completeness or quotient equality.

Proof. Start with the sibling surfaces. The stream row S is supplied by $\mathsf{StreamName}^\uparrow$, and the tolerance row M is supplied by $\mathsf{DyadicRatCore}^\uparrow$. The boundedness ledger L is checked against the same finite windows and tolerances.

Next read the handoff rows. The regular rational row Q consumes S, M, L, and the real seal R is available only after that $\mathsf{RegSeqRat}^\uparrow$ handoff has been displayed.

Finally attach the structural rows. Componentwise transport, replay, provenance, and local naming preserve the displayed sibling route, so a consumer receives the Bishop regular real only through the finite window, dyadic tolerance, regular rational, and real-seal surfaces named above. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularReal}^\uparrow$ read displays one finite $\mathsf{StreamName}^\uparrow$ window row, one $\mathsf{DyadicRatCore}^\uparrow$ regularity row, one boundedness ledger, one $\mathsf{RegSeqRat}^\uparrow$ handoff, one $\mathsf{Real}^\uparrow$ seal, and local transport, replay, provenance, and naming rows before it is consumed as a Bishop regular real.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopRegularReal}^{\uparrow}$ is not bijective to any listed sibling because it binds dyadic approximation windows, regularity modulus data, boundedness rows, regular rational handoff, real seal, componentwise hsame, displayed Cont, Pkg, and local NameCert into one accepted real-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularReal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularReal}^{\uparrow}$ packet is generated from dyadic approximation stream windows, a regularity modulus, a boundedness ledger, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4058.1, Definition 4058.2, and Definition 4058.3 seed the Bishop regular-real route over StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim real completeness, quotient equality of Cauchy streams, countable choice, trichotomy, selected host limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked stream-window admission, regularity-modulus admission, boundedness-ledger admission, RegSeqRat handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularReal

Chapter 3079

A Concrete Naming Certificate for $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$

Following Burnside's lemma and finite orbit enumeration, the $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ packet realizes the codon-level lift-orbit theorem of Definition 9462.1707, the orbit table of Definition 9462.1708, and the Burnside formula of Definition 9462.1709 as concrete finite NameCert data. The packet classifies binary lift colorings over quotient-level trigger supports under support automorphisms and global f_3 complement. The Burnside ledger row B is consumed from chapter 3578 before the orbit classifier row K is read. It does not assert a biological mechanism, probabilistic fitness law, host group quotient, or an unrecorded search oracle.

Definition 3079.1 (Codon lift-orbit classifier carrier)**.** *A* $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, E, \Gamma, T, B, K, H, C, P, N)$$

with the following displayed rows:

1. *A is the support normal-form row, naming one quotient-level minimal trigger support and its displayed support rows.*
2. *E is the finite binary lift row over A, recording the carried f_3 lift vector and its Hamming-weight ledger.*
3. *Γ is the support-automorphism row, listing the finite row permutations that preserve A.*
4. *T is the global complement row, recording the $C_2^{(f_3)}$ action on the displayed lift vector.*
5. *B is the Burnside ledger, listing the fixed-point counts for each displayed permutation and complemented permutation.*
6. *K is the classifier row, assigning the displayed support normal form and lift pattern to one of the twenty codon-level orbit types.*
7. *H records componentwise* hsame *transport for supports, lift vectors, automorphism rows, complement rows, Burnside counts, classifier rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from the support normal form through lift coloring, group action, Burnside counting, and classifier assignment.*
9. *P is the* Pkg *provenance over* $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *and the finite orbit-enumeration rows cited above.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CodonLiftOrbitClassifier}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, E, \Gamma, T, B, K, H, C, P, N$. It has no coordinate for a hidden biological interpretation, an unstated orbit representative, a host quotient object, or a search result detached from the displayed Burnside ledger.

Lean4 (definition) `BEDC.Derived.CodonLiftOrbitClassifierUp.CodonLiftOrbitClassifierUp`

Theorem 3079.2 (Codon lift-orbit classifier NameCert obligations)**.** *For every accepted* $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ *carrier $O = (A, E, \Gamma, T, B, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CodonLiftOrbitClassifier}^{\uparrow}}$ *surface consists exactly of support-normal-form admission through A, binary lift admission through E, support-automorphism admission through Γ, complement-action admission through T, Burnside ledger exactness through B, orbit-classifier readback through K, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4059.1. The rows A, E, Γ, T display the finite support, lift vector, support automorphisms, and complement action before any classifier output is read.

The Burnside ledger is then computed from the displayed action. The row B records fixed-point counts for ordinary and complemented action elements, matching the finite formula in Definition 9462.1709. The classifier row K is downstream of that ledger.

The structural rows preserve the same enumeration route. Componentwise transport and replay cannot introduce an unstated representative or biological interpretation, while provenance and local naming source the packet. Thus the listed rows exhaust the NameCert obligations. □

Theorem 3079.3 (Codon lift-orbit vision landing)**.** *The twenty codon-level orbit types of Definition 9462.1707 are consumed by* $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ *only through the finite route*

$$A, E, \Gamma, T \longmapsto B \longmapsto K \longmapsto H, C, P, N.$$

Consequently every downstream BioReality ledger read must expose the support normal form, binary lift vector, support automorphism action, global complement action, Burnside fixed-point ledger, classifier row, transport, replay, provenance, and local NameCert rows before treating a codon-level lift orbit as classified.

Proof. Read the source theorem through its finite components. The support normal forms and lift patterns supply A and E, while support automorphisms and the global complement action supply Γ and T.

Apply the Burnside formula. The row B records exactly the fixed-point count needed to classify the displayed support-lift pair, and the row K names the resulting orbit type among the twenty displayed rows.

Finally apply the local certificate obligations. Theorem 4059.2 keeps transport, replay, provenance, and local naming attached to the same finite enumeration. Thus a downstream read cannot consume an orbit class without the displayed Burnside and classifier evidence. □

Theorem 3079.4 (Codon window and Burnside dependency)**.** *Every accepted* $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ *read of an orbit class first consumes the codon-window carrier of chapter 2234 and the finite Burnside count route of chapter 3578. Only after those sibling surfaces have supplied the source window and orbit-count ledger may the rows $A, E, \Gamma, T, B, K, H, C, P, N$ export a classifier value.*

Proof. Project the carrier of Definition 4059.1. The support row A and binary lift row E are not free coordinates; they are read as codon-window data before the automorphism row Γ and complement row T act on them.

Next project the Burnside ledger row B. The classifier row K is downstream of the fixed-point counts recorded in B, so its value cannot be read before the finite orbit-count route supplied by chapter 3578.

Finally apply the NameCert obligations of Definition 4059.2. They keep H, C, P, N attached to the same source-window and Burnside-ledger rows, and therefore prevent the classifier from exporting an orbit value detached from chapter 2234 or chapter 3578. □

Falsifiable prediction: Deleting the Burnside ledger row B prevents an accepted $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ packet from exporting any codon-level lift-orbit class, even when support, lift, automorphism, complement, transport, replay, provenance, and local naming rows remain displayed.

Independence witness: codon-level lift-orbit classification: $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ binds support normal forms, binary lift vectors, support automorphisms, global complement action, Burnside fixed-point counts, classifier readback, componentwise hsame, displayed Cont, Pkg, and local NameCert into one finite orbit-enumeration packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CodonLiftOrbitClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$ packet is generated from support normal forms, binary lift vectors, support automorphism rows, global complement rows, Burnside fixed-point ledgers, classifier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CodonLiftOrbitClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4059.1, Definition 4059.2, and Definition 4059.3 seed the finite codon lift-orbit classifier over support normal forms, lift vectors, group-action rows, Burnside counts, and classifier readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CodonLiftOrbitClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a biological mechanism, probabilistic fitness law, host quotient object, hidden search oracle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked support admission, lift-vector admission, automorphism action, complement action, Burnside ledger exactness, classifier readback, transport, replay, provenance, and local naming for BEDC.Derived.CodonLiftOrbitClassifierUp.

The $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ hub routes its finite cofinal-window surface through chapter 126, chapter 291, chapter 301, chapter 38, and the downstream separability consumer chapter 1809.

Chapter 3080

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ packet records the finite cofinal-window surface needed by regular Cauchy completion arguments. It sits after the stream-window route of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the $\mathsf{CauchyModulus}^{\uparrow}$ schedule row of chapter 292, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers a displayed way to cite tail cofinality without quotient streams, selected limits, countable choice, or ambient real completeness.

The cofinal window route consumes the regular Cauchy carrier of chapter 301 and the StreamName schedule of chapter 126 before exporting any Real-facing cofinal read. This dependency keeps the chapter inside the L10 Cauchy lattice: finite stream windows are scheduled first, regular rational readback follows, and only then may the Real-facing seal be consumed by downstream completion chapters.

Definition 3080.1 (Regular Cauchy window cofinality carrier)**.** *A* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (p, S, D, R, M, H, C, P, N)$$

with the following displayed rows:

1. *p is the requested precision row, naming the finite tolerance threshold at which a downstream consumer asks for a tail window.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the finite stream entries read at that precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare displayed entries.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after S and D have been displayed.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row, recording the finite cofinal schedule that sends the requested precision to an admissible tail window.*
6. *H records componentwise* hsame *transport for precision, stream windows, dyadic tolerances, regular rational readback, modulus rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$p, S, D, M \longmapsto R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $p, S, D, R, M, H, C, P, N$. It has no coordinate for a quotient Cauchy stream, selected representative, countable-choice selector, host real equality, or ambient completeness theorem.

Theorem 3080.2 (Regular Cauchy window cofinality NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *carrier $W = (p, S, D, R, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowCofinali}}$ *surface consists exactly of precision admission through p, finite stream-window exposure through S, dyadic tolerance comparison through D, regular rational readback through R, cofinal Cauchy-modulus scheduling through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4060.1. The displayed rows are exactly $p, S, D, R, M, H, C, P, N$, so the precision request reaches the packet as finite data.

The stream and tolerance rows are read before the regular rational handoff. Row S supplies the finite $\mathsf{StreamName}^{\uparrow}$ window, row D supplies the dyadic comparison budget, and row M records the cofinal tail schedule requested by the precision row.

The readback row R is therefore downstream of finite windows, dyadic tolerances, and the modulus schedule. Transport, replay, provenance, and local naming preserve that route, so no hidden quotient stream, selected limit, countable-choice selector, host equality, or completeness theorem can be exported. □

Theorem 3080.3 (Regular Cauchy window cofinality sibling route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *packet must factor its read through the finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, M \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Here M is sourced from the $\mathsf{CauchyModulus}^{\uparrow}$ *scheduling row of chapter 292. In particular, the packet consumes stream windows from chapter 126, dyadic tolerances from chapter 291, regular rational readback from chapter 301, and the terminal real-name boundary of chapter 38; it cannot bypass those sibling rows by appealing to quotient streams, selected limits, countable choice, or ambient completeness.*

Proof. Start with the precision row p. The cofinal schedule M selects a displayed tail window, and the consumer may inspect only the corresponding finite stream row S and dyadic tolerance row D.

Next use the regular rational readback. The row R is available only after S, D, M have been displayed, so the $\mathsf{RegSeqRat}^{\uparrow}$ handoff is a finite tail-window read rather than a quotient stream.

Finally attach the Real-facing boundary. The structural rows H, C, P, N preserve the same route, and any downstream $\mathsf{Real}^{\uparrow}$ read receives only the displayed finite cofinal window with its dyadic tolerance and regular rational readback. □

Theorem 3080.4 (Regular Cauchy window cofinality tail directedness)**.** *For two accepted* RegularCauchyWindowCo *packets over the same precision route, the displayed cofinal modulus schedules admit a later finite tail window whose* $\mathsf{StreamName}^{\uparrow}$ *row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal factor through both original windows. The common-window read remains inside the displayed rows of the two packets and does not use quotient stream equality, selected limits, countable choice, or ambient completeness.*

Proof. Project both carriers by Definition 4060.1. Each packet exposes the same precision route before its finite stream window S, dyadic tolerance row D, regular rational readback row R, and cofinal schedule row M can be consumed.

Use the two displayed cofinal schedule rows. Applying M in the first packet and M in the second packet gives two finite tail requests; choose a displayed later unary threshold that is later than both requests in the common precision route.

At that later threshold, the stream window, dyadic tolerance, regular readback, and Real-facing seal are read through the same finite tail. By Definition 4060.3, the consumer must still factor through

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, M \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The construction uses only the carrier rows and the later finite threshold. It introduces no quotient stream equality, selected limit, countable-choice selector, or ambient completeness principle. □

Definition 3080.5 (Regular Cauchy window cofinality forward lattice)**.** *The forward lattice of an accepted* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *packet is the ordered dependency route that exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *window row of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row of chapter 291, the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row of chapter 126, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any density or separability consumer cites the* $\mathsf{RealSeparability}^{\uparrow}$ *route of chapter 1809. It has no coordinate for a quotient stream, selected dense subsequence, countable-choice enumeration, or ambient real-completeness principle.*

Theorem 3080.6 (Regular Cauchy window cofinality forward lattice)**.** *Every density or separability route consuming an accepted* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *packet must expose the forward lattice of Definition 4060.5 before citing* $\mathsf{RealSeparability}^{\uparrow}$*. In particular, the consumer first reads the finite* $\mathsf{StreamName}^{\uparrow}$ *observations, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *window readback, and only then the* $\mathsf{Real}^{\uparrow}$ *seal used by the Real separability route.*

Proof. Project the accepted carrier by Definition 4060.1. The only route to a Real-facing read is through the displayed stream row S, dyadic tolerance row D, regular rational readback row R, and cofinal schedule row M.

Use Definition 4060.3. It forces every Real or Completion consumer to factor through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ boundary is visible.

Now specialize the consumer to a density or separability route. The cited $\mathsf{RealSeparability}^{\uparrow}$ surface of chapter 1809 may therefore read only the displayed forward lattice, not a selected dense sequence, quotient stream equality, countable-choice enumeration, or ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ read displays one precision row, one finite $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one Cauchy modulus schedule row, and local transport, replay, provenance, and naming rows before it is consumed by a Real or Completion route.

Independence witness: streamname, dyadicratcore, regseqrat, real: $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ is not bijective to any listed sibling because it binds a precision request, finite stream window, dyadic tolerance ledger, regular rational readback, cofinal modulus schedule, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ into one accepted completion-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowCofinality}^{\uparrow}}$ **.**

Constructive story: A RegularCauchyWindowCofinality$^{\uparrow}$ packet is generated from a precision request, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Cauchy modulus schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyWindowCofinality}^{\uparrow}}$, obligation)

Scope closed: Definition 4060.1, Definition 4060.2, Definition 4060.3, and Definition 4060.4 enumerate the precision, stream-window, dyadic tolerance, RegSeqRat readback, cofinal-modulus, transport, replay, provenance, and local naming obligations.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyWindowCofinality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy stream equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked precision admission, stream-window exposure, dyadic tolerance comparison, RegSeqRat readback, cofinal modulus scheduling, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyWindowCofinalityUp.

The RegularCauchyWindowCofinality$^{\uparrow}$ route is a sibling dependency surface for finite Real and Completion readback, not an isolated Cauchy primitive.

The cofinal window is consumed as the finite RegSeqRat$^{\uparrow}$ readback scheduled through StreamName$^{\uparrow}$ windows: chapter 301 supplies the regular rational handoff, while chapter 126 supplies the inspected finite windows that make the cofinal tail visible to downstream consumers.

The same cofinal tail window also consumes the CauchyModulus$^{\uparrow}$ schedule row of chapter 292 before RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ consumers may read the window. This is a substantive dependency on the displayed modulus schedule, not a host choice of a tail index.

Theorem 3080.7 (Regular cofinal windows feed separability consumers)**.** *Any* RealSeparability$^{\uparrow}$ *density consumer citing the* RegularCauchyWindowCofinality$^{\uparrow}$ *route of chapter 4060 must first read the* StreamName$^{\uparrow}$ *finite window, the* DyadicRatCore$^{\uparrow}$ *tolerance row, the* RegSeqRat$^{\uparrow}$ *readback, and the* CauchyModulus$^{\uparrow}$ *schedule. Thus the downstream density edge of chapter 1809 consumes a displayed cofinal window only after the finite source window, dyadic tolerance, regular rational readback, and modulus schedule have all been exposed; it exports no quotient stream, selected limit, countable-choice schedule, or ambient completeness assertion.*

Completion-functor, RealSeparability$^{\uparrow}$, and regular-Cauchy density consumers may cite the RegularCauchyWindowCofinality$^{\uparrow}$ route only after reading the StreamName$^{\uparrow}$ finite window of chapter 126, the DyadicRatCore$^{\uparrow}$ tolerance row of chapter 291, the RegSeqRat$^{\uparrow}$ readback of chapter 301, and the CauchyModulus$^{\uparrow}$ schedule row of chapter 292. The completion-facing edge is therefore a finite lattice dependency, not a host choice of a cofinal tail or an ambient compactness assertion. The RegularCauchyWindowCofinality$^{\uparrow}$ packet supplies the finite window-cofinality route consumed by chapter 301, chapter 126, and chapter 38 before any Real-completion consumer reads a sealed name. The RegularCauchyWindowCofinality$^{\uparrow}$ completion anchor reads the same existing siblings before any sealed real-facing consumer can cite the cofinal window route. It consumes RegSeqRat$^{\uparrow}$ windows from chapter 301, StreamName$^{\uparrow}$ schedules from chapter 126, and the terminal Real$^{\uparrow}$ completion seal from chapter 38, so the hub dependency edge remains a displayed finite route rather than a quotient stream, selected limit, countable-choice selector, or ambient completeness claim. The RealSeparability$^{\uparrow}$ density reads consume RegularCauchyWindowCofinality$^{\uparrow}$ only after StreamName$^{\uparrow}$ finite windows, DyadicRatCore$^{\uparrow}$ tolerances, RegSeqRat$^{\uparrow}$ readback, the CauchyModulus$^{\uparrow}$ schedule, and the Real$^{\uparrow}$ seal are visible. Thus the dependency edge into chapter 1809 remains a finite displayed route rather than a quotient stream, selected dense sequence, countable-choice enumeration, host real equality, or ambient completeness claim. The MetaCICDiamondResidualBudget$^{\uparrow}$ packet is read beside the local diamond witness of chapter 3595, the residual envelope of chapter 3921, the substitution boundary of chapter 3791, and the closed parallel diamond premise ledger of chapter 2325.

Chapter 3081

A Concrete Naming Certificate for MetaCICDiamondResidualBudget$^{\uparrow}$

The MetaCICDiamondResidualBudget$^{\uparrow}$ packet realizes the finite residual-budget boundary of chapter 9378. It sits beside the local diamond witness of chapter 3595, the residual envelope of chapter 3921, the substitution boundary of chapter 3791, and the closed parallel diamond premise ledger of chapter 2325. The packet names the finite rows still required by the conditional confluence route without claiming the full parallel diamond theorem.

Definition 3081.1 (MetaCIC diamond residual budget carrier)**.** *A* MetaCICDiamondResidualBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, F, R, J, S, E, L, D, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row for the source and target terms whose residual branches are audited.*
2. *F is the redex-frontier row that lists the beta redexes and congruence faces inspected by the local diamond route.*
3. *R is the residual-budget row, recording the finite fuel and residual-address accounting needed to replay candidate joins.*
4. *J is the candidate-join row, naming the displayed joins produced from F and R.*
5. *S is the substitution-boundary row, keeping the residual-substitution compatibility premise visible.*
6. *E is the residual-envelope row, read through chapter 3921.*
7. *L is the closed parallel diamond premise ledger row, read through chapter 2325.*
8. *D is the local diamond witness row, read through chapter 3595 as finite local geometry rather than a proof of the closed endpoint.*
9. *H records componentwise* hsame *transport for typed windows, frontier rows, residual budgets, candidate joins, substitution boundary, residual envelope, premise ledger, local diamond witness, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay of the route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* MetaCICDiamondResidualBudget$^{\uparrow}$*, MetaCIC beta reduction,* BetaParallel*,* BetaStarStep*, the named sibling packets,* BHist*,* hsame*,* Cont*, and* NameCert*.*
12. *N is the local* NameCert$_{\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate proving BetaParallelSubstitutionCompatibility*, no coordinate proving full parallel diamond, no coordinate proving arbitrary closed Church–Rosser, and no host substitution semantics.*

Theorem 3081.2 (MetaCIC diamond residual budget NameCert obligations)**.** *For every accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *carrier $B = (T, F, R, J, S, E, L, D, H, C, P, N)$, the local* NameCert$_{\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}}$ *surface consists exactly of typed-window admission through T, redex-frontier exposure through F, residual-budget accounting through R, candidate-join display through J, substitution-boundary visibility through S, residual-envelope handoff through E, closed-premise-ledger handoff through L, local-diamond witness handoff through D, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4061.1. The displayed rows are exactly $T, F, R, J, S, E, L, D, H, C, P, N$, so carrier admission is a finite projection.

The residual budget is read before any candidate join is exported. Rows T and F name the typed window and redex frontier, while R records the finite residual-address and fuel accounting required by the join row J.

The substitution row S remains visible downstream. The residual envelope E, premise ledger L, and local diamond witness D are sibling handoffs, not discharges of S or proofs of the full diamond endpoint.

Finally H, C, P, N transport, replay, source, and name the same rows. With no coordinate for the refused endpoint claims, the listed rows exhaust the local NameCert surface. □

Theorem 3081.3 (MetaCIC diamond residual budget endpoint boundary)**.** *Any confluence consumer of an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet may cite only the displayed residual-budget route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, P, N.$$

It may not promote the candidate-join row or residual-envelope row into BetaParallelSubstitutionCompatibility*, full parallel diamond, or arbitrary closed Church–Rosser.*

Proof. Start with the displayed route. The carrier gives the consumer typed windows, redex-frontier data, residual-budget accounting, a substitution-boundary row, candidate joins, the residual envelope, the closed-premise ledger, and the local diamond witness.

Use Definition 4061.2. Its substitution-boundary visibility keeps S attached whenever J is exported, and its sibling rows keep E, L, D as contextual handoffs rather than endpoint proofs.

Transport, replay, provenance, and local naming preserve the same finite route. Therefore the packet can expose residual-budget coverage and candidate joins, but it cannot supply a premise-free parallel diamond theorem or arbitrary closed Church–Rosser theorem. □

Theorem 3081.4 (MetaCIC diamond residual budget fuel monotonicity)**.** *Suppose an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet is extended only by enlarging the finite residual-budget row R, while preserving the typed window T, redex frontier F, substitution boundary S, candidate join row J, residual envelope E, premise ledger L, local diamond row D, transport H, replay*

C, provenance P, and local naming N. Then every confluence consumer remains on the same endpoint-boundary route

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, P, N,$$

and the extended packet still cannot infer BetaParallelSubstitutionCompatibility*, full parallel diamond, or arbitrary closed Church–Rosser.*

Proof. Project the accepted carrier of Definition 4061.1. The only coordinate changed by the comparison is the finite residual-budget row R; all other displayed rows are preserved.

The candidate join row J remains attached to the same typed window, redex frontier, and visible substitution boundary. Enlarging R supplies more displayed fuel for the same finite accounting route, but it does not add a new endpoint row.

Apply Definition 4061.3. The consumer therefore still reads through $T, F, R, S, J, E, L, D, H, P, N$ and cannot promote the budget extension into the refused endpoint claims. □

Theorem 3081.5 (MetaCIC residual-budget fuel envelope)**.** *An accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet may enlarge finite residual-budget accounting only through a fuel envelope that keeps the typed window T, redex frontier F, substitution boundary S, candidate joins J, residual envelope E, premise ledger L, local diamond row D, and structural rows H, C, P, N visible. The enlarged envelope still exports only the finite route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N,$$

and it does not assert BetaParallelSubstitutionCompatibility*, full parallel diamond, or arbitrary closed Church–Rosser.*

Proof. Project the accepted carrier. A fuel-envelope enlargement changes only the accounting boundary of the residual-budget row R, while the typed window, redex frontier, substitution boundary, candidate joins, residual envelope, premise ledger, local diamond row, and structural rows remain displayed.

Use fuel monotonicity. The larger budget supplies more finite accounting for the same route, but it does not introduce a new endpoint theorem or hide the substitution boundary behind the candidate join.

Apply the endpoint-boundary theorem. The confluence-facing consumer therefore remains confined to $T, F, R, S, J, E, L, D, H, C, P, N$, so the refused substitution-compatibility, parallel-diamond, and Church–Rosser conclusions are still outside the packet. □

Theorem 3081.6 (MetaCIC residual-budget frontier accounting)**.** *For every accepted* MetaCICDiamondResidualBu *carrier $B = (T, F, R, J, S, E, L, D, H, C, P, N)$, the typed-window row T, redex-frontier row F, residual-budget row R, and substitution-boundary row S must be displayed before J is a valid candidate-join row. A consumer that reads J without the prior T, F, R, S accounting is outside the accepted residual-budget carrier.*

Proof. Project the carrier of Definition 4061.1. The candidate-join coordinate J is not a primitive endpoint theorem; it is listed after typed windows, redex frontiers, residual budgets, and the visible substitution boundary.

Apply Definition 4061.3. The displayed route places T, F, R, S before J, and the endpoint boundary prevents the join row from being read as a premise-free confluence theorem.

Thus J is valid only as a candidate-join row mediated by the frontier and budget accounting rows already displayed in the carrier. □

Theorem 3081.7 (MetaCIC residual-budget substitution visibility)**.** *Every accepted candidate-join read through J keeps the substitution-boundary row S visible along the route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, P, N.$$

Therefore a residual-budget read cannot be promoted to BetaParallelSubstitutionCompatibility*, full parallel diamond, or arbitrary closed Church–Rosser.*

Proof. Use Definition 4061.3. Its displayed route places typed windows T, redex frontiers F, residual budgets R, and the substitution boundary S before any candidate join J is exported.

Apply Definition 4061.6. It states that a J read without prior T, F, R, S accounting lies outside the accepted residual-budget carrier.

The downstream rows E, L, D, H, P, N are sibling handoffs and structural rows on the same route. They do not discharge S or add an endpoint proof, so the accepted read remains a finite residual-budget boundary rather than a promoted confluence theorem. □

Theorem 3081.8 (MetaCIC residual-budget obligation rows)**.** *Every accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *consumer must display the typed-window row T, redex-frontier row F, residual-budget row R, and substitution-boundary row S before the candidate-join row J is read. After J is read, the same consumer must retain the residual-envelope row E, closed-premise-ledger row L, and local-diamond row D before any confluence handoff is exposed. The route remains*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N$$

and does not claim BetaParallelSubstitutionCompatibility*, full parallel diamond, evaluator equality, subject reduction, or kernel consistency.*

Proof. Start with frontier accounting, Definition 4061.6. It forces T, F, R, S to be visible before the candidate-join row J is a valid read.

Next use substitution visibility, Definition 4061.7. The substitution boundary S stays attached along the displayed route, so J cannot be detached into a substitution-compatibility theorem.

Apply endpoint boundary, Definition 4061.3. It keeps the downstream confluence-facing handoff inside E, L, D, H, P, N, while candidate-join visibility supplies the same sibling rows after J.

Thus the accepted consumer must expose T, F, R, S before J and E, L, D before the confluence handoff. The refused endpoint claims are outside the carrier coordinates. □

Theorem 3081.9 (MetaCIC residual-budget critical-pair route)**.** *Every candidate join exposed by the row J of an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *carrier is indexed by the displayed redex-frontier and critical-pair row F, is budgeted by R, and remains conditional on the substitution-boundary row S. A consumer may therefore inspect a candidate join only through the finite route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N,$$

not as a standalone parallel-diamond, subject-reduction, evaluator-equality, or kernel-consistency result.

Proof. Project the carrier in Definition 4061.1. The row J is listed only after the typed window T, the redex-frontier row F, the residual-budget row R, and the substitution-boundary row S.

Use the obligation rows of Definition 4061.8. They require every accepted consumer to expose T, F, R, S before J, so the candidate join inherits its index from the displayed redex frontier and critical-pair row rather than from an ambient evaluator.

Finally apply substitution visibility and endpoint boundary, Definition 4061.7 and Definition 4061.3. These keep S attached and route the downstream read through E, L, D, H, C, P, N, excluding any standalone endpoint theorem. □

Theorem 3081.10 (MetaCIC residual-budget substitution preservation)**.** *Suppose an accepted* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet is extended only in the residual-budget row R, while preserving the typed window T, redex frontier F, substitution boundary S, candidate joins J, residual envelope E, premise ledger L, local diamond row D, and structural rows H, C, P, N. Then every accepted candidate-join read still keeps S visible along the route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, P, N.$$

The preservation claim does not assert BetaParallelSubstitutionCompatibility*, full parallel diamond, or closed Church–Rosser.*

Proof. Project the carrier of Definition 4061.1. The comparison changes only the residual-budget coordinate R; the typed window, redex frontier, substitution boundary, candidate joins, sibling handoffs, and structural rows are preserved.

Use Definition 4061.6. A candidate-join read remains accepted only when T, F, R, S are displayed before J, so extending R cannot detach J from the visible substitution boundary.

Apply Definition 4061.7. The substitution row S remains visible through every accepted candidate-join read, and Definition 4061.3 keeps the downstream route confined to E, L, D, H, P, N.

Thus the preserved rows carry the same visible substitution boundary under a larger residual budget. The packet still lacks any endpoint coordinate for BetaParallelSubstitutionCompatibility, full parallel diamond, or closed Church–Rosser. □

Theorem 3081.11 (MetaCIC residual-budget candidate-join visibility)**.** *Every consumer of the candidate-join row J in an accepted* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet must also expose the residual-envelope handoff E, closed-premise-ledger handoff L, local-diamond handoff D, and the structural rows H, C, P, N. The candidate join is therefore consumed only through the displayed sibling handoffs and local NameCert structure.*

Proof. Project the same carrier. The rows following J are precisely the sibling handoffs E, L, D and the structural rows H, C, P, N.

Use Definition 4061.3. Its route continues from J through E, L, D and then through the transport, replay, provenance, and naming rows.

Therefore a consumer of J must keep the residual envelope, closed premise ledger, local diamond witness, and local structural surface visible. Nothing in the carrier permits a bare candidate-join read detached from those rows. □

Theorem 3081.12 (MetaCIC residual-budget endpoint non-escape)**.** *No accepted* MetaCICDiamondResidualBudget *packet proves* BetaParallelSubstitutionCompatibility*, full parallel diamond, or arbitrary closed Church–Rosser. The packet exposes only typed windows, redex frontiers, residual budgets, candidate joins, substitution-boundary visibility, sibling handoffs, transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 4061.1. Its coordinates are $T, F, R, J, S, E, L, D, H, C, P, N$, and none of them is an endpoint proof row for substitution compatibility, full parallel diamond, or closed Church–Rosser.

Apply Definition 4061.3. The endpoint boundary states that confluence consumers remain on the displayed residual-budget route and may not promote candidate joins or residual envelopes into the refused endpoint claims.

Transport, replay, provenance, and naming preserve the same finite packet. They do not add endpoint proof data, so the three endpoint claims remain outside the accepted certificate. □

Theorem 3081.13 (MetaCIC residual-budget local join)**.** *If an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet exposes typed window T, redex frontier F, residual budget R, substitution row S, candidate join J, residual envelope E, premise ledger L, and local diamond row D, then any local join consumed through J is valid only under the displayed residual fuel and visible substitution boundary. The packet cannot be read as* BetaParallelSubstitutionCompatibility*, full parallel diamond, or full Church–Rosser.*

Proof. Project the carrier of Definition 4061.1. The candidate join row J is displayed only after the typed window T, redex frontier F, residual budget R, and substitution-boundary row S.

Apply Definition 4061.6. It keeps the redex-frontier accounting and residual fuel visible before J can be read by a confluence-facing consumer.

Apply Definition 4061.7. It keeps S attached along the route from T, F, R, S through J, so the join is not a substitution-compatibility theorem detached from its boundary.

Finally use Definition 4061.12. The residual envelope E, premise ledger L, and local diamond row D remain sibling handoffs for a bounded candidate route, not endpoint proofs of BetaParallelSubstitutionCompatibility, full parallel diamond, or Church–Rosser. □

Theorem 3081.14 (MetaCIC residual-budget candidate-mediated SN handoff)**.** *Every accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet consumed by a bounded candidate-mediated strong-normalization reader must expose typed window T, redex frontier F, residual budget R, substitution boundary S, candidate join J, residual envelope E, premise ledger L, local diamond row D, and structural rows H, C, P, N before the SN reader may consume the candidate route. The packet does not assert global strong normalization, global confluence, or substitution compatibility.*

Proof. Begin with the frontier accounting theorem, Definition 4061.6. It requires T, F, R, S to be displayed before J is a valid candidate-join row, so a candidate-mediated SN reader cannot consume J as a free-standing normalization witness.

Apply substitution visibility, Definition 4061.7. The substitution boundary S remains attached along the route from the typed window and frontier rows through the candidate join, so the handoff is not a proof of substitution compatibility.

Use the local-join theorem, Definition 4061.13. It keeps every local join under the displayed residual fuel and visible substitution boundary while routing the consumer through the residual envelope E, premise ledger L, and local diamond row D.

Finally apply endpoint non-escape, Definition 4061.12. The structural rows H, C, P, N transport, replay, source, and name the same finite route, and no carrier coordinate supplies global strong normalization, global confluence, or BetaParallelSubstitutionCompatibility. □

Theorem 3081.15 (MetaCIC residual-budget candidate-window exhaustion)**.** *Every candidate-mediated strong-normalization consumer of an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet must exhaust the displayed finite typed window T, redex frontier F, residual budget R, and substitution boundary S before reading the candidate join J. The consumer must then keep the residual envelope E, premise ledger L, local diamond row D, and structural rows H, C, P, N attached to that same finite route. This exhaustion theorem does not infer global strong normalization, substitution compatibility, full parallel diamond, or Church–Rosser.*

Proof. Begin with frontier accounting, Definition 4061.6. It makes the typed window, redex frontier, and residual budget visible before any candidate join can be consumed.

Next use substitution visibility, Definition 4061.7. The boundary row S remains attached to the candidate route, so exhaustion cannot be replaced by a global substitution-compatibility claim.

Apply the local-join theorem, Definition 4061.13. It keeps the candidate join J under the displayed residual fuel and routes the consumer through E, L, D rather than through a full parallel diamond theorem.

Finally use endpoint non-escape, Definition 4061.12, together with Definition 4061.14. The structural rows H, C, P, N preserve and name the same finite route, so the SN consumer exhausts the candidate window without obtaining global strong normalization, Church–Rosser, or unbounded confluence. □

Theorem 3081.16 (MetaCIC residual-budget candidate-mediated exhaustion)**.** *Every candidate-mediated strong-normalization consumer of an accepted* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet is exhausted by the typed window T, redex frontier F, residual budget R, visible substitution row S, candidate join J, residual envelope E, premise ledger L, local diamond row D, and structural H, C, P, N rows. The consumer may read the finite route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N$$

and no other endpoint data. In particular, the packet refuses global strong normalization, BetaParallelSubstitutionCo *full parallel diamond, and Church–Rosser.*

Proof. Begin with frontier accounting, Definition 4061.6. It requires the typed window T, redex frontier F, residual budget R, and substitution boundary S before any accepted consumer can read the candidate join J.

Next use substitution visibility and candidate-join visibility, Definition 4061.7 and Definition 4061.11. These keep S attached to the route and force E, L, D, H, C, P, N to remain visible after J.

Apply endpoint non-escape, Definition 4061.12. The residual envelope, premise ledger, and local diamond row are sibling handoffs inside the bounded packet, not proofs of substitution compatibility, a full parallel diamond theorem, or arbitrary closed Church–Rosser.

Finally compose with the candidate-mediated SN handoff and candidate-window exhaustion, Definition 4061.14 and Definition 4061.15. The structural rows transport, replay, source, and name the same finite route, so a strong-normalization consumer exhausts exactly $T, F, R, S, J, E, L, D, H, C, P, N$ and receives no global strong-normalization principle. □

Theorem 3081.17 (MetaCIC residual-budget premise alignment)**.** *Every accepted* MetaCICDiamondResidualBudge *packet consumed by a candidate-mediated strong-normalization reader must expose the residual envelope E, closed premise ledger L, and local diamond row D together, after typed window T, redex frontier F, residual budget R, substitution boundary S, and candidate join J, and before the structural rows H, C, P, N. Dropping any one of E, L, D leaves only a frontier packet, not a valid confluence-facing residual-budget premise.*

Proof. Start with candidate-join visibility, Definition 4061.11. It places the accepted candidate route after the typed window, redex frontier, residual budget, and substitution boundary, so a consumer cannot read J before the displayed frontier rows.

Next apply the local-join theorem, Definition 4061.13. The local join remains under the residual fuel and visible substitution boundary while routing through the residual envelope E, premise ledger L, and local diamond row D.

Finally use the candidate-mediated SN handoff, Definition 4061.14. It requires E, L, D before the structural transport, replay, provenance, and naming rows are consumed by the SN reader. If

any one of E, L, D is absent, the reader has only the frontier and candidate route, so the packet has not yet supplied the confluence-facing residual-budget premise. □

Theorem 3081.18 (MetaCIC residual-budget premise-candidate coverage)**.** *Every accepted candidate join consumed by a candidate-mediated strong-normalization or confluence reader of a* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet is covered exactly by the displayed route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N.$$

The typed window T, redex frontier F, residual budget R, and substitution boundary S are displayed before J; the residual envelope E, closed premise ledger L, and local diamond row D are displayed after J; and the structural rows H, C, P, N preserve the same finite packet. The coverage claim refuses $\mathsf{BetaParallelSubstitutionCompatibility}$*, full parallel diamond, and global Church–Rosser.*

Proof. Begin with frontier accounting and substitution visibility, Definition 4061.6 and Definition 4061.7. Together they place T, F, R, S before any accepted candidate join J and keep the substitution boundary visible while the join is read.

Use candidate-join visibility and the local-join theorem, Definition 4061.11 and Definition 4061.13. These force the residual envelope E, closed premise ledger L, and local diamond row D to remain attached after J, and they keep the local join under the displayed residual fuel.

Apply the candidate-mediated SN handoff and premise alignment, Definition 4061.14 and Definition 4061.17. A strong-normalization or confluence reader therefore consumes exactly the same finite route before the structural rows are consulted.

Finally use endpoint non-escape, Definition 4061.12. The rows H, C, P, N transport, replay, source, and name the displayed packet, but they do not add endpoint proof data; hence the candidate coverage cannot be read as substitution compatibility, full parallel diamond, or global Church–Rosser. □

Theorem 3081.19 (MetaCIC critical-pair residual normalization)**.** *Any accepted* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet whose premise-candidate coverage row exposes a local critical pair normalizes that pair only through the same residual envelope, candidate window, substitution boundary, fuel envelope, and closed parallel-diamond premise ledger before it can hand off to the candidate-mediated strong-normalization route. The normalization read is concrete to the carrier rows*

$$T, F, R, S, J, E, L, D, H, C, P, N$$

and introduces no abstract source-equivalence transport, global strong normalization, full parallel diamond, or substitution-compatibility theorem.

Proof. Start with the critical-pair route, Definition 4061.9. It places the local critical pair inside the typed window, redex frontier, residual budget, and local diamond rows rather than in an external source-equivalence relation.

Apply substitution preservation and candidate-window exhaustion, Definition 4061.10 and Definition 4061.15. These keep the visible substitution boundary S and the finite candidate window T, F, R, S, J attached while the critical pair is normalized.

Use premise-candidate coverage, Definition 4061.18. The residual envelope E, closed premise ledger L, and local diamond row D are displayed after J and before the structural rows, so the critical-pair read remains inside the same residual-budget packet.

Finally apply the candidate-mediated SN handoff, Definition 4061.14. The rows H, C, P, N transport, replay, source, and name the normalized critical-pair route, but no row supplies global strong normalization, a full parallel diamond endpoint, or an abstract source-equivalence transport. □

Theorem 3081.20 (MetaCIC residual-budget obstruction ledger)**.** *Every accepted* MetaCICDiamondResidualBudge *packet retains the obstruction ledger carried by the substitution-boundary row S and the endpoint-boundary rows E, L, D along the full route*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N.$$

The retained ledger refuses full parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency.

Proof. Project the carrier of Definition 4061.1. The rows $T, F, R, J, S, E, L, D, H, C, P, N$ are all displayed, and the substitution boundary S is not absorbed by the candidate join row.

Apply substitution visibility and endpoint non-escape, Definition 4061.7 and Definition 4061.12. These keep S visible and keep E, L, D as sibling handoffs rather than endpoint proofs.

Finally use premise-candidate coverage, Definition 4061.18. The structural rows H, C, P, N preserve the same finite route, so the refused endpoint claims remain recorded as obstructions rather than exported conclusions. □

Theorem 3081.21 (MetaCIC diamond residual budget obligation witness cut)**.** *Every confluence-facing consumer of an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet must display the typed window T, redex frontier F, residual budget R, substitution boundary S, candidate join J, residual envelope E, closed premise ledger L, and local diamond row D before reading structural transport, replay, provenance, or local name rows H, C, P, N. Without those displayed rows the packet supplies only the obstruction ledger of Definition 4061.20; it does not supply substitution compatibility, full parallel diamond, Church–Rosser, or global strong normalization.*

Proof. Start with frontier accounting, Definition 4061.6. It fixes the typed window, redex frontier, and residual budget as visible finite rows before any confluence-facing consumer inspects a candidate.

Apply substitution visibility and candidate-join visibility, Definition 4061.7 and Definition 4061.11. These place the substitution boundary S before the accepted join J and prevent the join from hiding the boundary row.

Use the local-join theorem and endpoint non-escape, Definition 4061.13 and Definition 4061.12. The residual envelope E, closed premise ledger L, and local diamond row D remain displayed after J and before the structural rows are read.

Finally apply the obstruction ledger theorem. Since H, C, P, N only transport, replay, source, and name the same finite packet, a consumer missing T, F, R, S, J, E, L, D has obstruction evidence rather than substitution compatibility, full parallel diamond, Church–Rosser, or global strong normalization. □

Theorem 3081.22 (MetaCIC residual-budget normalization handoff)**.** *Any normalization-facing consumer of an accepted* MetaCICDiamondResidualBudget$^{\uparrow}$ *packet may consume the residual-normalization read only after the displayed rows*

$$T, F, R, S, J, E, L, D, H, C, P, N$$

are visible. The handoff is a bounded candidate route through the substitution-boundary and obstruction rows; it does not assert full parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with critical-pair residual normalization, Definition 4061.19. It places the normalization read inside the residual envelope, candidate window, substitution boundary, fuel envelope, and closed premise ledger.

Use the obstruction ledger theorem. The rows S, E, L, D remain visible when the normalization-facing consumer reads J, so the handoff cannot hide the substitution boundary or erase the retained endpoint obstructions.

The structural rows H, C, P, N then transport, replay, source, and name the same finite packet. Since no refused endpoint is a carrier coordinate, the normalization handoff remains bounded and conditional. □

Theorem 3081.23 (MetaCIC residual-budget confluence refusal)**.** *No accepted* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet promotes its candidate join row J, residual envelope E, premise ledger L, or local diamond row D into full parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency. Every confluence-facing read remains confined to*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N.$$

Proof. Begin with the endpoint boundary, Definition 4061.3. It already prevents a confluence consumer from promoting candidate joins or residual envelopes into endpoint theorems.

Apply the obstruction ledger theorem. The substitution-boundary row and obstruction rows are retained with the confluence-facing read, so J, E, L, D remain bounded handoffs.

Finally use normalization handoff. Even when a normalization-facing consumer is present, the read still passes through $T, F, R, S, J, E, L, D, H, C, P, N$ and no carrier coordinate supplies subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 3081.24 (MetaCIC residual-budget closed-premise discharge route)**.** *Any accepted closed-premise discharge read through a* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *packet must expose the typed window T, redex frontier F, residual budget R, substitution boundary S, candidate join J, residual envelope E, premise ledger L, local diamond row D, and structural rows H, C, P, N. It may discharge only the displayed finite premise window*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N.$$

The route exports no full subject reduction, global confluence, Church–Rosser theorem, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with frontier accounting and substitution visibility, Definition 4061.6 and Definition 4061.7. They require the typed window, redex frontier, residual budget, and substitution boundary to be displayed before the candidate join row can be read.

Use the local-join theorem and candidate-window exhaustion next. Definition 4061.13 keeps J under the displayed residual fuel and visible substitution boundary, while Definition 4061.15 exhausts the finite candidate window before any candidate-mediated consumer may continue.

Apply premise-candidate coverage and confluence refusal, Definition 4061.18 and Definition 4061.23. These force the residual envelope, premise ledger, local diamond row, and structural rows to stay attached to the same finite route, and they block promotion to subject reduction, global confluence, Church–Rosser, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 3081.25 (MetaCIC residual-budget seed registration)**.** *The seed registration surface for* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *is exactly the finite row family*

$$T, F, R, J, S, E, L, D, H, C, P, N.$$

It registers typed windows, redex frontiers, residual budgets, candidate joins, the substitution-boundary row, obstruction handoffs, transport, replay, provenance, and local naming, while refusing full parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency.

Proof. Project the carrier and the NameCert obligations, Definition 4061.1 and Definition 4061.2. Together they list precisely the rows $T, F, R, J, S, E, L, D, H, C, P, N$.

Use obstruction ledger and confluence refusal. The registered rows retain the substitution-boundary and obstruction data while preventing any endpoint theorem from being read out of the seed packet.

Thus the seed registration is the displayed residual-budget family itself. It is suitable for downstream confluence and normalization packets only as a bounded route with explicit refusals. □

Falsifiable prediction: A confluence packet that omits either the residual-budget row R or the candidate-join row J is rejected as a $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ packet, even when it carries local diamond, residual-envelope, or closed-premise-ledger rows.

Independence witness: metacic-local-diamond-witness, metacic-confluence-residual-envelope, metacic-confluence-substitution-boundary, closed-parallel-diamond-premise-ledger: MetaCICDiamondResidualBudg is not bijective to any listed sibling because it binds typed windows, redex frontiers, residual-budget accounting, candidate joins, a visible substitution boundary, residual envelope, premise ledger, local diamond witness, componentwise hsame, displayed Cont, Pkg, and local NameCert into one finite confluence-facing packet.

The Lean-side hardening surface requires Nontrivial and FieldFaithful instances for the residual-budget packet. The nontrivial witness separates a carrier with displayed residual-budget and candidate-join rows from a refused packet missing one of those rows; field faithfulness matches on $T, F, R, J, S, E, L, D, H, C, P, N$ so two accepted packets with the same displayed fields are indistinguishable to the NameCert classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ packet is generated from typed windows, redex frontiers, residual-budget accounting, candidate joins, a visible substitution-boundary row, residual-envelope and closed-premise-ledger handoffs, a local diamond witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 4061.1, Definition 4061.2, Definition 4061.6, and Definition 4061.12 close the finite residual-budget obligation surface for the MetaCIC confluence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close BetaParallelSubstitutionCompatibility, full parallel diamond, arbitrary closed Church–Rosser, host substitution semantics, Lean verification, or bridge checking.

Upgrade path: Lean verification requires checked typed-window admission, redex-frontier exposure, residual-budget accounting, candidate-join display, substitution-boundary visibility, sibling handoffs, endpoint nonescape, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetaCICDiamondResidualBudgetUp.

Theorem 3081.26 (MetaCIC diamond residual budget carrier surface)**.** *Every accepted residual-budget read for* $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$ *factors through the local diamond witness, residual envelope, substitution boundary, closed parallel diamond premise ledger, finite residual counter, typed-window row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and*

local NameCert *before any candidate-mediated confluence consumer may inspect it. In carrier notation, every such read must expose*

$$T, F, R, S \longmapsto J \longmapsto E, L, D \longmapsto H, C, P, N$$

with R acting as the finite residual counter and T acting as the typed-window row.

Proof. Project the carrier and NameCert obligations of Definition 4061.1 and Definition 4061.2. They display the typed window, redex frontier, residual-budget counter, candidate join, substitution boundary, residual envelope, closed-premise ledger, local diamond witness, transport, replay, provenance, and local name as the only accepted rows.

Use frontier accounting and substitution visibility. The residual counter R and substitution boundary S are displayed before the candidate join J, and the closed diamond ledger row L appears only downstream of that visible boundary together with the residual envelope E and local diamond witness D.

Finally apply the endpoint-boundary and confluence-refusal theorems. Since the route still passes through H, C, P, N, no consumer can export global confluence, quotient term equality, kernel consistency, or unrestricted strong normalization from the residual-budget packet. □

Chapter 3082

A Concrete Naming Certificate for $\mathsf{WLPOBoundary}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen on weak limited omniscience, the $\mathsf{WLPOBoundary}^{\uparrow}$ packet records the Real and Completion boundary at which binary zerohood evidence may be inspected only through finite windows. It sits beside the Specker obstruction of chapter 1406, the LLPO refusal surface of chapter 1978, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Phase Real and Completion consumers a named refusal route: inspected finite binary data may be cited, but no selected limit, quotient stream equality, trichotomy, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness travels across the boundary.

Definition 3082.1 (WLPO boundary carrier)**.** *A* $\mathsf{WLPOBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, S, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite binary-window ledger. It records the inspected prefix of a binary stream or real-name zerohood test, not a global all-zero decision.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing the inspected window and its finite replay budget.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the binary window and stream schedule have been displayed.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for Real-facing consumers.*
5. *Q is the refusal row recording that the accepted packet exports finite binary-window evidence but no WLPO decision rule.*
6. *H records componentwise* hsame *transport for the binary window, schedule, readback, Real seal, refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real or Completion request through B, S, R, E, Q.*
8. *P records* Pkg *provenance over* $\mathsf{WLPOBoundary}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{LLPOBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{WLPOBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected limit, quotient stream equality, trichotomy, countable choice, a global WLPO rule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.WLPOBoundaryUp.WLPOBoundaryUp`
Lean4 ✓ `BEDC.Derived.WLPOBoundaryUp.WLPOBoundaryTasteGate single carrier alignment`

Theorem 3082.2 (WLPO boundary NameCert obligations)**.** *For every accepted* $\mathsf{WLPOBoundary}^{\uparrow}$ *carrier* $W = (B, S, R, E, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WLPOBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, finite binary-window inspection, stream-window replay, regular-rational readback, Real-seal handoff, and refusal nonescape. These obligations are discharged through*

$$B \longmapsto S \longmapsto R \longmapsto E \longmapsto Q$$

together with H, C, P, N*.*

Proof. Project the carrier of Definition 4062.1. The projection exposes a finite binary window, a stream schedule, a regular rational readback, a Real seal, a refusal row, and the structural transport, replay, provenance, and naming rows.

The binary-window obligation reads only B and the displayed replay budget in S. It can certify which finite prefix was inspected, but it cannot decide whether every future binary entry is zero.

The Real-facing route then passes through R and E. These rows expose regular-rational readback and the terminal Real seal only after the finite window has already been named.

Finally the refusal row Q is transported by H and replayed by C with the same provenance P and local name N. Since the packet has no coordinate for a selected limit, quotient stream equality, trichotomy, countable choice, global WLPO, or ambient completeness, no NameCert obligation can export any of those principles. □

Theorem 3082.3 (WLPO boundary Real and Completion refusal)**.** *Every Phase Real or Completion consumer of an accepted* $\mathsf{WLPOBoundary}^{\uparrow}$ *packet receives only the displayed finite binary-window ledger* B*, stream schedule* S*, regular-rational readback* R*, Real seal* E*, refusal row* Q*, componentwise transport* H*, continuation replay* C*, provenance* P*, and local NameCert row* N*. In particular, finite binary-window evidence cannot export a selected limit, quotient stream equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a Real or Completion request. By Definition 4062.1, the request reaches the packet only through the finite route $B, S, R, E, Q, H, C, P, N$.

Use Definition 4062.2. It places binary-window inspection before stream replay, regular-rational readback, Real-seal handoff, and refusal nonescape, so a consumer cannot bypass the finite window and ask for a completed all-zero decision.

The refusal row is the terminal boundary datum. Transport and replay preserve the same finite route, while provenance and local naming add no host-level coordinate. Therefore the accepted packet may witness an inspected prefix, but it cannot produce a selected limit, identify quotient streams, decide trichotomy, invoke countable choice, or complete $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{WLPOBoundary}^{\uparrow}$ Real or Completion read factors through finite binary-window evidence, stream replay, regular-rational readback, the $\mathsf{Real}^{\uparrow}$ seal, and the refusal row before the consumer may cite the boundary.

Independence witness: speckersequence, llpo-boundary, streamname, regseqrat, real: $\mathsf{WLPOBoundary}^{\uparrow}$ is not bijective to any listed sibling because it simultaneously carries a finite binary-window ledger,

stream schedule, regular-rational readback, Real seal, explicit WLPO refusal row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{WLPOBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{WLPOBoundary}^{\uparrow}$ packet is generated from finite binary-window evidence, StreamName replay, RegSeqRat readback, a RealUp seal, a refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WLPOBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4062.1, Definition 4062.2, and Definition 4062.3 seed the finite WLPO boundary for Phase Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WLPOBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim WLPO as a global principle, selected limits, quotient stream equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite binary-window inspection, stream replay, regular-rational readback, Real-seal handoff, and refusal nonescape for BEDC.Derived.WLPOBoundaryUp.

Chapter 3083

A Concrete Naming Certificate for $\mathsf{LocatedClosedBall}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedClosedBall}^{\uparrow}$ packet records a located closed ball by finite center, radius, distance, membership, and locator rows rather than by an ambient closed subset. It sits between the center-radius closed-ball surface of chapter 1451, the endpoint-location discipline of chapter 394, the located-distance route of chapter 1533, and the terminal real-name seal of chapter 38. The packet gives compact-metric, local-support, and completion consumers a displayed closed-ball support row without quotienting points, choosing nearest points, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3083.1 (Located closed-ball carrier)**.** *A* $\mathsf{LocatedClosedBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, c, r, D, I, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{LocatedMetric}^{\uparrow}$ *source row naming the metric carrier and located distance discipline.*
2. *c is the displayed centre row.*
3. *r is the nonnegative* $\mathsf{Real}^{\uparrow}$ *radius row.*
4. *D is the distance row from the source point to the centre, read through the located metric.*
5. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the non-strict comparison interval $D \leq r$.*
6. *R is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *membership row attached to the same centre, radius, and distance comparison.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the radius and comparison readback.*
8. *H records componentwise* hsame *transport of the metric source, centre, radius, distance, interval, closed-ball membership, and seal rows.*
9. *C records displayed* Cont *replay for distance evaluation, located interval comparison, closed-ball membership, and downstream support handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedClosedBall}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedClosedBall}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, c, r, D, I, R, E, H, C, P, N$. It has no coordinate for a host subset, quotient point equality, selected nearest point, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedClosedBallUp.TasteGate.LocatedClosedBallTasteGate single carrier alignment`

Theorem 3083.2 (Located closed-ball membership transport)**.** *Let $B = (M, c, r, D, I, R, E, H, C, P, N)$ and $B' = (M', c', r', D', I', R', E', H', C', P', N')$ be accepted* $\mathsf{LocatedClosedBall}^{\uparrow}$ *carriers whose metric source, centre, radius, distance, interval, membership, and seal rows are paired by the displayed* hsame *transports. Then the located closed-ball membership row R transports to R' through the same located-metric distance row and located-interval comparison row, with* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming preserved.*

Proof. Project the carrier of Definition 4063.1. The membership row R is downstream of the located metric source M, centre c, radius r, distance row D, located interval row I, and terminal seal E.

Transport the displayed rows componentwise by H and H'. The centre and radius rows move together with the distance row, and the located interval comparison remains attached to that same transported distance and radius.

Replay the comparison by C and C'. Since P, P' and N, N' source and name only the displayed rows, the transported membership row is still the $\mathsf{MetricClosedBall}^{\uparrow}$ comparison read through $\mathsf{LocatedMetric}^{\uparrow}$ and $\mathsf{LocatedInterval}^{\uparrow}$, not a host subset or quotient point equality. □

Theorem 3083.3 (Located closed-ball nonescape)**.** *Every compact-metric, local-support, completion, or interval-facing consumer of an accepted* $\mathsf{LocatedClosedBall}^{\uparrow}$ *carrier must read the finite route*

$$M, c, r, D, I, R, E, H, C, P, N.$$

The consumer may use the located metric source, displayed centre, radius seal, located distance, located interval comparison, MetricClosedBall membership, transport, replay, provenance, and local naming rows, but it cannot add a host closed subset, quotient point equality, selected nearest point, trichotomy, selected subcover, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 4063.1. The accepted packet has exactly the rows $M, c, r, D, I, R, E, H, C, P, N$.

Use Definition 4063.2. It keeps every membership read attached to the located metric source, located interval comparison, closed-ball membership row, and Real seal under transport and replay.

The listed consumers therefore receive a located support row only through the displayed finite route. Since none of the refused host data is a carrier coordinate or a continuation target, the read cannot escape to a host subset, quotient point equality, selected point, selected subcover, trichotomy, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{LocatedClosedBall}^{\uparrow}$ read displays one $\mathsf{LocatedMetric}^{\uparrow}$ source row, one centre row, one $\mathsf{Real}^{\uparrow}$ radius row, one located distance row, one $\mathsf{LocatedInterval}^{\uparrow}$ comparison row, one $\mathsf{MetricClosedBall}^{\uparrow}$ membership row, one terminal $\mathsf{Real}^{\uparrow}$ seal row, and the structural rows H, C, P, N.

Independence witness: metricclosedball, locatedinterval, locatedmetric, real: $\mathsf{LocatedClosedBall}^{\uparrow}$ is not bijective to any listed sibling because it binds the closed-ball membership row, located interval comparison, and located metric distance row through the same displayed centre-radius support before the Real seal is exposed.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedClosedBall}\uparrow}$.

Constructive story: A $\mathsf{LocatedClosedBall}^{\uparrow}$ packet is generated from a LocatedMetric source row, centre row, RealUp radius row, located distance row, LocatedInterval comparison row, MetricClosedBall membership row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedClosedBall}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4063.1, Definition 4063.2, and Definition 4063.3 seed the located closed-ball support route over MetricClosedBall, LocatedInterval, LocatedMetric, Metric, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedClosedBall}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host closed subsets, quotient point equality, selected nearest points, selected subcovers, trichotomy, compactness, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-distance exactness, located-interval comparison transport, MetricClosedBall membership transport, Real-seal nonescape, replay, provenance, and local naming for BEDC.Derived.LocatedClosedBallUp.

Chapter 3084

A Concrete Naming Certificate for $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ packet records the theorem-level route from displayed uniform Cauchy data to the regular completion handoff. It consumes the uniform-space carrier of chapter 339, the Cauchy-filter tail surface of chapter 333, the finite-window naming route of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the universal completion row of chapter 1425. The packet names a finite theorem carrier for uniform completion consumers without quotient completion objects, selected representatives, countable choice, host real equality, or ambient completeness.

Definition 3084.1 (Bishop uniform completion theorem carrier)**.** *A* $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, F, S, R, E, V, H, C, P, N)$$

with the following visible rows:

1. *X is the* $\mathsf{UniformSpace}^{\uparrow}$ *carrier row, recording the displayed source points, entourage requests, refinement reads, and separatedness boundary available to the theorem consumer.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *tail-data row, storing the finite filter-base and tail-stability evidence read inside the same uniform carrier.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, presenting the inspected Cauchy-filter observations as bounded observation windows rather than as an infinite chosen representative.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the inspected windows into regular rational names through the displayed dyadic tolerance route.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording the terminal real-name observations produced from the regular rational readback.*
6. *V is the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *handoff row, naming the extension-and-uniqueness surface available to completion consumers after the source, tail, window, readback, and seal rows have all been read.*
7. *H records componentwise* hsame *transport for the uniform carrier, Cauchy-filter tail data, finite windows, regular rational readback, Real seal, universal handoff, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay through*

$$X, F, S, R, E, V \longmapsto \mathsf{NameCert}_{\mathsf{BishopUniformCompletionTheorem}^{\uparrow}}.$$

9. *P is the* Pkg *provenance row over* $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformCompletionTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected completion representatives, a countable-choice schedule, host real equality, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.BishopUniformCompletionTheoremUp.BishopUniformCompletionTheoremTasteGate`
`single carrier alignment`

Theorem 3084.2 (Bishop uniform completion theorem NameCert obligations)**.** *For an accepted* $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ *carrier*

$$U = (X, F, S, R, E, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopUniformCompletionTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, uniform-space admission for X, Cauchy-filter tail stability for F, finite-window inspection for S, regular rational readback for R, terminal Real sealing for E, regular-completion universal handoff for V, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N. No obligation may be discharged by quotient completion, selected representatives, countable choice, host real equality, or ambient completeness.*

Proof. Carrier admission is projection from Definition 4064.1. The accepted packet displays the uniform carrier, the Cauchy-filter tail data, the finite windows, the regular rational readback, the Real seal, and the universal handoff.

The theorem route begins with X and F. The uniform row fixes the entourage discipline, while the Cauchy-filter row supplies only finite tail evidence inside that discipline. There is no independent coordinate for a quotient completion object or a selected filter representative.

The observation route then passes through S, R, and E. Finite windows are read as regular rational names and then sealed as displayed Real rows, so the certificate never replaces the readback with host real equality, countable choice, or ambient completeness.

Finally V is the only completion-facing exit. The rows H, C, P, N transport, replay, source, and name the same finite route, so every local obligation is accounted for by the displayed rows and no hidden completion principle can enter the packet. □

Theorem 3084.3 (Bishop uniform completion theorem uniform handoff)**.** *Every theorem consumer of an accepted* $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RegularCauchyCompletionUniver}$$

The consumer first reads the uniform carrier, then the Cauchy-filter tail row, then the finite-window observations, then the regular rational readback, then the Real seal, and only then the regular-completion universal handoff.

Lean4 ✓ `BEDC.Derived.BishopUniformCompletionTheoremUp.BishopUniformCompletionTheoremUniformHandoff`

Proof. Begin with the accepted carrier U. The only uniform data available to a theorem consumer is X, and the only Cauchy data is the tail row F read inside that same uniform carrier.

The consumer must next inspect the finite windows S and their regular rational readback R. These rows supply the named observations from which the Real seal E is produced; no selected representative or countable-choice schedule is present in the carrier.

The completion-facing handoff V can be read only after X, F, S, R, E have been opened. Since the remaining rows merely transport, replay, source, and locally name this route, every theorem consumer factors through the stated chain and cannot bypass it by invoking quotient completion, host real equality, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ theorem read factors through one UniformSpace carrier row, one CauchyFilter tail row, one StreamName finite-window row, one RegSeqRat readback row, one Real seal row, one RegularCauchyCompletionUniversal handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: uniformspace, cauchyfilter, streamname, regseqrat, real, regular-cauchy-completion-universal: $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source uniform structure, Cauchy-filter tail evidence, finite windows, regular rational readback, Real seal, universal completion handoff, and the transport/replay/provenance rows binding them into a theorem-level completion certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformCompletionTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformCompletionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4064.1, Definition 4064.2, and Definition 4064.3 seed the uniform completion theorem route over a uniform carrier, Cauchy-filter tail row, finite windows, regular rational readback, Real seal, universal handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformCompletionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-space admission, Cauchy-filter tail stability, finite-window inspection, regular rational readback, Real sealing, universal completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopUniformCompletionTheoremUp.

Constructive story: A $\mathsf{BishopUniformCompletionTheorem}^{\uparrow}$ packet is generated from one UniformSpace carrier row, one CauchyFilter tail-data row, one StreamName finite-window row, one RegSeqRat readback row, one Real seal row, one RegularCauchyCompletionUniversal handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3085

A Concrete Naming Certificate for $\mathsf{CantorPairing}^{\uparrow}$

Following Cantor's pairing function, the $\mathsf{CantorPairing}^{\uparrow}$ packet records a finite two-input natural-number indexing surface for schedules that must pass between paired observations and a single displayed countable index. It sits after the natural-number carrier of chapter 28, reads the finite product envelope of chapter 34, and supplies a countable schedule handoff to the finite stream-window discipline of chapter 126. The chapter names only a finite pairing and readback certificate; it does not import host natural-number arithmetic as an unrecorded oracle, quotient equality of pairs, countable choice, or a completed stream.

Definition 3085.1 (Cantor pairing carrier)**.** *A* $\mathsf{CantorPairing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, J, L, R, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{Nat}^{\uparrow}$ *input rows. They are read as finite unary natural-number names, not as ambient host numerals.*

2. *J is the pairing-code row. It records the displayed triangular code*

$$\pi(X, Y) = \frac{(X + Y)(X + Y + 1)}{2} + Y.$$

   The additions, multiplication, division by the displayed even triangular product, and final successor budget are all ledger rows over the two $\mathsf{Nat}^{\uparrow}$ *inputs.*

3. *L and R are projection rows. They read back the left and right coordinates from the displayed code by replaying the finite triangular search ledger and returning the unique pair of* $\mathsf{Nat}^{\uparrow}$ *rows whose recorded code is J.*

4. *H records componentwise* hsame *transport for the two input rows, the pairing-code row, the two projection rows, continuation replay, provenance, and the local naming row.*

5. *C records displayed* Cont *replay from the two* $\mathsf{Nat}^{\uparrow}$ *inputs through the* $\mathsf{Prod}^{\uparrow}$ *pair envelope, the pairing-code row, the projection readbacks, and the* $\mathsf{StreamName}^{\uparrow}$ *schedule handoff.*

6. *P is the* Pkg *provenance over* $\mathsf{CantorPairing}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

7. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorPairing}^\uparrow}$ *row.*

The carrier has no coordinate for host natural-number pairing, quotient equality of pairs, a selected enumeration, countable choice, or a completed infinite schedule.

Lean4 ✓ `BEDC.Derived.CantorPairingUp.CantorPairingTasteGate single carrier alignment`

Theorem 3085.2 (Cantor pairing NameCert obligations)**.** *For every accepted* $\mathsf{CantorPairing}^\uparrow$ *carrier* $K = (X, Y, J, L, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CantorPairing}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two* $\mathsf{Nat}^\uparrow$ *inputs, pairing-code row, projection rows, transport row, continuation row, provenance row, and local naming row;*
2. *pairing totality, requiring the displayed triangular computation to produce one finite* $\mathsf{Nat}^\uparrow$ *code row from the two finite input rows;*
3. *projection readback, requiring L and R to recover precisely the two displayed input rows when the same triangular ledger is replayed from J;*
4. *StreamName schedule handoff, requiring every downstream countable schedule consumer to read the paired observation through J, L, R before it treats the result as a single* $\mathsf{StreamName}^\uparrow$ *index;*
5. *ledger refusal, excluding unrecorded host natural-number arithmetic, quotient equality of pairs, selected enumerations, countable choice, and completed streams.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 4065.1. The projection exposes exactly two $\mathsf{Nat}^\uparrow$ input rows, one displayed pairing-code row, two projection rows, and the structural rows H, C, P, N.
