Falsifiable prediction: Every accepted $\mathsf{ProofObligationGap}^{\uparrow}$ route exposes the named obligation row before any downstream subject-reduction or consistency consumer can read the obstruction.

Independence witness: metaciccriticalpath, metacicconfluenceauditpacket, normalformconsistencyseal, bounded-normal-conversion-bridge: the gap packet is not bijective to these siblings because it jointly carries named obligations, obstruction/refusal rows, and downstream handoff routes rather than a positive confluence, normalization, or conversion endpoint.

The $\mathsf{ProofObligationGap}^{\uparrow}$ carrier is read after the MetaCIC critical-path packet of chapter 765 and before the bounded conversion boundary of chapter 3439 can consume an obstruction row.

Definition 3460.1 (Proof-obligation gap carrier)**.** *A* $\mathsf{ProofObligationGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (O, B, R, M, H, C, P, N)$$

with the following displayed rows:

1. *O is the named obligation row, carrying one of the four MetaCIC subject-reduction obligations isolated in section 9386.2.*
2. *B is the obstruction row, recording that the named obligation cannot be replaced by a blanket closed subject-reduction theorem at this boundary.*
3. *R is the refusal row, rejecting any route that tries to read the obstruction before the obligation name has been exposed.*
4. *M is the MetaCIC handoff row, routing accepted packets to downstream subject-reduction, consistency, critical-path, or audit consumers only after O, B, R have been displayed together.*
5. *H records componentwise* hsame *transport for obligation, obstruction, refusal, handoff, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a downstream MetaCIC request through O, B, R, M.*

7. *P is the* Pkg *provenance over* $\mathsf{ProofObligationGap}^{\uparrow}$*, the MetaCIC open-problem frontier,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

8. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofObligationGap}^{\uparrow}}$ *row.*

The classifier accepts exactly packets where a named obligation row is paired with its obstruction and refusal rows before any MetaCIC handoff is available. It has no coordinate for positive confluence, normalization, bounded conversion, closed subject reduction, or a consistency seal.

Theorem 3460.2 (Proof-obligation gap NameCert obligations)**.** *For every accepted* $\mathsf{ProofObligationGap}^{\uparrow}$ *carrier $G = (O, B, R, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProofObligationGap}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the named obligation, obstruction, refusal, MetaCIC handoff, transport, replay, provenance, and local naming rows;*

2. *obligation-first exposure, requiring O to be visible before any downstream consumer reads B;*

3. *refusal exactness, requiring R to reject obstruction-only reads and three-row subject-reduction shortcuts;*

4. *handoff confinement, requiring M to route only the displayed O, B, R surface to MetaCIC consumers;*

5. *structural non-escape, requiring H, C, P, N to preserve and name the same packet without exporting confluence, normalization, conversion, closed subject reduction, or consistency-seal evidence.*

Lean `TasteGate.lean` *will include explicit* `Nontrivial ProofObligationGapUp` *and* `FieldFaithful ProofObligationGapUp` *instances so the accepted and refused surfaces remain distinct and the row order O, B, R, M, H, C, P, N is preserved by faithful reads.*

Lean4 ✓ `BEDC.Derived.ProofObligationGapUp.ProofObligationGapTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 3460.1. The accepted packet displays one named obligation row, one obstruction row, one refusal row, one handoff row, and the structural rows.

Obligation-first exposure follows from the classifier. The obstruction row B is accepted only together with the named obligation row O, so a downstream subject-reduction or consistency consumer cannot read B as a standalone discharge.

Refusal exactness is the role of R. It rejects routes that omit O, routes that treat the obstruction as a positive theorem, and routes that offer fewer than the named obligation surface required by section 9386.2.

The handoff row M then confines downstream reads to the displayed surface O, B, R. The structural rows H, C, P, N transport, replay, source, and name that packet, and they add no coordinate for confluence, normalization, conversion, closed subject reduction, or a consistency seal. □

Theorem 3460.3 (Proof-obligation gap MetaCIC handoff)**.** *Every accepted* $\mathsf{ProofObligationGap}^{\uparrow}$ *handoff to a MetaCIC subject-reduction, consistency, critical-path, or audit consumer first exposes the named obligation row O, then the obstruction row B, then the refusal row R, and only then the handoff row M. Consequently the packet records the obstruction surface as a finite named gap and exports no positive confluence theorem, normalization endpoint, bounded conversion bridge, closed subject-reduction theorem, or consistency seal.*

Proof. Project an accepted carrier $G = (O, B, R, M, H, C, P, N)$. The only consumer-facing handoff coordinate is M, and it is displayed after the named obligation, obstruction, and refusal rows.

Replay through C preserves that order. A downstream MetaCIC request must pass through O, B, R before it can read M, so the obstruction is always seen together with the obligation name and the refusal boundary.

The packet has no endpoint row for confluence, normalization, bounded conversion, closed subject reduction, or consistency sealing. Provenance and local naming therefore authenticate only the finite gap surface, not any positive theorem at those endpoints. □

Theorem 3460.4 (Proof-obligation gap MetaCIC sibling dependency)**.** *Every accepted* $\mathsf{ProofObligationGap}^{\uparrow}$ *packet consumed by a MetaCIC critical-path or bounded-normal-conversion consumer must cite the named obligation row before it can hand off to chapter 765 or chapter 3439. This sibling dependency is substantive: those consumers can read the finite gap only after obligation-first exposure and refusal exactness, not as positive confluence evidence, normalization evidence, bounded-conversion evidence, or a closed subject-reduction endpoint.*

Proof. Project an accepted carrier $G = (O, B, R, M, H, C, P, N)$. The named obligation row O is displayed before the obstruction row B, the refusal row R, and the MetaCIC handoff row M.

A critical-path consumer may therefore cite chapter 765 only after reading O together with the obstruction and refusal boundary. A bounded-normal-conversion consumer may likewise cite chapter 3439 only after the same obligation-first exposure.

The dependency is not a positive endpoint. The rows B and R record obstruction and refusal exactness, while M, H, C, P, N preserve and name that finite gap surface. No row supplies confluence, normalization, bounded conversion, or closed subject reduction. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProofObligationGap}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofObligationGap}^{\uparrow}$ packet is generated from named MetaCIC obligation rows, obstruction rows, refusal rows, downstream MetaCIC handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofObligationGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3460.1, Definition 3460.2, Definition 3460.3, and Definition 3460.4 seed the finite proof-obligation gap surface for MetaCIC subject-reduction obstruction consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofObligationGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close positive confluence, normalization, bounded conversion, closed subject reduction, consistency sealing, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, obligation-first exposure, refusal exactness, MetaCIC handoff confinement, transport, replay, provenance, local naming, Nontrivial ProofObligationGapUp, and Field-Faithful ProofObligationGapUp.

Chapter 3461

A Concrete Naming Certificate for $\mathsf{MeasurableFunction}^{\uparrow}$

Following Caratheodory and Bourbaki measurable maps, the $\mathsf{MeasurableFunction}^{\uparrow}$ packet records the finite preimage surface by which a source measurable-event family is routed into a target measurable-event family. It sits after the event rows of chapter 92, the generated-set boundary of chapter 3384, the $\mathsf{SetLike}^{\uparrow}$ set-membership carrier discipline, the terminal real-name seal of chapter 38, and the finite observation windows of chapter 126. The packet names measurable-map behavior as finite preimage ledgers, not as a host function space, quotient equality of functions, selected representatives, or ambient completed measure theory.

Definition 3461.1 (MeasurableFunction carrier)**.** *A* $\mathsf{MeasurableFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, A, B, G, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source measurable carrier row, read through* $\mathsf{Measure}^{\uparrow}$ *or through a* $\mathsf{BorelSet}^{\uparrow}$ *event source when the map is real-facing.*
2. *T is the target measurable carrier row, again read through* $\mathsf{Measure}^{\uparrow}$ *or the* $\mathsf{BorelSet}^{\uparrow}$ *generated-set boundary.*
3. *A is the source event-family row, with membership and subset readback routed through* $\mathsf{SetLike}^{\uparrow}$*.*
4. *B is the target event-family row, with target membership readback routed through* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and finite* $\mathsf{StreamName}^{\uparrow}$ *observations when the target is a real or Borel source.*
5. *G is the graph-read row naming the finite source-to-target observation pairs exposed to the packet.*
6. *R is the preimage ledger assigning each displayed target event row in B to a displayed source event row in A and recording the finite membership readback for the graph row G.*
7. *H stores componentwise* hsame *transport for the source carrier, target carrier, event-family rows, graph row, preimage ledger, provenance, and local naming rows.*
8. *C stores the displayed* Cont *replay by which a consumer reads target events, preimage events, graph observations, and source memberships.*
9. *P is the* Pkg *provenance over* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{BorelSet}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MeasurableFunction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, T, A, B, G, R, H, C, P, N$. It has no coordinate for a host function type, quotient equality of functions, almost-everywhere equality, completion of a measure, or a selected representative.

Lean4 (definition) `BEDC.Derived.MeasurableFunctionUp.MeasurableFunctionUp`

Theorem 3461.2 (MeasurableFunction NameCert obligations)**.** *For the carrier of Definition 3461.1, the local* $\mathsf{NameCert}_{\mathsf{MeasurableFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, source-event admission, target-event admission, graph-read admission, preimage-ledger exactness, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every accepted measurable-map consumer must read a target event through B, its displayed preimage through R, and the source-event result through A before any* $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *sibling row is exposed.*

Proof. Project the carrier $F = (S, T, A, B, G, R, H, C, P, N)$. The source and target carrier rows S, T supply the measurable contexts, while A and B supply the only event-family rows available to the packet.

Read a target event request through B. The preimage ledger R is the unique row that assigns that target event to a source event in A, and the graph row G supplies the finite membership readback tying source observations to target observations.

The structural rows add no host function object. The componentwise transport H, replay row C, provenance row P, and local naming row N preserve the same displayed route through the sibling certificates, so the listed rows exhaust the NameCert obligation surface. □

Theorem 3461.3 (MeasurableFunction simple preimage ledger)**.** *Every simple target-event read of an accepted* $\mathsf{MeasurableFunction}^{\uparrow}$ *packet factors through the finite ledger route*

$$B \longmapsto R \longmapsto A \longmapsto G \longmapsto H, C, P, N.$$

For real-facing Borel targets, the target membership observation reaches $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *only through the displayed* $\mathsf{BorelSet}^{\uparrow}$ *row in B and the graph-read row G. Thus preimage formation exports a named source event row, not a host inverse-image function, almost-everywhere quotient, completed measure, selected representative, or ambient function equality.*

Proof. Start with an accepted target-event request. The request is not a free subset of a host codomain; it is a displayed target event row in B, transported through the target carrier row T.

The preimage ledger R is then inspected. It names the corresponding source event row in A and records the graph-read membership comparison supplied by G. For real-facing Borel targets, this graph read is the only place where $\mathsf{Real}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ observations enter the route.

Finally replay the structural rows. The rows H, C, P, N transport, replay, source, and name the same finite route over $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, and $\mathsf{SetLike}^{\uparrow}$. Since no further coordinate is present, the excluded host inverse-image, quotient, completion, representative-selection, and ambient equality objects cannot be exported. □

Falsifiable prediction: A $\mathsf{MeasurableFunction}^{\uparrow}$ consumer that obtains a host function equality, an almost-everywhere quotient class, a completed measure, or a selected representative without first reading the displayed preimage ledger R refutes the carrier surface.

Independence witness: measure, borelset, setlike, real, streamname: no listed sibling supplies the whole ten-row packet $F = (S, T, A, B, G, R, H, C, P, N)$, because each sibling contributes only

event-family, generated-set, membership, real-seal, or finite-window data while this chapter binds the measurable-map preimage ledger with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MeasurableFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MeasurableFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3461.1, Definition 3461.2, and Definition 3461.3 seed the finite measurable-map surface over source events, target events, graph reads, preimage ledgers, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MeasurableFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close random variables, distributions, integrals, almost-everywhere equality, completed measures, quotient function spaces, selected representatives, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, preimage-ledger exactness, graph-read preservation, componentwise transport, and ledger-refusal proofs for BEDC.Derived.MeasurableFunctionUp.

Constructive story: A $\mathsf{MeasurableFunction}^{\uparrow}$ packet is generated from source and target measurable carrier rows, source and target event-family rows, a graph-read row, a preimage ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3462

A Concrete Naming Certificate for $\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}$

Following Kelley, Moore–Smith, and Bourbaki, the $\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}$ packet records the finite comparison surface between directed Cauchy nets and Cauchy filter bases before any completion-facing consumer reads a Real seal. It sits between the Cauchy-net carrier of chapter 589, the Cauchy-filter carrier of chapter 333, the Moore–Smith completion packet of chapter 2190, the uniform completion route of chapter 1473, and the Real readback boundary of chapter 38. The packet is finite BEDC data: directed index rows, tail rows, filter-base rows, cofinal comparison rows, completion handoff rows, readback rows, transport, replay, provenance, and a local NameCert. It does not import quotient completions, selected limits, countable choice, or an ambient completed space.

Definition 3462.1 (Moore–Smith Cauchy-net/filter bridge carrier)**.** *A* $\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, T, F, K, U, M, S, R, Y, E, H, C, P, N)$$

with the following displayed rows:

1. D *is the* $\mathsf{DirectedSet}^{\uparrow}$ *index row naming the finite directed comparisons used by the net side;*
2. T *is the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row, recording eventual containment tests over the directed index surface* D*;*
3. F *is the* $\mathsf{CauchyFilter}^{\uparrow}$ *base row, recording finite base refinements and Cauchy diameter tests;*
4. K *is the cofinal net-filter comparison row, displaying the finite route from directed tails to filter bases and back to cofinal tail data;*
5. U *is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row, read only after* D, T, F, K *have been displayed;*
6. M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row for metric-facing completion consumers;*
7. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by completion-facing readback;*
8. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same window and comparison data;*
9. Y *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic comparison ledger used to bound the displayed tails, bases, and readbacks;*

10. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the net, filter, cofinal, completion, and readback rows have been displayed;*
11. *H records componentwise* hsame *transport for all displayed rows;*
12. *C records displayed* Cont *replay from directed tails through filter bases, completion handoff, readback windows, and the Real seal;*
13. *P is the* Pkg *provenance over* $\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}}$ *row.*

The public carrier exports the finite packet B and no quotient completion, selected subnet, chosen filter limit, countable-choice schedule, or ambient completeness datum.

Lean4 ✓ `BEDC.Derived.MooreSmithCauchyNetFilterBridgeUp.MooreSmithCauchyNetFilterBridgeTasteGate`
`single carrier alignment`

Theorem 3462.2 (Moore–Smith Cauchy-net/filter bridge NameCert obligations)**.** *For the carrier of Definition 3462.1, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for $B = (D, T, F, K, U, M, S, R, Y, E, H, C, P, N)$; directed-index admission through D; Cauchy-net tail admission through T; Cauchy-filter base admission through F; cofinal comparison through K; uniform and metric completion handoff through U and M; StreamName, RegSeqRat, DyadicRatCore, and Real readback through S, R, Y, E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the accepted carrier. The rows D, T, F, K expose the directed index surface, the Cauchy-net tails, the Cauchy-filter bases, and the cofinal comparison between them as visible coordinates of one finite packet.

The completion and readback rows are downstream. The uniform and metric completion handoffs U, M are read only after the net/filter comparison row is displayed, and the finite readback rows S, R, Y, E attach the StreamName, RegSeqRat, dyadic, and Real-facing reads to the same displayed route.

The structural rows exhaust the NameCert surface. Componentwise transport, displayed replay, provenance, and local naming are exactly H, C, P, N, so a consumer cannot obtain a quotient completion, selected subnet, chosen filter limit, countable-choice schedule, or ambient completion principle from the packet. □

Theorem 3462.3 (Moore–Smith Cauchy-net/filter bridge handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}$ *carrier factors through the displayed route*

$$D, T, F, K, U, M, S, R, Y, E, H, C, P, N$$

before reading any $\mathsf{Real}^{\uparrow}$ *seal. In particular, a consumer moving between chapter 589, chapter 333, chapter 2190, and chapter 1473 reads the cofinal net/filter rows before it can use the Real-facing readback of chapter 38.*

Proof. Begin with a completion-facing request. Carrier admission forces the directed index row D, Cauchy-net tail row T, Cauchy-filter base row F, and cofinal comparison row K to be visible before any completion handoff row appears.

The handoff rows U and M then carry only the displayed comparison route. They do not identify completion classes, choose a subnet, or select a filter limit; they pass the finite net/filter comparison to uniform and metric completion consumers.

Finally the readback rows S, R, Y, E and the structural rows H, C, P, N keep the Real seal downstream of the same displayed route. Since the packet has no coordinate for quotient completion, countable choice, selected limits, or ambient completeness, every completion-facing read factors through the named rows before it reaches $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}$ packet is generated from directed index data, Cauchy-net tail rows, Cauchy-filter base rows, a cofinal net-filter comparison, uniform and metric completion handoff rows, StreamName windows, RegSeqRat and DyadicRatCore readbacks, a RealUp seal, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3462.1, Definition 3462.2, and Definition 3462.3 bind the finite net/filter/cofinal route before uniform, metric, and Real readback consumers inspect the packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNetFilterBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completions, selected limits, countable choice, or ambient completed-space completeness.

Upgrade path: Obligation closure requires checked carrier admission, cofinal comparison, completion handoff, transport stability, replay, provenance, and local naming for BEDC.Derived.MooreSmithCauchyNetFilterBridgeUp.

Chapter 3463

A Concrete Naming Certificate for $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$

The $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ packet realizes the punctured WNA cube, CUN square, bridge-edge, and articulation-gate support graph of Definition 9462.1293 as finite NameCert data. Its carrier records the cube vertex rows, the deleted ACA row, the CUN square, the UAG and AGG bridge rows, adjacency ledgers, biconnected-component rows, transport, replay, provenance, and local naming. It sits beside the codon source-window carrier of chapter 2234, the DNA window boundary tile of chapter 3393, and the codon-window spectral inverse of chapter 2161. The packet is a finite combinatorial support certificate; it does not assert a biochemical mechanism, a selected evolutionary path, or a host-level graph quotient.

Definition 3463.1 (Punctured cube skeleton carrier)**.** *A* $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (W, A, C, B, G, E, H, T, Q, R, N)$$

with the following displayed rows:

1. *W is the WNA cube row listing the eight codon vertices with first coordinate in* $\{\mathrm{U}, \mathrm{A}\}$*, middle coordinate in* $\{\mathrm{U}, \mathrm{C}, \mathrm{A}, \mathrm{G}\}$*, and terminal coordinate* A*;*
2. *A is the puncture row deleting* ACA *and retaining the seven displayed WNA vertices;*
3. *C is the CUN square row over* $\{\mathrm{CUU}, \mathrm{CUC}, \mathrm{CUA}, \mathrm{CUG}\}$*;*
4. *B is the bridge-edge row carrying* $\{\mathrm{CUA}, \mathrm{UUA}\}$*,* $\{\mathrm{UAA}, \mathrm{UAG}\}$*, and* $\{\mathrm{AGA}, \mathrm{AGG}\}$*;*
5. *G is the articulation-gate row identifying the finite support graph induced by A, C, B;*
6. *E is the edge-decomposition ledger comparing the cube face, CUN square, bridge edges, and biconnected components;*
7. *H records componentwise* hsame *transport for the vertex, puncture, square, bridge, gate, and edge-decomposition rows;*
8. *T records displayed* Cont *replay from the support formula to the induced graph and component rows;*
9. *Q is the* Pkg *provenance over* $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*;*
10. *R is the TasteGate requirement row for later* Nontrivial $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ *and* FieldFaithful PuncturedCubeS *instances;*

11. N is the local $\mathsf{NameCert}_{\mathsf{PuncturedCubeSkeleton}^{\uparrow}}$ *row.*

Theorem 3463.2 (Punctured cube skeleton NameCert obligations)**.** *For the carrier of Definition 3463.1, the local* $\mathsf{NameCert}_{\mathsf{PuncturedCubeSkeleton}^{\uparrow}}$ *surface consists exactly of WNA cube admission, puncture admission, CUN square admission, bridge-edge admission, articulation-gate admission, edge-decomposition admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, TasteGate nontriviality and field-faithfulness requirements, and local naming. The future Lean-facing TasteGate surface must distinguish the puncture row A from the unpunctured cube row W and must preserve every field $W, A, C, B, G, E, H, T, Q, R, N$.*

Lean4 ✓ `BEDC.Derived.PuncturedCubeSkeletonUp.PuncturedCubeSkeletonTasteGate single carrier alignment`

Proof. Project the carrier. The rows W, A, C, B, G, E display the finite support formula, the puncture, the CUN square, the bridge edges, the articulation gate, and the induced edge-decomposition ledger.

Transport and replay are structural. The rows H, T, Q, N preserve and name the same finite graph support data without adding a host quotient or a biological mechanism.

The TasteGate requirement row R records the exact Lean obligations: nontriviality must separate the punctured packet from a collapsed graph, and field faithfulness must preserve every displayed vertex, puncture, bridge, gate, and decomposition row. These obligations are part of the carrier surface and do not assert that the Lean instances already exist. □

Theorem 3463.3 (Punctured cube skeleton boundary nonescape)**.** *Every consumer of an accepted* $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ *carrier factors through*

$$W, A, C, B, G, E, H, T, Q, R, N$$

before reading the punctured cube skeleton as finite NameCert data. Consequently the consumer cannot erase the ACA *puncture, collapse the CUN square into the WNA cube, drop the bridge-edge rows, replace the articulation gate by a host graph quotient, or bypass the later* Nontrivial *and* FieldFaithful *TasteGate requirements.*

Proof. Start from the support rows. The WNA cube, puncture, CUN square, bridge edges, articulation gate, and edge-decomposition ledger are separate coordinates of the carrier.

Now use componentwise transport and replay. The rows H and T preserve those coordinates as finite BHist data, while Q and N record provenance and local naming for the same route.

Finally read the TasteGate row. Because R is displayed before a downstream carrier can be admitted, any later Lean realization must keep nontriviality and field faithfulness visible. Thus no consumer can erase the puncture, collapse the support graph, or bypass the stated gate requirements. □

Theorem 3463.4 (Punctured cube skeleton philosophy route)**.** *Every accepted* $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ *carrier is the finite support-graph consumer of Definition 9462.1293: the rows $W, A, C, B, G, E, H, T, Q, R, N$ record the displayed punctured WNA cube, CUN square, bridge edges, articulation gate, decomposition ledger, transport, replay, provenance, TasteGate requirements, and local name. Its concrete sibling route is through the codon source-window packet of chapter 2234, the DNA window boundary tile of chapter 3393, and the codon-window spectral inverse packet of chapter 2161; those chapters supply finite window, boundary-tile, and spectral-inverse rows, not biochemical mechanism claims.*

Proof. The philosophy theorem supplies the displayed support formula. The carrier rows W, A, C, B, G, E are exactly the finite graph-support data used to read that formula as a punctured cube skeleton.

The sibling chapters named in the statement provide only finite BEDC routes: codon windows, DNA boundary tiles, and codon-window spectral inverse rows. Reading them alongside H, T, Q, R, N records a dependency route for the support graph, not an empirical biochemical assertion.

Thus the packet leaves kernel-only isolation by naming its concrete finite consumers while retaining the same boundary as Definition 3463.3. □

Falsifiable prediction: A packet that omits the ACA puncture row, the CUN square row, or one of the bridge-edge rows cannot be accepted as a $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ carrier.

Independence witness: codon-window-six-bridge, dna-window-six-dynamics-bridge, codon-window-spectral-inverse: none is bijective to $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ because this carrier binds the punctured WNA cube, CUN square, bridge edges, articulation gate, edge decomposition, TasteGate requirement row, transport, replay, provenance, and local naming as one finite support graph packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PuncturedCubeSkeleton}^{\uparrow}}$.

Constructive story: A $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ packet is generated from WNA cube vertices, the deleted ACA puncture row, CUN square rows, bridge-edge rows, an articulation-gate support graph, an edge-decomposition ledger, hsame transports, Cont replay, Pkg provenance, a TasteGate requirement row, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PuncturedCubeSkeleton}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3463.1, Definition 3463.2, and Definition 3463.3 bind the finite punctured cube skeleton support graph and its TasteGate requirements.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PuncturedCubeSkeleton}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, biochemical mechanism, evolutionary pathway selection, host graph quotients, or completed TasteGate instances.

Upgrade path: Obligation closure requires checked carrier admission, boundary nonescape, transport stability, replay, provenance, local naming, and explicit Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.PuncturedCubeSkeletonUp.

Chapter 3464

A Constructive Closed Metric Ball Certificate for $\mathsf{ClosedMetricBall}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ClosedMetricBall}^{\uparrow}$ packet records the center-radius containment object of a constructive metric space as finite BEDC NameCert data. It sits after the metric carrier of chapter 57, the terminal real-name seal of chapter 38, the separated comparison boundary of chapter 1411, the complete-metric limit surface of chapter 128, and the regular-Cauchy equality route of chapter 1412. The packet names non-strict metric containment for one displayed center and radius; it does not import host subsets, open-cover compactness, quotient point equality, or ambient completeness.

Definition 3464.1 (Closed metric ball carrier)**.** *A* $\mathsf{ClosedMetricBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, X, c, r, \rho, D, R, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row supplying the distance-read interface.*
2. *X is the inspected point row.*
3. *c is the displayed center row.*
4. *r is the* $\mathsf{Real}^{\uparrow}$ *or rational radius row.*
5. *ρ is the nonnegative-radius ledger, read before any containment classifier is consumed.*
6. *D is the metric-distance witness row for the finite comparison $d(c, X)$.*
7. *R is the ordered-real comparison row recording $d(c, X) \leq r$ through the* $\mathsf{Real}^{\uparrow}$ *seal.*
8. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *compatibility row, used only to transport zero-distance agreement through the same metric source.*
9. *Q is the optional* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *handoff row for consumers that arrive from completed or regular-Cauchy names.*
10. *H stores componentwise* hsame *transport for $M, X, c, r, \rho, D, R, S, Q$ and the structural rows.*
11. *C stores displayed* Cont *replay from the metric source and radius ledger to the distance witness, ordered comparison, separated route, and completion-facing handoff.*

12. *P is the* Pkg *provenance over* $\mathsf{ClosedMetricBall}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedMetricBall}^{\uparrow}}$ *row.*

The carrier compares accepted containment packets only through $M, X, c, r, \rho, D, R, S, Q, H, C, P, N$. It has no coordinate for arbitrary subsets, topology closure, selected limits, open-cover compactness, quotient point equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedMetricBallUp.ClosedMetricBallTasteGate single carrier alignment`

Theorem 3464.2 (Closed metric ball NameCert obligations)**.** *For an accepted* $\mathsf{ClosedMetricBall}^{\uparrow}$ *carrier $B = (M, X, c, r, \rho, D, R, S, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedMetricBall}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure, center and point exposure, radius nonnegativity, distance-witness visibility, ordered-real containment, separated-metric compatibility, completion-facing handoff when Q is present, componentwise transport, continuation replay, provenance, and local naming. Every containment read therefore follows the displayed route*

$$M, X, c, r, \rho \longmapsto D \longmapsto R \longmapsto S, Q \longmapsto H, C, P, N$$

and no host subset or compactness principle supplies an extra membership coordinate.

Proof. Project the carrier rows. The metric source, inspected point, center, radius, nonnegative-radius ledger, distance witness, ordered-real comparison, separated route, completion-facing row, transport, replay, provenance, and local name are the only public coordinates.

The containment classifier reads the distance witness D only after M, X, c, r, ρ have been displayed. The row R then records the non-strict comparison through the $\mathsf{Real}^{\uparrow}$ seal rather than through an ambient subset predicate.

Separated and completed consumers are downstream. The row S can transport only zero-distance agreement already visible in the same metric source, and the row Q can hand a completed or regular-Cauchy read to the same comparison route only after the closed-ball rows are present.

Finally H, C, P, N preserve, replay, source, and name the route. Since the carrier contains no host subset, topological closure, open-cover, selected-limit, quotient, choice, trichotomy, or ambient-completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 3464.3 (Closed metric ball containment handoff)**.** *Every separated, bounded, complete, or compact metric consumer of an accepted* $\mathsf{ClosedMetricBall}^{\uparrow}$ *packet must read the finite containment route $M, X, c, r, \rho, D, R, S, Q, H, C, P, N$ before it may use the point as lying in the closed ball. The exported handoff is only the center-radius comparison $d(c, X) \leq r$ with its displayed transport, replay, provenance, and local name; it does not provide a compactness theorem, a host-level closed subset, quotient equality of points, a selected completion limit, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the containment request. The rows M, X, c, r, ρ fix the metric source, point, center, radius, and nonnegative-radius ledger before a distance comparison can be consumed.

The distance and ordered-real rows are next. The row D supplies the displayed metric-distance read, and R supplies the non-strict $\mathsf{Real}^{\uparrow}$ comparison. This is the only route by which the packet exposes membership.

Downstream metric consumers then read S or Q only as compatibility rows. They preserve the same center-radius comparison for separated or completed contexts, but they cannot replace it by topology closure, host set equality, compactness, or selected limits.

The structural rows H, C, P, N carry the route forward without adding mathematical content. Therefore every exported handoff remains the finite closed-ball containment certificate described above. □

Falsifiable prediction: A downstream metric consumer that omits the metric source row, the center-radius ledger, or the ordered-real containment row cannot read a $\mathsf{ClosedMetricBall}^{\uparrow}$ packet as a closed ball.

Independence witness: metric, real, separatedmetric, completemetric, cauchysequenceequivalence, metricclosedball: $\mathsf{ClosedMetricBall}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source, inspected point, center, radius, nonnegative-radius ledger, distance witness, ordered-real containment, separated compatibility, completion-facing handoff, transport, replay, provenance, and local naming as one center-radius containment packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedMetricBall}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedMetricBall}^{\uparrow}$ packet is generated from a MetricUp source row, an inspected point row, a center row, a RealUp or rational radius row, a nonnegative-radius ledger, a metric-distance witness, an ordered-real containment comparison, separated-metric compatibility, completion-facing handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedMetricBall}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3464.1, Definition 3464.2, and Definition 3464.3 seed the finite center-radius containment packet for constructive metric spaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedMetricBall}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subsets, topology closure, open-cover compactness, quotient point equality, selected completion limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exposure, radius nonnegativity, distance-witness visibility, ordered-real containment, separated compatibility, completion-facing handoff, transport and replay stability, provenance non-escape, and local naming.

Chapter 3465

A Concrete Naming Certificate for $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen, the $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ packet records finite-prefix dependence of Baire and choice-sequence functionals as NameCert data. It sits beside the Baire-space surface of chapter 334, the choice-sequence rows of chapter 1482, the spread-law route of chapter 1532, and the finite stream-window surface of chapter 126. The packet also routes rational and real readbacks through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, keeping the continuity claim as a finite-prefix certificate rather than as a host functional, countable-choice selector, quotient stream equality, or ambient real-completeness theorem.

Definition 3465.1 (Brouwer continuity principle carrier)**.** *A* $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, Q, S, W, R, E, M, H, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *source row, exposing only finite inspected prefixes of the input sequence;*
2. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *row, recording the displayed choice-sequence presentation used by the functional read;*
3. *S is the* $\mathsf{SpreadLaw}^{\uparrow}$ *row, naming the spread law that admits the finite prefixes consumed by the packet;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, storing the requested prefix length, inspected stream cells, and pullback route to the source rows;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational observations made from the accepted finite prefix;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same finite-window and rational-readback data;*
7. *M is the finite modulus row, stating which prefix length is sufficient for the displayed output read;*
8. *H records componentwise* hsame *transports for B, Q, S, W, R, E, M and the local naming row;*
9. *C records the displayed* Cont *replay by which consumers read $B, Q, S, W, R, E, M, H, P, N$ in that order;*
10. *P is the* Pkg *provenance over* $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerContinuityPrinciple}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through the displayed finite prefix, modulus, readback, seal, transport, continuation, package, and local NameCert rows.

Theorem 3465.2 (Brouwer continuity principle NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BrouwerContinuityPrinciple}^{\uparrow}}$ *surface for Definition 3465.1 consists exactly of carrier admission for $K = (B, Q, S, W, R, E, M, H, C, P, N)$, Baire-source exposure through B, choice-sequence exposure through Q, spread-law admission through S, finite stream-window inspection through W, rational readback through R, real-seal routing through E, finite-modulus display through M, componentwise transport through H, continuation replay through C, package provenance through P, and local naming through N. Every accepted continuity read is classified only by these displayed rows.*

Lean4 ✓ `BEDC.Derived.BrouwerContinuityPrincipleUp.BrouwerContinuityPrincipleTasteGate single carrier alignment`

Proof. Project the carrier tuple K. The Baire source, choice-sequence presentation, spread law, finite stream window, rational readback, real seal, finite modulus, transports, continuations, package row, and local name are all stored coordinates.

The source and admissibility obligations project B, Q, S, W. The output-facing obligations project R, E, M, so the real read is reached only after the finite prefix and rational readback have been displayed.

The structural obligations project H, C, P, N. Since no coordinate names a host functional, global continuity theorem, countable-choice selector, quotient stream equality, selected real representative, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the local certificate exports only the finite-prefix route. □

Theorem 3465.3 (Brouwer continuity principle finite-prefix modulus)**.** *For every accepted* BrouwerContinuityPrinci *carrier, each output read from a Baire or choice-sequence input factors through the finite route*

$$B, Q, S \longmapsto W \longmapsto M \longmapsto R \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Thus the consumer receives a displayed prefix length and the corresponding inspected $\mathsf{StreamName}^{\uparrow}$ *window before it reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows. The route exports no host functional continuity theorem, no choice-selected modulus, no quotient stream equality, no arbitrary bar induction principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Read B, Q, S first. These rows display the Baire-space source, the choice-sequence presentation, and the spread-law admission surface on which the functional read is allowed to depend.

Next read the finite-window and modulus rows W, M. They name the inspected prefix and the prefix length sufficient for the displayed output read, so the rational and real observations cannot be consumed before the finite prefix is exposed.

Finally route the output through R, E, H, C, P, N. Componentwise transport and continuation replay preserve the same finite-prefix packet for downstream consumers, while provenance records the sibling Baire-space, choice-sequence, spread-law, stream-name, regular-rational, and real rows. Since no refused object is a carrier coordinate, the output read remains a finite-prefix NameCert route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerContinuityPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ packet is generated from $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, finite-modulus, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{BrouwerContinuityPrinciple}^{\uparrow}}$, seed)

Scope closed: Definition 3465.1, Definition 3465.2, and Definition 3465.3 seed the finite-prefix continuity route over the displayed Baire-space, choice-sequence, spread-law, stream-name, regular-rational, real-seal, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{BrouwerContinuityPrinciple}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close a Lean implementation, host functional continuity theorem, choice-selected modulus, quotient stream equality, arbitrary bar induction principle, selected real representative, ambient Real$^{\uparrow}$ completeness theorem, or bridge-checked standard model.

Upgrade path: Formal closure requires a Lean carrier and obligation package for the same BaireSpace$^{\uparrow}$, ChoiceSequence$^{\uparrow}$, SpreadLaw$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, and NameCert route.

Chapter 3466

A Concrete Naming Certificate for $\mathsf{CauchyHadamard}^{\uparrow}$

Following Cauchy and Hadamard's power-series radius formula, the $\mathsf{CauchyHadamard}^{\uparrow}$ packet records the constructive radius route for a real power series as finite BEDC certificate data. It sits over the coefficient windows of chapter 1583, the radius seal of chapter 66, the regular root-bound route of chapter 1481, and the sibling ratio-test comparison route of chapter 1461. The chapter packages the traditional formula as a NameCert route through displayed coefficient windows, dyadic tolerance rows, and regular-Cauchy readbacks rather than through a host limsup, quotient stream, choice-selected radius, or ambient completeness theorem.

Definition 3466.1 (Cauchy-Hadamard carrier)**.** *A* $\mathsf{CauchyHadamard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, W, R, G, D, H, C, P, N)$$

with the following visible rows:

1. *A is the* $\mathsf{RealPowerSeries}^{\uparrow}$ *source row, exposing only the displayed coefficient family and its finite inspection windows;*
2. *W is the coefficient-window ledger, recording the inspected unary indices, absolute-coefficient reads, and root-bound requests used by the packet;*
3. *R is the* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *root-bound route, read from the same coefficient windows and tolerance requests;*
4. *G is the* $\mathsf{ConvRad}^{\uparrow}$ *seal row reached from the root-bound route and the power-series source;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic slack and comparison budgets used by the root-bound and radius rows;*
6. *H records componentwise* hsame *transports for the source row, coefficient windows, root-bound route, radius seal, tolerance ledger, and local naming row;*
7. *C records the displayed* Cont *replay by which consumers read A, W, R, G, D, H, P, N in that order;*
8. *P is the* Pkg *provenance over* $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{ConvRad}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyHadamard}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows and their recorded transport, continuation, package, and local NameCert provenance.

Lean4 ✓ `BEDC.Derived.CauchyHadamardUp.CauchyHadamardTasteGate single carrier alignment`

Theorem 3466.2 (Cauchy-Hadamard NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyHadamard}^{\uparrow}}$ *surface for Definition 3466.1 consists exactly of carrier admission for* $K = (A, W, R, G, D, H, C, P, N)$*, coefficient-window exposure through* A, W*, root-bound exposure through* R*, radius-seal exposure through* G*, dyadic tolerance exactness through* D*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*. Every accepted radius read is classified only by the displayed power-series row, finite coefficient windows, root-bound route, tolerance ledger, radius seal, and structural rows.*

Proof. Project the carrier tuple K. The source row, coefficient-window ledger, root-bound route, radius seal, dyadic tolerance ledger, transport rows, continuation routes, package row, and local name are all stored coordinates.

Carrier admission and coefficient exposure are therefore finite projections from A and W. The root-bound and radius obligations project R and G, with D recording the tolerance comparisons used by both rows.

The structural obligations project H, C, P, N. Since no coordinate names a host limsup, quotient stream, choice-selected radius, or ambient completeness theorem, the local certificate exports only the displayed Cauchy-Hadamard route. □

Theorem 3466.3 (Cauchy-Hadamard root-bound handoff)**.** *For every accepted* $\mathsf{CauchyHadamard}^{\uparrow}$ *carrier, each root-bound request consumed by the radius row factors through the finite route*

$$A \longmapsto W \longmapsto D \longmapsto R \longmapsto G \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The handoff uses the $\mathsf{RealPowerSeries}^{\uparrow}$ *coefficient source, the* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *root-bound row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{ConvRad}^{\uparrow}$ *seal. The* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ *sibling is available only as a comparison provenance row in* P *and does not replace the displayed root-bound route.*

Proof. Read A, W, D, R, G from the carrier. A radius request first opens the power-series coefficient source and the finite coefficient-window ledger, so the root-bound row sees only displayed coefficient data.

Use the dyadic tolerance ledger D to align the slack and comparison budget consumed by R. The radius seal G is then read after the root-bound route, not from a host supremum or selected limsup witness.

The continuation and provenance rows preserve the same order for downstream consumers. The ratio-test sibling remains a recorded dependency anchor in P, while the accepted handoff itself is the root-bound route through $A, W, D, R, G, H, C, P, N$. □

Theorem 3466.4 (Cauchy-Hadamard root-bound NameCert route)**.** *Any accepted* $\mathsf{CauchyHadamard}^{\uparrow}$ *radius read whose* $\mathsf{ConvRad}^{\uparrow}$ *row consumes a Cauchy-Hadamard exactness witness factors through the displayed* $\mathsf{RealPowerSeries}^{\uparrow}$ *coefficient source, finite coefficient windows,* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *route,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{ConvRad}^{\uparrow}$ *seal. The exactness row is a local witness inside the displayed packet, not a host limsup, quotient stream, selected radius representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier $K = (A, W, R, G, D, H, C, P, N)$ of Definition 3466.1. The coefficient source is A, the finite windows are W, the root-bound route is R, the tolerance ledger is D, and the radius seal is G.

Apply the root-bound handoff theorem. It orders every radius request through A, W, D, R, G before the structural rows H, C, P, N expose the local certificate to a consumer.

The Cauchy-Hadamard exactness witness is therefore read as part of the local $\mathsf{ConvRad}^{\uparrow}$ seal row. Since no carrier coordinate stores a host limsup, quotient coefficient stream, selected radius, or ambient completeness theorem, the NameCert route remains the displayed finite root-bound packet. □

Theorem 3466.5 (Cauchy-Hadamard radius nonescape)**.** *Every* $\mathsf{ConvRad}^{\uparrow}$ *read exported by an accepted* $\mathsf{CauchyHadamard}^{\uparrow}$ *packet factors through the displayed* $\mathsf{RealPowerSeries}^{\uparrow}$ *source row, finite coefficient windows,* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *root-bound route,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* BHist *histories,* hsame *transports,* Cont *replay,* Pkg *provenance, and local* NameCert *row. It exports no host limsup, real supremum row, quotient coefficient stream, countable-choice selector, selected radius representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the radius seal row G. By the carrier definition, G is reached only after the source row A, coefficient windows W, tolerance ledger D, and root-bound route R have been displayed.

Apply the NameCert obligations. They identify the structural support of the read as H, C, P, N and keep componentwise transport and continuation replay attached to the same finite packet.

No refused object has a row in the carrier. Therefore a downstream $\mathsf{ConvRad}^{\uparrow}$ consumer cannot escape the displayed Cauchy-Hadamard route by invoking a host limsup, real supremum, quotient stream, choice selector, selected radius, or ambient real-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyHadamard}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyHadamard}^{\uparrow}$ packet is generated from a $\mathsf{RealPowerSeries}^{\uparrow}$ coefficient source row, finite coefficient windows, a $\mathsf{RegularCauchyRootTest}^{\uparrow}$ root-bound route, a $\mathsf{ConvRad}^{\uparrow}$ seal row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyHadamard}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 3466.1, Definition 3466.2, Definition 3466.3, and Definition 3466.5 bind the constructive power-series radius route over $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{ConvRad}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyHadamard}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close a Lean implementation, host limsup, real supremum row, quotient coefficient stream, countable-choice selector, selected radius representative, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, or bridge-checked standard model.

Upgrade path: Formal closure requires a Lean carrier and obligation package for the same $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{ConvRad}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, hsame, Cont, Pkg, and NameCert route.

Chapter 3467

A Concrete Naming Certificate for $\mathsf{DyadicSubsequence}^{\uparrow}$

Following Bishop and Bridges, constructive subsequence extraction is read as a finite choice of inspected windows and monotone index evidence before any compactness conclusion is invoked. The $\mathsf{DyadicSubsequence}^{\uparrow}$ packet records that L10 selection surface over the bounded real sequence rows of chapter 3451, the finite observation route of chapter 126, the regular rational readback of chapter 301, and the compactness-facing route of chapter 1254. It packages dyadic tolerance windows, monotone unary reindexing, and Real-seal readback as displayed NameCert data rather than as an ambient subsequence selector or a completed compactness theorem.

Definition 3467.1 (Dyadic subsequence carrier)**.** *A* $\mathsf{DyadicSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, D, I, O, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the bounded real sequence source row, exposing only the displayed sequence name, bound certificate, and finite request interface.*
2. *W is the finite window ledger, recording the sequence windows inspected before each subsequence output is admitted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, storing dyadic comparison budgets for window selection, bound reuse, and later readback.*
4. *I is the monotone unary reindexing row, recording a finite increasing index map from output positions to inspected source positions.*
5. *O is the* $\mathsf{StreamName}^{\uparrow}$ *output-window row, exposing the selected subsequence only by finite windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from O, W, D, I.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for each accepted readback request, exposed only after the source, window, tolerance, index, stream, and regular-readback rows are displayed.*
8. *H records componentwise* hsame *transport for the bounded sequence source, windows, dyadic ledger, monotone index row, stream windows, regular readback, Real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a subsequence or compactness-facing request through* $A, W, D, I, O, R, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{RealBoundedSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, D, I, O, R, E, H, C, P, N$. It has no coordinate for a global choice function, quotient stream, selected limit, ambient compactness theorem, or host completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3467.2 (Dyadic subsequence classifier)**.** *Two accepted* $\mathsf{DyadicSubsequence}^{\uparrow}$ *carriers*

$$S = (A, W, D, I, O, R, E, H, C, P, N) \quad \text{and} \quad S' = (A', W', D', I', O', R', E', H', C', P', N')$$

are classified as the same local subsequence certificate exactly when the displayed bounded-source rows agree, the finite window ledgers present the same inspected source windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows agree on every recorded comparison budget, the monotone unary reindexing rows choose the same finite output-to-source positions, the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback rows agree after the recorded* hsame *transports, and the* Cont, Pkg, *and* NameCert *rows replay and name the same packet.*

Theorem 3467.3 (Dyadic subsequence NameCert obligations)**.** *For every accepted* $\mathsf{DyadicSubsequence}^{\uparrow}$ *carrier $S = (A, W, D, I, O, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicSubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded sequence source, finite windows, dyadic tolerance rows, monotone index row, finite stream output, regular rational readback, terminal Real seals, componentwise transport, continuation replay, package provenance, and local naming. Every compactness-facing read of the packet is classified only by these displayed rows and exports no global selector, quotient stream, selected limit, ambient compactness theorem, or host Real-completeness coordinate.*

Proof. Carrier admission is projection from Definition 3467.1. The tuple displays the bounded source, inspected windows, dyadic budgets, monotone reindexing row, output stream windows, regular readback, Real seals, and structural rows.

The classifier of Definition 3467.2 fixes equality of accepted packets by those same rows. Thus a NameCert consumer cannot compare subsequence data by an off-packet selector or by an ambient limit object.

The structural obligations project H, C, P, N. They transport, replay, source, and name only the displayed packet, so the excluded global choice, quotient-stream, selected-limit, compactness, and Real-completeness coordinates remain absent. □

Lean4 ✓ `BEDC.Derived.DyadicSubsequenceUp.TasteGate.DyadicSubsequenceTasteGate single carrier alignment`

Theorem 3467.4 (Dyadic subsequence window extraction)**.** *Every finite output window exported by an accepted* $\mathsf{DyadicSubsequence}^{\uparrow}$ *packet factors through the route*

$$A \longmapsto W \longmapsto D \longmapsto I \longmapsto O \longmapsto R \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The route first opens a bounded real sequence source, then records the inspected source windows, dyadic tolerances, and monotone unary reindexing before exposing the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback rows. No output window may be read directly from an ambient subsequence choice function or from a Bolzano-Weierstrass compactness conclusion.*

Proof. Start from an accepted carrier $S = (A, W, D, I, O, R, E, H, C, P, N)$. A finite output-window request is replayed through C, so it must expose the bounded source A, the source windows W, the dyadic tolerance ledger D, and the monotone index row I before it reads the output stream row O.

Regular rational readback and Real sealing occur after those rows. The packet reaches R and E only through the displayed stream window and tolerance route, with H preserving componentwise transport.

Finally P and N source and name the same finite route. Since no carrier coordinate stores an ambient selector or compactness theorem, every exported output window remains a finite window-extraction certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicSubsequence}^{\uparrow}$ packet is generated from a bounded real sequence source, finite source windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, monotone unary reindexing, finite $\mathsf{StreamName}^{\uparrow}$ output windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3467.1, Definition 3467.2, Definition 3467.3, and Definition 3467.4 seed the finite L10 subsequence-selection surface between bounded real sequence windows and compactness-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean implementation, Bolzano-Weierstrass compactness, selected limits, quotient streams, countable choice, host Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic tolerance exactness, monotone index-window extraction, StreamName output, RegSeqRat readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicSubsequenceUp.

Chapter 3468

A Concrete Naming Certificate for $\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}$ packet records when a finite tail shift preserves the named regular Cauchy object as displayed BEDC data. It sits over the finite schedule rows of chapter 126, the regular rational classifier of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-shift packet of chapter 1578, and the terminal real-name seal of chapter 38. The packet is a NameCert surface for tail-shift equivalence of regular Cauchy names, not a quotient of streams, not selected host equality, and not an ambient completeness theorem.

Definition 3468.1 (Regular Cauchy shift equivalence carrier)**.** *A* $\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, k, S, R, D, H, C, P, N)$$

with the following visible rows:

1. *Q is the source regular Cauchy name row, presented through the same regular rational readback used by the original* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier.*
2. *k is the finite tail-shift index, displayed as a unary prefix length and carrying no unbounded selector.*
3. *S is the shifted* $\mathsf{StreamName}^{\uparrow}$ *row whose window request at n reads the source name at the displayed index $n + k$.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row for the shifted readback, attached to Q through the displayed schedule S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the dyadic slack preserved by the shifted readback.*
6. *H records componentwise* hsame *transport for the source name, shift index, shifted stream row, classifier row, dyadic ledger, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an equivalence request through k, S, R, D, and the source row Q, and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected representatives, host sequence equality, countable-choice tail selectors, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyShiftEquivalenceUp.RegularCauchyShiftEquivalenceTasteGate`
`single carrier alignment`

Theorem 3468.2 (Regular Cauchy shift equivalence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}$ *carrier* $E = (Q, k, S, R, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source regular Cauchy name, finite shift index, shifted* $\mathsf{StreamName}^{\uparrow}$ *row, shifted* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, transports, continuation, provenance, and local naming row;*
2. *source-name retention, requiring the shifted classifier to read the same source regular Cauchy name Q after the finite index shift;*
3. *shifted-window exposure, requiring every request to pass through the displayed shift index k before it can inspect S;*
4. *classifier stability, requiring the shifted* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to remain attached to the displayed windows in S and the tolerance ledger D;*
5. *real-seal compatibility, requiring every* $\mathsf{Real}^{\uparrow}$*-facing read to pass through Q, k, S, R, D before any seal-facing consumer can inspect the structural rows;*
6. *ledger refusal, excluding quotient stream equality, selected representatives, host sequence equality, countable-choice tail selection, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 3468.1. The displayed coordinates are exactly the source regular Cauchy name, finite shift index, shifted stream row, shifted regular-rational classifier, dyadic tolerance ledger, and the structural rows H, C, P, N.

Replay the continuation row C. An equivalence request first consumes the finite shift index k, then reads the shifted schedule S and the shifted classifier row R attached to the source row Q.

The dyadic ledger D is read on the same route. It supplies the tolerance data needed before a $\mathsf{Real}^{\uparrow}$-facing consumer can inspect the shifted readback as a real-name seal.

The remaining rows only transport, replay, package, and locally name that finite route. Since no coordinate stores quotient stream equality, selected representatives, host sequence equality, countable-choice tail selection, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 3468.3 (Regular Cauchy shift equivalence tail stability)**.** *Let* $E = (Q, k, S, R, D, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}$ *carrier. Every tail-equivalence consumer and every* $\mathsf{Real}^{\uparrow}$*-facing consumer factors through the finite route*

$$Q \longmapsto k \longmapsto S \longmapsto R \longmapsto D \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Thus the shifted regular Cauchy name remains stable under the displayed finite tail shift before quotient streams, host sequence equality, selected representatives, countable-choice tail selectors, or ambient completion data are available.

Proof. Begin with a consumer request for the shifted regular Cauchy name. Carrier admission supplies only the source row Q, the finite shift index k, the shifted schedule S, the classifier row R, the dyadic ledger D, and the structural rows.

The shifted schedule is read after k. Hence every displayed window of the shifted name is still a window of the source name at the translated finite index, and the classifier row R remains attached to that same readback.

The tolerance ledger D travels with the shifted read. Transport by H and replay by C preserve the route through Q, k, S, R, D, while P and N only record provenance and local naming for that route.

No refused object has a carrier coordinate. A tail-equivalence or $\mathsf{Real}^{\uparrow}$-facing consumer therefore receives the displayed finite shift route and no quotient stream, host sequence equality row, selected representative, choice selector, or ambient completion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}$ packet is generated from a source regular Cauchy name row, finite tail-shift index, shifted StreamName row, RegSeqRat classifier row, DyadicRatCore tolerance ledger, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3468.1, Definition 3468.2, and Definition 3468.3 seed the finite tail-shift equivalence route over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyShiftEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream equality, selected representatives, host sequence equality, countable-choice tail selection, ambient Real completeness, Lean verification, or a checked standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, shifted-window exposure, classifier stability, dyadic tolerance preservation, real-seal compatibility, and ledger refusal for BEDC.Derived.RegularCauchyShiftEquivalenceUp.

Chapter 3469

A Concrete Naming Certificate for $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ packet records the constructive diagonal extraction of a regular Cauchy subsequence as finite BEDC NameCert data. It sits beside the stream-window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the subsequence and interleaving routes of chapter 1854 and chapter 3405. The packet names a diagonal finite-window selector for one displayed family of tails; it is not host subsequence equality, a chosen limit, quotient equality of real names, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3469.1 (Diagonal Cauchy subsequence carrier)**.** *A* $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, R, T, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *schedules whose rows display the source sequence windows and the tail windows available to the diagonal construction;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger attached to the same source and tail schedules;*
3. *T is the Cauchy subsequence extraction row, recording the finite increasing-index and tail-request data consumed from the* $\mathsf{CauchySubsequenceExtraction}^{\uparrow}$ *and* $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ *sibling routes;*
4. *Q is the diagonal selector row, pairing each requested precision window with the subsequence tail whose regular rational readback is admitted for that window;*
5. *H records componentwise* hsame *transport for schedules, regular readbacks, extraction rows, diagonal selector rows, replay, provenance, and local naming;*
6. *C records displayed* Cont *replay from a diagonal request through S, R, T, Q, H before any* $\mathsf{Real}^{\uparrow}$ *seal is readable;*
7. *P is the* Pkg *provenance over* $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchySubsequenceExtra}$ $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalCauchySubsequence}^{\uparrow}}$ *row.*

The carrier exports a finite diagonal extraction surface. It has no coordinate for host subsequence equality, selected limits, quotient equality of real names, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiagonalCauchySubsequenceUp.DiagonalCauchySubsequenceTasteGate single carrier alignment`

Theorem 3469.2 (Diagonal Cauchy subsequence NameCert obligations)**.** *For every accepted* $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ *carrier* $D = (S, R, T, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DiagonalCauchySubsequence}^{\uparrow}}$ *surface consists exactly of schedule admission for the* $\mathsf{StreamName}^{\uparrow}$ *rows in* S*; regular rational readback admission through* R*; subsequence-extraction admission through* T*; diagonal selector exactness through* Q*; preservation under the componentwise* hsame *rows of* H*; displayed* Cont *replay through* C*; provenance through* P*; and local naming through* N*. These obligations keep the diagonal selector inside the finite schedule, readback, extraction, transport, replay, provenance, and naming rows.*

Proof. Project the carrier. The schedules, regular readbacks, extraction row, selector row, transports, replay, provenance, and local name are the only visible coordinates of D.

Read the analytic rows in order. The $\mathsf{StreamName}^{\uparrow}$ schedules in S display the finite source and tail windows, R supplies the regular rational readbacks for those windows, and T records the subsequence extraction data supplied by the sibling subsequence and interleaving criteria.

The diagonal row Q is downstream of those reads. It may choose among displayed windows already admitted by S, R, T, but it has no socket for a host subsequence, a selected real limit, quotient equality, trichotomy, or ambient completeness.

Finally use H, C, P, N. Transport and replay preserve the same finite rows, and the package and local certificate name that route without adding any external diagonal principle. □

Theorem 3469.3 (Diagonal Cauchy subsequence regularity)**.** *For an accepted* $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ *carrier* $D = (S, R, T, Q, H, C, P, N)$*, every diagonal read exported to a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer preserves the regular Cauchy windows displayed by* S *and* R*. The consumer route factors through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchySubsequenceExtraction}^{\uparrow},\ \mathsf{CauchyInterleavingCriterion}^{\uparrow},\ Q, H, C, P, N.$$

Consequently the packet cannot expose host subsequence equality, selected limits, quotient equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted diagonal read. The route must first inspect the finite schedules S and the attached regular rational readbacks R, so the read is already tied to displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows.

Next inspect the subsequence and interleaving row T. It records only finite increasing-index and tail-window evidence from the sibling Cauchy routes, and the diagonal selector Q can select only from those displayed rows.

The structural rows preserve the same regular windows. Componentwise hsame transport and displayed Cont replay carry S, R, T, Q together, while P, N source and name the accepted packet. Since no excluded object is a coordinate of the carrier, no consumer can obtain host subsequence equality, a selected limit, quotient equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness from the diagonal packet. □

Falsifiable prediction: Every accepted $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ read factors through displayed StreamName schedules, RegSeqRat readbacks, a Cauchy subsequence extraction row, a diagonal selector row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any RealUp seal is consumed.

Independence witness: streamname, regseqrat, real, cauchysubsequencecriterion, cauchy-interleaving-criterion: $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source schedules, regular readbacks, extraction data, a diagonal selector, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{DiagonalCauchySubsequence}^{\uparrow}$ packet is generated from StreamName schedules, RegSeqRat readbacks, a Cauchy subsequence extraction row, a diagonal selector row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiagonalCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3469.1, Definition 3469.2, and Definition 3469.3 seed the finite diagonal subsequence route through stream schedules, regular readbacks, and RealUp seal boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiagonalCauchySubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subsequence equality, selected limits, quotient equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal selector exactness, regular-window preservation, non-escape, and bridge-facing consumer rows for BEDC.Derived.DiagonalCauchySubsequenceUp.

Chapter 3470

A Concrete Naming Certificate for $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$

The $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ packet realizes the trigger-support and coverage-rank rows of subsection 9462.28.21 as finite BEDC NameCert data. It consumes the six-coordinate codon source of chapter 2234, the boundary-tile classifier of chapter 3393, the punctured support skeleton of chapter 3463, and the inverse spectral route of chapter 2161. The packet records coverage witnesses for boundary-trigger rows; it is not a biological code table, a stochastic evolutionary model, a quotient codon space, or a hidden global semantics.

Definition 3470.1 (Six boundary tile coverage carrier)**.** *A* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, T, G, R, A, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source-window row exposing the six bit coordinates on which trigger support is read;*
2. *T is the* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *boundary-tile row exposing the stop/Trp and Ile/Met boundary classifiers;*
3. *G is the* $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$ *support graph row listing the puncture, bridge, CUN-square, and articulation rows used by coverage reads;*
4. *R is the coverage-rank row, recording which displayed boundary triggers cover which support faces and which rows remain uncovered;*
5. *A is the* $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$ *inverse-spectral handoff row, used only after W, T, G, R are displayed;*
6. *H records componentwise* hsame *transport for source windows, boundary tiles, support graph rows, coverage-rank rows, inverse-spectral handoff, replay, provenance, and local naming;*
7. *C records displayed* Cont *replay from a trigger-coverage request through W, T, G, R, A, H;*
8. *P is the* Pkg *provenance over* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{PuncturedCubeSkeleton}^{\uparrow}$, $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$, *the source vision of subsection 9462.28.21,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SixBoundaryTileCoverage}^{\uparrow}}$ *row.*

The carrier accepts coverage only when every trigger read is exhausted by $W, T, G, R, A, H, C, P, N$. It has no coordinate for a hidden biological table, quotient codon equality, selected stochastic dynamics, or global semantic equivalence.

Theorem 3470.2 (Six boundary tile coverage NameCert obligations)**.** *For every accepted* SixBoundaryTileCoverage *carrier $K = (W, T, G, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SixBoundaryTileCoverage}^{\uparrow}}$ *surface consists exactly of six-bit source-window admission through W, boundary-tile admission through T, punctured-skeleton support admission through G, coverage-rank exactness through R, inverse-spectral handoff through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.SixBoundaryTileCoverageUp.SixBoundaryTileCoverageTasteGate single carrier alignment`

Proof. Project the accepted carrier. The rows $W, T, G, R, A, H, C, P, N$ list all source-window, boundary-tile, support-graph, coverage-rank, inverse-spectral, transport, replay, provenance, and naming data available to the packet.

The trigger-support surface is finite. A coverage request first reads the six-coordinate source window W, then the boundary tile row T, and then the punctured support row G before the rank ledger R can be inspected.

The inverse-spectral handoff A is downstream of that support route. It may compare coverage rows with spectral inverse data, but it cannot replace them by a hidden code table or by stochastic semantics.

Finally H, C, P, N preserve and name the same finite route. Since every accepted coverage read is exhausted by those rows, no quotient codon space, selected dynamics, or global biological semantics is exported. □

Theorem 3470.3 (Six boundary tile trigger nonescape)**.** *Every accepted trigger-coverage read of a* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *packet factors through*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{PuncturedCubeSkeleton}^{\uparrow},\ R,\ \mathsf{CodonWindowSpectralInverse}^{\uparrow},\ H$$

In particular, a trigger coverage claim cannot escape the displayed six-coordinate source, boundary-tile classifier, punctured support graph, coverage-rank row, inverse-spectral handoff, componentwise transport, replay, provenance, and local naming rows.

Proof. Start with the source rows. The six-bit window W exposes the coordinates on which a trigger is read, while T restricts the trigger to the displayed boundary-tile classifier.

Next read the support and rank rows. The punctured skeleton G supplies the support faces, and R records exactly which displayed triggers cover which faces. The spectral inverse row A is only a handoff from this route, not an alternate coverage source.

The structural rows close the route. Componentwise transport and replay preserve W, T, G, R, A together, while provenance and local naming source the accepted packet. Thus a consumer cannot obtain a hidden biological table, quotient codon equality, selected stochastic dynamics, or global semantic equivalence from a trigger-coverage read. □

Falsifiable prediction: A concrete trigger-coverage nonescape claim for $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ is that every accepted boundary-trigger read preserving $W, T, G, R, A, H, C, P, N$ remains inside the displayed six-coordinate source, boundary tile, punctured support graph, coverage-rank, and inverse-spectral route.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, punctured-cube-skeleton, codon-window-spectral-inverse: $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries trigger support, coverage rank, inverse-spectral handoff, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.SixBoundaryTileCoverageUp.TasteGate` must provide explicit Nontrivial $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ and FieldFaithful $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ instances preserving $W, T, G, R, A, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{SixBoundaryTileCoverage}^{\uparrow}}$.

Constructive story: A $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ packet is generated from codon six-bit windows, boundary-tile classifiers, punctured support skeleton rows, coverage-rank rows, inverse-spectral handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SixBoundaryTileCoverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3470.1, Definition 3470.2, and Definition 3470.3 seed the finite trigger-coverage packet over six-bit windows, boundary tiles, support skeletons, and spectral inverse rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SixBoundaryTileCoverage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological table identity, stochastic evolutionary modeling, quotient codon equality, global semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trigger-support exactness, coverage-rank nonescape, inverse-spectral handoff, Nontrivial SixBoundaryTileCoverageUp, and FieldFaithful SixBoundaryTileCoverageUp for BEDC.Derived.SixBoundaryTileCoverageUp.

Chapter 3471

A Concrete Naming Certificate for $\mathsf{HeineBorelFiniteNet}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of compact intervals by finite approximation data, the $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ packet records the interval-cover certificate obtained from a located closed interval, a displayed finite net, a positive Lebesgue-number ledger, and the endpoint real-name boundary. It consumes the finite-net interval surface of chapter 1808, the compact-cover radius route of chapter 2301, the compact uniform-modulus route of chapter 3444, the terminal real-name seal of chapter 38, and the dyadic tolerance rows of chapter 291. The packet is a finite-net interval-cover certificate; it is not a general open-cover compactness theorem, an unrestricted Heine-Borel principle, a selected subcover functional, or an ambient completeness assertion.

Definition 3471.1 (Heine-Borel finite-net carrier)**.** *A* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, F, L, C, R, D, E, T, Q, P, N)$$

with the following displayed rows:

1. *I is the located closed interval source row, exposing the lower endpoint, upper endpoint, and endpoint order data as* $\mathsf{Real}^{\uparrow}$ *histories.*
2. *F is the* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *finite-net row, listing the displayed mesh scale and finite interval net consumed by the cover request.*
3. *L is the* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *positive-radius row attached to the displayed finite cover or pointwise radius family.*
4. *C is the* $\mathsf{HeineCantor}^{\uparrow}$ *compact-uniformity row that may be read only as a sibling route through the same finite-net and radius data.*
5. *R is the cover-read row, assigning each listed net point to its displayed cover witness and recording the finite neighborhood test used for nearby interval points.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording mesh width, endpoint containment, radius comparison, and finite cover slack checks.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the endpoint and cover-boundary reads.*
8. *T records componentwise* hsame *transport for the interval source, finite-net row, Lebesgue-number row, Heine-Cantor row, cover-read row, dyadic ledger, Real seal, replay row, provenance row, and local naming row.*

9. *Q records displayed* Cont *replay from an interval-cover request through I, F, L, R, D, E and, when needed by a uniform-continuity consumer, through the sibling row C.*

10. *P is the* Pkg *provenance over* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{LebesgueNumberLemma}^{\uparrow}$, $\mathsf{HeineCantor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, L, C, R, D, E, T, Q, P, N$. It has no coordinate for arbitrary open covers, unrestricted Heine-Borel compactness, selected subcovers, quotient interval representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HeineBorelFiniteNetUp.HeineBorelFiniteNetTasteGate single carrier alignment`

Theorem 3471.2 (Heine-Borel finite-net NameCert obligations)**.** *For every accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *carrier $H = (I, F, L, C, R, D, E, T, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteNet}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the located interval source, finite-net row, Lebesgue-number row, Heine-Cantor sibling row, cover-read row, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*

2. *interval finite-net exposure, requiring the cover request to display I and F before any cover witness is read;*

3. *radius compatibility, requiring the positive-radius row L and dyadic ledger D to control mesh width, endpoint containment, cover slack, and finite neighborhood tests;*

4. *sibling uniformity compatibility, requiring the* $\mathsf{HeineCantor}^{\uparrow}$ *row C to be read only as a sibling route over the same finite-net and radius rows;*

5. *non-escape, requiring T, Q, P, N to transport, replay, source, and name only the displayed finite packet and to export no arbitrary open-cover compactness, unrestricted Heine-Borel principle, selected subcover, countable-choice row, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Carrier admission is projection from Definition 3471.1. The tuple displays exactly the interval source, finite net, positive-radius row, sibling uniformity route, cover reads, dyadic tolerance ledger, Real seal, and structural rows.

The interval-cover computation first reads I and F. Thus every point-facing cover read is tied to the displayed located interval and to a listed finite mesh row before any neighborhood witness can be inspected.

The radius and cover checks are finite. The row L supplies the positive radius ledger, while D records the mesh-width and containment comparisons that let R transfer a cover witness from a listed net point to the interval point under inspection.

The sibling uniformity row C is only a compatibility route. It can be consumed by a Heine-Cantor-style downstream reader, but it does not replace the finite-net cover row or introduce an open-cover compactness principle.

Finally, the refused objects have no carrier coordinate. Since T, Q, P, N transport, replay, source, and name only the displayed packet, no accepted $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ certificate exports unrestricted Heine-Borel compactness, a selected subcover, countable choice, host equality, or ambient Real completeness. □

Theorem 3471.3 (Heine-Borel finite-net interval-cover route)**.** *Every interval-cover read from an accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longmapsto \mathsf{LebesgueNumberLemma}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{HeineCantor}^{\uparrow}$ *row is available as the sibling compact-uniformity route over the same finite-net and radius data, but the exported certificate remains the displayed finite-net interval-cover route.*

Proof. Project the accepted carrier $H = (I, F, L, C, R, D, E, T, Q, P, N)$. The interval source and finite-net row are I and F, the positive-radius row is L, the dyadic comparison ledger is D, and the terminal endpoint seal is E.

Replay through Q keeps that order. A cover request opens the finite net, reads the positive-radius ledger, checks the dyadic slack against the mesh and endpoint rows, and only then exposes the Real-facing endpoint seal.

The row C records the compatible Heine-Cantor route for consumers that also need compact uniformity. It remains tied to the same finite rows, so it cannot introduce a selected subcover, an unrestricted open-cover theorem, or an ambient completeness coordinate. □

Definition 3471.4 (Heine-Borel finite-net grid refinement)**.** *Let* $H = (I, F, L, C, R, D, E, T, Q, P, N)$ *be an accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *carrier and let a displayed dyadic submesh refine the finite net row* F*. The grid refinement is the packet obtained by transporting the positive-radius row* L *through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger* D *while keeping the located interval source* I*, cover-read row* R*, endpoint seal* E*, transport row* T*, replay row* Q*, provenance row* P*, and local name row* N *unchanged. The refinement preserves the same finite mesh route and does not add any selected subcover coordinate.*

Theorem 3471.5 (Heine-Borel finite-net grid refinement stability)**.** *Refining the finite net row* F *of an accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet by a displayed dyadic submesh and transporting the positive-radius row* L *through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger yields another accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet with the same* $\mathsf{Real}^{\uparrow}$ *endpoint seal and the same nonescape boundary. The refined packet still factors through the finite route*

$$\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longmapsto \mathsf{LebesgueNumberLemma}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

and it exports no selected subcover, quotient interval equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3471.1. The finite net row F and the positive-radius row L are the only rows changed by the displayed dyadic submesh.

Replay Definition 3471.3. It forces the refined mesh to be read through the located interval source, the positive-radius ledger, the dyadic comparison row, and the Real seal in the same order as the unrefined packet.

Now use the grid-refinement packet itself. Because the refinement keeps I, R, E, T, Q, P, N unchanged and only retunes the mesh through L and D, the consumer still sees the same finite-net interval-cover route and no selected subcover or ambient completeness coordinate. □

Theorem 3471.6 (Heine-Borel finite-net obligation lattice)**.** *Any accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet must be read in the obligation order*

$$\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longmapsto \mathsf{LebesgueNumberLemma}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{HeineCantor}^{\uparrow}$ *row is only a sibling uniformity consumer over the same finite interval, positive-radius, dyadic, and Real-seal rows. The packet does not export general open-cover compactness, unrestricted Heine-Borel, selected subcovers, quotient interval representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (I, F, L, C, R, D, E, T, Q, P, N)$. The finite interval source and net rows are I and F, the positive-radius row is L, the dyadic tolerance ledger is D, and the terminal Real-facing seal is E.

The cover-read row R can be consumed only after the interval and finite-net rows have been displayed, and the replay row Q keeps the Lebesgue-number row ahead of every dyadic slack check. Thus the finite-net obligation surface is ordered by interval net, positive radius, dyadic comparison, and Real seal.

The row C is read differently. It is available to a $\mathsf{HeineCantor}^{\uparrow}$ consumer that needs compact uniformity over the same finite rows, but it does not precede the finite-net route and does not replace F, L, D, E.

Finally the structural rows T, P, N transport, source, and name only the displayed packet. Since the refused objects have no coordinate in H, the obligation lattice cannot escape to unrestricted compactness, selected subcovers, quotient representatives, countable choice, host equality, or ambient completeness. □

Theorem 3471.7 (Heine-Borel finite-net scope witness)**.** *Every accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet reads only the displayed located-closed-interval finite-net row, the Lebesgue-number positive-radius row, the Heine-Cantor sibling row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. Thus the chapter scope is closed at the finite-net interval-cover certificate boundary and does not extend to general open-cover compactness, unrestricted Heine-Borel compactness, selected subcovers, quotient interval representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier definition Definition 3471.1 lists exactly the rows $I, F, L, C, R, D, E, T, Q, P, N$ and states that the classifier compares accepted packets only through those rows.

Apply Definition 3471.2 to identify the local NameCert obligations, Definition 3471.3 to force every interval-cover read through the located interval, finite net, positive radius, dyadic ledger, and Real seal, and Definition 3471.6 to keep the Heine-Cantor row as a sibling uniformity route over the same finite data.

The refused objects have no coordinate in the carrier and are excluded by all three displayed theorem blocks. Therefore the accepted packet reads exactly the stated finite-net scope. □

Theorem 3471.8 (Heine-Borel finite-net subcover extraction)**.** *The finite subcover row consumes the finite-net interval carrier of chapter 1808 and the positive-radius witness of chapter 2301 before the extracted witness list reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Let $H = (I, F, L, C, R, D, E, T, Q, P, N)$ *be an accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet. If the cover-read row* R *reaches the displayed finite net* F*, then the packet extracts a finite subcover row only through the route*

$$\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow},\quad \mathsf{LebesgueNumberLemma}^{\uparrow},\quad \mathsf{HeineCantor}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{hsame},$$

The extracted row is the finite list of cover witnesses already recorded by R *for the net points and transported to interval points through* L, D, E, T, Q, P, N*. It is not an arbitrary open-cover*

compactness theorem, a selected subcover functional, a quotient-interval construction, a countable-choice principle, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

The same extracted finite subcover row is the cover input consumed by $\mathsf{ContinuousIntervalImage}^{\uparrow}$ *through chapter 1897 when interval-image connectedness or compact interval-image routes need finite cover data.*

Proof. Project the carrier of Definition 3471.1. The only cover-facing rows are the located interval source I, the finite net F, the positive-radius ledger L, the sibling uniformity row C, the cover-read row R, the dyadic ledger D, and the Real seal E.

Use Definition 3471.2 to keep every accepted cover read inside the local NameCert obligations. In particular, the cover request must display the interval and finite-net rows before a witness from R can be inspected, and the radius compatibility check must pass through L and D.

Apply Definition 3471.3 to order the extraction. The finite list of witnesses is read from R along the located finite net, then transported across the Lebesgue-number and dyadic slack rows to the endpoint Real seal.

Finally apply Definition 3471.7. It keeps the $\mathsf{HeineCantor}^{\uparrow}$ row as a sibling compact-uniformity route and confines transport, replay, provenance, and naming to $\mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$. Since the refused objects have no carrier coordinate, the extracted finite subcover row cannot be read as arbitrary compactness, selected choice, quotient interval data, countable choice, or ambient Real completeness. □

Theorem 3471.9 (Heine-Borel finite-net obligation-closure package)**.** *The exact obligation-closure surface of a* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet is the package consisting of the carrier of Definition 3471.1, the NameCert obligations of Definition 3471.2, the interval-cover route of Definition 3471.3, the obligation lattice of Definition 3471.6, the scope witness of Definition 3471.7, and the subcover extraction row of Definition 3471.8. Any downstream interval compactness consumer must read those rows as one finite packet over* $I, F, L, C, R, D, E, T, Q, P, N$ *and cannot replace them by arbitrary open-cover compactness, a selected subcover functional, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First project the carrier. It fixes the displayed rows $I, F, L, C, R, D, E, T, Q, P, N$ and leaves no coordinate outside the located interval, finite-net, positive-radius, sibling uniformity, cover-read, dyadic, Real-seal, transport, replay, provenance, and local naming data.

Next apply the NameCert obligations, interval-cover route, and obligation lattice. These rows force the cover request to pass through $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{LebesgueNumberLemma}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with $\mathsf{HeineCantor}^{\uparrow}$ available only as a sibling uniformity route over the same finite data.

Finally apply the scope witness and subcover extraction theorem. They identify the exportable finite subcover row as the witnessed cover reads already recorded by R and transported through L, D, E, T, Q, P, N. Since no refused object appears in the carrier, the displayed package is exactly the obligation-closure surface. □

Theorem 3471.10 (Heine-Borel finite-subcover extraction scope)**.** *Any finite subcover row exported by an accepted* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *packet remains scoped to* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{LebesgueNumberLemma}^{\uparrow}$, $\mathsf{HeineCantor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *It may be read only through the displayed rows* $I, F, L, C, R, D, E, T, Q, P, N$*, so it is not arbitrary open-cover compactness, a choice-selected subcover, quotient interval equality, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from Definition 3471.8. The extracted row is already the finite list of witnesses recorded by R for the displayed finite net and transported to interval points through the positive-radius and dyadic slack rows.

Use Definition 3471.9 to keep that row inside the whole packet. The admissible dependencies are exactly the located finite-net source, Lebesgue-number radius, Heine-Cantor sibling route, dyadic ledger, Real seal, and structural $\mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$ rows.

The refused readings have no carrier coordinate and no replay route. Therefore the exported finite subcover row cannot be detached from the finite-net interval certificate or promoted into unrestricted compactness or choice-selected subcover data. □

Theorem 3471.11 (Heine-Borel finite-net primitive induction route)**.** *Let $H = (I, F, L, C, R, D, E, T, Q, P, N)$ be an accepted $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ packet. The finite-net cell list displayed by F supports primitive finite induction from the first accepted cell through each subsequent Cont replay row in Q. At every step the induction reads only the current net cell, the corresponding radius check in L, the dyadic slack row in D, the retained cover read in R, and the endpoint seal in E. The resulting induction route is stable under componentwise hsame transport in T and remains inside the provenance and local naming ledger P, N.*

Proof. Project the carrier of Definition 3471.1. The finite list is the displayed row F, and the replay row Q records how a cover request advances through the listed cells.

The base step reads the first accepted cell together with its positive-radius row from L, dyadic slack row from D, cover witness from R, and endpoint seal from E. The successor step repeats the same displayed read for the next cell and adjoins the resulting witness to the finite subcover row.

Componentwise transport through T preserves each cell, radius, slack, cover-read, and endpoint-seal row. Since P and N name only the same displayed packet, the induction route cannot leave the local NameCert ledger or import an arbitrary open-cover compactness principle. □

Theorem 3471.12 (Heine-Borel choice-free located net)**.** *For every accepted $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ carrier*

$$H = (I, F, L, C, R, D, E, T, Q, P, N),$$

the extracted located-net cover row is read only from the displayed located interval source I, finite-net row F, Lebesgue-number row L, Heine-Cantor sibling row C, DyadicRatCore ledger D, Real seal E, componentwise hsame transport T, displayed Cont replay Q, Pkg provenance P, and local $\mathsf{NameCert}$ row N. The route packages a finite located-net handoff and does not claim general open-cover compactness, unrestricted Heine-Borel compactness, selected subcover functionals, quotient interval representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Proof. Begin with the finite subcover extraction theorem Definition 3471.8. It identifies the exported row as the finite list of cover witnesses already recorded for the displayed finite net and transported across the positive-radius, dyadic, endpoint, structural, provenance, and naming rows.

The finite-subcover extraction scope of Definition 3471.10 keeps that row inside the located interval, Lebesgue-number, Heine-Cantor sibling, DyadicRatCore, Real, hsame, Cont, Pkg, and $\mathsf{NameCert}$ surface. Thus no external subcover selector or open-cover compactness object is available.

Finally apply the primitive induction route of Definition 3471.11. The witness list is assembled by finite induction over the displayed cells of F, with each step reading only the current radius check, dyadic slack row, retained cover read, and endpoint seal. Therefore the located-net handoff is choice-free and remains confined to the accepted packet rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteNet}^{\uparrow}}$.

Constructive story: A $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ packet is generated from a located closed interval source, a LocatedClosedIntervalFiniteNet row, a LebesgueNumberLemma positive-radius ledger, a HeineCantor sibling route, finite cover reads, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteNet}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 3471.1, Definition 3471.2, and Definition 3471.3 seed the constructive finite-net interval-cover certificate over located interval, positive-radius, dyadic tolerance, Heine-Cantor sibling, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, unrestricted Heine-Borel compactness, selected subcovers, quotient interval representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net interval exposure, radius compatibility, sibling uniformity compatibility, cover-read exactness, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.HeineBorelFiniteNetUp.

Chapter 3472

A Concrete Naming Certificate for $\mathsf{HilbertBasis}^{\uparrow}$

Following Hilbert's basis theorem and constructive commutative algebra, the $\mathsf{HilbertBasis}^{\uparrow}$ packet records the finite generating rows needed to read a polynomial ideal as a named basis surface. It sits after the polynomial constructors of chapter 50, the ring and commutative-ring ledgers of chapter 43 and chapter 44, the ideal carrier of chapter 81, and the finite reduction route of chapter 2197.

Definition 3472.1 (HilbertBasis carrier)**.** *A* $\mathsf{HilbertBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{HB}(P, R, C, I, G, B, H, K, Q, N)$$

with the following rows.

- P *is the* $\mathsf{Poly}^{\uparrow}$ *source row for the ambient polynomial syntax and monomial ledger.*
- R *is the* $\mathsf{Ring}^{\uparrow}$ *source row for coefficient addition, multiplication, zero, one, and additive inverse.*
- C *is the* $\mathsf{CommRing}^{\uparrow}$ *row that makes coefficient multiplication commute for the displayed polynomial operations.*
- I *is the* $\mathsf{Ideal}^{\uparrow}$ *row naming the finite ideal-membership and generator surface.*
- G *is the* $\mathsf{GroebnerBasis}^{\uparrow}$ *reduction row used only as a finite normal-form witness.*
- B *is the displayed Hilbert-basis list of polynomial generators, together with the bounded reduction traces that place each ideal row under that list.*
- H, K, Q, N *are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{HilbertBasis}^{\uparrow}}$ *naming rows.*

The packet has no coordinate for quotient ideals, host noetherianity, excluded middle over ideals, selected infinite generator search, or choice-produced basis extraction.

Lean4 ✓ `BEDC.Derived.HilbertBasisUp.HilbertBasisTasteGate single carrier alignment`

Theorem 3472.2 (HilbertBasis NameCert obligations)**.** *For an accepted* $\mathsf{HilbertBasis}^{\uparrow}$ *carrier* $\mathsf{HB}(P, R, C, I, G, B, H, K, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HilbertBasis}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, polynomial-source compatibility through* P*, coefficient-ring compatibility through* R *and* C*, ideal generator access through* I*, finite reduction replay through* G*, basis-list exactness through* B*, componentwise transport through* H*, continuation replay through* K*, package provenance through* Q*, and local naming through* N*.*

Proof. Project the carrier of Definition 3472.1. The only rows available to the local certificate are $P, R, C, I, G, B, H, K, Q, N$.

The polynomial, ring, commutative-ring, and ideal rows supply the algebraic source surface. The Groebner row supplies finite reduction traces only after those source rows have been displayed.

The basis-list row B records the finitely many generators and the reductions that witness their coverage. Transport, continuation, provenance, and local naming then repack the same finite rows, so quotient ideals, host noetherianity, and choice data cannot enter the certificate. □

Theorem 3472.3 (HilbertBasis polynomial-ideal route)**.** *Every downstream consumer of an accepted* $\mathsf{HilbertBasis}^{\uparrow}$ *packet that asks for a polynomial-ideal basis must read the route*

$$\mathsf{Poly}^{\uparrow} \longrightarrow \mathsf{Ring}^{\uparrow} \longrightarrow \mathsf{CommRing}^{\uparrow} \longrightarrow \mathsf{Ideal}^{\uparrow} \longrightarrow \mathsf{GroebnerBasis}^{\uparrow} \longrightarrow \mathsf{NameCert}_{\mathsf{HilbertBasis}^{\uparrow}}.$$

The exported object is the finite generator row B together with its displayed reduction traces and structural rows H, K, Q, N; it is not a quotient ideal, not an infinite ascending-chain argument, not a host noetherian theorem, and not a selected basis obtained by choice.

Proof. Start with the polynomial row P and coefficient rows R, C. These determine the syntax and coefficient operations that an ideal consumer is allowed to inspect.

Next read the ideal row I and the finite Groebner row G. The ideal surface provides the finite membership and generator coordinates, while the Groebner route provides terminating reduction traces for the displayed basis list.

Finally apply the NameCert obligations of Definition 3472.2. They force the exported basis to remain inside B, H, K, Q, N, so no quotient ideal, no ambient noetherian principle, and no choice-produced generator search is exported. □

Falsifiable prediction: Every $\mathsf{HilbertBasis}^{\uparrow}$ consumer that claims a polynomial-ideal basis must exhibit the polynomial row, ring row, commutative-ring row, ideal row, Groebner reduction row, basis-list row, transport, continuation, provenance, and local naming row.

Independence witness: polynomial, ring, commring, ideal, groebner-basis: $\mathsf{HilbertBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries polynomial syntax, coefficient algebra, ideal membership, finite reduction traces, and a named basis-list surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{HilbertBasis}^{\uparrow}$ packet is generated from PolynomialUp syntax rows, RingUp and CommRingUp coefficient rows, an IdealUp generator surface, a GroebnerBasisUp reduction row, a finite basis-list row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HilbertBasis}^{\uparrow}}$, seed)

Scope closed: Definition 3472.1, Definition 3472.2, and Definition 3472.3 seed the finite polynomial-ideal basis interface over PolynomialUp, RingUp, CommRingUp, IdealUp, GroebnerBasisUp, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HilbertBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient ideals, host noetherianity, excluded middle over ideals, selected infinite generator search, choice-produced basis extraction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, polynomial and coefficient compatibility, ideal generator access, finite reduction replay, basis-list exactness, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.HilbertBasisUp.

Chapter 3473

A Concrete Naming Certificate for $\mathsf{CantorBernstein}^{\uparrow}$

Following Cantor, Bernstein, and Schroeder, the $\mathsf{CantorBernstein}^{\uparrow}$ packet records the finite BEDC route by which two displayed injection classifiers determine one mutual-injection equivalence boundary. It sits beside the equality and comparison surfaces of chapter 1404, the stream-window classifier surface of chapter 126, and the governance naming discipline of chapter 9467. The packet exposes classifier rows, finite zig-zag decomposition data, BHist inspection, hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming; it is not a host quotient equality theorem, a selected bijection from ambient set theory, or a hidden choice principle.

Definition 3473.1 (Cantor–Bernstein carrier)**.** *A* $\mathsf{CantorBernstein}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, I, J, X, Y, Z, H, C, P, N)$$

with the following displayed rows:

1. *A is the first classifier surface, naming the observed source-side rows and their equality test before any target-side identification is read.*
2. *B is the second classifier surface, naming the observed target-side rows and their equality test before any source-side identification is read.*
3. *I is the displayed injection row from A into B, including source classifier preservation and target classifier reflection for every inspected finite row.*
4. *J is the displayed injection row from B into A, including target classifier preservation and source classifier reflection for every inspected finite row.*
5. *X is the finite zig-zag decomposition ledger. It separates forward chains, backward chains, anchored components, and unresolved boundary components using only the two displayed injection rows.*
6. *Y is the classifier-equivalence route read from X. It records which side supplies the representative for each finite zig-zag component without identifying host quotient classes.*
7. *Z is the mutual-injection boundary row exported to later classifier consumers.*
8. *H records componentwise* hsame *transport for the two classifier surfaces, the two injection rows, the zig-zag decomposition ledger, the classifier-equivalence route, and the exported boundary row.*

9. *C records displayed* Cont *replay from classifier inspection through injection preservation, zig-zag decomposition, and boundary export.*
10. *P is the* Pkg *provenance over* $\mathsf{CantorBernstein}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *and the sibling classifier chapters cited above.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorBernstein}^{\uparrow}}$ *row.*

The carrier compares the two classifier surfaces only through the rows listed here. It exports no host quotient of classifiers, no ambient set equality, no selected global bijection, no arbitrary chain choice, and no completed StreamName or Real equivalence theorem.

Lean4 ✓ `BEDC.Derived.CantorBernsteinUp.CantorBernsteinTasteGate single carrier alignment`

Theorem 3473.2 (Cantor–Bernstein NameCert obligations)**.** *For every accepted* $\mathsf{CantorBernstein}^{\uparrow}$ *carrier*

$$K = (A, B, I, J, X, Y, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorBernstein}^{\uparrow}}$ *surface consists exactly of carrier admission, two displayed classifier surfaces, two injection rows, finite zig-zag decomposition, classifier-equivalence routing, exported mutual-injection boundary data, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the boundary row Z must factor through*

$$A, B, I, J \longmapsto X, Y, Z \longmapsto H, C, P, N.$$

Thus the mutual-injection theorem surface is available as finite BEDC certificate data while refusing host quotient equality, ambient set extensionality, arbitrary chain choice, and a selected global bijection.

Proof. Project the carrier of Definition 3473.1. The two classifier surfaces A and B are visible before either injection row is consumed, so no side is treated as a hidden quotient of the other.

Read the injections next. The row I records classifier preservation and reflection from A to B, while J records the corresponding route from B to A. These two rows are the only admissible source of mutual reachability data.

Build the finite zig-zag ledger X from the displayed reachability rows. The ledger separates chain components by finite inspection and hands the representative-side decision to Y without invoking an ambient chain selector.

The exported row Z is then a boundary for downstream classifier consumers. Transport by H and replay by C preserve the same displayed rows, while P and N record provenance and local naming. No additional quotient, extensionality, or choice row is present in the packet. □

Falsifiable prediction: Removing either displayed injection row or the finite zig-zag decomposition ledger prevents a consumer from distinguishing mutual-injection classifier equivalence from a host quotient or selected bijection.

Independence witness: regularcauchyequivalence, streamname, real: none is bijective to $\mathsf{CantorBernstein}^{\uparrow}$ because the packet jointly carries two classifier surfaces, two displayed injection rows, a finite zig-zag decomposition ledger, classifier-equivalence routing, boundary export, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorBernstein}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorBernstein}^{\uparrow}$ packet is generated from two displayed classifier surfaces, two injection rows, finite zig-zag decomposition data, classifier-equivalence routing, a mutual-injection boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CantorBernstein}\uparrow}$, seed)

Scope closed: Definition 3473.1 and Definition 3473.2 seed the finite mutual-injection classifier-equivalence boundary over displayed BEDC rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CantorBernstein}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host quotient equality, ambient set extensionality, arbitrary chain choice, a selected global bijection, StreamName equivalence, Real equivalence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two classifier surfaces, two injection rows, finite zig-zag decomposition, classifier-equivalence routing, boundary export, transport, replay, provenance, and local naming for BEDC.Derived.CantorBernsteinUp.

Chapter 3474

A Concrete Naming Certificate for $\mathsf{HyperbolicMetric}^{\uparrow}$

Following Gromov's four-point metric viewpoint and Kelley's topology-side use of metric balls, the $\mathsf{HyperbolicMetric}^{\uparrow}$ packet realizes hyperbolic metric geometry as finite BEDC certificate data. It sits after the metric readback of chapter 57, the center-radius surface of chapter 1450, the ordered-real comparison rows of chapter 38, the topology handoff of chapter 88, and the bounded-set ledger of chapter 1757. The chapter names a finite four-point metric surface without turning the host disk, smooth hyperbolic manifold, ideal boundary, or ambient metric completion into a primitive model.

Definition 3474.1 (Hyperbolic metric carrier)**.** *A* $\mathsf{HyperbolicMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, d, b, t, \beta, q, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite* $\mathsf{Met}^{\uparrow}$ *carrier row whose displayed distance comparisons are the only metric data read by the packet.*
2. *d is the* $\mathsf{Real}^{\uparrow}$ *valued distance row, naming the finite comparisons used by the four-point ledger.*
3. *b is the* $\mathsf{MetricBall}^{\uparrow}$ *neighborhood row, exposing center-radius packets that can be transported without an ambient powerset.*
4. *t is the* $\mathsf{Topology}^{\uparrow}$ *handoff row, reading the ball-neighborhood surface as an indexed-open request.*
5. *β is the* $\mathsf{BoundedSet}^{\uparrow}$ *boundary ledger, recording bounded containment data for the displayed ball rows.*
6. *q is the four-point inequality row, comparing the three paired sums determined by four displayed metric observations.*
7. *F is the refusal row excluding smooth hyperbolic manifolds, quotient ideal boundaries, host geodesic completions, ambient Real completeness, physical cosmology, and internal observer-substance readings.*
8. *H records componentwise* hsame *transport for the metric carrier, distance, ball, topology, bounded-set, four-point, and refusal rows.*
9. *C records displayed* Cont *replay through finite metric observations, ball-neighborhood transport, topology handoff, bounded containment, four-point comparison, provenance, and refusal.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicMetric}^{\uparrow}}$ *row.*

The carrier exports a hyperbolic metric-read packet only through these rows. It contains no primitive smooth hyperbolic space, no quotient boundary, no completed geodesic model, no host powerset of balls, no ambient Real completeness principle, and no object-level observer substance.

Theorem 3474.2 (Hyperbolic metric NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicMetric}^{\uparrow}$ *carrier*

$$M = (X, d, b, t, \beta, q, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicMetric}^{\uparrow}}$ *surface consists exactly of metric-carrier admission, real-valued distance readback, metric-ball neighborhood transport, topology handoff, bounded-set boundary ledger, four-point inequality exposure, refusal exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every metric consumer must factor through*

$$X, d, b \longmapsto t, \beta, q, F \longmapsto H, C, P, N.$$

Thus hyperbolic geometry is read as a finite four-point metric certificate, not as a primitive ambient model.

Proof. Project the carrier of Definition 3474.1. The metric carrier row X is visible before any distance is read, and the distance row d is tied to displayed $\mathsf{Met}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ observations.

Read the ball, topology, and bounded rows next. The row b records center-radius neighborhoods, t exposes the topology-side indexed-open request, and β records the bounded-set boundary ledger without creating a host subset.

The four-point row q is the only hyperbolic comparison row. The refusal row F keeps smooth hyperbolic geometry, quotient boundary equality, completed geodesic space, physical cosmology, and ambient Real completeness outside the packet.

Finally H, C, P, N transport, replay, source, and name only these displayed rows. Since the carrier has no coordinate for a primitive smooth hyperbolic space, quotient boundary, completed metric model, physical cosmology, or observer substance, no consumer can extract those readings from the NameCert surface. □

Lean4 ✓ `BEDC.Derived.HyperbolicMetricUp.HyperbolicMetricCarrier namecert obligations`

Theorem 3474.3 (Hyperbolic metric four-point obligation surface)**.** *For every accepted* $\mathsf{HyperbolicMetric}^{\uparrow}$ *carrier* $M = (X, d, b, t, \beta, q, F, H, C, P, N)$*, carrier admission, four-point inequality exposure, ball-neighborhood transport, bounded-set boundary reading, topology handoff, and non-escape from smooth hyperbolic geometry or host metric completion are available only through the displayed rows*

$$X, d, b, t, \beta, q, F, H, C, P, N.$$

The row q may compare four displayed points by the usual hyperbolic four-point ledger, but it may not import a smooth manifold, an ideal-boundary compactification, a selected geodesic model, a host powerset of balls, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is the projection of Definition 3474.1. It exposes X as the metric carrier and d as the real-valued distance row before any hyperbolic comparison is inspected.

The four-point surface is row q. It reads only the finite distance comparisons supplied by d, so the hyperbolic inequality is a ledger entry over displayed observations rather than a theorem about an ambient smooth model.

Ball-neighborhood transport uses b together with H and C. The same transported center-radius rows are handed to t for the topology request and to β for bounded-set boundary accounting.

The refusal row F is then preserved by the structural rows H, C, P, N. Hence every consumer receives a finite NameCert surface over metric, ball, real, topology, bounded-set, transport, replay, provenance, and naming rows, with no coordinate from which smooth hyperbolic geometry or host metric completion can be recovered. □

Falsifiable prediction: Omitting the metric carrier row, distance row, metric-ball row, or four-point row prevents carrier acceptance because the packet can no longer distinguish finite hyperbolic metric reading from a primitive host geometry.

Independence witness: metric, metricball, real, topology, boundedset: none is bijective to $\mathsf{HyperbolicMetric}^{\uparrow}$ because the packet jointly carries metric carrier data, real-valued distance reads, ball-neighborhood rows, topology handoff, bounded-set boundary accounting, four-point comparison, refusal exactness, transport, replay, package sourcing, and local naming.

The Lean follow-up for this packet must provide explicit $\mathsf{Nontrivial\ HyperbolicMetric}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicMetric}^{\uparrow}$ TasteGate instances. Those instances must keep $X, d, b, t, \beta, q, F, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicMetric}^{\uparrow}$ packet is generated from Metric carrier observations, Real distance reads, MetricBall neighborhoods, Topology handoff, BoundedSet boundary accounting, a four-point comparison ledger, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3474.1, Definition 3474.2, and Definition 3474.3 seed the finite four-point metric surface through metric, ball, real, topology, bounded-set, refusal, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close smooth hyperbolic manifold geometry, quotient boundary equality, host metric completion, physical cosmology, observer-substance readings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric rows, ball rows, real comparison rows, topology handoff, bounded-set boundary accounting, four-point ledger exactness, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.HyperbolicMetricUp.

Chapter 3475

A Concrete Naming Certificate for $\mathsf{DenseIsometryExtension}^{\uparrow}$

Following Bishop and Bridges on constructive completions and isometric extension, the $\mathsf{DenseIsometryExtension}^{\uparrow}$ packet records the finite surface by which an isometry on a dense displayed source is extended through the completion interface. It sits after the entry surface of chapter 1512, the extension-and-uniqueness surface of chapter 397, the separated comparison boundary of chapter 1411, the regular rational readback of chapter 301, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names only the displayed dense-source extension route; it does not construct quotient completions, select limit representatives, assert host function equality, import ambient completeness, or add bridge checking.

Definition 3475.1 (Dense isometry extension carrier)**.** *A* $\mathsf{DenseIsometryExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, J, U, S, F, W, T, R, H, C, P, N)$$

with the following visible rows:

1. *D is the dense-source row, exposing the displayed source observations and their finite density witnesses.*
2. *J is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *entry row that sends dense-source observations into the completion-facing surface.*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension-and-uniqueness row attached to the same dense source and target route.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row that makes zero-distance agreement a displayed classifier fact.*
5. *F is the source isometry row, recording finite distance preservation on the dense source through* $\mathsf{Real}^{\uparrow}$ *readback rows.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect dense-source names.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling approximation requests.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational handoff row whose observations feed the terminal real seal.*
9. *H records componentwise* hsame *transport for dense source, completion entry, universal-property, separatedness, isometry, finite-window, tolerance, regular-rational, and real-seal rows.*

10. *C records displayed* Cont *replay through the same rows.*

11. *P is the* Pkg *provenance over* DenseIsometryExtension$^{\uparrow}$, CompletionEmbedding$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{DenseIsometryExtension}^{\uparrow}}$ *row.*

The carrier exports an extension service only through these rows. It contains no quotient completion object, no selected limit, no host function equality, no unrecorded completeness theorem, and no hidden choice schedule.

Lean4 ✓ `BEDC.Derived.DenseIsometryExtensionUp.TasteGate.DenseIsometryExtensionTasteGate single carrier alignment`

Theorem 3475.2 (Dense isometry extension NameCert obligations)**.** *For every accepted* DenseIsometryExtension$^{\uparrow}$ *carrier*

$$E = (D, J, U, S, F, W, T, R, H, C, P, N),$$

the local NameCert$_{\text{DenseIsometryExtension}^{\uparrow}}$ *surface consists exactly of dense-source admission, completion-entry exposure, universal-property extension, separated comparison, source isometry preservation, finite-window exposure, dyadic tolerance accounting, regular-rational handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every extension consumer must factor through*

$$D, J, F, W, T, R \longmapsto U, S \longmapsto H, C, P, N.$$

Thus the extension is read as finite NameCert data over the dense source and its completion route, not as a host-level function on a quotient completion.

Proof. Project the carrier of Definition 3475.1. The dense-source row D, completion-entry row J, source isometry row F, finite-window row W, dyadic ledger T, and regular-rational row R are the only rows from which a source observation can be read.

Next use the universal-property row U. It repacks those displayed observations as an extension route, while the separated comparison row S supplies the zero-distance classifier boundary needed for uniqueness of the extended isometry.

Finally transport and replay are confined to H and C, with P and N recording provenance and local naming. Since the carrier has no coordinate for a quotient completion, selected representative, host function equality, ambient completeness theorem, or choice schedule, every accepted extension consumer is forced through the displayed finite route. □

Theorem 3475.3 (Dense isometry extension completion handoff)**.** *Let $E = (D, J, U, S, F, W, T, R, H, C, P, N)$ be an accepted* DenseIsometryExtension$^{\uparrow}$ *carrier. Any completion-facing consumer of the extended isometry first reads the dense-source observations through D, W, T, R, then reads the completion-entry row J, then reads the universal-property and separatedness rows U, S, and only then receives transport, replay, provenance, and naming through H, C, P, N.*

The handoff is therefore a finite completion-extension service. It exports no quotient completion equality, selected host limit, host function equality, countable-choice schedule, ambient Real$^{\uparrow}$ *completeness theorem, or bridge-checking credential.*

Proof. Begin with the source side. The dense-source row D is inspected only through the finite windows W, dyadic tolerances T, and regular-rational handoff R, so a completion-facing request cannot skip directly to a completed target.

The completion-entry row J is the first completion-facing coordinate. After J has exposed the source observation as completion-entry data, U supplies the extension-and-uniqueness ledger and S supplies the separated classifier boundary.

The suffix H, C, P, N does not add mathematical content beyond transport, replay, provenance, and local naming of the displayed rows. Therefore the completion handoff is exactly the stated finite route, with no coordinate from which a quotient completion, selected limit, host function, choice schedule, ambient completeness theorem, or bridge credential could be read. □

Falsifiable prediction: Every accepted $\mathsf{DenseIsometryExtension}^{\uparrow}$ consumer reads the dense-source row, completion-entry row, universal-property row, separated comparison row, source isometry row, finite-window schedule, dyadic tolerance ledger, regular-rational handoff, transport, replay, provenance, and local naming before any completion-facing extension service is exposed.

Independence witness: completionembedding, completionuniversalproperty, separatedmetric, regseqrat, streamname, dyadicratcore, real: none is bijective to $\mathsf{DenseIsometryExtension}^{\uparrow}$ because the packet jointly carries dense-source admission, completion entry, universal-property extension, separated uniqueness, isometry preservation, finite windows, tolerance accounting, regular-rational readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DenseIsometryExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseIsometryExtension}^{\uparrow}$ packet is generated from dense-source observations, a CompletionEmbedding entry row, a CompletionUniversalProperty extension-and-uniqueness row, a SeparatedMetric comparison row, source isometry preservation, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal access, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseIsometryExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3475.1, Definition 3475.2, and Definition 3475.3 seed the finite dense-isometry extension route through dense source, completion entry, universal property, separated comparison, source isometry, finite observation, tolerance, readback, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseIsometryExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion construction, selected limit extraction, host function equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source exposure, completion-entry handoff, universal-property extension, separated uniqueness, source isometry preservation, finite-window and tolerance accounting, regular-rational readback, and local naming for BEDC.Derived.DenseIsometryExtensionUp.

Chapter 3476

A Concrete Naming Certificate for $\mathsf{IsometricCompletionExtension}^{\uparrow}$

Following Bourbaki and Kelley on metric completion, the $\mathsf{IsometricCompletionExtension}^{\uparrow}$ packet records the finite dense-isometry extension route that begins with the completion certificate of **??**, passes through the dense-source extension surface of chapter 3475, and reads uniqueness only through the complete-metric comparison boundary of chapter 5983. The packet names the universal extension theorem as finite BEDC completion data; it does not construct quotient completions, select completion points, invoke countable choice, or import an ambient complete metric space.

Definition 3476.1 (Isometric completion extension carrier)**.** *An* $\mathsf{IsometricCompletionExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (M, D, K, G, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric carrier row, read through the same public metric surface used by* $\mathsf{IsometricCompletion}^{\uparrow}$*.*
2. *D is the dense isometry row, recording the displayed dense-source isometry and its finite approximation witnesses through* $\mathsf{DenseIsometryExtension}^{\uparrow}$*.*
3. *K is the completion target row, exposing the completion handoff named by* $\mathsf{IsometricCompletion}^{\uparrow}$ *before any extension value is public.*
4. *G is the unique extension graph row, recording source agreement, completion-facing extension reads, and uniqueness only as finite graph data.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance readback row used for distance preservation, dense approximation, and zero-distance comparison.*
6. *H records componentwise* hsame *transport for M, D, K, G, R and the local naming row.*
7. *C records displayed* Cont *replay of metric admission, dense-isometry handoff, completion handoff, extension-graph readback, and Real tolerance sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{IsometricCompletionExtension}^{\uparrow}$*,* $\mathsf{IsometricCompletion}^{\uparrow}$*,* $\mathsf{DenseIsometryExtension}^{\uparrow}$*,* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{IsometricCompletionExtension}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a selected completion point, quotient metric equality, countable choice, host function equality, or an ambient complete metric space.

Lean4 (statement) `BEDC.Derived.IsometricCompletionExtensionUp`

Theorem 3476.2 (Isometric completion extension NameCert obligations)**.** *For every accepted* $\mathsf{IsometricCompletionExtension}^{\uparrow}$ *carrier* $X = (M, D, K, G, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IsometricCompletionExtension}^{\uparrow}}$ *surface consists exactly of five obligation rows before structural replay is consumed:*

1. *source metric carrier exposure through* M*;*
2. *dense isometry exposure through* D*;*
3. *completion target handoff through* K*;*
4. *unique extension graph exposure through* G*;*
5. $\mathsf{Real}^{\uparrow}$ *tolerance readback through* R*.*

The remaining rows H, C, P, N *transport, replay, source, and locally name that five-row surface, and no accepted carrier exports selected completion points, quotient metric equality, countable choice, host function equality, or ambient completeness.*

Proof. Project the carrier of Definition 3476.1. The rows M, D, K, G, R are displayed before a completion-facing extension value can be read.

The source side is M, D. The metric carrier fixes the distance surface, while the dense isometry row supplies only finite dense-source observations and their Real tolerance readback.

The completion side is K, G, R. The completion target row is read before the graph row, and uniqueness of graph reads is routed through the same Real tolerance row and the complete-metric limit uniqueness boundary.

Finally H, C, P, N preserve the displayed route under transport, continuation replay, provenance, and local naming. Since the carrier contains no further coordinate, the excluded completion point, quotient, choice, host equality, and ambient completeness services cannot be exported. □

Theorem 3476.3 (Isometric completion extension unique factorization)**.** *Every completion-facing extension read from an accepted* $\mathsf{IsometricCompletionExtension}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DenseIsometryExtension}^{\uparrow},\ \mathsf{IsometricCompletion}^{\uparrow},\ \mathsf{CompleteMetricLimitUniqueness}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Name}$$

In carrier notation, a consumer must first expose the dense isometry row D*, the completion handoff row* K*, the complete-metric uniqueness comparison attached to* G*, and the Real tolerance row* R *before it reads any extension value. The factorization exports no selected completion point, quotient metric equality, countable-choice schedule, host function equality, or ambient complete metric space.*

Proof. Start with an accepted packet $X = (M, D, K, G, R, H, C, P, N)$. The dense-source portion is read through D over the metric source M, so the consumer begins with the finite dense-isometry surface rather than a host map on a completion.

Next read the completion handoff K. This is the only coordinate that names a completion target, and it is supplied by the finite $\mathsf{IsometricCompletion}^{\uparrow}$ route.

The graph row G is then interpreted through complete-metric limit uniqueness and the terminal Real tolerance row R. This gives the unique factorization route for extension reads while keeping equality-like comparison inside displayed zero-distance and Real readback data.

The structural suffix H, C, P, N transports, replays, sources, and names the same route. It adds no selected point, quotient equality, choice schedule, host function equality, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{IsometricCompletionExtension}^{\uparrow}$ extension read exposes source metric, dense isometry, completion handoff, unique extension graph, Real tolerance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any completion-facing value is public.

Independence witness: isometriccompletion, denseisometryextension, completemetriclimituniqueness, real: none is bijective to $\mathsf{IsometricCompletionExtension}^{\uparrow}$ because the packet jointly carries the source metric row, dense isometry row, completion handoff, unique extension graph, Real tolerance readback, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{IsometricCompletionExtension}^{\uparrow}}$.

Constructive story: An $\mathsf{IsometricCompletionExtension}^{\uparrow}$ packet is generated from a source MetricUp row, a DenseIsometryExtensionUp row, an IsometricCompletionUp completion target row, a CompleteMetricLimitUniquenessUp uniqueness comparison, a RealUp tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IsometricCompletionExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3476.1, Definition 3476.2, and Definition 3476.3 seed the finite dense-isometry completion-extension route over metric, completion, uniqueness, and Real tolerance rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IsometricCompletionExtension}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.IsometricCompletionExtensionUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion construction, selected completion points, quotient metric equality, countable choice, host function equality, ambient completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-isometry exposure, completion handoff, unique extension graph exactness, Real tolerance preservation, transport and replay stability, provenance non-escape, and field faithfulness for BEDC.Derived.IsometricCompletionExtensionUp.

Chapter 3477

A Concrete Naming Certificate for $\mathsf{CauchyCompletionProductPreservation}^{\uparrow}$

Following Bishop and Bridges' constructive completion theory and Mac Lane's finite-product interface, the $\mathsf{CauchyCompletionProductPreservation}^{\uparrow}$ packet records the finite BEDC surface at which completion reads commute with binary product reads. It consumes the Cauchy completion monad route of chapter 378, the metric-completion surface of chapter 1506, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the product naming envelope of chapter 34. The packet names a finite product-preservation handoff; it does not assert quotient completion equality, selected limits, countable choice, or an ambient completed product.

Definition 3477.1 (Cauchy completion product-preservation carrier)**.** *A* $\mathsf{CauchyCompletionProductPreservation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{CPP}(L, R, M, \Pi, S, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the left source-completion route, read through the Cauchy completion monad and the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *source.*
2. *R is the right source-completion route, read through the same completion discipline for the second source.*
3. *M is the product metric row, recording the finite product carrier, projection rows, and coordinatewise tolerance ledger.*
4. *Π is the product projection row, exposing the two completed-coordinate projections and their recombination read.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the paired finite windows and coordinatewise regular rational data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the coordinate tolerances and the product distance read.*
7. *H stores componentwise* hsame *transport for the two completion routes, product row, projection row, readback, seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a product-completion request through L, R, M, Π, S, E.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionProductPreservation}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionProductPreservation}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, R, M, \Pi, S, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, ambient product completion, or host equality of completed points.

```
Lean4 ✓  BEDC.Derived.CauchyCompletionProductPreservationUp.CauchyCompletionProductPreservationTasteGate
single carrier alignment
```

Theorem 3477.2 (Cauchy completion product-preservation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionProductPreservation}^{\uparrow}$ *carrier* $\mathsf{CPP}(L, R, M, \Pi, S, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionProductPreservation}^{\uparrow}}$ *surface consists exactly of carrier admission for the two source completion routes, product metric row, projection row, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows; coordinate compatibility through L, R, M, Π; readback compatibility through S, E; and non-escape from quotient completions, selected limits, countable choice, ambient completed products, and host equality.*

Proof. Carrier admission is projection from Definition 3477.1. The displayed tuple exposes exactly the two completion routes, product row, projection row, readback row, Real seal, and structural rows.

Coordinate compatibility is forced by L, R, M, Π. The left and right completion routes are read before the product projection row, and the product row records only the coordinatewise product carrier and finite tolerance ledger.

Readback compatibility is then carried by S and E. The regular rational row reads paired finite windows, and the terminal Real seal presents only the coordinate tolerances and the product distance read produced from those windows.

Finally H, C, P, N transport, replay, source, and name the same finite rows. Since the carrier has no coordinate for quotient completion equality, selected representatives, countable choice, ambient product completion, or host equality, the listed obligations exhaust the local certificate surface. □

Theorem 3477.3 (Cauchy completion finite-product handoff)**.** *Every downstream consumer that reads completion after a finite product, or a finite product after two completion reads, must factor through the same displayed route*

$$\mathsf{CauchyCompletionMonad}^{\uparrow} \longrightarrow \mathsf{MetricCompletion}^{\uparrow} \longrightarrow \mathsf{Prod}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The exported object is the finite product-preservation handoff carried by $L, R, M, \Pi, S, E, H, C, P, N$, not a quotient-level isomorphism of completions and not a selected-limit construction.

Proof. Start with the accepted carrier of Definition 3477.1. The only completion-facing rows are L and R, and both are routed through the Cauchy completion monad and the metric-completion source surface.

The product read is M, Π. These rows expose the finite product carrier, coordinate projections, recombination read, and coordinatewise tolerance ledger without adding an ambient completed product.

The numerical handoff is S, E. Paired finite windows are read through $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal records the coordinate tolerances and product distance read.

Apply Definition 3477.2. The transport, replay, provenance, and local naming rows preserve exactly that route, so every finite-product completion consumer factors through the displayed handoff and cannot export quotient equality or selected limits. □

Theorem 3477.4 (Cauchy completion product-preservation scoped ledger)**.** *Every accepted* CauchyCompletionProd *packet factors its visible product-preservation read through exactly the following scoped ledger:*

1. *the two completion routes L and R, each read through* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$*;*
2. *the product metric row M and projection row Π, including the displayed finite product carrier, coordinate projections, recombination read, and coordinatewise tolerance ledger;*
3. *the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row S and terminal* $\mathsf{Real}^{\uparrow}$ *seal row E;*
4. *componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionProductPreservation}^{\uparrow}}$ *row N.*

No accepted packet exports quotient completion equality, selected-limit data, countable-choice schedules, ambient completed products, or host equality of completed points outside this ledger.

Proof. Start from Definition 3477.3. The handoff route already forces every completion-product read through the displayed completion, metric, product, regular-rational, and Real rows.

The carrier of Definition 3477.1 names the ledger entries. The rows L and R are the two source completion routes, while M and Π are the only product metric and projection rows.

The numerical readback is confined to S and E. These rows pair the regular rational windows and then seal the coordinate tolerances and product distance read at the $\mathsf{Real}^{\uparrow}$ boundary.

Finally H, C, P, N preserve the same ledger under transport, replay, provenance, and local naming. Since no other carrier coordinate exists, the scoped ledger is exact and the excluded quotient, selection, choice, ambient-product, and host-equality data cannot be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionProductPreservation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionProductPreservation}^{\uparrow}$ packet is generated from two CauchyCompletionMonad and MetricCompletion source routes, a product metric row, projection rows, RegSeqRat paired-window readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionProductPreservation}^{\uparrow}}$, seed)

Scope closed: Definition 3477.1, Definition 3477.2, Definition 3477.3, and Definition 3477.4 seed the finite completion-product handoff over CauchyCompletionMonadUp, MetricCompletionUp, ProdUp, RegSeqRatUp, RealUp, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionProductPreservation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, selected limits, countable choice, ambient completed products, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coordinate compatibility, paired RegSeqRat readback, Real seal exactness, projection non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionPro

Chapter 3478

A Concrete Naming Certificate for $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$

The $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ packet realizes the finite support-closure algebra of Definition 9462.1609 and Definition 9462.1618 as BEDC NameCert data. It consumes the boundary-tile row of chapter 3393, the coverage-rank row of chapter 3470, the finite observation interface of chapter 1007, the observer support lattice of chapter 1122, and the finite residue boundary of chapter 1167. The packet names closure of visible trigger supports under finite windows; it is not a hidden global semantics, stochastic evolution model, quotient codon space, or infinite coverage oracle.

Definition 3478.1 (Window coverage-trigger algebra carrier)**.** *A* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, C, F, L, R, A, H, Q, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *trigger-boundary row exposing the finite window classifiers whose supports are read.*
2. *C is the* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *coverage row, recording which visible triggers cover which displayed support faces.*
3. *F is the* $\mathsf{FiniteObservationInterface}^{\uparrow}$ *row that bounds every trigger read by a selected finite window and an omitted-tail ledger.*
4. *L is the* $\mathsf{ObserverSupportLattice}^{\uparrow}$ *support-lattice row, used only as a finite inclusion and coverage-rank ledger.*
5. *R is the* $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$ *residue row, recording which support faces remain outside the current closure.*
6. *A is the trigger-algebra row, carrying the finite support set, closure set, blocker row, coverage threshold row, and handoff to the $(4, 2)$ codon instance when that instance is requested.*
7. *H records componentwise* hsame *transport for the trigger-boundary, coverage, finite-window, support-lattice, residue, algebra, replay, provenance, and naming rows.*
8. *Q records displayed* Cont *replay from a coverage-trigger request through T, C, F, L, R, A.*

9. *P is the* Pkg *provenance over* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{FiniteObservationInterface}^{\uparrow}$, $\mathsf{ObserverSupportLattice}^{\uparrow}$, FiniteObservationResidueBounda *the source vision of Definition 9462.1609,* BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, C, F, L, R, A, H, Q, P, N$. It has no coordinate for hidden biological semantics, stochastic transition laws, quotient codon equality, global support completion, infinite search over triggers, or a final coverage oracle.

Theorem 3478.2 (Window coverage-trigger algebra NameCert obligations)**.** *For every accepted* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *carrier $W = (T, C, F, L, R, A, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WindowCoverageTriggerAlg}}$ *surface consists exactly of boundary-trigger admission through T, coverage-rank admission through C, finite-window exposure through F, support-lattice inclusion through L, residue-boundary accounting through R, algebra-row exactness through A, componentwise transport through H, displayed replay through Q, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.WindowCoverageTriggerAlgebraUp.WindowCoverageTriggerAlgebraTasteGate`
`single carrier alignment`

Proof. Carrier admission is projection from Definition 3478.1. The accepted packet exposes only the boundary trigger, coverage, finite-window, support-lattice, residue, trigger-algebra, transport, replay, provenance, and naming rows.

The trigger read starts with T, C, F. A consumer first sees the displayed boundary-tile classifiers, then the coverage-rank row, and then the finite observation interface that records the selected window and omitted-tail ledger.

The support and residue stages are L, R. The support lattice provides finite inclusion and coverage-rank comparison, while the residue row records which faces remain outside the displayed closure.

The algebra row A may then package the support set, closure set, blocker row, threshold row, and $(4, 2)$ handoff. The structural rows H, Q, P, N preserve only this displayed route, so hidden semantics, stochastic laws, quotient codon equality, global support completion, infinite trigger search, and final coverage oracles have no carrier coordinate. □

Theorem 3478.3 (Window coverage-trigger vision handoff)**.** *Every concrete read of the universal coverage-trigger system through* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *factors through the finite route*

$$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow} \longrightarrow \mathsf{SixBoundaryTileCoverage}^{\uparrow} \longrightarrow \mathsf{FiniteObservationInterface}^{\uparrow} \longrightarrow \mathsf{ObserverSupportLa}$$

The exported object is the finite support-closure trigger algebra carried by $T, C, F, L, R, A, H, Q, P, N$, with the source vision used only as provenance for the displayed closure, blocker, threshold, and codon-instance rows.

Proof. Start with the coverage-trigger definitions in Definition 9462.1609. The concrete packet does not import the whole vision as an oracle; it reads only the finite trigger-boundary and coverage rows T, C.

Next bind finite access through F. The selected window and omitted-tail ledger determine which trigger supports are visible before any closure row can be exported.

Then read L and R. The support lattice records finite inclusion and coverage rank, while the residue boundary records the uncovered faces that remain outside the current closure.

Finally package the closure, blocker, threshold, and codon-instance handoff through A, H, Q, P, N. Since these rows preserve the displayed finite route, every concrete read of the universal coverage-trigger algebra factors through the NameCert packet rather than through hidden semantics, quotient codon equality, stochastic dynamics, or infinite trigger search. □

Theorem 3478.4 (Window coverage-trigger algebra Markov source route)**.** *Every Markov-trigger-facing consumer of* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *must read the boundary-trigger row of chapter 3393, the coverage-rank row of chapter 3470, the finite-observation window row of chapter 1007, the support-lattice row of chapter 1122, and the residue-boundary row of chapter 1167 before any Markov state transition row can be formed.*

Thus the rank-sensitive transition surface of Definition 9462.1541 is reached only after the finite support-closure route $T, C, F, L, R, A, H, Q, P, N$ *has exposed boundary triggers, coverage rank, finite windows, support inclusion, and residue accounting. The route exports no stochastic evolution law, hidden biological semantics, quotient codon equality, global support completion, or infinite trigger search.*

Proof. Start with a consumer that requests a Markov-trigger-facing transition row. The carrier of Definition 3478.1 exposes no transition coordinate before the boundary-trigger, coverage, finite-window, support-lattice, and residue rows have been read.

The source route is therefore T, C, F, L, R. These rows are supplied by the five sibling concrete chapters named in the statement and fix the displayed boundary triggers, rank data, finite observation window, support inclusion, and residue boundary before any transition-facing handoff is admissible.

Only after that route is displayed may A, H, Q, P, N package the trigger algebra for the rank-sensitive surface of Definition 9462.1541. Since the carrier contains no stochastic evolution row, hidden biological semantics, quotient codon equality, global support completion, or infinite trigger-search coordinate, none of those objects can be introduced by the Markov source route. □

Falsifiable prediction: Every accepted $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ consumer that claims coverage-trigger closure must exhibit the boundary-trigger row, coverage-rank row, finite-observation row, support-lattice row, residue-boundary row, algebra row, componentwise transport, replay, provenance, and local naming row. A consumer omitting any of probe-bundle, finite-observation, support-lattice, namecert, or trigger-boundary sibling slugs refutes the packet.

Independence witness: probe-bundle, finite-observation, support-lattice, namecert, trigger-boundary, six-boundary-tile-coverage: $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries boundary triggers, coverage rank, finite-window access, support closure, residue accounting, algebraic blocker and threshold rows, transport, replay, provenance, and local naming.

The later Lean route for `BEDC.Derived.WindowCoverageTriggerAlgebraUp` must provide explicit $\mathsf{Nontrivial}\ \mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ instances preserving $T, C, F, L, R, A, H, Q, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}}$**.**

Constructive story: A $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ packet is generated from boundary-trigger rows, coverage-rank rows, finite observation windows, support-lattice inclusion rows, residue-boundary rows, a trigger-algebra row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3478.1, Definition 3478.2, and Definition 3478.3 seed the finite support-closure trigger algebra over boundary tiles, coverage rows, finite observation windows, support lattices, residue boundaries, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{WindowCoverageTriggerAlgebra}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close hidden biological semantics, stochastic transition laws, quotient codon equality, global support completion, infinite trigger search, final coverage oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-trigger exactness, coverage-rank exactness, finite-window non-escape, support-lattice inclusion, residue accounting, Nontrivial WindowCoverageTriggerAlgebraUp, and FieldFaithful WindowCoverageTriggerAlgebraUp for BEDC.Derived.WindowCoverageTriggerAlgebraUp.

Chapter 3479

A Concrete Naming Certificate for $\mathsf{BorelFunction}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on Borel maps between topological and real-facing spaces, the $\mathsf{BorelFunction}^{\uparrow}$ packet records the finite pullback route by which a displayed source topology reads target Borel rows. It sits between the generated-set boundary of chapter 3384, the measurable-map preimage surface of chapter 3461, the terminal real-name seal of chapter 38, and the topology interface of chapter 88. The packet names Borel pullback stability as a local BEDC certificate, not as a host inverse-image operation, quotient equality of functions, countable-choice enumeration of Borel codes, or ambient measure completion.

Definition 3479.1 (BorelFunction carrier)**.** *A* $\mathsf{BorelFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, B, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the source topology row read through* $\mathsf{Topology}^{\uparrow}$*, including the finite open-neighbourhood data needed by the current source-side query.*
2. *B is the target* $\mathsf{BorelSet}^{\uparrow}$ *row whose generated-set boundary supplies the target event being pulled back.*
3. *R is the pullback ledger assigning the displayed target Borel row in B to a displayed source Borel row over X.*
4. *Q is the* $\mathsf{Real}^{\uparrow}$ *readback row used when the target Borel query is real-facing; it is consumed only through the displayed Borel row and the pullback ledger.*
5. *H stores componentwise* hsame *transport for the source topology, target Borel row, pullback ledger, real readback, continuation, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay from a source query through the target Borel row, the pullback ledger, and the real-facing readback row.*
7. *P is the* Pkg *provenance over* $\mathsf{Topology}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{MeasurableFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BorelFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, B, R, Q, H, C, P, N. It has no coordinate for host set preimages, quotient equality of functions, countable-choice selection of Borel codes, completed measure spaces, almost-everywhere equality, or an ambient function space.

Lean4 ✓ `BEDC.Derived.BorelFunctionUp.BorelFunctionTasteGate single carrier alignment`

Theorem 3479.2 (BorelFunction NameCert obligations)**.** *For the carrier of Definition 3479.1, the local* $\mathsf{NameCert}_{\mathsf{BorelFunction}^{\uparrow}}$ *surface consists exactly of source-topology admission, target Borel-row admission, pullback-ledger exactness, real-facing readback through* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every accepted Borel-function consumer must read the source row X, the target Borel row B, and the pullback ledger R before any* $\mathsf{BorelSet}^{\uparrow}$*,* $\mathsf{MeasurableFunction}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or topology-facing sibling row is exposed.*

Proof. Project the carrier $F = (X, B, R, Q, H, C, P, N)$. The rows X and B are the only source-topology and target-Borel coordinates, and the row R is the only coordinate that relates them.

Read a real-facing target query through B and Q. The readback row Q is downstream of the displayed Borel row, while the source-side result is named only by the pullback ledger R over X.

The structural rows add no host inverse-image operation. Transport through H, replay through C, provenance through P, and local naming through N preserve the same finite route, so the excluded quotient, choice, completion, almost-everywhere, and ambient function-space objects remain outside the packet. □

Theorem 3479.3 (BorelFunction pullback stability)**.** *Let $F = (X, B, R, Q, H, C, P, N)$ and*

$$F' = (X', B', R', Q', H', C', P', N')$$

be accepted $\mathsf{BorelFunction}^{\uparrow}$ *carriers. If the source topology rows, target* $\mathsf{BorelSet}^{\uparrow}$ *rows, pullback ledgers, and real-facing readback rows agree componentwise through the displayed* hsame *transports, then every accepted source-side Borel read produced from F is transported to the corresponding read produced from F'. The comparison uses only*

$$X, B, R, Q, H, C, P, N$$

and

$$X', B', R', Q', H', C', P', N'.$$

It exports pullback stability as a finite certificate, not as host set preimage equality, quotient equality of functions, countable-choice enumeration, completed measure semantics, almost-everywhere equality, or ambient function equality.

Proof. Apply Definition 3479.2 to both carriers. Any accepted target Borel read first passes through the displayed target rows B and B', then through the pullback ledgers R and R'.

Use the componentwise transports. The hypotheses identify the source topology rows, target Borel rows, pullback ledgers, and real readback rows, while H, C, P, N and H', C', P', N' preserve, replay, source, and name those same routes.

The transported consumer sees only the displayed coordinates. Since neither carrier contains a host inverse-image coordinate, quotient-function equality, choice-selected code sequence, completed measure, almost-everywhere class, or ambient function object, the stability claim is exactly the preservation of the finite pullback ledger. □

Falsifiable prediction: A $\mathsf{BorelFunction}^{\uparrow}$ consumer that obtains a host set preimage, a quotient equality of functions, a countable-choice enumeration of Borel codes, a completed measure, or an almost-everywhere representative without first reading the displayed pullback ledger R refutes the carrier surface.

Independence witness: borelset, measurablefunction, real, topology: no listed sibling supplies the whole eight-row packet $F = (X, B, R, Q, H, C, P, N)$, because each sibling contributes only generated-set, measurable-map, real-readback, or source-topology data while this chapter binds the Borel pullback ledger with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BorelFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3479.1, Definition 3479.2, and Definition 3479.3 seed the finite Borel-function pullback boundary over source topology, target Borel rows, real readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, almost-everywhere equality, quotient function spaces, countable-choice Borel codes, host set preimages, ambient function equality, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, pullback-ledger exactness, real-readback preservation, componentwise transport, and ledger-refusal proofs for BEDC.Derived.BorelFunctionUp.

Constructive story: A $\mathsf{BorelFunction}^{\uparrow}$ packet is generated from a source topology row, a target BorelSet row, a pullback ledger, a RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3480

A Concrete Naming Certificate for $\mathsf{ChebyshevPolynomial}^{\uparrow}$

Following Chebyshev and the classical approximation-theory presentation of Chebyshev polynomials, the $\mathsf{ChebyshevPolynomial}^{\uparrow}$ packet names the finite recurrence surface for the displayed family T_n without importing an ambient real-function algebra. It sits after the terminal real-name seal of chapter 38, the polynomial carrier of chapter 50, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the stream-window surface of chapter 126. The packet supplies a traditional approximation-theory object as finite NameCert data for later minimax and constructive approximation routes.

Definition 3480.1 (Chebyshev polynomial carrier)**.** *A* $\mathsf{ChebyshevPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(d, T_0, T_1, R, W, Q, H, C, P, N).$$

Here d is the unary degree row, T_0 and T_1 are the displayed recurrence seeds, R is the recurrence-step ledger for $T_{n+1} = 2xT_n - T_{n-1}$, W is the dyadic evaluation-window schedule, Q is the $\mathsf{Real}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback row, H records componentwise* hsame *transport, C records* Cont *replay of the recurrence route, P records* Pkg *provenance from the polynomial and real-name sources, and N is the local* $\mathsf{NameCert}_{\mathsf{ChebyshevPolynomial}^{\uparrow}}$ *row. A consumer of the packet may inspect a Chebyshev read only through these displayed rows.*

Lean4 ✓ `BEDC.Derived.ChebyshevPolynomialUp.ChebyshevPolynomialTasteGate single carrier alignment`

Theorem 3480.2 (Chebyshev polynomial NameCert obligations)**.** *For every accepted* $\mathsf{ChebyshevPolynomial}^{\uparrow}$ *carrier $(d, T_0, T_1, R, W, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChebyshevPolynomial}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 3480.1. The degree row chooses the recurrence depth, the seed rows display T_0 and T_1, the recurrence ledger displays each finite step, the dyadic window and regular readback rows mediate evaluation, and the transport, replay, provenance, and local naming rows export the resulting polynomial certificate. The packet imports no host polynomial equality, selected infinite family, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the packet rows in order. The degree row d bounds the visible recurrence segment, so the seed rows and recurrence ledger already determine every displayed polynomial row consumed by the packet.

The evaluation side factors through W and Q. The dyadic windows give the finite tolerance requests, while the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal keep coefficient and value reads inside the existing real-name route.

Finally use H, C, P, N. These rows transport equal displayed histories, replay the recurrence computation, remember the polynomial and real-name provenance, and attach the local certificate name. No additional host equality or infinite polynomial family is available to a consumer outside the listed rows. □

Theorem 3480.3 (Chebyshev recurrence handoff)**.** *Every accepted* $\mathsf{ChebyshevPolynomial}^{\uparrow}$ *recurrence read factors through*

$$d \longmapsto T_0, T_1 \longmapsto R \longmapsto W \longmapsto Q \longmapsto H, C, P, N$$

before any approximation-facing consumer receives a polynomial value or coefficient row. Thus the Chebyshev recurrence is handed to later constructive approximation packets as finite degree, seed, recurrence, dyadic-window, real-readback, transport, replay, provenance, and naming data, not as an external analytic theorem about an infinite sequence of polynomials.

Proof. Start with the carrier of Definition 3480.1. The only recurrence coordinates exposed by the packet are d, T_0, T_1, R, so any accepted recurrence read is bounded by the displayed unary degree and the finite seed-and-step ledger.

Next read the evaluation interface. The route through W and Q forces every value-facing request to pass through dyadic windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ seal before it can be consumed as approximation data.

The remaining rows provide structural export. Componentwise hsame transport, Cont replay, Pkg provenance, and the local NameCert row preserve the same finite recurrence route for downstream minimax, interpolation, and approximation packets. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChebyshevPolynomial}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChebyshevPolynomial}^{\uparrow}$ packet is generated from a unary degree row, recurrence seed rows, a finite recurrence-step ledger, dyadic evaluation windows, regular rational and Real readback, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChebyshevPolynomial}^{\uparrow}}$, obligation)

Scope closed: Definition 3480.1, Definition 3480.2, and Definition 3480.3 declare the finite recurrence certificate surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChebyshevPolynomial}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, minimax optimality, Markov or Bernstein inequalities, Jackson approximation, host polynomial equality, selected infinite families, or ambient RealUp completeness.

Upgrade path: Checked closure requires Lean carrier admission, recurrence ledger stability, evaluation-window readback, and recurrence handoff for the same finite packet.

Chapter 3481

A Concrete Naming Certificate for $\mathsf{CellularWindowTrace}^{\uparrow}$

The $\mathsf{CellularWindowTrace}^{\uparrow}$ packet realizes the cellular-carrier alternative of chapter 9391 as finite orbit-window NameCert rows while leaving the BEDC kernel carrier as BHist. It consumes the cellular automaton and substrate readings of chapter 934 and chapter 942, the finite BHist encoding discipline of chapter 943, the stream-window surface of chapter 126, and the bounded universal trace boundary of chapter 944. The packet names a finite window of a cellular orbit, not a replacement foundation for BEDC histories.

Definition 3481.1 (Cellular window trace carrier)**.** *A* $\mathsf{CellularWindowTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(w, r, i, o, B, H, C, P, N).$$

Here w is the displayed width row, r is the local-rule row, i is the initial cell-row encoding, o is the finite orbit-window ledger, B is the BHist *encoding of the selected rows, H records componentwise* hsame *transport, C records* Cont *replay of the local update route, P records* Pkg *provenance from the cellular-substrate sources, and N is the local* $\mathsf{NameCert}_{\mathsf{CellularWindowTrace}^{\uparrow}}$ *row.*

Theorem 3481.2 (Cellular window trace NameCert obligations)**.** *For every accepted* $\mathsf{CellularWindowTrace}^{\uparrow}$ *carrier $(w, r, i, o, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CellularWindowTrace}^{\uparrow}}$ *surface consists exactly of width, local-rule, initial-row, finite orbit-window,* BHist *encoding, transport, replay, provenance, and local naming rows. A consumer may read the cellular window only by first consuming these rows; it receives no global orbit, no infinite cellular history, no substrate replacement of* BHist*, and no bijection between cellular traces and all BEDC histories.*

Lean4 ✓ `BEDC.Derived.CellularWindowTraceUp.CellularWindowTraceTasteGate single carrier alignment`

Proof. Project the displayed carrier rows. The width and local-rule rows determine which finite cell row can be updated, and the initial row gives the only starting configuration available to the packet.

The orbit-window ledger o records the finite segment that is actually visible. Its BHist encoding row B translates that segment into the BEDC kernel carrier without changing the carrier used by the surrounding certificate.

Finally H, C, P, N export the route. Transport preserves the displayed rows, replay records the local update computation, provenance ties the route to the cellular-substrate sources, and the local certificate names this finite window only. □

Theorem 3481.3 (Cellular window trace finite-read factorization)**.** *Every accepted read of a* $\mathsf{CellularWindowTrace}^{\uparrow}$ *packet factors through*

$$w \longmapsto r \longmapsto i \longmapsto o \longmapsto B \longmapsto H, C, P, N.$$

Thus the cellular-carrier alternative is exposed as finite orbit-window data before any downstream consumer can treat it as a cellular trace.

Proof. Read the packet in dependency order. Width and local rule are needed before the initial row can be updated, and the finite orbit window is the only displayed result of those updates.

The BHist encoding row then returns the trace to the BEDC carrier. Since transport, replay, provenance, and naming are all downstream of that encoding, the public consumer sees a finite cellular-window certificate rather than a direct cellular replacement for BHist. □

Falsifiable prediction: Every accepted cellular-window read of $\mathsf{CellularWindowTrace}^{\uparrow}$ factors through width, local-rule, initial-row, finite orbit-window, BHist encoding, hsame transport, Cont replay, Pkg provenance, and local naming rows before any downstream cellular-trace consumer can inspect it.

Independence witness: cellularsubstrate, cellularautomaton, streamname, bhist-arity16-eventflow, boundeduniversaltrace: the cellular-window packet is not bijective with the BEDC carrier. It records one finite orbit window with a displayed encoding, while BHist supplies the kernel carrier independently of any chosen cellular width, rule, initial row, or orbit segment.

On the Lean side, the formal carrier should supply ‘Nontrivial CellularWindowTraceUp‘ and ‘FieldFaithful CellularWindowTraceUp‘ instances in ‘lean4/BEDC/Derived/CellularWindowTraceUp/TasteGate.l

Closure status for $\mathsf{NameCert}_{\mathsf{CellularWindowTrace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CellularWindowTrace}^{\uparrow}$ packet is generated from a width row, local-rule row, initial-row encoding, finite orbit-window ledger, BHist encoding, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CellularWindowTrace}^{\uparrow}}$, obligation)

Scope closed: Definition 3481.1, Definition 3481.2, and Definition 3481.3 declare the finite orbit-window certificate surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CellularWindowTrace}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CellularWindowTraceUp.CellularWindowTraceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim a global cellular orbit, an infinite cellular history, a substrate replacement for BHist, a bijection between cellular traces and all BEDC histories, or bridge checking.

Upgrade path: Checked closure requires Lean carrier admission, finite orbit-window factorization, BHist encoding transport, and TasteGate instance rows for the same finite packet.

Chapter 3482

A Concrete Naming Certificate for $\mathsf{WeakKonigBoundary}^{\uparrow}$

Following Kleene and Bishop–Bridges on finite binary trees, Cantor-space paths, and constructive real completion, the $\mathsf{WeakKonigBoundary}^{\uparrow}$ packet records the boundary at which finite tree inspection remains available while weak König path selection is refused as a BEDC primitive. It sits after the finite obstruction surface of chapter 1622, the Cantor and FanTheorem interfaces of chapter 1475 and chapter 400, the finite window and regular readback route of chapter 126 and chapter 301, and the completion-facing seal rows of chapter 38 and chapter 1714. The packet names the finite-tree/path-selection boundary used by Real and Completion consumers without turning that boundary into countable choice, quotient stream equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3482.1 (WeakKonigBoundary carrier)**.** *A* $\mathsf{WeakKonigBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, A, F, S, Q, R, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{KleeneTree}^{\uparrow}$ *finite-prefix tree packet, including the decidable node ledger and obstruction row of Definition 1622.1.*
2. *A is the* $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix observation row offered to consumers that inspect binary path fragments.*
3. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar test row available only as displayed finite cover data, not as open-cover compactness.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which every path-like request must pass.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from displayed finite windows before any Real-facing seal is inspected.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *and completion-facing seal row reached only after K, A, F, S, Q have been displayed.*
7. *O is the boundary-refusal row: no infinite branch selector, no countable-choice functional, no quotient stream equality, no open-cover compactness principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of the packet.*

8. *H records componentwise* hsame *transport for the tree packet, Cantor prefix row, fan row, stream windows, regular readback, Real seal, refusal row, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite tree or path request through $K, A, F, S, Q, R, O, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{WeakKonigBoundary}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{WeakKonigBoundary}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite tree/path boundary packet. It has no coordinate for an infinite branch, a path-selection functional, countable choice, quotient stream equality, open-cover compactness, selected completion limits, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.WeakKonigBoundaryUp.TasteGate.WeakKonigBoundaryTasteGate single carrier alignment`

Theorem 3482.2 (WeakKonigBoundary NameCert obligations)**.** *For every accepted* $\mathsf{WeakKonigBoundary}^{\uparrow}$ *carrier $W = (K, A, F, S, Q, R, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakKonigBoundary}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed* $\mathsf{KleeneTree}^{\uparrow}$ *packet,* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row,* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, refusal row, transport, replay, provenance, and local naming;*

2. *tree-window exactness, requiring every path-like read to pass through the finite tree row K and finite window row S before any Cantor, FanTheorem, RegSeqRat, Real, or Completion-facing row is exposed;*

3. *regular-readback discipline, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q to be obtained from displayed finite windows rather than from quotient stream equality;*

4. *seal nonescape, requiring the Real and completion-facing row R to remain downstream of K, A, F, S, Q and the refusal row O;*

5. *boundary refusal, excluding infinite branch selection, countable choice, quotient stream equality, open-cover compactness, and ambient Real completeness from the packet.*

No WeakKonigBoundary obligation is stored outside these rows.

Proof. Project the carrier of Definition 3482.1. The projection exposes exactly the Kleene tree packet K, Cantor prefix row A, FanTheorem finite-bar row F, stream windows S, regular readback Q, Real seal R, refusal row O, and structural rows H, C, P, N.

Tree-window exactness is inherited from the finite route displayed by Definition 1622.3. A path-like request first reads the finite tree and the finite stream window; it cannot jump directly to an infinite branch or completed Cantor point.

The regular-readback and seal rows are downstream. The row Q is admitted only after the finite windows are fixed, and the row R is reached only after K, A, F, S, Q and the refusal row have been displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since none of the carrier rows stores an infinite branch selector, countable-choice functional, quotient stream equality, open-cover compactness object, or ambient Real-completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 3482.3 (WeakKonigBoundary Real-completion refusal)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{WeakKonigBoundary}^{\uparrow}$ *carrier factors through the finite route*

$$K, A, F, S, Q, R, O, H, C, P, N.$$

Consequently the consumer may reuse finite Kleene-tree prefixes, Cantor-space observations, Fan-Theorem finite-bar rows, StreamName windows, and RegSeqRat readbacks, but it receives no infinite branch selection, no countable-choice schedule, no quotient stream equality, no open-cover compactness principle, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Begin with a Real or Completion-facing read of $W = (K, A, F, S, Q, R, O, H, C, P, N)$. Carrier admission gives the consumer the tree, Cantor, fan, stream-window, regular-readback, and seal rows only as the displayed finite packet.

Use the Kleene-tree boundary from Definition 1622.10. Any Real-facing interpretation of tree data must already pass through finite $\mathsf{StreamName}^{\uparrow}$ windows and the obstruction row before a real seal is inspected.

The $\mathsf{WeakKonigBoundary}^{\uparrow}$ carrier adds the refusal row O at the same boundary. Thus the completion-facing row R can be read only after the finite tree/path route and cannot supply a path selector, quotient stream equality, open-cover compactness, or ambient Real completeness.

Transport and replay through H and C, with provenance and naming through P and N, preserve the displayed route. Therefore every Real or Completion consumer receives the finite boundary package and none of the excluded principles. □

Falsifiable prediction: A $\mathsf{WeakKonigBoundary}^{\uparrow}$ consumer that obtains an infinite branch selector, countable-choice schedule, quotient stream equality, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem without first reading the displayed route $K, A, F, S, Q, R, O, H, C, P, N$ refutes the carrier surface.

Independence witness: kleene-tree, cantorspace, fantheorem, streamname, regseqrat, real, separable-completion: $\mathsf{WeakKonigBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite tree packet, Cantor prefix row, fan row, stream windows, regular readback, Real seal, refusal row, transport, replay, provenance, and local NameCert row in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakKonigBoundary}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakKonigBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3482.1, Definition 3482.2, and Definition 3482.3 seed the finite tree/path-selection boundary separating Real and Completion-facing reads from weak König path selection.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakKonigBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close weak König's lemma, infinite branch selection, countable choice, quotient stream equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tree-window exactness, regular-readback discipline, seal nonescape, and boundary-refusal proofs for BEDC.Derived.WeakKonigBoundaryUp.

Constructive story: A $\mathsf{WeakKonigBoundary}^{\uparrow}$ packet is generated from a KleeneTreeUp finite tree packet, CantorSpace finite-prefix row, FanTheorem finite-bar row, StreamName finite windows, RegSeqRat readback, RealUp seal, explicit refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3483

A Concrete Naming Certificate for $\mathsf{CauchyCutBridge}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCutBridge}^{\uparrow}$ packet records the finite handoff by which a regular Cauchy real name supplies located-cut observations without identifying either presentation by quotient equality. It sits between the regular-rational route of chapter 301, the located-cut surface of chapter 404, the dyadic arithmetic ledger of chapter 291, the finite stream windows of chapter 126, and the terminal real-name seal of chapter 38. The packet is a bridge for displayed approximation data, not a Dedekind-completeness theorem or an equality principle for completed reals.

Definition 3483.1 (Cauchy-cut bridge carrier)**.** *A* $\mathsf{CauchyCutBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, L, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the regular Cauchy rational source.*
2. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *row recording the lower and upper located observations obtained from the same regular name.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare regular readbacks with located lower–upper brackets.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule listing the finite precision rows at which the regular name and located cut are jointly inspected.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after Q, L, D, W have been displayed.*
6. *H records componentwise* hsame *transport for the regular readback, located-cut row, dyadic ledger, stream windows, Real seal, replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay of the bridge route*

$$Q, W, D \longmapsto L \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCutBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCutBridge}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient reals, Dedekind completeness, host equality of real names, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCutBridgeUp.TasteGate.CauchyCutBridgeTasteGate single carrier alignment`

Theorem 3483.2 (Cauchy-cut bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCutBridge}^{\uparrow}$ *carrier* $B = (Q, L, D, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCutBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed regular readback, located-cut row, dyadic tolerance ledger, stream-window schedule, Real seal, componentwise transport, continuation replay, package provenance, and local naming row; regular-to-located exposure through* Q, W, D, L*; Real-seal exposure through* E*; and refusal of quotient reals, Dedekind-completeness claims, host equality, trichotomy, choice, and ambient completeness.*

Proof. Project the carrier of Definition 3483.1. The visible rows are exactly $Q, L, D, W, E, H, C, P, N$, so carrier admission exposes the regular readback, located-cut observation, dyadic ledger, stream schedule, terminal seal, and structural rows.

The bridge exposure is supplied by the replay row C. It first reads the regular name through Q and the finite windows W, then checks the matching dyadic tolerances in D, and only then exposes the located-cut row L.

The Real seal and structural rows are downstream of that route. Transport through H, provenance through P, and local naming through N record the same finite bridge, while no refused object appears as a carrier coordinate. □

Theorem 3483.3 (Cauchy-cut bridge regular-located handoff)**.** *Let* $B = (Q, L, D, W, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCutBridge}^{\uparrow}$ *carrier. Every located-cut observation exported by* B *factors through the finite handoff*

$$Q, W, D \longmapsto L \longmapsto E, H, C, P, N.$$

Thus the bridge reads the regular Cauchy name through $\mathsf{RegSeqRat}^{\uparrow}$*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows before the* $\mathsf{LocatedCut}^{\uparrow}$ *data or the terminal* $\mathsf{Real}^{\uparrow}$ *seal can be consumed. It does not export quotient reals, Dedekind completeness, host equality, trichotomy, countable choice, or ambient completeness.*

Proof. Begin with a consumer of the located-cut row. The carrier definition gives L only as a displayed row of B, and the continuation row records that it is reached from Q, W, D.

Use the sibling routes cited in the chapter introduction. $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational readback, $\mathsf{StreamName}^{\uparrow}$ supplies finite windows, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance comparison that turns the readback into lower–upper located observations.

Finally read the terminal seal row E and the structural rows H, C, P, N. They transport, replay, source, and name the same handoff; none of them stores quotient equality, a Dedekind-completeness witness, a host equality test, trichotomy, choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCutBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCutBridge}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{LocatedCut}^{\uparrow}$ observation row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCutBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3483.1, Definition 3483.2, and Definition 3483.3 seed the finite bridge from regular Cauchy readbacks to located-cut observations over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCutBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, Dedekind-completeness claims, host equality of real names, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, regular-to-located exposure, tolerance exactness, Real-seal nonescape, and ledger-refusal proofs for the same finite packet.

Chapter 3484

A Concrete Naming Certificate for $\mathsf{BishopCompletionTheorem}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompletionTheorem}^{\uparrow}$ packet records the theorem-level completion handoff as finite BEDC certificate data. It sits after the explicit modulus surface of chapter 1438, the finite-window naming surface of chapter 126, the regular rational readback of chapter 301, the terminal Real surface of chapter 38, and the universal regular-Cauchy handoff of chapter 1425. The packet names the constructive theorem route without quotient limits, selected representatives, countable choice, or ambient completeness.

Definition 3484.1 (Bishop completion theorem carrier)**.** *A* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. M *is the* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *row recording the explicit tolerance-to-tail schedule.*
2. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window source row inspected by the theorem route.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback obtained from the displayed windows and modulus schedule.*
4. E *is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after* M, S, R *have been displayed.*
5. U *is the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *handoff row for extension and uniqueness consumers.*
6. H *records componentwise* hsame *transport for the modulus, stream, readback, Real seal, universal handoff, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a theorem consumer through* M, S, R, E, U.
8. P *is the* Pkg *provenance over* $\mathsf{BishopCompletionTheorem}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionTheorem}^{\uparrow}}$ *row.*

The carrier exports only this theorem route. It contains no quotient limit, selected representative, host convergence predicate, host real equality test, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.BishopCompletionTheoremUp.BishopCompletionTheoremTasteGate single carrier alignment`

Theorem 3484.2 (Bishop completion theorem NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionTheore}$ *carrier* $B = (M, S, R, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission, explicit Cauchy-modulus exposure, finite StreamName source exposure, RegSeqRat readback, Real seal handoff, regular-Cauchy universal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming. Every theorem consumer must factor through*

$$M \longmapsto S \longmapsto R \longmapsto E \longmapsto U \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Proof. Project the carrier of Definition 3484.1. The accepted packet displays exactly $M, S, R, E, U, H, C, P, N$.

Read the analytic route in order. The explicit modulus row M licenses the finite StreamName windows S, the windows feed the regular rational readback R, and only then can the Real seal E be consumed.

The universal handoff U is downstream of the same displayed route. The structural rows H, C, P, N transport, replay, source, and name the route, while the refused quotient, selected, host, choice, and ambient-completeness objects have no carrier coordinate. □

Theorem 3484.3 (Bishop completion theorem regular Cauchy existence route)**.** *Every accepted* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *carrier* $B = (M, S, R, E, U, H, C, P, N)$ *exposes the regular Cauchy existence route as finite certificate composition:*

$$\mathsf{CauchyConvergenceModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$$

The route witnesses existence only as a displayed regular-Cauchy handoff through $M, S, R, E, U, H, C, P, N$*; it does not create a quotient limit, select a representative, invoke countable choice, compare host real values, or assert ambient completeness.*

Proof. Start with the modulus-controlled source. The row M supplies the displayed tolerance schedule, and S supplies the finite windows inspected at those requests.

Compose the readback and seal rows. The row R repacks the finite windows as regular rational data, and E records the terminal Real-facing seal reached by that regular route.

Finally consume the universal handoff U. By projection and finite route composition, any theorem consumer reaches the regular-Cauchy existence surface only after M, S, R, E and before H, C, P, N close transport, replay, provenance, and naming. The excluded quotient, selected, choice, host, and ambient-completeness objects are absent from the packet. □

Falsifiable prediction: A claimed $\mathsf{BishopCompletionTheorem}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ without the displayed CauchyConvergenceModulus, StreamName, and RegSeqRat rows refutes the carrier surface.

Independence witness: cauchyconvergencemodulus, streamname, regseqrat, real, regularcauchycompletionuniversal: no listed sibling is bijective to $\mathsf{BishopCompletionTheorem}^{\uparrow}$ because the theorem packet binds the modulus-controlled source, finite windows, regular readback, Real seal, universal handoff, transport, replay, provenance, and local NameCert rows in one theorem-level carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionTheorem}^{\uparrow}}$.

Constructive story: A BishopCompletionTheorem$^{\uparrow}$ packet is generated from a CauchyConvergenceModulus row, StreamName finite windows, RegSeqRat readback, RealUp seal, RegularCauchyCompletionUniversal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopCompletionTheorem}\uparrow}$, seed)

Scope closed: Definition 3484.1, Definition 3484.2, and Definition 3484.3 seed the finite theorem-level route from modulus-controlled Cauchy data through regular rational readback into Real and regular-completion handoff rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopCompletionTheorem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion, selected representatives, countable choice, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, modulus exposure, finite StreamName windows, RegSeqRat readback, Real seal handoff, regular-Cauchy universal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionTheoremUp.

Chapter 3485

A Concrete Naming Certificate for $\mathsf{BaireUltrametric}^{\uparrow}$

Following Brouwer's spread semantics and the prefix-space practice of Troelstra–van Dalen and Bishop–Bridges, the $\mathsf{BaireUltrametric}^{\uparrow}$ packet names the common-prefix ultrametric surface on Baire streams. It sits between the finite prefix carrier of chapter 334, the prefix metric route of chapter 1602, the general ultrametric discipline of chapter 1535, the finite-window readback of chapter 126, and the completion-facing packet of chapter 1884. The chapter names the finite common-prefix distance interface; it is not host stream equality, quotient equality of streams, countable choice, a selected branch principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The finite prefix route consumes the $\mathsf{StreamName}^{\uparrow}$ window discipline of chapter 126 and the strong-triangle comparison surface of chapter 1535; the present packet only binds those sibling rows to the Baire prefix classifier.

Definition 3485.1 (Baire ultrametric carrier)**.** *A* $\mathsf{BaireUltrametric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, M, V, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *finite prefix row, naming the two inspected Baire prefixes and their common-prefix length.*
2. *M is the* $\mathsf{BaireMetric}^{\uparrow}$ *row, recording the dyadic distance value attached to the first displayed disagreement or to full agreement on the inspected window.*
3. *V is the* $\mathsf{UltrametricSpace}^{\uparrow}$ *comparison row, exposing the strong-triangle comparison only through finite common-prefix witnesses.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing exactly the stream coordinates read before the prefix distance is declared.*
5. *H records componentwise* hsame *transport for prefix rows, metric rows, ultrametric comparisons, finite windows, replay rows, provenance, and local naming.*
6. *C records displayed* Cont *replay of the same finite prefix windows and distance rows.*
7. *P is the* Pkg *provenance over* $\mathsf{BaireUltrametric}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{UltrametricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireUltrametric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, M, V, S, H, C, P, N. It has no coordinate for host stream equality, quotient stream equality, selected branches, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Lean4 (definition) `BEDC.Derived.BaireUltrametricUp.BaireUltrametricCarrier`

Theorem 3485.2 (Baire ultrametric NameCert obligations)**.** *For every accepted* $\mathsf{BaireUltrametric}^{\uparrow}$ *carrier* $U = (B, M, V, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireUltrametric}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed Baire prefix row, BaireMetric distance row, UltrametricSpace comparison row, StreamName window row, transport, replay, provenance, and local naming;*
2. *common-prefix distance exactness, requiring each distance read to be the dyadic value named by the first displayed disagreement, or the zero-distance window when the inspected prefixes agree throughout the displayed window;*
3. *finite-cylinder classifier stability, requiring every cylinder comparison to transport only the displayed prefix rows through componentwise* hsame *and displayed* Cont *replay;*
4. *StreamName readback, requiring every coordinate read to pass through the finite window row S before the metric row M or ultrametric row V is consulted;*
5. *nonescape, excluding selected branches, quotient stream equality, countable choice, ambient Real completeness, host stream equality, Lean verification, and bridge checking.*

No BaireUltrametric obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BaireUltrametricUp.BaireUltrametricCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 3485.1. The accepted packet displays exactly the Baire prefix row, the prefix metric row, the ultrametric comparison row, the finite StreamName window, and the structural rows.

Common-prefix distance exactness is read from B and M. The prefix row records the inspected coordinates and the first displayed disagreement if one exists; the metric row records the corresponding dyadic distance, with the zero-distance window available only for agreement across the displayed finite window.

Finite-cylinder classifier stability is supplied by H and C. Componentwise hsame transport identifies the displayed prefix rows, and displayed Cont replay rereads the same finite windows before any classifier output is compared.

StreamName readback is the row S. Since every coordinate request must pass through S, the ultrametric row V can only witness the strong-triangle comparison through finite common-prefix evidence already displayed by the packet.

The listed rows contain no selector for an infinite branch, no quotient equality of streams, no countable-choice operation, no host stream equality predicate, and no ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. Thus the five rows exhaust the local naming surface. □

Theorem 3485.3 (Baire ultrametric prefix stability)**.** *Let* $U = (B, M, V, S, H, C, P, N)$ *and* $U' = (B', M', V', S', H', C', P', N')$ *be accepted* $\mathsf{BaireUltrametric}^{\uparrow}$ *carriers. If the displayed* $\mathsf{BaireSpace}^{\uparrow}$ *prefix rows,* $\mathsf{BaireMetric}^{\uparrow}$ *common-prefix distance rows,* $\mathsf{UltrametricSpace}^{\uparrow}$ *comparison rows, and* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows transport componentwise under* hsame *and replay through displayed* Cont *routes, then U and U' determine the same finite-cylinder classifier value and the same common-prefix ultrametric route.*

Lean4 ✓ `BEDC.Derived.BaireUltrametricUp.BaireUltrametricCarrier prefix stability`

Proof. Project both carriers through Definition 3485.1. The only analytic rows available for comparison are the prefix rows B, B', the metric rows M, M', the ultrametric rows V, V', and the window rows S, S'.

Use the assumed componentwise hsame transports to identify the displayed prefix and distance rows. The displayed Cont replays then force the same finite StreamName coordinates to be reread before either carrier can expose a classifier value.

Apply Definition 3485.2. Common-prefix distance exactness fixes the dyadic value from the first displayed disagreement or from the displayed agreement window, and finite-cylinder classifier stability keeps the classifier on those same rows.

The structural rows P, N and P', N' provide provenance and local naming only for the already transported route. Since no excluded branch, quotient, choice, host equality, or ambient Real-completeness coordinate is present, both carriers determine the same finite common-prefix ultrametric surface. □

Theorem 3485.4 (Baire ultrametric finite-cylinder separation)**.** *Let $U = (B, M, V, S, H, C, P, N)$ and $U' = (B', M', V', S', H', C', P', N')$ be accepted* BaireUltrametric$^{\uparrow}$ *packets. Suppose their displayed* BaireSpace$^{\uparrow}$ *prefix rows expose a first-disagreement window before length k, and suppose the* StreamName$^{\uparrow}$ *rows S, S' list every coordinate inspected up to that window. Then the* BaireMetric$^{\uparrow}$ *rows M, M' display a positive dyadic common-prefix distance for the two inspected names, and the packets determine disjoint finite cylinders before any* CompleteBaireSpace$^{\uparrow}$ *consumer reads a limit row.*

Lean4 ✓ `BEDC.Derived.BaireUltrametricUp.BaireUltrametricCarrier finite cylinder separation`

Proof. Project both carriers through Definition 3485.1. The only rows capable of naming the disagreement are the BaireSpace$^{\uparrow}$ prefix rows B, B', the BaireMetric$^{\uparrow}$ distance rows M, M', and the finite StreamName$^{\uparrow}$ windows S, S'.

Use the displayed first-disagreement window in B, B'. It identifies a least inspected coordinate at which the two finite prefixes differ, while S, S' certify that the coordinate is part of the finite window actually read by the packets.

The positive distance is then read from M, M'. By Definition 3485.2, common-prefix distance exactness assigns the dyadic value named by that first displayed disagreement, so the two packets cannot be assigned the zero-distance window for the inspected prefixes.

The finite cylinders are the two prefix cylinders ending at the displayed disagreement window. Any stream extending the first prefix must keep the first value at the disagreement coordinate, and any stream extending the second prefix must keep the second value there; the two finite-cylinder rows are therefore disjoint without consulting a completed limit.

Finally, V, V' are used only for the strong-triangle boundary. They preserve the finite-cylinder separation when a later consumer compares a third prefix, but they do not introduce an infinite branch, selected limit, quotient equality, or host stream equality. Thus a CompleteBaireSpace$^{\uparrow}$ consumer receives the positive dyadic separation before any completion-facing limit row is read. □

Theorem 3485.5 (Baire ultrametric cylinder refinement)**.** *Let $U = (B, M, V, S, H, C, P, N)$ and $U' = (B', M', V', S', H', C', P', N')$ be accepted* BaireUltrametric$^{\uparrow}$ *packets. If U displays a finite prefix cylinder and U' extends the same prefix through a longer* StreamName$^{\uparrow}$ *window without changing the already inspected coordinates, then the later cylinder refines the earlier one and the common-prefix ultrametric distance cannot increase on the displayed window. The refinement route*

uses only finite prefix rows, StreamName readback, componentwise hsame *comparison, and the finite strong-triangle boundary; it exports no selected branch, quotient stream equality, countable choice, host stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BaireUltrametricUp.BaireUltrametricCarrier cylinder refinement`

Proof. Project both packets through Definition 3485.1. The rows B, B' name the displayed finite prefixes, S, S' name the inspected StreamName windows, M, M' name the common-prefix distances, and V, V' supply only the finite ultrametric comparison boundary.

Use the StreamName readback and common-prefix exactness clauses of Definition 3485.2. The longer window in S' rereads every coordinate already present in S, and the hypothesis says that those displayed coordinates are unchanged.

Compare the two finite prefix rows componentwise through H and H'. The shared coordinates are identified by hsame, while the additional coordinates in the later packet can only shrink the cylinder by imposing more displayed prefix data; they cannot move a stream outside the earlier cylinder.

The distance comparison is then read from M, M' with V, V' used only as a finite strong-triangle boundary. Extending a common displayed prefix cannot create an earlier disagreement on the already inspected window, so the common-prefix ultrametric distance on that window cannot increase.

The remaining rows C, C', P, P', N, N' replay, source, and name this finite route. Since no row contains a selected infinite branch, quotient stream equality, countable choice, host stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the refinement stays inside finite prefix evidence before any $\mathsf{CompleteBaireSpace}^{\uparrow}$ completion row is read. □

Theorem 3485.6 (Baire ultrametric finite-cylinder completion handoff)**.** *Every* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *consumer reading a limit boundary from an accepted* $\mathsf{BaireUltrametric}^{\uparrow}$ *packet* $U = (B, M, V, S, H, C, P, N)$ *must first expose the* $\mathsf{BaireSpace}^{\uparrow}$ *finite prefix row* B*, the* $\mathsf{BaireMetric}^{\uparrow}$ *distance row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, the* $\mathsf{UltrametricSpace}^{\uparrow}$ *comparison row* V*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*. The completion handoff is therefore a finite-cylinder route, not a selected branch, quotient stream equality, countable choice, host stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier through Definition 3485.1. The only rows visible before a completion-facing boundary are the prefix row, distance row, ultrametric comparison row, finite StreamName window, and the structural support rows.

Apply Definition 3485.2. Carrier admission and StreamName readback order the read through B, M, V, S, H, C, P, N, while common-prefix distance exactness keeps the distance row attached to displayed finite prefix witnesses.

Use finite-cylinder separation and refinement, Definition 3485.4 and Definition 3485.5. Separation gives the positive finite-cylinder handoff before a completion row can read a limit boundary, and refinement keeps later windows inside the same displayed prefix route.

Finally repeat the nonescape clauses from the local NameCert surface. Since the packet has no coordinate for a selected branch, quotient stream equality, countable choice, host stream equality, or ambient completeness, a $\mathsf{CompleteBaireSpace}^{\uparrow}$ consumer receives only the finite-cylinder route before the limit boundary. □

Lean4 ✓ `BEDC.Derived.BaireUltrametricUp.BaireUltrametricCarrier finite cylinder completion handoff`

Falsifiable prediction: Every $\mathsf{BaireUltrametric}^{\uparrow}$ read factors through a displayed $\mathsf{BaireSpace}^{\uparrow}$ prefix row, a $\mathsf{BaireMetric}^{\uparrow}$ common-prefix distance row, a finite $\mathsf{StreamName}^{\uparrow}$ window row, an $\mathsf{UltrametricSpace}^{\uparrow}$ strong-triangle comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: bairespace, bairemetric, ultrametricspace, streamname, complete-bairespace: $\mathsf{BaireUltrametric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite Baire prefixes, common-prefix dyadic distances, ultrametric comparisons, finite stream windows, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireUltrametric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireUltrametric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3485.1, Definition 3485.2, Definition 3485.3, and Definition 3485.4 seed the common-prefix ultrametric route from Baire prefixes through prefix distances, finite StreamName windows, finite-cylinder separation, ultrametric comparison rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireUltrametric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host stream equality, quotient stream equality, selected branches, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-prefix distance exactness, finite-cylinder classifier stability, finite-cylinder separation, StreamName readback, prefix stability, and nonescape for BEDC.Derived.BaireUltrametric

Constructive story: A $\mathsf{BaireUltrametric}^{\uparrow}$ packet is generated from finite Baire prefix rows, BaireMetric common-prefix distance rows, UltrametricSpace comparison rows, StreamName finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3486

A Concrete Naming Certificate for $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$

The $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ packet realizes the observer-expansion reading of section 9463.4 as finite BEDC certificate data. It sits after the disk-coordinate surface of chapter 377, the complex phase readout of chapter 39, the finite flow route of chapter 195, the Poincare disk transport packet of chapter 3455, and the metric-read packet of chapter 3474. The chapter names expansion as a records-side ledger reading, not as global time, physical cosmology, or object-level boundary fixedness.

Definition 3486.1 (Hyperbolic expansion ledger carrier)**.** *A* $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (F, D, G, M, B, A, H, C, P, N)$$

with the following displayed rows:

1. *F is the focused-ledger row recording the visible record family whose growth is being read.*
2. *D is the disk-readout row over* $\mathsf{UnitDisk}^{\uparrow}$*,* $\mathsf{Complex}^{\uparrow}$*, and* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *coordinates.*
3. *G is the* Cont*-growth row comparing local continuation extension with successive ledger readouts.*
4. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row consumed only after F, D, G have been displayed.*
5. *B is the boundary-refusal row excluding global clock, physical cosmology, completed boundary object, and object-level boundary fixedness.*
6. *A is the provenance row tying F, D, G, M, B to the hyperbolic observer-expansion reading.*
7. *H records componentwise* hsame *transport for focused-ledger, disk-readout, growth, metric-read, boundary-refusal, provenance, replay, and local naming rows.*
8. *C records displayed* Cont *replay through the focused ledger, disk readout, growth route, metric read, and refusal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$*,* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$*,* $\mathsf{HyperbolicMetric}^{\uparrow}$*,* $\mathsf{UnitDisk}^{\uparrow}$*,* $\mathsf{DynSystem}^{\uparrow}$*,* $\mathsf{Complex}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicExpansionLedger}^{\uparrow}}$ *row.*

The carrier exports expansion only as a finite focused-ledger and metric-read route. It contains no global clock, no empirical cosmology, no completed boundary model, and no object-level fixed boundary.

Theorem 3486.2 (Hyperbolic expansion ledger NameCert obligations)**.** *For every accepted* HyperbolicExpansionLe *carrier* $X = (F, D, G, M, B, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicExpansionLedger}^{\uparrow}}$ *surface consists exactly of focused-ledger admission, disk-readout admission,* Cont*-growth routing, metric-read admission, boundary-refusal exactness, provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted expansion read factors through*

$$F \longmapsto D \longmapsto G \longmapsto M \longmapsto B \longmapsto A \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Lean4 ✓ `BEDC.Derived.HyperbolicExpansionLedgerUp.HyperbolicExpansionLedgerTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3486.1. The focused ledger F, disk readout D, growth row G, metric read M, and boundary-refusal row B are displayed before provenance and naming are consumed.

Read the route in the stated order. The disk metric is available only after the focused ledger and Cont-growth route have been displayed, so expansion is a records-side reading rather than a global clock.

The rows A, H, C, P, N then record provenance, transport, replay, package sourcing, and local naming. Since no global clock, physical cosmology, completed boundary model, or object-level fixed boundary has a carrier coordinate, none can be exported by the NameCert surface. □

Theorem 3486.3 (Hyperbolic expansion ledger Cont-growth route)**.** *Every accepted expansion read of a* $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ *packet factors through the focused ledger and* Cont*-growth route before disk metric consumption:*

$$F, D, G \longmapsto M.$$

The hyperbolic metric row M may compare displayed disk readouts only after the local continuation-growth row G has been opened, and the boundary-refusal row B prevents the comparison from becoming a global clock, physical cosmology, completed boundary, or object-level fixedness claim.

Proof. Start with a metric consumer of M. Carrier projection shows that M is downstream of the focused ledger F, disk readout D, and continuation-growth row G.

Use the displayed Cont replay row C. It can replay metric consumption only along the focused-ledger and growth route, so the disk metric cannot be read as an independent time parameter.

Finally apply boundary-refusal exactness through B. The packet refuses global clock, physical cosmology, completed boundary, and object-level fixedness readings, leaving only the finite records-side expansion route. □

Falsifiable prediction: Every accepted expansion read factors through the focused ledger and Cont-growth route before disk metric consumption; a consumer that reads the hyperbolic metric without F, D, G refutes the $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ carrier.

Independence witness: poincare-disk-phase-transport, hyperbolic-metric, unitdisk, dynsystem, complex: no listed sibling is bijective to $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ because the packet jointly binds focused-ledger growth, disk readout, Cont-growth routing, metric consumption, boundary refusal, provenance, transport, replay, package sourcing, and local naming.

The Lean follow-up for this packet must provide explicit Nontrivial HyperbolicExpansionLedger$^{\uparrow}$ and FieldFaithful HyperbolicExpansionLedger$^{\uparrow}$ TasteGate instances. Those instances must keep $F, D, G, M, B, A, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for NameCert$_{\text{HyperbolicExpansionLedger}^{\uparrow}}$.

Constructive story: A HyperbolicExpansionLedger$^{\uparrow}$ packet is generated from a focused-ledger row, disk-readout row, Cont-growth route, HyperbolicMetric read, boundary-refusal row, provenance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicExpansionLedger}^{\uparrow}}$, seed)

Scope closed: Definition 3486.1, Definition 3486.2, and Definition 3486.3 seed the finite observer-expansion route through focused-ledger, disk-readout, Cont-growth, metric-read, boundary-refusal, provenance, transport, replay, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicExpansionLedger}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.HyperbolicExpansionLedgerUp.HyperbolicExpansionLedgerTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not close global clock semantics, physical cosmology, completed boundary geometry, object-level boundary fixedness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, focused-ledger rows, disk-readout rows, Cont-growth routing, metric-read rows, boundary-refusal exactness, TasteGate nontriviality, field faithfulness, provenance, and local naming for BEDC.Derived.HyperbolicExpansionLedgerUp.

Chapter 3487

A Concrete Naming Certificate for $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$

The $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ packet realizes the reversible phase-transport conservation row of Definition 9463.4 as finite NameCert data. It sits between the complex-history surface of chapter 39, the phase-transport carrier of chapter 3455, the metric readback of chapter 3474, and the expansion ledger of chapter 3486. The packet records conservation only as auditable preservation of source, transport, classifier, and GAP provenance rows; it does not assert a completed symplectic manifold, a global Hamiltonian flow, a host Liouville measure, or an ambient unitary group.

Falsifiable prediction: Any accepted $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ route preserves source, transport, classifier, and GAP provenance rows before a conserved phase read is exported.

Independence witness: complex, unitarygroup, dynsystem, poincare-disk-phase-transport, hyperbolic-metric: the ledger-conservation packet is not bijective to these siblings because it records reversible preservation of finite source, route, classifier, and GAP provenance rows rather than a complex carrier, ambient unitary group, dynamical system, disk-transport chart, or metric tensor alone.

Definition 3487.1 (Liouville ledger-conservation carrier)**.** *A* $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, T, K, G, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source phase-surface row, carrying the finite visible histories whose distinctions must remain readable.*
2. *T is the reversible transport row, read through the local phase-transport surface and recording the forward and return continuations as displayed data.*
3. *K is the classifier-preservation row, requiring the transported surface to preserve the classifier readout attached to S.*
4. *G is the* GAP *provenance row, recording that residues, exits, and unresolved boundary data remain ledger-visible after transport.*
5. *Q is the conserved phase-read row. It is exposed only after S, T, K, G have all been displayed.*
6. *H records componentwise* hsame *transport for source, reversible transport, classifier preservation,* GAP *provenance, conserved read, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a conservation request through S, T, K, G, Q, H, P, N.*

8. *P is the* Pkg *provenance over* LiouvilleLedgerConservation$^{\uparrow}$, PoincareDiskPhaseTransport$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicExpansionLedger$^{\uparrow}$, Complex$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LiouvilleLedgerConservation}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose conserved phase read Q is downstream of source exposure, reversible transport, classifier preservation, and GAP *provenance. It has no coordinate for host measure theory, a symplectic manifold, an ambient Hilbert space, a hidden unitary operator, or a global dynamical-system solution.*

Theorem 3487.2 (Liouville ledger-conservation NameCert obligations)**.** *For every accepted* LiouvilleLedgerConserva *carrier*

$$L = (S, T, K, G, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LiouvilleLedgerConservation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for the source phase surface, reversible transport, classifier preservation,* GAP *provenance, conserved phase read, transport, replay, package provenance, and local naming rows;*

2. *source preservation, requiring every conserved read to keep the displayed source distinctions of S visible after transport;*

3. *route reversibility, requiring T to expose both the forward and return transport rows before conservation is read;*

4. *classifier preservation, requiring K to certify the transported classifier readout before Q is exported;*

5. GAP *ledger preservation, requiring G to keep residue and boundary provenance visible rather than erasing it into the conserved read;*

6. *structural non-escape, requiring H, C, P, N to preserve and name the same packet without adding an ambient unitary group, host Hamiltonian flow, completed phase volume, or hidden global state.*

Future Lean `TasteGate.lean` *will provide explicit* `Nontrivial LiouvilleLedgerConservationUp` *and* `FieldFaithful LiouvilleLedgerConservationUp` *instances so the accepted conservation packet remains distinct from refused routes and faithful reads preserve all displayed rows.*

Proof. Carrier exposure is projection from Definition 3487.1. The displayed packet contains exactly the source, reversible transport, classifier, GAP provenance, conserved read, and structural rows.

Source preservation and route reversibility are enforced before any conserved read is available. The row Q is downstream of S and T, so a consumer cannot export conservation after forgetting either the source distinctions or the return route.

Classifier and GAP preservation are separate rows. The classifier row K records preservation of the readout, while G keeps residues and boundary provenance visible as provenance rather than absorbing them into the phase read.

The structural rows then confine the packet. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming preserve only S, T, K, G, Q and add no coordinate for the excluded host structures. □

Lean4 ✓ `BEDC.Derived.LiouvilleLedgerConservationUp.LiouvilleLedgerConservation namecert obligations`

Theorem 3487.3 (Liouville ledger-conservation export discipline)**.** *Every accepted* $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ *route exports a conserved phase read only along*

$$S, T, K, G \longmapsto Q \longmapsto H, C, P, N.$$

Consequently a downstream consumer receives source exposure, reversible transport, classifier preservation, GAP *provenance, the conserved read, transport, replay, package provenance, and local naming, and receives no host Liouville measure, ambient unitary operator, global dynamical system, completed symplectic phase space, or hidden state.*

Proof. Project an accepted carrier $L = (S, T, K, G, Q, H, C, P, N)$. The only conservation-facing row is Q, and it is displayed after the source, transport, classifier, and GAP rows.

Replay through C preserves that order. A downstream conservation request must pass through S, T, K, G before it can read Q, so the conserved phase read remains tied to visible source distinctions, route data, classifier preservation, and boundary provenance.

The structural rows authenticate only that finite route. Since the carrier has no host-measure, unitary-operator, global-dynamics, symplectic-manifold, or hidden-state coordinate, none of those structures can be exported from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LiouvilleLedgerConservation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LiouvilleLedgerConservation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3487.1, Definition 3487.2, and Definition 3487.3 seed the finite reversible ledger-conservation surface over source, transport, classifier, GAP provenance, conserved-read, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LiouvilleLedgerConservation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Liouville measure theory, ambient unitary dynamics, completed symplectic geometry, global Hamiltonian flow, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source preservation, reversible transport, classifier preservation, GAP ledger preservation, export discipline, Nontrivial LiouvilleLedgerConservationUp, and FieldFaithful LiouvilleLedgerConservationUp.

Constructive story: A $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ packet is generated from finite source phase-surface rows, reversible transport rows, classifier-preservation rows, GAP provenance rows, a conserved phase-read row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3488

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ packet records the located-real completion boundary as finite NameCert data. It consumes the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the located-real observation row of chapter 1933, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a human-origin completion route for displayed located Cauchy data; it is not a quotient-real construction, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3488.1 (Bishop located-real completion carrier)**.** *A* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the requested radii and comparison budgets.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family inspected at those dyadic tolerances.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback obtained from the displayed finite windows.*
4. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *locatedness row recording lower–upper separation evidence for the same readback windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R, L have been displayed.*
6. *H records componentwise* hsame *transport for the tolerance, window, readback, locatedness, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each completion-facing request through D, S, R, L, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected representatives, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedRealCompletionUp.BishopLocatedRealCompletionTasteGate single carrier alignment`

Theorem 3488.2 (Bishop located-real completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *carrier* $K = (D, S, R, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, DyadicRatCore tolerance exposure, finite StreamName window exposure, RegSeqRat readback, LocatedReal locatedness exposure, Real seal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming. Every completion-facing consumer reads only the displayed route*

$$D \longmapsto S \longmapsto R \longmapsto L \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Proof. Project the carrier of Definition 3488.1. Its analytic rows are the dyadic tolerance ledger, finite stream windows, regular rational readback, locatedness row, and Real seal.

Read the route in order. The tolerance row D fixes the finite request, S opens the corresponding window, R repacks that window as regular rational data, and L supplies the located lower–upper evidence attached to the same displayed readback.

The seal row E is downstream of those four rows. The structural rows H, C, P, N transport, replay, source, and name the route, while quotient streams, selected limits, host equality, choice, trichotomy, compactness, and ambient completeness have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.BishopLocatedRealCompletionUp.BishopLocatedRealCompletion namecert obligations`

Theorem 3488.3 (Bishop located-real completion tolerance-window exactness)**.** *For an accepted* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *carrier* $K = (D, S, R, L, E, H, C, P, N)$*, every located completion request fixes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *before selecting the* $\mathsf{StreamName}^{\uparrow}$ *window* S*. The* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *and* $\mathsf{LocatedReal}^{\uparrow}$ *row* L *are then read over that same window before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed.*

Proof. Project the carrier of Definition 3488.1. The tolerance ledger D is the first analytic row of the packet, and the finite window row S is admitted only as the stream window inspected at those dyadic tolerances.

Apply the NameCert obligations of Definition 3488.2. They force the completion route to read D before S, then R, then L, and only then the terminal seal E.

The located Cauchy handoff of Definition 3488.4 keeps the regular readback and locatedness evidence on the same displayed window. Since quotient streams, selected representatives, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate, no completion request can replace this tolerance-window route with a broader Real construction. □

Theorem 3488.4 (Bishop located-real completion located Cauchy handoff)**.** *Every* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *consumer that treats a displayed regular Cauchy name as a located real must pass through* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{LocatedReal}^{\uparrow}$ *row before reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff exposes located Cauchy evidence only as the finite packet* $D, S, R, L, E, H, C, P, N$*.*

Proof. Start with the NameCert obligations. They place the dyadic tolerance ledger before the window family and the regular rational readback.

The locatedness row is then forced to share the same finite windows. Since L is read after R, a consumer cannot substitute a host located real, a quotient stream class, or a selected representative for the displayed regular readback.

Finally the Real seal is reached through E and preserved by H, C, P, N. The handoff is therefore the finite BEDC route through chapter 291, chapter 126, chapter 301, chapter 1933, and chapter 38. □

Theorem 3488.5 (Located-real completion Cauchy representation)**.** *Every accepted* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *packet exposes its regular Cauchy representation only through the shared rows* D, S, R, L *before the terminal* E *seal. Thus* $\mathsf{Real}^{\uparrow}$ *consumers can read DyadicRatCore tolerances, StreamName finite windows, RegSeqRat readback, and LocatedReal locatedness evidence, but they cannot read quotient-stream representatives, selected limits, host equality, countable choice, trichotomy, or ambient Real completeness from the packet.*

Proof. Project the carrier of Definition 3488.1. The rows D, S, R, L are the only analytic coordinates available before the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Apply Definition 3488.2 and Definition 3488.3. These results force the representation route to pass through the displayed tolerance ledger, finite window, regular rational readback, and locatedness row on the same window.

Now apply Definition 3488.4 and Definition 3488.6. The handoff identifies the regular Cauchy representation consumed by located-real clients, and the seal nonescape theorem excludes quotient-stream representatives, selected limits, host equality, choice, trichotomy, and ambient completeness from the exported $\mathsf{Real}^{\uparrow}$ surface. □

Theorem 3488.6 (Bishop located-real completion Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *packet factors through the displayed rows* $D, S, R, L, E, H, C, P, N$*. The seal exports no quotient-real equality, selected host limit, host real equality test, countable-choice selector, trichotomy split, open-cover compactness witness, or ambient completeness theorem.*

Proof. Read the carrier definition. The only route to E is through the tolerance ledger, finite windows, regular readback, and locatedness row.

Apply the located Cauchy handoff. It identifies D, S, R, L as the exact finite route consumed before the terminal seal can be inspected.

The structural rows do not add analytic content. They preserve and name the displayed route, while the refused quotient, selected, host, choice, order, compactness, and ambient-completeness objects are absent from the carrier and from the local NameCert provenance. □

Falsifiable prediction: A claimed $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the displayed DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, and LocatedReal locatedness row refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, locatedreal, real: no listed sibling supplies the whole $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ packet, because each sibling contributes only tolerance, window, readback, locatedness, or terminal seal data while this chapter binds all five rows with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, LocatedReal locatedness row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3488.1, Definition 3488.2, Definition 3488.4, and Definition 3488.6 seed the finite located-real completion route through dyadic tolerances, stream windows, regular rational readback, locatedness rows, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real construction, selected host limits, countable choice, trichotomy, open-cover compactness, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window exactness, regular readback, locatedness handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealCompletion

Chapter 3489

A Concrete Naming Certificate for $\mathsf{LocatedDyadicCut}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedDyadicCut}^{\uparrow}$ packet records a two-sided dyadic located-cut interface for Real and Completion consumers. It sits after the dyadic tolerance arithmetic of chapter 291, the finite window discipline of chapter 126, the regular rational readback route of chapter 301, the located-cut surface of chapter 404, and the regular Cauchy located-cut handoff of chapter 7018. The packet names lower and upper dyadic rows with a located gap request before the terminal $\mathsf{Real}^{\uparrow}$ seal; it is not a quotient Dedekind real, a selected limit, countable choice, trichotomy, or ambient completeness principle.

Definition 3489.1 (Located dyadic cut carrier)**.** *A* $\mathsf{LocatedDyadicCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, G, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower dyadic cut row, recording rounded lower observations at displayed dyadic scales.*
2. *U is the upper dyadic cut row, recording rounded upper observations over the same displayed dyadic scales.*
3. *G is the located gap request row, exposing the lower–upper separation request before a consumer treats the cut as located.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic row used to compare dyadic endpoints and request radii.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *inspection row naming the finite windows used by the dyadic observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational data attached to those windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reached only after L, U, G, D, S, R have stayed visible.*
8. *H records componentwise* hsame *transport for lower, upper, gap, arithmetic, window, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each Real-facing or Completion-facing request through $L, U, G, D, S, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedDyadicCut}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicCut}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $L, U, G, D, S, R, E, H, C, P, N$. It has no coordinate for quotient Dedekind equality, selected Cauchy limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.LocatedDyadicCutUp`

Theorem 3489.2 (Located dyadic cut NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDyadicCut}^{\uparrow}$ *carrier $K = (L, U, G, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicCut}^{\uparrow}}$ *surface consists exactly of carrier admission for those eleven rows; lower roundedness through L; upper roundedness through U; located gap exposure through G; dyadic tolerance handoff through D; finite window inspection through S; regular rational readback through R; Real-seal nonescape through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 3489.1. Its analytic rows are exactly the lower cut, upper cut, located gap request, dyadic tolerance arithmetic, stream inspection, regular rational readback, and terminal Real seal.

Read the lower and upper sides separately. Roundedness for the lower row is recorded only in L, roundedness for the upper row only in U, and locatedness is exposed only after the gap request row G is displayed with the same dyadic tolerance row D.

Now route the numeric data through S and R. The finite StreamName windows and RegSeqRat readback bind the dyadic observations to displayed regular rational data before the seal row E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no refused quotient, selected limit, choice, trichotomy, or ambient-completeness object is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3489.3 (Located dyadic cut Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{LocatedDyadicCut}^{\uparrow}$ *carrier $K = (L, U, G, D, S, R, E, H, C, P, N)$ must read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{LocatedCut}^{\uparrow}$ *lower–upper row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before using the cut as a Real-facing boundary. The consumer route is the finite handoff*

$$D, S, R, L, U, G \longmapsto E, H, C, P, N$$

refined by the regular Cauchy located-cut sibling of chapter 7018 and the dyadic arithmetic core of chapter 291.

Proof. Start with a Real-facing or Completion-facing consumer. Carrier projection exposes D, S, R, L, U, G before E, so the consumer cannot read the terminal seal without first opening tolerance arithmetic, finite windows, regular rational readback, and the two located-cut sides.

Use the sibling route through chapter 7018. It identifies the regular Cauchy readback discipline consumed by the lower and upper located rows, while chapter 291 supplies the dyadic tolerance handoff used by the gap request.

The structural rows then preserve the same boundary. Componentwise transport H, replay C, provenance P, and local naming N keep the seal attached to the displayed rows and provide no coordinate for quotient Dedekind completeness, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: A claimed $\mathsf{LocatedDyadicCut}^{\uparrow}$ consumer that reaches the $\mathsf{Real}^{\uparrow}$ seal without first reading DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, LocatedCut lower–upper rows, and the located gap request refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, locatedcut, real: no listed sibling supplies the whole $\mathsf{LocatedDyadicCut}^{\uparrow}$ packet, because each sibling contributes only arithmetic, window, readback, lower–upper, or terminal seal data while this chapter binds all rows with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDyadicCut}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDyadicCut}^{\uparrow}$ packet is generated from lower and upper dyadic cut rows, a located gap request, DyadicRatCore tolerance arithmetic, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedDyadicCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3489.1, Definition 3489.2, and Definition 3489.3 seed the finite two-sided dyadic located-cut route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedDyadicCut}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.LocatedDyadicCutUp`

Bridge status: none

Not claimed: This chapter does not close quotient Dedekind completeness, selected limits, countable choice, trichotomy, ambient RealUp completeness, checked obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower and upper roundedness, located gap exposure, dyadic tolerance handoff, finite window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedDyadicCutUp.

Chapter 3490

A Concrete Naming Certificate for $\mathsf{KirszbraunExtension}^{\uparrow}$

Following Kirszbraun and the Banach-space tradition around nonexpansive and Lipschitz extension theorems, the $\mathsf{KirszbraunExtension}^{\uparrow}$ packet records the finite certificate surface needed to read a Lipschitz map on a metric subspace as a convex inner-product-valued extension request. It sits beside the metric subspace packet of chapter 1519, the Lipschitz map packet of chapter 410, the reusable extension interface of chapter 3650, the convex target surface of chapter 208, the inner-product target source of chapter 86, and the metric source of chapter 57. The chapter names the finite Kirszbraun-facing route without claiming Hilbert-space completeness, a host extension operator, pointwise equality of functions, or a selected global formula.

Definition 3490.1 (Kirszbraun extension carrier)**.** *A* $\mathsf{KirszbraunExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, A, L, Y, V, B, F, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *row for the source observations.*
2. *A is the* $\mathsf{MetricSubspace}^{\uparrow}$ *row, including the membership, inclusion, and inherited-distance route from A into X.*
3. *L is the source* $\mathsf{LipschitzMap}^{\uparrow}$ *row on A, carrying the finite graph window and displayed Lipschitz constant.*
4. *Y is the target* $\mathsf{InnerProduct}^{\uparrow}$ *row, read through its vector, scalar-form, norm-seed, and metric-seed observations.*
5. *V is the target* $\mathsf{ConvexSet}^{\uparrow}$ *row inside the inner-product carrier, recording the admitted convex codomain surface for extension values.*
6. *B is the Lipschitz-constant ledger, recording the rational bound, the source-distance reads through A, X, and the target-distance reads through Y, V.*
7. *F is the extension graph row over the ambient metric window X with values admitted by V.*
8. *R is the restriction and bound row, requiring source points admitted by A to replay the graph of L and requiring every displayed ambient pair of F to respect the same ledger B.*

9. *H records componentwise* hsame *transport for the ambient metric, subspace, source Lipschitz map, target inner-product, convex codomain, Lipschitz ledger, extension graph, restriction, replay, provenance, and local name rows.*
10. *C records displayed* Cont *replay from a Kirszbraun extension request through $X, A, L, Y, V, B, F, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{KirszbraunExtension}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KirszbraunExtension}^{\uparrow}}$ *row.*

The classifier compares accepted carriers componentwise through these rows. It contains no coordinate for a host Hilbert space, a global extension operator, quotient equality of functions, countable choice, ambient compactness, or unbounded real completion.

Lean4 ✓ `BEDC.Derived.KirszbraunExtensionUp.KirszbraunExtensionTasteGate single carrier alignment`

Theorem 3490.2 (Kirszbraun extension NameCert obligations)**.** *For every accepted* $\mathsf{KirszbraunExtension}^{\uparrow}$ *carrier $K = (X, A, L, Y, V, B, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KirszbraunExtension}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, metric-subspace inclusion through A, source Lipschitz-map admission through L, inner-product target admission through Y, convex codomain admission through V, Lipschitz-constant ledger readback through B, extension-graph admission through F, restriction and bound exactness through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

The finite route is

$$X, A \longmapsto L \longmapsto Y, V \longmapsto B, F, R \longmapsto H, C, P, N.$$

No obligation is discharged by a host extension formula, a quotient of maps, or a hidden Hilbert-space theorem.

Proof. Carrier admission is projection from Definition 3490.1. The displayed rows are exactly $X, A, L, Y, V, B, F, R, H, C, P, N$.

The source side is read through X, A, L. The subspace row admits source points and inherited distances, and the Lipschitz-map row exposes the finite graph window and bound that the extension must preserve.

The target side is read through Y, V. The inner-product row supplies the target metric seed, while the convex-set row supplies the admitted value surface for extension graph reads.

The ledger and graph clauses are B, F, R. The ledger stores the single Lipschitz constant and both source and target distance reads, the graph row stores ambient observations, and the restriction row forces source points to replay the original Lipschitz map.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no host extension operator, quotient-function coordinate, choice row, compactness row, or completion theorem coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3490.3 (Kirszbraun extension non-escape)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, *or* $\mathsf{InnerProduct}^{\uparrow}$ *consumer of an accepted* $\mathsf{KirszbraunExtension}^{\uparrow}$ *packet factors through*

$$X, A, L, Y, V, B, F, R, H, C, P, N.$$

It may read the packet as a finite extension candidate whose graph restricts to the source Lipschitz map and whose target values remain in the displayed convex inner-product row, but it cannot export a host Kirszbraun theorem, a chosen extension operator, a quotient-map equality, countable choice, compactness, or ambient Hilbert completeness.

Proof. Start from the obligation surface of Definition 3490.2. Every accepted consumer route must read the ambient metric, subspace, source Lipschitz map, target inner-product row, convex codomain row, ledger, graph, restriction, transport, replay, provenance, and name rows.

A source-facing consumer reaches the extension only through A, L, R. Thus an admitted source point is compared with the original Lipschitz graph before any ambient graph read is treated as an extension value.

A target-facing consumer reaches values only through Y, V, B, F. The inner-product row supplies the metric seed, the convex row admits values, and the ledger checks the same Lipschitz constant against displayed distances.

The remaining rows H, C, P, N repack that route. They preserve and name the carrier but do not add a host theorem, operator selector, quotient equality, choice schedule, compactness witness, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{KirszbraunExtension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KirszbraunExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3490.1, Definition 3490.2, and Definition 3490.3 seed the finite Kirszbraun extension carrier over metric subspace, Lipschitz map, convex target, inner-product target, extension graph, and Lipschitz-ledger rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KirszbraunExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Kirszbraun theorem, global Hilbert completeness, quotient equality of functions, selected extension operators, countable choice, compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subspace inclusion, source Lipschitz admission, convex inner-product target admission, Lipschitz-ledger readback, graph admission, restriction exactness, transport, replay, provenance, and non-escape for BEDC.Derived.KirszbraunExtensionUp.

Constructive story: A $\mathsf{KirszbraunExtension}^{\uparrow}$ packet is generated from an ambient Metric row, a MetricSubspace source row, a source LipschitzMap row, an InnerProduct target row, a ConvexSet target row, a Lipschitz-constant ledger, an extension graph, a restriction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3491

A Concrete Naming Certificate for HyperbolicGeodesicBoundary$^{\uparrow}$

The HyperbolicGeodesicBoundary$^{\uparrow}$ packet realizes the boundary-geodesic route of chapter 9463 as finite Poincare-disk, hyperbolic-metric, phase-transport, and provenance rows. It sits after the disk-coordinate surface of chapter 377, reversible transport in chapter 219, finite flow rows in chapter 195, the disk-phase carrier of chapter 3455, and the metric-read surface of chapter 3474. The packet names geodesic-boundary data without treating the boundary as a completed host circle, quotient ideal point, physical horizon, or observer substance.

Definition 3491.1 (HyperbolicGeodesicBoundary carrier)**.** *A* HyperbolicGeodesicBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, M, T, B, J, F, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the* UnitDisk$^{\uparrow}$ *disk-coordinate row, including the finite radius and boundary-approach observations used by the packet.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *T is the* PoincareDiskPhaseTransport$^{\uparrow}$ *transport row, retaining reversible phase movement, finite flow data, and fiber provenance.*
4. *B is the boundary-geodesic incidence row, recording which finite disk observations are read as approaching the same geodesic far-end.*
5. *J is the classifier-stability row, preserving disk-coordinate, hyperbolic-metric, phase-transport, and boundary-geodesic classifiers under the displayed route.*
6. *F is the refusal row excluding quotient boundary equality, completed geodesic compactification, host horocycle selection, physical cosmology, and observer-substance readings.*
7. *A is the audit row tying D, M, T, B, J, F to the hyperbolic phase vision and to the Poincare-disk metric and transport packets.*
8. *H records componentwise* hsame *transport for disk-coordinate, metric-read, phase-transport, boundary-geodesic, classifier-stability, refusal, and audit rows.*
9. *C records displayed* Cont *replay through finite disk observations, metric reads, phase transport, boundary-geodesic checks, classifier stability, provenance, and refusal.*

10. *P is the* Pkg *provenance over* HyperbolicGeodesicBoundary$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, PoincareDiskPhaseTra UnitaryGroup$^{\uparrow}$, DynSystem$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HyperbolicGeodesicBoundary}^{\uparrow}}$ *row.*

The carrier exports boundary-geodesic data only through these rows. It has no coordinate for a completed hyperbolic plane, quotient ideal boundary, selected horocycle, global physical evolution law, or object-level observer substance.

Theorem 3491.2 (HyperbolicGeodesicBoundary NameCert obligations)**.** *For every accepted* HyperbolicGeodesicBo *carrier*

$$G = (D, M, T, B, J, F, A, H, C, P, N),$$

the local NameCert$_{\text{HyperbolicGeodesicBoundary}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, hyperbolic-metric read admission, Poincare-disk phase-transport admission, boundary-geodesic incidence, classifier stability, refusal exactness, audit provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every boundary-geodesic consumer must factor through

$$D, M, T \longmapsto B, J, F, A \longmapsto H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.HyperbolicGeodesicBoundaryUp.HyperbolicGeodesicBoundaryTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3491.1. The visible surface begins with disk-coordinate row D, metric-read row M, and phase-transport row T.

Read the incidence and stability rows next. The row B records boundary-geodesic incidence as finite far-end evidence, while J preserves the disk, metric, transport, and boundary classifiers across the displayed data.

The refusal and audit rows keep the packet aligned with the hyperbolic phase reading without exporting host geometry. Finally H, C, P, N transport, replay, source, and name only those displayed rows, so no quotient boundary, selected horocycle, physical horizon, or observer-substance reading can be extracted. □

Theorem 3491.3 (HyperbolicGeodesicBoundary phase handoff)**.** *Every phase-transport consumer of an accepted* HyperbolicGeodesicBoundary$^{\uparrow}$ *carrier receives the geodesic far-end only after the route*

UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, PoincareDiskPhaseTransport$^{\uparrow}$, UnitaryGroup$^{\uparrow}$, DynSystem$^{\uparrow}$, BHist, hsame, Cont, Pkg

has been displayed. The consumer may use finite disk coordinates, hyperbolic metric reads, reversible phase transport, finite flow, boundary incidence, classifier stability, provenance, and local naming. It may not read quotient boundary equality, completed geodesic compactification, selected horocycles, physical cosmology, or observer substance.

Proof. Start from the NameCert obligation surface of Definition 3491.2. It places the disk-coordinate row, hyperbolic metric read, and phase-transport route before boundary incidence is exposed.

Use the phase-transport ledger of Definition 3455.2. The reversible transport and finite flow rows keep the source ledger visible while the boundary-geodesic row is read.

The hyperbolic metric obligations of Definition 3474.2 supply the metric-read discipline. Together with H, C, P, N, these rows give a finite phase handoff and no stronger host-side boundary object. □

Falsifiable prediction: A $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ consumer that obtains quotient boundary equality, selected horocycle data, or a completed geodesic compactification without first reading the route $D, M, T, B, J, F, A, H, C, P, N$ refutes the carrier surface.

Independence witness: hyperbolic_metric, unitdisk, unitarygroup, dynsystem, poincare_disk_phase_transpor $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk-coordinate observations, hyperbolic metric reads, phase transport, boundary-geodesic incidence, classifier stability, refusal, audit provenance, transport, replay, package sourcing, and local NameCert rows.

The Lean follow-up for this packet must provide explicit $\mathsf{Nontrivial\ HyperbolicGeodesicBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicGeodesicBoundary}^{\uparrow}$ TasteGate instances. Those instances must keep $D, M, T, B, J, F, A, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ packet is generated from UnitDisk disk coordinates, HyperbolicMetric metric reads, PoincareDiskPhaseTransport rows, boundary-geodesic incidence, classifier stability, refusal exactness, audit provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3491.1, Definition 3491.2, and Definition 3491.3 seed the finite boundary-geodesic route over disk-coordinate, hyperbolic-metric, phase-transport, and provenance rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HyperbolicGeodesicBoundaryUp.HyperbolicGeodesicBoundaryTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close quotient boundary equality, completed geodesic compactification, selected horocycles, physical cosmology, observer-substance readings, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-geodesic incidence, metric-read stability, phase-transport handoff, refusal exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicGeodesicBoundaryUp.

Chapter 3492

A Concrete Naming Certificate for $\mathsf{UniformClosure}^{\uparrow}$

Following Bishop-style metric and uniform-space practice, the $\mathsf{UniformClosure}^{\uparrow}$ packet records the closure interface whose tests are uniform-neighbourhood rows rather than host open covers. It sits between the metric closure surface of chapter 3342, the completion handoff of chapter 1506, the separation boundary of chapter 1411, the terminal real seal of chapter 38, and the regular-rational readback route of chapter 301. The packet names closure by finite entourage, window, and seal data; it is not open-cover compactness, quotient closure, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3492.1 (UniformClosure carrier)**.** *A* $\mathsf{UniformClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, Q, S, L, E, W, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricClosure}^{\uparrow}$ *row naming the metric closure surface whose point, source, and candidate-limit data are being read.*
2. *Q is the uniform-neighbourhood ledger, recording the finite entourage requests admitted for the same carrier.*
3. *S is the source subset or located-source row being closed under those uniform requests.*
4. *L is the candidate closure point, read only through the displayed uniform and metric rows.*
5. *E is the entourage-to-metric comparison row that routes uniform requests into the metric tests already visible in M.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface used to inspect the approximating observations and the candidate point.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same windows, tolerances, and comparison requests.*
8. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, Q, S, L, E, W, R have been displayed.*
9. *H records componentwise* hsame *transport for the metric-closure, uniform-ledger, source, candidate, comparison, window, readback, and seal rows.*
10. *C records displayed* Cont *replay from an entourage request through the metric-closure test, finite windows, regular-rational readback, and real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{UniformClosure}^{\uparrow}$, $\mathsf{MetricClosure}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformClosure}^{\uparrow}}$ *row.*

The classifier accepts only packets whose uniform requests, metric closure route, candidate point, finite windows, regular readbacks, real seal, transport, replay, provenance, and local naming are displayed. It has no coordinate for open-cover compactness, quotient closure, selected limits, a quotient completion object, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformClosureUp.UniformClosureTasteGate single carrier alignment`

Theorem 3492.2 (UniformClosure NameCert obligations)**.** *For every accepted* $\mathsf{UniformClosure}^{\uparrow}$ *carrier* $U = (M, Q, S, L, E, W, R, Z, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{MetricClosure}^{\uparrow}$ *row, uniform-neighbourhood ledger, source row, candidate closure point, entourage-to-metric comparison row, finite window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every public uniform-closure read must factor through

$$M, Q, S, L, E, W, R, Z, H, C, P, N$$

before the candidate closure point can be consumed.

Proof. Project the carrier of Definition 3492.1. The only admissible source data are the metric-closure row M, uniform ledger Q, source row S, and candidate closure point L.

The comparison row E then binds each uniform request to the metric tests already exposed by M. The finite window row W, regular-rational readback R, and real seal Z give the displayed numerical route for those tests.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores open-cover compactness, quotient closure, selected limits, a quotient completion object, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 3492.3 (UniformClosure completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformClosure}^{\uparrow}$ *carrier reads the closure candidate only through the finite route*

$$\mathsf{MetricClosure}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The consumer receives the displayed metric-closure row, uniform-neighbourhood ledger, entourage-to-metric comparison, regular-rational readback, real seal, separation-facing identity boundary, transport, replay, provenance, and local naming. It receives no selected completion limit, quotient closure object, open-cover compactness principle, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the public route of Definition 3492.2. It places the uniform ledger and entourage-to-metric comparison before any completion-facing consumer can read the candidate point.

Use the metric-closure handoff of Definition 3342.3. The same finite windows and regular-rational readback rows feed the completion-facing side, so the consumer cannot detach the candidate from the displayed metric closure surface.

The separated-metric boundary of Definition 1411.48 supplies the identity discipline for zero-distance reads. Transport, replay, provenance, and naming through H, C, P, N preserve that route without adding selected limits, quotient closure, compactness, or ambient real completeness. □

Theorem 3492.4 (UniformClosure separated stability)**.** *Let $U = (M, Q, S, L, E, W, R, Z, H, C, P, N)$ be an accepted* $\mathsf{UniformClosure}^{\uparrow}$ *carrier. If a downstream separated-metric consumer compares two transported closure candidates from U, the comparison must pass through the displayed metric-closure row M, uniform ledger Q, comparison row E, finite windows W, regular-rational readback R, real seal Z, and the structural rows H, C, P, N before the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier can be read.*

Thus separated stability is a finite transport-and-seal obligation over the displayed rows, not a quotient closure equality or host identity theorem.

Proof. Project the two transported candidates through the componentwise hsame rows in H. The transport preserves the metric-closure row, uniform ledger, comparison row, windows, readback, and real seal as displayed rows of the same packet.

Replay the comparison through C. The route reaches the $\mathsf{Real}^{\uparrow}$ seal only after M, Q, E, W, R are fixed, and then uses the separated-metric identity boundary rather than host equality.

The provenance and local naming rows P, N expose this route as the public certificate. Since no quotient closure object, selected limit, open-cover compactness row, or ambient real-completeness coordinate occurs in U, the separated-stability conclusion remains confined to the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformClosure}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformClosure}^{\uparrow}$ packet is generated from a MetricClosureUp row, a uniform-neighbourhood ledger, source and candidate rows, an entourage-to-metric comparison row, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformClosure}^{\uparrow}}$, seed)

Scope closed: Definition 3492.1, Definition 3492.2, Definition 3492.3, and Definition 3492.4 seed the finite uniform-closure interface for completion and separated-metric consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformClosure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient closure, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-neighbourhood ledger stability, entourage-to-metric comparison, RegSeqRat readback, Real seal nonescape, completion handoff, separated stability, transport, replay, provenance, and local naming for BEDC.Derived.UniformClosureUp.

Chapter 3493

A Concrete Naming Certificate for CauchyFilterLocatedRealExtraction$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the CauchyFilterLocatedRealExtraction$^{\uparrow}$ packet records the finite route by which a Cauchy-filter surface is read as located-real window data. It consumes the Cauchy filter interface of chapter 3416, the located-real comparison surface of chapter 3395, the stream-name observation windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite extraction route only; it is not ambient Real completeness, a quotient filter construction, a selected limit, or a countable-choice principle.

Definition 3493.1 (Cauchy-filter located-real extraction carrier)**.** *A* CauchyFilterLocatedRealExtraction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, L, S, Q, D, R, T, C, P, N)$$

with the following displayed rows:

1. *F is the* CauchyFilter$^{\uparrow}$ *base row, exposing the filter-facing Cauchy surface and its finite request windows.*
2. *L is the* LocatedReal$^{\uparrow}$ *window row, recording the lower and upper located cuts read from the accepted filter request.*
3. *S is the* StreamName$^{\uparrow}$ *observation row, listing the finite observation windows through which the filter data are sampled.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row, translating the sampled filter windows into regular rational approximants.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, recording the dyadic mesh, modulus, and separation checks used by the located window.*
6. *R is the* Real$^{\uparrow}$ *seal row for the extracted endpoint and readback data.*
7. *T records componentwise* hsame *transport for $F, L, S, Q, D, R, C, P, N$.*
8. *C records displayed* Cont *replay from a filter request through the observation, rational readback, dyadic tolerance, located-window, and Real-seal rows.*
9. *P is the* Pkg *provenance over* CauchyFilterLocatedRealExtraction$^{\uparrow}$*,* CauchyFilter$^{\uparrow}$*,* LocatedReal$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyFilterLocatedRealExtraction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, L, S, Q, D, R, T, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient filters, selected limits, countable choice, host real equality, or an unrestricted completion principle.*

Lean4 ✓ `BEDC.Derived.CauchyFilterLocatedRealExtractionUp.CauchyFilterLocatedRealExtractionTasteGate`
`single carrier alignment`

Theorem 3493.2 (Cauchy-filter located-real extraction)**.** *Every accepted* $\mathsf{CauchyFilterLocatedRealExtraction}^{\uparrow}$ *packet extracts a located-real finite-window route from the Cauchy-filter surface:*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The exported route is the displayed finite packet $E = (F, L, S, Q, D, R, T, C, P, N)$ and no stronger completeness, quotient-filter, selected-limit, or countable-choice object is produced.

Proof. Project the accepted carrier. The Cauchy-filter surface is F, the finite observation windows are S, the regular rational readback is Q, the dyadic tolerance ledger is D, the located-real window is L, and the terminal Real-facing seal is R.

Replay through C keeps these rows in extraction order. A filter request is sampled only through the displayed stream-name windows, those observations are read back as regular rational data, and the dyadic ledger checks the tolerance needed before the located window is exposed.

Transport and provenance do not add new mathematical objects. The rows T, P, N move and name only the displayed packet, so the extraction cannot escape to quotient filters, selected limits, countable choice, ambient Real completeness, or host real equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterLocatedRealExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterLocatedRealExtraction}^{\uparrow}$ packet is generated from a CauchyFilter base row, LocatedReal finite window, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyFilterLocatedRealExtraction}^{\uparrow}}$, seed)

Scope closed: Definition 3493.1 and Definition 3493.2 seed the finite extraction route from Cauchy-filter windows to located-real readback data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyFilterLocatedRealExtraction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, quotient filters, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observation-window readback, dyadic tolerance exactness, located-window extraction, Real-seal compatibility, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterLocatedRealExtractionUp.

Chapter 3494

A Concrete Naming Certificate for $\mathsf{SignedDyadicExpansion}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers presented by finite approximation data, the $\mathsf{SignedDyadicExpansion}^{\uparrow}$ packet records the finite signed dyadic prefix route before a prefix may be consumed as a regular rational name or sealed as a $\mathsf{Real}^{\uparrow}$ object. It sits between the binary expansion surface of chapter 418, the signed-digit stream interface of chapter 316, the signed dyadic normal form row of $\mathsf{SignedDyadicNormalForm}^{\uparrow}$, the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite signed dyadic readback data; it is not a quotient stream, a selected infinite expansion, a uniqueness theorem for dual binary tails, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3494.1 (Signed dyadic expansion carrier)**.** *A* $\mathsf{SignedDyadicExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, W, E, T, F, A, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the sign row, recording whether the displayed prefix is read with positive, negative, or zero orientation before any numeric readback is opened.*
2. *W is the finite dyadic digit-prefix window, exposing the inspected binary cells and their request index as finite data.*
3. *E is the exponent and tail-radius ledger, recording the dyadic scale of the prefix and the displayed dyadic radius bounding the unseen tail.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row consumed by the tail-radius ledger and by every readback request.*
5. *F is the* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *row, normalizing the sign, exponent, and visible digit window without selecting an infinite expansion.*
6. *A is the* $\mathsf{StreamName}^{\uparrow}$ *window row that identifies which finite prefix cells are inspected at each requested tolerance.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from S, W, E, T, F, A.*
8. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the signed prefix, dyadic tolerance, normal-form, stream-window, and regular-rational rows have been displayed.*

9. *H records componentwise* hsame *transport for the sign, digit window, exponent ledger, tail-radius ledger, normal form, stream window, regular readback, real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$S, W, E, T, F, A \longmapsto R \longmapsto L.$$

11. *P is the* Pkg *provenance over* $\mathsf{SignedDyadicExpansion}^{\uparrow}$, $\mathsf{BinaryExpansion}^{\uparrow}$, $\mathsf{SignedDigitStream}^{\uparrow}$, $\mathsf{SignedDyadicNormalForm}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDyadicExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, E, T, F, A, R, L, H, C, P, N$. It has no coordinate for quotient stream equality, a selected infinite signed dyadic expansion, uniqueness at dual binary tails, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SignedDyadicExpansionUp.SignedDyadicExpansionTasteGate single carrier alignment`

Theorem 3494.2 (Signed dyadic expansion NameCert obligations)**.** *For every accepted* $\mathsf{SignedDyadicExpansion}^{\uparrow}$ *carrier*

$$X = (S, W, E, T, F, A, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SignedDyadicExpansion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the sign row, finite dyadic digit-prefix window, exponent and tail-radius ledger, dyadic tolerance row, signed dyadic normal form, stream window, regular rational handoff, real seal, transport, replay, provenance, and local name;*

2. *sign-prefix coherence, requiring S and W to expose the same finite signed prefix before any rational readback is admitted;*

3. *exponent and tail-radius visibility, requiring E and T to bound the unseen dyadic tail by a displayed dyadic tolerance;*

4. *normal-form locality, requiring F to normalize only the displayed sign, exponent, and digit-window rows;*

5. *window exactness, requiring A to select exactly the finite prefix cells consumed by the requested tolerance;*

6. *handoff order, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to consume S, W, E, T, F, A before the terminal* $\mathsf{Real}^{\uparrow}$ *seal L becomes available;*

7. *componentwise transport, displayed replay, package provenance, and local naming for the same rows through H, C, P, N;*

8. *refusal of quotient stream equality, selected infinite expansions, dual-tail uniqueness, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No signed dyadic expansion obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.SignedDyadicExpansionUp.SignedDyadicExpansionCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 3494.1. The accepted packet displays exactly the sign row, finite digit window, exponent and tail-radius ledger, dyadic tolerance row, signed normal form, stream window, regular readback, real seal, and structural rows.

The prefix information is read first. The sign row S and digit window W determine the visible signed dyadic prefix, while E and T expose the dyadic scale and the tail-radius budget that bounds all unseen cells relevant to the request.

The normal-form and window rows keep the readback local. The row F normalizes only the displayed finite prefix data, and A selects the finite cells consumed at the requested tolerance.

The handoff is ordered through R and L. A regular rational name may be read only after S, W, E, T, F, A are displayed, and the $\mathsf{Real}^{\uparrow}$ seal is terminal over that regular rational row.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row stores quotient stream equality, an infinite expansion selector, a dual-tail uniqueness decision, trichotomy, countable choice, or ambient completeness, none of those objects becomes a local obligation. □

Theorem 3494.3 (Signed dyadic expansion Real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{SignedDyadicExpansion}^{\uparrow}$ *carrier factors through the finite route*

$$S, W, E, T, F, A \longmapsto R \longmapsto L \longmapsto H, C, P, N.$$

Thus a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the sign row, finite dyadic prefix window, exponent and tail-radius ledger,* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *window, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row before the regular rational handoff and terminal real seal are available. The route exports no quotient stream, selected infinite expansion, dual-tail uniqueness theorem, trichotomy, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with a consumer request for the terminal real-facing row. The accepted carrier exposes L only after the signed prefix and tolerance route has been displayed.

The request first opens S, W, E, T, F, A. These rows determine the visible sign, dyadic digit prefix, exponent, tail radius, normal form, and inspected window as finite BEDC data.

The regular rational handoff R is then read from that same finite route. Because the tail-radius bound is already displayed in E and T, the handoff does not require a quotient stream or an infinite representative.

The seal L and structural rows H, C, P, N package the readback for downstream consumers. The excluded coordinates are absent from the carrier, so every exported real read remains a finite signed dyadic expansion certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDyadicExpansion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDyadicExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3494.1, Definition 3494.2, and Definition 3494.3 seed the finite signed dyadic prefix route from sign and digit-window rows through DyadicRatCore tolerances, SignedDyadicNormalForm rows, StreamName windows, RegSeqRat handoff, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDyadicExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected infinite expansions, dual-tail uniqueness, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, sign-prefix coherence, exponent and tail-radius visibility, normal-form locality, window exactness, handoff order, transport, replay, provenance, and local naming for BEDC.Derived.SignedDyadicExpansionUp.

Constructive story: A $\mathsf{SignedDyadicExpansion}^{\uparrow}$ packet is generated from a sign row, finite dyadic digit-prefix window, exponent and tail-radius ledger, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{FrechetSpace}^{\uparrow}$ hub routes complete metrizable locally convex structure through chapter 1506, chapter 3386, and chapter 205.

Chapter 3495

A Concrete Naming Certificate for $\mathsf{FrechetSpace}^{\uparrow}$

Following Frechet and Bourbaki on complete metrizable locally convex spaces, the $\mathsf{FrechetSpace}^{\uparrow}$ packet records the finite BEDC surface where a topological vector space, a locally convex neighbourhood ledger, a displayed compatible metric, and a completion-facing row are read as one carrier. It sits beside the metric-completion surface of chapter 1506, the locally convex source of chapter 3386, and the topological-vector-space source of chapter 205. The chapter names only the carrier rows needed for a Frechet-space read; it does not import a host complete locally convex space, a selected metric, quotient completion equality, countable choice, or an infinite seminorm enumeration.

Every complete-metrizable $\mathsf{FrechetSpace}^{\uparrow}$ read consumes the $\mathsf{TopVecSpace}^{\uparrow}$ operation-continuity surface of chapter 205, the $\mathsf{LocallyConvexSpace}^{\uparrow}$ seminorm and neighbourhood ledger of chapter 3386, and the $\mathsf{MetricCompletion}^{\uparrow}$ completion handoff of chapter 1506 through the displayed rows $V, L, M, C, Q, H, R, P, N$ before a functional-analysis consumer can replay completeness or local convexity.

Definition 3495.1 (Frechet space carrier)**.** *A* $\mathsf{FrechetSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, L, M, C, Q, H, R, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{TopVecSpace}^{\uparrow}$ *source row, exposing the vector carrier, topology, addition-continuity ledger, and scalar-continuity ledger.*
2. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *row, recording the finite seminorm and convex balanced neighbourhood evidence consumed by local convexity reads.*
3. *M is the compatible* $\mathsf{Met}^{\uparrow}$ *row, recording the finite distance witnesses and the topology-compatibility comparison used by metrizable consumers.*
4. *C is the completeness ledger, read through Cauchy windows, Cauchy-filter or Cauchy-net evidence, and displayed convergence rows without selecting a completed point.*
5. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row, used only to expose the completion-facing boundary of the compatible metric.*
6. *H records componentwise* hsame *transport for V, L, M, C, Q and for the replay, provenance, and local naming rows.*

7. *R records displayed* Cont *replay through the topological-vector source, locally convex source, compatible metric, completeness ledger, metric-completion handoff, transport, provenance, and local naming rows.*

8. *P is the* Pkg *provenance over* $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $V, L, M, C, Q, H, R, P, N$. It has no coordinate for a host Frechet space, an external complete metric, a selected translation-invariant metric, quotient completion equality, countable choice, or an infinite family of seminorms.

Theorem 3495.2 (Frechet space NameCert obligations)**.** *For every accepted* $\mathsf{FrechetSpace}^{\uparrow}$ *carrier $F = (V, L, M, C, Q, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetSpace}^{\uparrow}}$ *surface consists exactly of topological-vector source exposure through V; locally convex source exposure through L; compatible metric exposure through M; completeness evidence through C; metric-completion handoff through Q; componentwise transport through H; displayed replay through R; provenance through P; and local naming through N.*

Proof. Project the accepted carrier of Definition 3495.1. Its mathematical rows are the topological-vector source V, the locally convex row L, the compatible metric row M, the completeness ledger C, and the metric-completion handoff Q.

The topological and locally convex rows are consumed before the metric row. Thus a Frechet-space consumer first reads vector operations, topology, continuity, seminorm probes, and convex balanced neighbourhood evidence through the already named $\mathsf{TopVecSpace}^{\uparrow}$ and $\mathsf{LocallyConvexSpace}^{\uparrow}$ surfaces.

The compatible metric and completeness rows then give the metrizable complete handoff. The row M supplies only displayed distance and topology-compatibility evidence, while C records Cauchy and convergence checks without adding a selected completion point.

Finally Q, H, R, P, N transport, replay, source, and name the same finite route. Since the carrier contains no host Frechet object, selected metric, quotient-completion equality, countable-choice schedule, or infinite seminorm enumeration, the listed rows exhaust the local NameCert surface. □

Theorem 3495.3 (Frechet space metrizable complete handoff)**.** *Let $F = (V, L, M, C, Q, H, R, P, N)$ be an accepted* $\mathsf{FrechetSpace}^{\uparrow}$ *carrier. Every downstream functional-analysis, completion, or locally convex consumer that asks for metrizability and completeness must factor through*

$$V, L, M, C, Q \longmapsto H, R, P, N.$$

The handoff exposes the topological-vector source, locally convex source, compatible metric, completeness ledger, metric-completion boundary, transport, replay, provenance, and local naming, and it exports no host complete locally convex space, selected compatible metric, quotient completion, countable-choice row, or infinite seminorm-family object.

Proof. Start with a downstream request for a Frechet-space read. The vector and topology data are not independent host structure; they are obtained from the $\mathsf{TopVecSpace}^{\uparrow}$ row V.

The locally convex evidence is read next through L. This forces finite seminorm probes and convex balanced neighbourhood rows to remain visible before any metric or completion claim is consumed.

The metric and completeness portion then passes through M, C, Q. The compatible metric row M supplies the displayed distance and topology comparison, C supplies the finite completeness ledger, and Q exposes only the $\mathsf{MetricCompletion}^{\uparrow}$ handoff boundary.

The structural rows H, R, P, N preserve that same route under transport, replay, provenance, and local naming. Therefore a consumer receives a metrizable complete locally convex carrier only as the displayed finite packet above, not as a host Frechet space, selected metric, quotient completion, choice principle, or infinite seminorm family. □

Falsifiable prediction: Any accepted $\mathsf{FrechetSpace}^{\uparrow}$ consumer that cites complete metrizability without first reading $V, L, M, C, Q, H, R, P, N$ refutes the carrier surface.

Independence witness: `metriccompletion`, `locally_convex_space`, `topvecspace`: no listed sibling is bijective with $\mathsf{FrechetSpace}^{\uparrow}$, because this carrier alone binds topological-vector data, locally convex seminorm and neighbourhood rows, a compatible metric, completeness evidence, metric-completion handoff, transport, replay, provenance, and local NameCert rows into one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetSpace}^{\uparrow}$ packet is generated from a topological-vector source, a locally convex source, a compatible metric row, a completeness ledger, a metric-completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3495.1, Definition 3495.2, and Definition 3495.3 seed the finite Frechet-space carrier over $V, L, M, C, Q, H, R, P, N$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, barrelledness, Baire category, nuclearity, selected compatible metrics, quotient completions, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked topological-vector source, locally convex source, compatible metric, completeness ledger, metric-completion handoff, transport, replay, provenance, and local naming rows for BEDC.Derived.FrechetSpaceUp.

After the complete metric row of Definition 3495.1 has been displayed, any $\mathsf{FrechetSpace}^{\uparrow}$ consumer that needs a Baire-category conclusion must leave the Frechet carrier through the theorem route of chapter 3570 and the inspected complete-metric surface of chapter 3535. The Frechet packet supplies local convexity, topological-vector continuity, compatible metric data, and completion-facing rows; the dense-open theorem route is a separate sibling surface.

Theorem 3495.4 (Frechet Baire dependency route)**.** *Every accepted* $\mathsf{FrechetSpace}^{\uparrow}$ *read that asks for Baire-category evidence factors first through the complete metric row* C *and the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff* Q *of Definition 3495.1, and then through the* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *and* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *chapters cited above. The route adds no Hahn–Banach separation, selected generic point, countable-choice schedule, host intersection object, or ambient complete locally convex space to the Frechet carrier.*

Proof. Project the Frechet carrier as $F = (V, L, M, C, Q, H, R, P, N)$. The rows V, L, M, C, Q expose topological-vector structure, local convexity, compatible metric data, completeness evidence, and the metric-completion boundary before any theorem consumer reads the packet.

A Baire-category request is not one of those Frechet rows. Route it through chapter 3535 for the inspected complete-metric Baire surface and through chapter 3570 for the theorem-level dense-open package.

The remaining rows H, R, P, N only transport, replay, source, and name the displayed route. Since no row stores Hahn–Banach separation, a selected generic point, a countable-choice schedule,

a host intersection object, or an ambient complete locally convex space, none can be exported by the dependency route. □

Theorem 3495.5 (Frechet Baire-category completeness route)**.** *Every* $\mathsf{FrechetSpace}^{\uparrow}$ *consumer that needs dense-open completeness must expose the full carrier*

$$F = (V, L, M, C, Q, H, R, P, N)$$

and then pass through chapter 3570 and chapter 3535. The Frechet chapter contributes the displayed vector, local-convex, compatible-metric, complete-metric, completion-handoff, transport, replay, provenance, and local naming rows; the dense-open conclusion remains a theorem-level sibling route rather than a hidden field of F*.*

Proof. Project the accepted carrier as $F = (V, L, M, C, Q, H, R, P, N)$. The rows V, L, M, C, Q expose the topological-vector, local-convex, compatible-metric, complete-metric, and completion-handoff data needed before a dense-open consumer can even form its request.

Now apply the theorem route. The complete-metric surface is supplied by chapter 3535, while the dense-open theorem statement is supplied by chapter 3570. These two sibling chapters are therefore the only exits from the Frechet carrier toward Baire-category completeness.

The remaining rows H, R, P, N preserve and name the route. Since they contain only componentwise transport, replay, provenance, and the local $\mathsf{NameCert}_{\mathsf{FrechetSpace}^{\uparrow}}$ row, they cannot introduce a selected generic point, a countable-choice schedule, or an ambient complete locally convex space outside the displayed dependency route. □

Every $\mathsf{FrechetSpace}^{\uparrow}$ consumer reads the locally convex linear-topology surface of chapter 3386 before it treats the compatible metric as complete. The route then passes through the metric-completion handoff of chapter 1506, so Baire-category and metric-completion readers receive the displayed locally convex, complete-metric, transport, replay, provenance, and local naming rows rather than a host Frechet space or an unbounded seminorm schedule. Every $\mathsf{FrechetSpace}^{\uparrow}$ read first consumes the topological vector-space carrier of chapter 205 and the locally convex carrier of chapter 3386. It then reads the compatible metric row M, the completeness ledger C, and the $\mathsf{MetricCompletion}^{\uparrow}$ handoff row Q supplied by the metric-completion route of chapter 1506. The handoff is only the displayed carrier route needed to replay a complete locally convex packet through the local NameCert surface; it exports no selected compatible metric, quotient completion, countable-choice schedule, or infinite seminorm family.

Chapter 3496

A Concrete Naming Certificate for $\mathsf{FinitePartitionMesh}^{\uparrow}$

Following Bishop and Bridges on constructive partitions of real intervals, the $\mathsf{FinitePartitionMesh}^{\uparrow}$ packet records the finite dyadic mesh surface used before interval estimates may pass to Darboux or regular-completion consumers. It sits between the real endpoint seal of chapter 38, the dyadic tolerance rows of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the closed bounded interval Darboux partition route of chapter 3429, and the finite Darboux-sum boundary of chapter 1880. The packet names only displayed endpoint rows, dyadic breakpoints, mesh adjacency, refinement witnesses, and downstream handoff rows; it is not a selected tagged partition, an open-cover compactness theorem, a quotient equality of functions, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 3496.1 (Finite partition mesh carrier)**.** *A* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, W, Q, M, R, B, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *closed-interval endpoint row, exposing the lower endpoint, upper endpoint, endpoint order, and terminal real seal used by the mesh.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *breakpoint ledger naming the dyadic cut points and the dyadic mesh bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family in which endpoint and breakpoint reads are inspected.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed endpoints and dyadic breakpoints.*
5. *M is the finite mesh row listing the cells, endpoint adjacency, left-to-right order, and boundary inclusion witnesses.*
6. *R is the displayed common-refinement row comparing M with any accepted finite dyadic submesh over the same interval.*
7. *B is the* $\mathsf{ClosedBoundedIntervalDarbouxPartition}^{\uparrow}$ *handoff row reached only after I, D, W, Q, M, R have been displayed.*
8. *S is the* $\mathsf{DarbouxSum}^{\uparrow}$ *consumer row for finite lower and upper sum reads over the cells of M or its displayed refinement.*

9. *H records componentwise* hsame *transport of interval endpoints, dyadic breakpoints, windows, readbacks, mesh cells, refinement witnesses, Darboux handoff, sum rows, provenance, and local naming.*

10. *C records displayed* Cont *replay from endpoint rows to dyadic breakpoints, from breakpoints to mesh cells, and from mesh refinement to Darboux partition and sum handoffs.*

11. *P is the* Pkg *provenance over* $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalDarbouxPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePartitionMesh}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite partition, a selected tag family, quotient function equality, measure completion, open-cover compactness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness beyond the displayed endpoint seal.*

Lean4 ✓ `BEDC.Derived.FinitePartitionMeshUp.FinitePartitionMeshTasteGate single carrier alignment decode encode`

Theorem 3496.2 (Finite partition mesh refinement obligations)**.** *For the carrier of Definition 3496.1, the local* $\mathsf{NameCert}_{\mathsf{FinitePartitionMesh}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (I, D, W, Q, M, R, B, S, H,$ interval endpoint exposure through I; dyadic breakpoint and mesh-bound exposure through D; finite observation windows through W; regular rational readback through Q; mesh-cell exposure through M; common-refinement evidence through R; closed bounded interval Darboux partition handoff through B; finite Darboux-sum handoff through S; componentwise transport through H; displayed continuation replay through C; provenance through P; and local naming through N.*

Every accepted refinement request must therefore route a $\mathsf{Real}^{\uparrow}$ *interval consumer, a* ClosedBoundedIntervalDarbo *consumer, or a* $\mathsf{DarbouxSum}^{\uparrow}$ *consumer through the finite path*

$$I \longmapsto D \longmapsto W \longmapsto Q \longmapsto M \longmapsto R \longmapsto B \longmapsto S \longmapsto (H, C, P, N)$$

before any lower-sum, upper-sum, or interval estimate can be read. The route exports no selected tags, quotient stream, host partition predicate, countable-choice schedule, open-cover compactness row, measure-completion object, or ambient real-completeness theorem.

Proof. Project the displayed packet. The interval row I, dyadic ledger D, finite windows W, regular readback Q, and mesh row M are all finite certificate rows, so the carrier exposes a bounded list of cells before a refinement witness can be inspected.

Read the refinement row next. Since R compares mesh cells only through the already displayed endpoint, breakpoint, window, and readback rows, every common refinement remains a finite dyadic submesh over the same interval boundary.

Finally inspect the Darboux handoff rows. The rows B and S are downstream of the finite mesh and its refinement witness, while H, C, P, N only transport, replay, source, and name that route. The excluded tag, quotient, choice, compactness, measure, and ambient-completeness objects have no carrier coordinate, so the listed rows exhaust the refinement obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePartitionMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitePartitionMesh}^{\uparrow}$ packet is generated from RealUp interval endpoint rows, DyadicRatCoreUp breakpoint rows, StreamNameUp finite windows, RegSeqRatUp readbacks, finite mesh cells, a displayed common-refinement row, ClosedBoundedIntervalDarbouxPartitionUp and DarbouxSumUp handoff rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FinitePartitionMesh}^{\uparrow}}$, seed)

Scope closed: Definition 3496.1 and Definition 3496.2 seed the finite dyadic partition-mesh route over $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalDarbouxPartition}^{\uparrow}$, and $\mathsf{DarbouxSum}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePartitionMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected tags, quotient stream equality, host partition predicates, countable choice, open-cover compactness, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, breakpoint exactness, finite mesh refinement, Darboux partition handoff, Darboux-sum handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.FinitePartitionMeshU

Chapter 3497

A Concrete Naming Certificate for ChoiceWindowSequence$^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on choice sequences, the ChoiceWindowSequence$^{\uparrow}$ packet isolates the finite inspected windows by which a choice sequence becomes available to an L10 StreamName$^{\uparrow}$ consumer. It refines the finite-prefix surface of chapter 1482, keeps the lawless-sequence boundary of chapter 1495 visible, and reads Baire-style prefix data from chapter 334. The packet uses Nat$^{\uparrow}$ positions and answer rows, Bool$^{\uparrow}$ presence rows, and the StreamName$^{\uparrow}$ hand-off only as displayed finite data; it does not import countable choice, a completed host sequence, quotient stream equality, or a global law selecting all future answers.

Definition 3497.1 (ChoiceWindowSequence finite-window carrier)**.** *A* ChoiceWindowSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Q, L, B, S, I, A, O, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* ChoiceSequence$^{\uparrow}$ *prefix packet whose currently available answers may be inspected;*
2. *L is the sibling* LawlessSequence$^{\uparrow}$ *boundary row, recording that the packet reads only displayed answers and no governing law for future positions;*
3. *B is the* BaireSpace$^{\uparrow}$ *finite-prefix context in which the window is interpreted;*
4. *S is the* StreamName$^{\uparrow}$ *schedule naming the finite positions requested by the consumer;*
5. *I is the* Nat$^{\uparrow}$ *index ledger listing the positions of the inspected window;*
6. *A is the* Nat$^{\uparrow}$ *answer ledger attached to the positions in I;*
7. *O is the* Bool$^{\uparrow}$ *presence classifier for each requested position, distinguishing displayed answers from absent future data;*
8. *H records componentwise* hsame *transport for Q, L, B, S, I, A, O and the local naming row;*
9. *C records displayed* Cont *replay of the same finite-window read;*
10. *P is the* Pkg *provenance over* ChoiceWindowSequence$^{\uparrow}$*,* ChoiceSequence$^{\uparrow}$*,* LawlessSequence$^{\uparrow}$*,* BaireSpace$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* Nat$^{\uparrow}$*,* Bool$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoiceWindowSequence}^\uparrow}$ *row.*
The carrier accepts only the finite window displayed by S, I, A, O. It exports no completed function $\mathsf{Nat}^\uparrow \to \mathsf{Nat}^\uparrow$*, no countable-choice selector, no quotient infinite stream, no hidden tail oracle, and no law determining positions outside the displayed window.*

Lean4 ✓ `BEDC.Derived.ChoiceWindowSequenceUp.ChoiceWindowSequenceTasteGate single carrier alignment`

Theorem 3497.2 (ChoiceWindowSequence carrier admission obligations)**.** *For every accepted* $\mathsf{ChoiceWindowSequence}^\uparrow$ *carrier $W = (Q, L, B, S, I, A, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChoiceWindowSequence}^\uparrow}$ *surface consists exactly of carrier admission for the source* $\mathsf{ChoiceSequence}^\uparrow$ *row, the lawless-sequence boundary row, the* $\mathsf{BaireSpace}^\uparrow$ *prefix context, the finite* $\mathsf{StreamName}^\uparrow$ *schedule, the* $\mathsf{Nat}^\uparrow$ *index and answer ledgers, the* $\mathsf{Bool}^\uparrow$ *presence classifier, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Project the carrier of Definition 3497.1. The visible coordinates are precisely $Q, L, B, S, I, A, O, H, C, P, N$, so carrier admission reads no object outside the displayed finite packet.

The source rows Q, L, B identify the traditional choice-sequence, lawless-sequence, and Baire-prefix context. The inspection rows S, I, A, O then name the finite schedule, the requested positions, the displayed answers, and the presence decisions.

The structural rows H, C, P, N transport, replay, source, and name the same finite window. Since the carrier has no coordinate for a total host sequence, countable-choice selector, quotient stream equality, hidden tail oracle, or global law, the listed rows exhaust the local NameCert obligation surface. □

Theorem 3497.3 (ChoiceWindowSequence window classifier stability)**.** *Let $W = (Q, L, B, S, I, A, O, H, C, P, N)$ and $W' = (Q', L', B', S', I', A', O', H', C', P', N')$ be accepted* $\mathsf{ChoiceWindowSequence}^\uparrow$ *carriers. If the displayed* $\mathsf{StreamName}^\uparrow$ *schedules,* $\mathsf{Nat}^\uparrow$ *index ledgers,* $\mathsf{Nat}^\uparrow$ *answer ledgers, and* $\mathsf{Bool}^\uparrow$ *presence classifiers agree componentwise under the available* hsame *rows, then every public finite-window read classifies W and W' the same way. The classifier is insensitive to tail values or laws outside the displayed window.*

Proof. Begin with the displayed schedules and ledgers. Agreement of S, I, A, O and S', I', A', O' gives the same requested positions, the same visible answer rows, and the same present-or-absent decisions for every finite request a consumer may replay.

The source context is read only through those windows. The $\mathsf{ChoiceSequence}^\uparrow$ and $\mathsf{BaireSpace}^\uparrow$ rows supply finite-prefix data, while the $\mathsf{LawlessSequence}^\uparrow$ row records that no law for undisplayed positions is part of the packet.

Finally transport the read through H, H' and replay it through C, C'. Since public reads factor through the displayed window and the carrier contains no tail oracle, completed function, quotient stream, or countable-choice selector, no classifier distinction can be obtained outside the agreed finite data. □

Theorem 3497.4 (ChoiceWindowSequence StreamName handoff)**.** *Every* $\mathsf{StreamName}^\uparrow$ *consumer of an accepted* $\mathsf{ChoiceWindowSequence}^\uparrow$ *packet factors through the finite route*

$$\mathsf{ChoiceSequence}^\uparrow,\ \mathsf{LawlessSequence}^\uparrow,\ \mathsf{BaireSpace}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow,\ \mathsf{Nat}^\uparrow,\ \mathsf{Bool}^\uparrow \longmapsto \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Na}$$

The handoff supplies a finite inspected choice-sequence window to the L10 StreamName-facing interface and supplies no countable choice, total host sequence, quotient stream equality, selected future value, or law for undisplayed positions.

Proof. Read the source side first. The consumer receives a choice-sequence prefix row, a lawless-sequence boundary row, and a Baire-prefix context, all as finite displayed packets.

Next open the StreamName-facing window. The schedule row S selects the inspected positions, the $\mathsf{Nat}^{\uparrow}$ rows I, A list the requested indices and displayed answers, and the $\mathsf{Bool}^{\uparrow}$ row O records which requested positions are currently present.

Finally pass through H, C, P, N. Componentwise transport and continuation replay preserve the same finite window, while provenance and local naming attach the packet to the BEDC kernel rows. No excluded global choice object is introduced by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceWindowSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoiceWindowSequence}^{\uparrow}$ packet is generated from a ChoiceSequence prefix row, LawlessSequence boundary row, BaireSpace finite-prefix context, StreamName finite schedule, NatUp index and answer ledgers, BoolUp presence classifiers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceWindowSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3497.1, Definition 3497.2, Definition 3497.3, and Definition 3497.4 seed the finite inspected-window route for choice-sequence data consumed by StreamName-facing L10 packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceWindowSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, a total host sequence, quotient stream equality, selected future values, a global law for undisplayed positions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window classifier stability, StreamName handoff, transport, continuation, provenance, and non-escape proofs for BEDC.Derived.ChoiceWindowSequenceUp.

Chapter 3498

A Concrete Naming Certificate for $\mathsf{ProximinalSet}^{\uparrow}$

Following Bishop and Bridges on located sets in metric spaces, a proximinal set is read here as a located subset whose displayed distance data may be accompanied by finite distance-attainment witnesses. The $\mathsf{ProximinalSet}^{\uparrow}$ packet sits between the located-subset interface of chapter 1541, the located-metric handoff of chapter 1533, the real distance seal of chapter 38, and the Hilbert or convex projection specialization of chapter 2356. It records displayed distance-attainment witness rows and deliberately does not export a host nearest-point selector, quotient point equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3498.1 (Proximinal set carrier)**.** *A* $\mathsf{ProximinalSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (X, L, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the parent* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, distance witness, metric-law ledger, and finite observation histories.*
2. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row. It supplies the displayed subspace admission, located-distance ledger, rational comparison windows,* $\mathsf{Real}^{\uparrow}$ *distance seal, and* $\mathsf{LocatedMetric}^{\uparrow}$ *handoff already exposed by the located-set packet.*
3. *D is the located-metric distance-read row. It records that the ambient point, admitted set row, and requested tolerance are read through the* $\mathsf{LocatedMetric}^{\uparrow}$ *and* $\mathsf{LocatedSet}^{\uparrow}$ *interfaces before any attainment evidence is inspected.*
4. *W is the distance-attainment witness row. For each displayed request it stores a finite admitted point row and a finite equality-of-distance certificate tying that point to the real distance name supplied by L and D.*
5. *E is the real attainment seal. It records the* $\mathsf{Real}^{\uparrow}$ *comparison between the displayed distance name and the displayed witness point distance, without adding trichotomy, quotient point equality, or ambient real completeness.*
6. *H stores componentwise* hsame *transport for the parent metric row, located-set row, located-metric distance read, attainment witness row, real seal, continuation replay, provenance, and local naming row.*

7. *C stores displayed* Cont *replay from ambient point observations into located-set distance data, from located-set distance data into D, from D into W, and from the witness row into E.*
8. *P is the* Pkg *provenance over* $\mathsf{ProximinalSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProximinalSet}^{\uparrow}}$ *row.*

The classifier compares packets only through $X, L, D, W, E, H, C, P, N$. It has no coordinate for a host nearest-point function, quotient equality of ambient points, trichotomy, open-cover compactness, a Hilbert projection theorem, or full ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.ProximinalSetUp.ProximinalSetUp`

Theorem 3498.2 (Proximinal set NameCert obligations)**.** *For an accepted* $\mathsf{ProximinalSet}^{\uparrow}$ *carrier $Z = (X, L, D, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProximinalSet}^{\uparrow}}$ *obligations are exactly carrier admission, parent metric compatibility, located-set distance compatibility, located-metric read ordering, displayed distance-attainment witness stability, real attainment seal readback, and structural non-escape. These obligations are discharged by the finite route*

$$X \longmapsto L \longmapsto D \longmapsto W \longmapsto E$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.ProximinalSetUp.ProximinalSetTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 3498.1. The tuple lists the parent metric row, located-set row, located-metric distance read, attainment witness row, real seal, and structural rows.

Parent metric compatibility and located-set distance compatibility are read first. The consumer sees ambient points through X and sees set distance data through L, so the packet inherits the nearest-point refusal boundary of the located-set interface before any attainment row can be consumed.

The row D fixes the located-metric read order. It prevents an attainment witness from being read as a primitive selector by forcing the request through the located-set and located-metric distance route.

The witness row W then stores only displayed request-specific evidence: an admitted point row and a finite equality-of-distance certificate. The real seal E compares that displayed point distance with the real distance name already read from L and D.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for a host nearest-point function, quotient point equality, trichotomy, open-cover compactness, Hilbert projection, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 3498.3 (Proximinal set distance-witness route)**.** *Every accepted* $\mathsf{ProximinalSet}^{\uparrow}$ *packet exposes distance-attainment data only through the route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{LocatedSet}^{\uparrow} \longmapsto \mathsf{LocatedMetric}^{\uparrow} \longmapsto W \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a $\mathsf{MetricProjection}^{\uparrow}$ *or compactness consumer may read a displayed witness row, but it must supply any host nearest-point selector, quotient point equality principle, trichotomy branch, open-cover compactness argument, or ambient real-completeness principle outside the packet.*

Proof. Start with Definition 3498.1. The only analytic rows available before the witness are the parent metric row X, the located-set row L, and the located-metric distance read D.

Apply Definition 1541.3 and Definition 1541.4. These force located-set distance data through parent metric observations, subspace admission, located-distance ledgers, rational windows, and a $\mathsf{Real}^{\uparrow}$ seal before a consumer can read the distance as real data.

The $\mathsf{ProximinalSet}^{\uparrow}$ carrier then adds W only as a displayed witness row for that already-read distance. It does not turn the row into a host function from ambient points to nearest points, because the witness is indexed by the finite request already present in the packet.

The terminal seal E records the equality-of-distance readback for the displayed witness. The structural rows H, C, P, N preserve the same route, so downstream projection or compactness consumers receive a finite distance-attainment witness boundary rather than quotient point equality, trichotomy, open-cover compactness, Hilbert projection, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{ProximinalSet}^{\uparrow}$ read from an accepted packet factors through the parent $\mathsf{Met}^{\uparrow}$ row, $\mathsf{LocatedSet}^{\uparrow}$ distance interface, $\mathsf{LocatedMetric}^{\uparrow}$ handoff, displayed distance-attainment witness row, $\mathsf{Real}^{\uparrow}$ attainment seal, componentwise transport, continuation replay, provenance, and local NameCert before any projection, compactness, or completion consumer reads the route.

Independence witness: locatedset, locatedmetric, metricprojection, real: $\mathsf{ProximinalSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries displayed located-set distance data and request-indexed distance-attainment witness rows while refusing host nearest-point selection, quotient point equality, trichotomy, open-cover compactness, and ambient real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ProximinalSet}^{\uparrow}}$.

Constructive story: A $\mathsf{ProximinalSet}^{\uparrow}$ packet starts from a parent Metric row, reads a LocatedSet distance interface, routes the distance through a LocatedMetric handoff, records displayed request-indexed distance-attainment witnesses, seals the equality of distance in a RealUp row, and preserves the same route through componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProximinalSet}^{\uparrow}}$, seed)

Scope closed: Definition 3498.1, Definition 3498.2, and Definition 3498.3 seed the finite proximinal-set interface through located-set distance data, located-metric reads, displayed attainment witnesses, and real distance seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProximinalSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host nearest-point selection, quotient point equality, trichotomy, open-cover compactness, Hilbert projection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, parent metric compatibility, located-set distance compatibility, located-metric read ordering, displayed distance-attainment witness stability, RealUp attainment seal readback, structural non-escape, Nontrivial ProximinalSetUp, and FieldFaithful ProximinalSetUp.

Chapter 3499

A Concrete Naming Certificate for $\mathsf{CompletionUnitComparison}^{\uparrow}$

Following Bourbaki and Bishop-style completion theory, the $\mathsf{CompletionUnitComparison}^{\uparrow}$ packet records the finite route by which the Cauchy-completion unit is compared with the naturality and triangle-identity certificates that consume it. It sits after the unit packet of chapter 1527, the triangle surface of chapter 2256, and the naturality comparison of chapter 2102. The chapter names a displayed comparison object for unit-facing completion reads; it does not import quotient completions, selected representatives, host equality of completed objects, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3499.1 (Completion unit comparison carrier)**.** *A* $\mathsf{CompletionUnitComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (Q, N, T, S, R, H, C, P, L)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row exposing the source-to-completion unit used by the comparison.*
2. *N is the* $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *row recording naturality compatibility for the same displayed unit.*
3. *T is the* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *row recording triangle-identity compatibility for the same unit-facing route.*
4. *S is the source-and-target ledger over the finite stream, regular-rational, dyadic-tolerance, and terminal Real rows read by the unit comparison.*
5. *R is the refusal row excluding quotient completion equality, selected representatives, host equality of completed carriers, countable-choice schedules, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*
6. *H records componentwise* hsame *transport for unit, naturality, triangle, source-target, refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the unit row through naturality compatibility and triangle compatibility before any consumer reads the comparison.*
8. *P is the* Pkg *provenance over* $\mathsf{CompletionUnitComparison}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}$ $\mathsf{CompletionUnitTriangle}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{CompletionUnitComparison}^{\uparrow}}$ *row.*

The carrier compares only displayed completion-unit routes. It has no coordinate for host quotient completions, representative selection, equality of completed objects, choice principles, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionUnitComparisonUp.CompletionUnitComparisonTasteGate single carrier alignment`

Theorem 3499.2 (Completion unit comparison NameCert obligations)**.** *For every accepted* CompletionUnitCompar *carrier*

$$U = (Q, N, T, S, R, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionUnitComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *unit-comparison exposure, requiring every comparison consumer to cite the displayed* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row Q;*
2. *naturality compatibility, requiring the comparison to pass through the* $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$ *row N for the same source and target data;*
3. *triangle compatibility, requiring the comparison to pass through the* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *row T before any completion-facing return is exported;*
4. *transport and provenance stability, requiring H, C, P, L to transport, replay, source, and name only the rows Q, N, T, S, R;*
5. *refusal of host quotient completion, requiring the row R to exclude quotient equality, selected representatives, host equality of completed carriers, countable-choice schedules, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No unit-comparison obligation is stored outside these rows.

Proof. Project the accepted carrier. The comparison-facing rows are $Q, N, T, S, R, H, C, P, L$.

The unit row Q supplies the only source-to-completion entry. Naturality compatibility must therefore read the same source and target data through N, and triangle compatibility must read the same unit-facing route through T.

The transport, replay, provenance, and local naming rows H, C, P, L preserve exactly this displayed route. Since the refusal row R contains the only host-side exclusions and no quotient-completion coordinate appears in the carrier, the five listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{CompletionUnitComparison}^{\uparrow}$ consumer factors through displayed $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionComparisonNaturality}^{\uparrow}$, $\mathsf{CompletionUnitTriangle}^{\uparrow}$, source-target ledger, refusal, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: cauchycompletionunit, cauchy-completion-comparison-naturality, completion-unit-triangle: the unit packet records source admission without the comparison route, the naturality packet records functorial compatibility without the triangle return, and the triangle packet records return compatibility without the naturality comparison. None is bijective to $\mathsf{CompletionUnitComparison}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionUnitComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompletionUnitComparison}^{\uparrow}$ packet is generated from a CauchyCompletionUnit row, CauchyCompletionComparisonNaturality row, CompletionUnitTriangle row, source-target ledger, refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompletionUnitComparison}^{\uparrow}}$, seed)

Scope closed: Definition 3499.1 and Definition 3499.2 seed the finite completion-unit comparison route over unit, naturality, triangle, transport, provenance, and refusal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompletionUnitComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host equality of completed carriers, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked unit-comparison exposure, naturality compatibility, triangle compatibility, transport and provenance stability, and refusal exactness for BEDC.Derived.CompletionUnitComparisonUp.

Chapter 3500

A Concrete Naming Certificate for PoincareBoundaryFixedTransport$^{\uparrow}$

The PoincareBoundaryFixedTransport$^{\uparrow}$ packet realizes the boundary-fixed disk transport reading of Definition 9463.10 as finite disk-map, boundary, hyperbolic-metric, reversible-transport, provenance, refusal, and local naming rows. It sits after the disk-coordinate surface of chapter 377, the disk-phase transport packet of chapter 3455, the metric-read surface of chapter 3474, and the geodesic far-end boundary of chapter 3491. The chapter names a finite boundary-preserving transport object; it does not turn the Poincare disk into a host plane, identify ideal boundary points by quotient equality, choose a global geodesic representative, or assert physical observer motion.

Definition 3500.1 (Poincare boundary-fixed transport carrier)**.** *A* PoincareBoundaryFixedTransport$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, F, M, T, P, R, H, C, A, N)$$

with the following displayed rows:

1. *D is the* UnitDisk$^{\uparrow}$ *disk-map row, exposing the finite source and target disk-coordinate observations.*
2. *F is the boundary far-end row, recording the displayed* HyperbolicGeodesicBoundary$^{\uparrow}$ *far-end that must remain fixed by the transport.*
3. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row over the same disk-map data.*
4. *T is the reversible* PoincareDiskPhaseTransport$^{\uparrow}$ *row carrying the phase-transport route between the displayed disk observations.*
5. *P is the provenance row tying D, F, M, T to the hyperbolic phase vision and to the sibling UnitDisk, HyperbolicMetric, PoincareDiskPhaseTransport, and HyperbolicGeodesicBoundary packets.*
6. *R is the refusal row excluding host disk automorphisms, quotient ideal-boundary equality, selected geodesic representatives, physical observer motion, and global cosmological dynamics.*
7. *H records componentwise* hsame *transport for disk-map, boundary far-end, metric-read, reversible-transport, provenance, refusal, replay, and local naming rows.*
8. *C records displayed* Cont *replay through disk-map admission, boundary far-end preservation, metric-read compatibility, reversible transport, provenance, and refusal.*

9. *A records the local transport audit row: every accepted replay must preserve the displayed boundary far-end while reading the same disk-map and metric rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}}$ *row.*

The carrier exports boundary-fixed disk transport only through $D, F, M, T, P, R, H, C, A, N$. It has no coordinate for a host-level disk automorphism, quotient boundary point, selected infinite geodesic, physical observer trajectory, or completed hyperbolic plane.

Lean4 (definition) `BEDC.Derived.PoincareBoundaryFixedTransportUp.PoincareBoundaryFixedTransportUp`
Lean4 ✓ `BEDC.Derived.PoincareBoundaryFixedTransportUp.PoincareBoundaryFixedTransportTasteGate`
`single carrier alignment`

Theorem 3500.2 (Poincare boundary-fixed transport NameCert obligations)**.** *For every accepted* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *carrier*

$$B = (D, F, M, T, P, R, H, C, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}}$ *surface consists exactly of disk-map admission, boundary far-end preservation, hyperbolic-metric read compatibility, reversible Poincare-disk transport, provenance, refusal exactness, componentwise* hsame *transport, displayed* Cont *replay, local transport audit, and local naming.*

Every accepted transport preserving the boundary far-end must factor through

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, BHist, hsame, Cont, Pk

Proof. Project the accepted carrier. Disk-map admission is row D, the fixed far-end is row F, the metric read is row M, and the reversible disk transport is row T.

The provenance and refusal rows P, R bind these four rows to the sibling packets and exclude host-level automorphisms, quotient boundary equality, selected geodesics, physical observer motion, and global cosmology.

Transport through H and replay through C preserve the same displayed route. The audit row A checks that the far-end row F is the same before and after the transport, and N names the resulting packet. No further row remains, so the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ transport preserving the boundary far-end factors through displayed $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, provenance, refusal, hsame, Cont, and local NameCert rows.

Independence witness: unitdisk, poincare-disk-phase-transport, hyperbolic-metric, hyperbolic-geodesic-boundary: the UnitDisk packet records disk coordinates without reversible transport or fixed far-end data, the Poincare disk phase-transport packet records reversible transport without fixed-boundary audit, the HyperbolicMetric packet records metric reads without transport preservation, and the HyperbolicGeodesicBoundary packet records far-end incidence without a disk-map transport replay. None is bijective to $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ packet is generated from UnitDisk disk-map rows, HyperbolicGeodesicBoundary far-end rows, HyperbolicMetric metric reads, PoincareDiskPhaseTransport reversible transport, provenance, refusal exactness, componentwise hsame transport, displayed Cont replay, local transport audit, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}}$, seed)

Scope closed: Definition 3500.1 and Definition 3500.2 seed the finite boundary-fixed disk transport route over disk-map, boundary, metric, transport, provenance, refusal, replay, audit, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareBoundaryFixedTransport}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host disk automorphisms, quotient boundary equality, selected geodesic representatives, physical observer motion, global cosmological dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-map admission, boundary far-end preservation, metric-read compatibility, reversible transport, provenance, refusal exactness, transport, replay, audit, and local naming for BEDC.Derived.PoincareBoundaryFixedTransportUp.

Chapter 3501

A Concrete Naming Certificate for $\mathsf{MetricCompletionNaturality}^{\uparrow}$

Following Bishop and Bridges on constructive metric completion and uniform continuity, the $\mathsf{MetricCompletionNaturality}^{\uparrow}$ packet records the finite L10 square by which a uniformly continuous source map is read by completion-facing consumers. It sits over the metric-completion surface of chapter 1506, the map carrier of chapter 130, the extension route of chapter 769, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the displayed naturality packet; it is not a quotient completion construction, not a selected representative principle, not host function equality, not countable choice, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3501.1 (Metric completion naturality carrier)**.** *A* $\mathsf{MetricCompletionNaturality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (M_X, M_Y, F, E, S, R, A, H, C, P, L)$$

with the following displayed rows:

1. M_X *is the source* $\mathsf{MetricCompletion}^{\uparrow}$ *row, exposing the finite Cauchy-window requests inspected before the map is applied.*
2. M_Y *is the target* $\mathsf{MetricCompletion}^{\uparrow}$ *row, exposing the completion-facing consumer reached after the map and extension rows have been displayed.*
3. F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the displayed source map and the finite continuity data it exposes to the packet.*
4. E *is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *row that transports the same displayed map through the completion interface.*
5. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the source completion, target completion, and extension reads.*
6. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which numerical tolerance requests are answered.*
7. A *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream window and regular readback rows have been fixed.*
8. H *records componentwise* hsame *transport for the source completion, target completion, map, extension, stream-window, readback, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the naturality route*

$$M_X \longmapsto F, E \longmapsto S, R, A \longmapsto M_Y.$$

10. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionNaturality}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionNaturality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M_X, M_Y, F, E, S, R, A, H, C, P, L$. It has no coordinate for quotient completion equality, selected representatives, host function equality, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.MetricCompletionNaturalityUp.MetricCompletionNaturalityTasteGate single carrier alignment`

Theorem 3501.2 (Metric completion naturality NameCert obligations)**.** *For every accepted* MetricCompletionNatu *carrier*

$$N = (M_X, M_Y, F, E, S, R, A, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionNaturality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source completion, target completion, continuous-map, uniform-extension, stream-window, regular-readback, real-seal, transport, replay, provenance, and local naming rows;*
2. *source-before-extension exposure, requiring any completion-facing read to inspect M_X and F before the extension row E can be consumed;*
3. *target-consumer routing, requiring M_Y to be reached only after the displayed extension route has passed through S, R, A;*
4. *finite observation exactness, requiring the shared* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows to be the only numerical readback route between the extension row and the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *classifier stability, requiring componentwise* hsame *transport through H and displayed replay through C to preserve the same finite naturality route;*
6. *ledger non-escape, excluding quotient completions, selected representatives, host function equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking from the packet.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3501.1. The accepted packet displays exactly the two completion rows, the map row, the extension row, the finite observation rows, and the structural rows.

Source-before-extension exposure is read from M_X, F, E. The map row F is available only with the source completion observations in M_X, and the extension row E records the completion-facing transport of that same displayed map.

Target-consumer routing is read from M_Y together with S, R, A. The target completion row can be offered to a consumer only after the extension has exposed the finite stream windows, regular readback, and real seal used by the route.

Classifier stability is componentwise transport through H followed by replay through C. Since P and L only source and name the same displayed route, there is no separate row from which quotient completion equality, selected representatives, host function equality, choice, ambient completeness, Lean verification, or bridge credentials could be projected. □

Theorem 3501.3 (Metric completion naturality consumer nonescape)**.** *Every completion-facing or real-seal-facing consumer of an accepted* $\mathsf{MetricCompletionNaturality}^{\uparrow}$ *carrier*

$$N = (M_X, M_Y, F, E, S, R, A, H, C, P, L)$$

must factor through the finite route

$$M_X, F \longmapsto E \longmapsto S, R, A \longmapsto M_Y \longmapsto H, C, P, L.$$

Consequently the consumer receives only the displayed source completion row, continuous-map row, uniform-extension row, shared finite window, regular readback, terminal real seal, target completion row, transport, replay, provenance, and local name. It exports no quotient completion, no selected representative, no host function equality, no countable-choice schedule, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no bridge-checking credential.*

Proof. Start with a completion-facing or real-seal-facing read of the carrier. Projection first exposes the source completion row M_X and the continuous-map row F, so the consumer cannot begin from a hidden completed representative or a host function.

The extension row E is then the only row carrying the displayed map through the completion interface. It does not add a quotient completion object; it only names the finite extension route attached to the same source and map rows.

The read next passes through S, R, A. These rows fix the finite observation windows, the regular rational readback, and the terminal real seal before the target completion row M_Y is available.

Finally H, C, P, L transport, replay, source, and name the same displayed route. Because the carrier has no further coordinates, the stated excluded principles cannot be exported by any consumer of the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionNaturality}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionNaturality}^{\uparrow}$ packet is generated from source and target MetricCompletion rows, a ContinuousMap row, a UniformContinuousExtension row, shared StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionNaturality}^{\uparrow}}$, seed)

Scope closed: Definition 3501.1, Definition 3501.2, and Definition 3501.3 seed the finite naturality route from source metric completion through displayed continuous-map extension to target completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionNaturality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-before-extension exposure, target-consumer routing, finite observation exactness, classifier stability, consumer nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.MetricCompletionNaturalityUp.

Chapter 3502

A Concrete Naming Certificate for AsymptoticSequence$^{\uparrow}$

Following Hardy and Littlewood on asymptotic comparison of sequences, the AsymptoticSequence$^{\uparrow}$ packet records finite tail-comparison data for displayed sequence names rather than importing host sequence equality or completed real analysis. It sits over the StreamName$^{\uparrow}$ window surface of chapter 126, the RegSeqRat$^{\uparrow}$ rational readback of chapter 301, the limit-facing handoff of chapter 1413, the symmetric tail comparison of chapter 1738, and the cofinal route comparison of chapter 1255. The packet is a named consumer for Real and Completion tail comparisons: it exposes finite windows, thresholds, readbacks, transport, replay, provenance, and local naming, while refusing quotient streams, arbitrary subsequence choice, and ambient Real$^{\uparrow}$ completeness.

Definition 3502.1 (AsymptoticSequence carrier)**.** *An* AsymptoticSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, T, W, M, Q, L, E, F, H, C, P, N)$$

with the following displayed rows:

1. *S and T are the two source sequence-name rows, read only through finite* StreamName$^{\uparrow}$ *windows.*
2. *W is the paired* StreamName$^{\uparrow}$ *window ledger naming the inspected source cells and the corresponding comparison windows.*
3. *M is the tail-threshold row recording which displayed unary tail must be reached before the comparison classifier is read.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the rational observations attached to W and M.*
5. *L is the* RealSequenceLimit$^{\uparrow}$ *handoff row available only after the scheduled windows and rational readbacks are displayed.*
6. *E is the* CauchyTailEquivalence$^{\uparrow}$ *provenance row for symmetric regular-Cauchy tail comparison.*
7. *F is the* CofinalTailEquivalence$^{\uparrow}$ *provenance row for cofinal reindexing and tail-route comparison.*
8. *H records componentwise* hsame *transport for the source rows, windows, threshold, readback, limit handoff, tail-equivalence rows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from each asymptotic-comparison request through $S, T, W, M, Q, L, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* AsymptoticSequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealSequenceLimit$^{\uparrow}$, CauchyTailEquivalence$^{\uparrow}$, CofinalTailEquivalence$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticSequence}^\uparrow}$ *row.*
The carrier exports no quotient equality of streams, no host asymptotic relation, no selected subsequence, no trichotomy row, and no ambient $\mathsf{Real}^\uparrow$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.AsymptoticSequenceUp.AsymptoticSequenceTasteGate single carrier alignment`

Theorem 3502.2 (AsymptoticSequence NameCert obligations)**.** *For every accepted* $\mathsf{AsymptoticSequence}^\uparrow$ *carrier*

$$A = (S, T, W, M, Q, L, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AsymptoticSequence}^\uparrow}$ *surface consists exactly of carrier admission for the two source sequence rows, paired* $\mathsf{StreamName}^\uparrow$ *windows, the displayed tail threshold,* $\mathsf{RegSeqRat}^\uparrow$ *readback,* $\mathsf{RealSequenceLimit}^\uparrow$ *handoff,* $\mathsf{CauchyTailEquivalence}^\uparrow$ *provenance,* $\mathsf{CofinalTailEquivalence}^\uparrow$ *provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted comparison reads W and M before Q, reads Q before L, E, F, and reaches H, C, P, N only as structural support for the same finite route.*

Proof. Project the carrier of Definition 3502.1. The source rows S, T expose only the finite $\mathsf{StreamName}^\uparrow$ windows stored in W, and the comparison cannot inspect a tail before the threshold row M has been displayed.

The readback row Q is then forced by the $\mathsf{RegSeqRat}^\uparrow$ surface of chapter 301. It consumes the same windows and threshold data rather than a host sequence value.

The analytic rows are downstream of that readback. The limit-facing handoff L is the finite route supplied by chapter 1413, while E and F record the symmetric and cofinal tail provenance of chapter 1738 and chapter 1255.

Finally H, C, P, N transport, replay, source, and name only the displayed route. Since no carrier coordinate contains quotient stream equality, host asymptotic comparison, a selected subsequence, trichotomy, or ambient completeness, none can appear as a local NameCert obligation. □

Theorem 3502.3 (AsymptoticSequence tail classifier)**.** *Let $A = (S, T, W, M, Q, L, E, F, H, C, P, N)$ and $A' = (S', T', W', M', Q', L', E', F', H', C', P', N')$ be accepted* $\mathsf{AsymptoticSequence}^\uparrow$ *carriers. Their accepted tail classifiers agree exactly when the paired source rows, displayed* $\mathsf{StreamName}^\uparrow$ *windows, tail-threshold rows,* $\mathsf{RegSeqRat}^\uparrow$ *readbacks,* $\mathsf{RealSequenceLimit}^\uparrow$ *handoff rows,* $\mathsf{CauchyTailEquivalence}^\uparrow$ *provenance rows,* $\mathsf{CofinalTailEquivalence}^\uparrow$ *provenance rows, componentwise* hsame *transports, displayed* Cont *replays, package provenance rows, and local naming rows agree under the displayed transport. The classifier has no further coordinate for host sequence equality, quotient tails, arbitrary subsequence choice, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. For the forward direction, read an accepted classifier agreement through the NameCert obligations of Definition 3502.2. The agreement must pass through $S, T, W, M, Q, L, E, F, H, C, P, N$, so each corresponding displayed row is preserved under the componentwise transport.

For the reverse direction, assume the listed rows agree under the displayed transport. Carrier admission reconstructs the same paired windows and tail threshold, the same $\mathsf{RegSeqRat}^\uparrow$ readback, and the same limit, Cauchy-tail, and cofinal-tail provenance rows.

Displayed replay through C and C' then gives the same consumer route, while P, N and P', N' record the same source and local naming surface. The absence of quotient, choice, host equality, and completeness coordinates shows that no hidden classifier field remains. □

Falsifiable prediction: Every $\mathsf{AsymptoticSequence}^\uparrow$ comparison read factors through paired StreamName windows, one displayed tail threshold, RegSeqRat readback, RealSequenceLimit

handoff, CauchyTailEquivalence provenance, CofinalTailEquivalence provenance, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, realsequencelimit, cauchytailequivalence, cofinaltailequivalence: $\mathsf{AsymptoticSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries paired source windows, a tail threshold, rational readback, limit handoff, symmetric tail comparison, cofinal route comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticSequence}^{\uparrow}}$.

Constructive story: An $\mathsf{AsymptoticSequence}^{\uparrow}$ packet is generated from paired source sequence rows, finite StreamName windows, a tail-threshold row, RegSeqRat readback, RealSequenceLimit handoff, CauchyTailEquivalence and CofinalTailEquivalence provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AsymptoticSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3502.1, Definition 3502.2, and Definition 3502.3 seed the finite tail-comparison certificate for sequence-limit and Cauchy-criterion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AsymptoticSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient stream equality, host asymptotic comparison, arbitrary subsequence choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Formal closure requires a Lean carrier and obligation package for the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{CofinalTailEquivalence}^{\uparrow}$, hsame, Cont, Pkg, and NameCert route.

Chapter 3503

A Concrete Naming Certificate for FiniteSubcoverCriterion$^{\uparrow}$

Following the Heine–Borel and Bishop finite-subcover discipline, the FiniteSubcoverCriterion$^{\uparrow}$ packet records the finite-net criterion that lets a compactness consumer use displayed metric cover data without importing arbitrary open-cover compactness. It sits next to the compact metric carrier of chapter 129, the finite center family of chapter 1767, the located interval boundary of chapter 394, and the terminal real-name seal of chapter 38. The packet names a finite criterion over already displayed rows; it does not select subcovers from arbitrary covers, choose representatives, assert countable choice, or use ambient Real$^{\uparrow}$ completeness.

Definition 3503.1 (FiniteSubcoverCriterion carrier)**.** *A* FiniteSubcoverCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, E, L, R, Q, D, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposed only through its displayed finite-net and metric coverage fields.*
2. *E is the* FiniteEpsilonNet$^{\uparrow}$ *center-bundle row for the requested positive scale.*
3. *L is the* LocatedInterval$^{\uparrow}$ *or located source-window row when the compact source is an interval-facing carrier.*
4. *R is the* Real$^{\uparrow}$ *seal row attached to endpoint, radius, and distance comparisons already displayed by the source.*
5. *Q is the cover-read ledger, recording for each bundled center the finite witness row that covers the corresponding metric ball.*
6. *D is the dyadic or rational comparison ledger certifying that the center radius and mesh slack fit the requested coverage scale.*
7. *H records componentwise* hsame *transport for the compact source, finite-net row, located window, Real seal, cover-read ledger, comparison ledger, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a finite cover request through $K, E, L, R, Q, D, H, P, N$.*
9. *P is the* Pkg *provenance over* FiniteSubcoverCriterion$^{\uparrow}$, CompactMetric$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, LocatedInterval$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSubcoverCriterion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, E, L, R, Q, D, H, C, P, N$. It has no coordinate for arbitrary open covers, countable choice, selected representatives, a host finite-subcover operation, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteSubcoverCriterionUp.FiniteSubcoverCriterionTasteGate single carrier alignment`

Theorem 3503.2 (FiniteSubcoverCriterion NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *carrier $S = (K, E, L, R, Q, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteSubcoverCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the compact metric source, finite epsilon-net row, located source-window row, Real seal, cover-read ledger, rational comparison ledger, transport, replay, provenance, and local naming rows;*
2. *finite-net exposure, requiring every cover read to display the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *center bundle E before any covering witness is inspected;*
3. *source compatibility, requiring K, L, R to be read as the compact metric, located-window, and Real-seal rows already carried by sibling chapters;*
4. *radius exactness, requiring Q and D to record the finite center-to-cover and radius-slack checks that make the criterion usable by downstream compactness consumers;*
5. *non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed packet and to export no open-cover compactness, countable choice, selected representatives, host finite-subcover operation, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3503.1. Its coordinates are exactly the compact source, finite net, located source window, Real seal, cover-read ledger, comparison ledger, and structural rows.

Finite-net exposure is immediate from the order of the displayed packet. A cover consumer must first read E, so each later covering witness is tied to a named center bundle rather than to an arbitrary family of open sets.

Source compatibility is supplied by K, L, R. These rows identify the compact metric, located-window, and Real-seal surfaces already present in the sibling chapters, while Q and D record only finite coverage and comparison checks.

Finally, the refused objects have no coordinate in S. Transport, replay, provenance, and local naming preserve the same finite rows, so no accepted packet exports open-cover compactness, countable choice, selected representatives, host finite-subcover selection, quotient real equality, or ambient Real completeness. □

Theorem 3503.3 (FiniteSubcoverCriterion net extraction)**.** *Every compactness-facing read from an accepted* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The exported object is the displayed finite-net subcover criterion over $K, E, L, R, Q, D, H, C, P, N$, not an open-cover compactness theorem.

Proof. Begin with an accepted carrier $S = (K, E, L, R, Q, D, H, C, P, N)$. The compactness-facing source is K, and the finite centers are exposed by E before the located and Real-facing rows L and R are read.

The cover ledger Q assigns the displayed cover witnesses only to the bundled centers, while D records the rational slack needed to pass from center coverage to the requested metric scale. Thus the extraction is a finite read from the listed packet rows.

Replay through C, with transport through H and provenance through P, preserves that route. The local naming row N therefore exports the finite-net criterion and cannot add open-cover compactness, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 3503.4 (FiniteSubcoverCriterion compact-metric consumer)**.** *Let $S = (K, E, L, R, Q, D, H, C, P, N)$ be an accepted* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *carrier. Any compact-metric consumer that reads the finite subcover criterion must first display the* $\mathsf{CompactMetric}^{\uparrow}$ *source data K, the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *center family E, the* $\mathsf{LocatedInterval}^{\uparrow}$ *or located-radius boundary row L, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows carried by D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal R before the cover-read ledger Q is consumed. The exported criterion is therefore a finite compact-metric route through $K, E, L, D, R, Q, H, C, P, N$, with no arbitrary open-cover compactness, selected representative, countable choice, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 3503.1. The only compact-metric source coordinate is K, and the only finite center-family coordinate is E.

By Definition 3503.2, source compatibility and finite-net exposure require K and E to be visible before any cover witness is inspected. The located boundary row L and the terminal seal row R are part of the same source-compatibility boundary.

By Definition 3503.3, every compactness-facing read factors through the finite route from compact metric data to finite epsilon nets, located boundary rows, and the Real seal. The dyadic tolerance ledger D records the finite radius slack that makes the cover-read ledger Q meaningful to that route.

The remaining coordinates H, C, P, N only transport, replay, source, and name the same finite packet. Since the carrier has no row for arbitrary open-cover compactness, selected representatives, countable choice, quotient real equality, or ambient Real completeness, no compact-metric consumer can obtain one from the finite subcover criterion. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubcoverCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a FiniteEpsilonNetUp center bundle, a LocatedIntervalUp source-window row, a RealUp seal, finite cover reads, rational comparison ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteSubcoverCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 3503.1, Definition 3503.2, and Definition 3503.3 seed the finite-net compactness criterion consumed by later compact-continuity and Heine–Borel routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteSubcoverCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, selected representatives, a host finite-subcover operation, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, source compatibility, radius exactness, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSubcoverCriterionUp.

Chapter 3504

A Concrete Naming Certificate for $\mathsf{RieszMarkov}^{\uparrow}$

Following Riesz and Markov, the $\mathsf{RieszMarkov}^{\uparrow}$ packet isolates the compact positive functional representation surface: a positive linear functional on continuous real-valued observables over a displayed compact source is read only through a representing Radon row and an integral-readback ledger. It consumes the real scalar boundary of chapter 38, the compact source of chapter 60, the continuous observable rows of chapter 130, the regular measure packet of chapter 2263, and the broader representation boundary of chapter 1643. The chapter names the finite BEDC obligation surface needed by compact-analysis consumers without choosing a representing measure from a host theorem.

3504.1 Compact positive functional carrier

Definition 3504.1 (RieszMarkov compact positive functional carrier)**.** *A* $\mathsf{RieszMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{RieszMarkov}(K, F, L, M, I, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, read through* $\mathsf{Compact}^{\uparrow}$ *over the inherited* $\mathsf{Real}^{\uparrow}$ *scalar boundary;*
2. *F is the continuous real-valued observable row, read through* $\mathsf{ContinuousMap}^{\uparrow}$ *with codomain* $\mathsf{Real}^{\uparrow}$*;*
3. *L is the positive functional ledger, recording linear scalar reads and positivity reads on the displayed observable rows;*
4. *M is the representing* $\mathsf{RadonMeasure}^{\uparrow}$ *row over the same compact source;*
5. *I is the integral-readback row comparing each displayed functional value with the corresponding integral against M;*
6. *H is the componentwise* hsame *transport ledger for K, F, L, M, I, C, P, N;*
7. *C is the displayed* Cont *replay ledger for compact source, observable, functional, representing measure, and integral-readback routes;*
8. *P is the* Pkg *provenance over* $\mathsf{RieszMarkov}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{RieszRepresentation}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RieszMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, L, M, I, H, C, P, N$. It does not identify host functions, host measures, arbitrary sigma-algebras, quotient measure classes, selected representing measures, or ambient functional extensionality.

3504.2 Certificate obligations

Theorem 3504.2 (RieszMarkov NameCert obligations)**.** *For every accepted* $\mathsf{RieszMarkov}^{\uparrow}$ *carrier*

$$R = \mathsf{RieszMarkov}(K, F, L, M, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszMarkov}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, real-valued continuity admission through F, positive-functional ledger visibility through L, representing Radon row visibility through M, integral-readback exactness through I, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

The certificate refuses arbitrary choice of representing measures, host sigma-algebras beyond the displayed $\mathsf{RadonMeasure}^{\uparrow}$ *rows, quotient equality of measures, host equality of functionals, and ambient functional extensionality. A consumer may use the representation only by reading the finite rows of R.*

Lean4 ✓ `BEDC.Derived.RieszMarkovUp.RieszMarkovCarrier namecert obligations`

Proof. Project the carrier of Definition 3504.1. The compact source and continuous observable are fixed by K and F, so the functional ledger L is read on displayed observables rather than on a host function space.

The representing object is the displayed Radon row M. The readback row I is the only route from a functional value to an integral value, and it is attached to the same compact source and observable rows.

Transport and replay are componentwise through H and C, while P and N source and name the route. Since no carrier coordinate stores a selector for representing measures, a larger host sigma-algebra, a quotient measure equality, host functional equality, or functional extensionality, the stated rows exhaust the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszMarkov}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RieszMarkov}^{\uparrow}}$, seed)

Scope closed: Definition 3504.1 and Definition 3504.2 seed the compact positive functional representation packet over Real, Compact, ContinuousMap, RadonMeasure, RieszRepresentation, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RieszMarkov}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary representing-measure choice, host sigma-algebras beyond displayed Radon rows, quotient measure equality, ambient functional extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-functional ledger visibility, representing Radon row visibility, integral-readback exactness, transport replay, and consumer refusal for BEDC.Derived.RieszMarkovUp.

Constructive story: A $\mathsf{RieszMarkov}^{\uparrow}$ packet is generated from compact source, continuous real-valued observable, positive functional ledger, representing Radon row, integral-readback row, componentwise transport, replay, provenance, and local NameCert rows.

Chapter 3505

A Constructive Apartness Certificate for $\mathsf{MetricApartness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{MetricApartness}^{\uparrow}$ packet records the positive-distance separation surface of a constructive metric space as finite BEDC NameCert data. It sits after the metric carrier of chapter 57, the terminal real-name seal of chapter 38, the separated zero-distance classifier of chapter 1411, and the completion boundary of chapter 1506. The packet supplies a finite apartness interface for metric and completion consumers; it does not import host inequality, real trichotomy, quotient classes, selected representatives, or ambient completeness.

Definition 3505.1 (MetricApartness carrier)**.** *A* $\mathsf{MetricApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, x, y, D, R, Z, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row supplying the displayed distance-read interface.*
2. *x and y are the two inspected point rows over the same metric source.*
3. *D is the metric-distance witness row for the finite read $d(x, y)$.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *positive-distance row, recording that the displayed distance has a positive real witness.*
5. *Z is the* $\mathsf{Real}^{\uparrow}$ *zero-distance refusal row, recording that the accepted apartness read rejects the zero-distance branch by displayed real data.*
6. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier-comparison row, used only to compare the zero-distance boundary with the displayed point classifier.*
7. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *finite-window transport row for completion-facing consumers.*
8. *H records componentwise* hsame *transport for the metric source, point rows, distance witness, real positivity row, zero-distance refusal row, separated comparison, finite-window transport, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an apartness request through $M, x, y, D, R, Z, S, Q, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricApartness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricApartness}^{\uparrow}}$ *row.*

The classifier compares accepted apartness packets only through these displayed rows. It contains no host inequality predicate, no trichotomy of real numbers, no quotient-completion class, no selected representative, and no ambient completeness witness.

Lean4 ✓ `BEDC.Derived.MetricApartnessUp.TasteGate.MetricApartnessTasteGate single carrier alignment`

Theorem 3505.2 (MetricApartness NameCert obligations)**.** *For every accepted* $\mathsf{MetricApartness}^{\uparrow}$ *carrier* $A = (M, x, y, D, R, Z, S, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricApartness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source and point rows, distance-witness visibility through* D*, positive-distance readback through* R*, zero-distance refusal through* Z*, separated classifier comparison through* S*, completion-facing finite-window transport through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. Every apartness read therefore follows the route*

$$M, x, y \longmapsto D \longmapsto R, Z \longmapsto S, Q \longmapsto H, C, P, N.$$

No additional coordinate can decide apartness by host inequality, real trichotomy, quotient class comparison, selected representative equality, or ambient completeness.

Proof. Project the carrier of Definition 3505.1. The rows M, x, y expose the metric source and the two inspected points, and D is the only row from which their displayed distance can be read.

The real-facing branch is then forced through R and Z. The row R supplies positive-distance evidence, while Z records refusal of the zero-distance branch by the same $\mathsf{Real}^{\uparrow}$ readback surface.

Separated and completion-facing consumers are downstream. The row S compares the zero-distance boundary with the separated classifier, and Q transports finite-window completion reads through $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ without creating quotient classes or selected representatives.

Finally H, C, P, N preserve, replay, source, and name the displayed route. Since no row stores host inequality, real trichotomy, quotient comparison, selected representative equality, or ambient completeness, the listed coordinates exhaust the NameCert surface. □

Theorem 3505.3 (MetricApartness completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CauchySequenceEquivalence}$ *consumer of an accepted* $\mathsf{MetricApartness}^{\uparrow}$ *packet must read the finite route* $M, x, y, D, R, Z, S, Q, H, C, P, N$ *before treating the two displayed names as apart. The exported handoff is only the positive-distance certificate together with zero-distance refusal, separated-classifier comparison, finite-window transport, componentwise transport, replay, provenance, and local naming. It does not export host inequality, real trichotomy, quotient-completion equality, selected representatives, or an ambient completeness principle.*

Proof. Begin with a completion-facing apartness request. The metric source and inspected point rows M, x, y must be displayed before the distance witness D can be consumed.

The rows R and Z bind the constructive apartness decision to real readback: one row supplies positive-distance evidence, and the other refuses the zero-distance branch. This gives the separated row S a displayed classifier boundary to compare.

The finite-window row Q is then the only completion-facing handoff. It transports the same distance and refusal data through $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ consumers, while H, C, P, N record transport, replay, provenance, and local naming.

Thus the completion consumer receives exactly the finite apartness route described above, with no hidden route through host inequality, trichotomy, quotient classes, selected representatives, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{MetricApartness}^{\uparrow}$ read factors through a MetricUp source, two displayed point rows, a distance witness, RealUp positive-distance evidence, RealUp zero-distance refusal, a SeparatedMetric classifier comparison, MetricCompletion and CauchySequenceEquivalence finite-window transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metric, real, separatedmetric, metriccompletion, cauchysequenceequivalence: $\mathsf{MetricApartness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source, two displayed point rows, positive-distance evidence, zero-distance refusal, separated classifier comparison, completion-facing finite-window transport, transport, replay, provenance, and local naming as one apartness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricApartness}^{\uparrow}$ packet is generated from a MetricUp source row, two displayed point rows, a metric-distance witness, RealUp positive-distance evidence, RealUp zero-distance refusal, a SeparatedMetric classifier-comparison row, MetricCompletion and CauchySequenceEquivalence finite-window transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3505.1, Definition 3505.2, and Definition 3505.3 seed the finite constructive apartness surface for metric and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inequality, real trichotomy, quotient-completion equality, selected representatives, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distance-witness visibility, positive-distance evidence, zero-distance refusal, separated classifier comparison, completion-facing finite-window transport, transport and replay stability, provenance non-escape, and local naming for BEDC.Derived.MetricApartnessUp.

Chapter 3506

A Concrete Naming Certificate for $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive analysis, the $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ packet records the finite orbit-to-Cauchy-completion handoff produced by a contraction before any fixed-point endpoint is sealed. It sits after the contraction-map surface of chapter 1418, the Picard-step ledger of chapter 395, the complete-metric service of chapter 128, the convergence-modulus boundary of chapter 1438, and the fixed-point endpoint discipline of chapter 396. The packet exposes the finite carrier and residual-modulus rows that a completion consumer must read before speaking about a completed orbit point.

Definition 3506.1 (ContractiveCauchyOrbit carrier)**.** *A* $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, T, I, W, R, M, K, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the carried* $\mathsf{CompleteMetric}^{\uparrow}$ *row over which distances between displayed orbit entries are read.*
2. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *row, including the displayed contraction ratio and the self-map application route.*
3. *I is the* $\mathsf{PicardContraction}^{\uparrow}$ *finite iterate ledger recording the visible orbit entries $x_0, \ldots, x_n$ and the application rows $x_{k+1} = T(x_k)$.*
4. *W is the finite iterate-window exactness row, recording which adjacent orbit windows are available to every tolerance request.*
5. *R is the residual-distance row, storing the adjacent distance comparisons and ratio propagation read from X, T, I, W.*
6. *M is the extracted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *row, obtained from the residual ledger without selecting a limit.*
7. *K is the completion handoff row, naming the* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer that may read the Cauchy orbit after M is displayed.*
8. *E is the endpoint-seal boundary available only after the completion handoff has been read by a downstream fixed-point or real-name consumer.*

9. *H records componentwise* hsame *transport for the metric, contraction, iterate, window, residual, modulus, completion handoff, endpoint boundary, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from contraction admission through finite orbit windows, residual comparisons, modulus extraction, completion handoff, and endpoint separation.*
11. *P is the* Pkg *provenance over* ContractiveCauchyOrbit$^{\uparrow}$, ContractionMapping$^{\uparrow}$, PicardContraction$^{\uparrow}$, CompleteMetric$^{\uparrow}$, CauchyConvergenceModulus$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{ContractiveCauchyOrbit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected fixed point, host limit equality, quotient completion representative, function extensionality, countable choice, or ambient completeness outside the displayed CompleteMetric$^{\uparrow}$ *row.*

Lean4 (definition) `BEDC.Derived.ContractiveCauchyOrbitUp.ContractiveCauchyOrbitUp`
Lean4 ✓ `BEDC.Derived.ContractiveCauchyOrbitUp.ContractiveCauchyOrbitTasteGate single carrier alignment`

Theorem 3506.2 (ContractiveCauchyOrbit NameCert obligations)**.** *For every accepted* ContractiveCauchyOrbit$^{\uparrow}$ *carrier*

$$O = (X, T, I, W, R, M, K, E, H, C, P, N),$$

the local NameCert$_{\text{ContractiveCauchyOrbit}^{\uparrow}}$ *surface consists exactly of carrier admission, contraction-row visibility, finite iterate-window exactness, residual Cauchy-modulus extraction, completion handoff, endpoint-boundary separation, componentwise transport, displayed continuation replay, package provenance, local naming, and ledger non-escape for the rows of Definition 3506.1.*

Proof. Carrier admission projects the displayed tuple. The rows X, T, I, W expose the complete metric, contraction map, finite Picard ledger, and exact finite windows before any convergence-facing row is read.

The residual row R is then forced through the same finite data. It records adjacent distances and contraction-ratio propagation, so the modulus row M is extracted from displayed orbit windows rather than from a host convergence theorem.

The completion handoff K and endpoint boundary E remain downstream. They may be inspected only after the residual-to-modulus route has been displayed, and they do not add a selected fixed point or quotient representative.

Finally H, C, P, N transport, replay, source, and name exactly these rows. Thus every NameCert obligation is visible in the carrier, and the ledger has no escape route outside the twelve displayed coordinates. □

Theorem 3506.3 (ContractiveCauchyOrbit completion handoff)**.** *Every completion-facing consumer of an accepted* ContractiveCauchyOrbit$^{\uparrow}$ *carrier must read the ordered route*

$$\text{ContractionMapping}^{\uparrow},\ \text{PicardContraction}^{\uparrow},\ \text{CompleteMetric}^{\uparrow} \longmapsto W, R, M \longmapsto K, E, H, C, P, N.$$

The consumer receives the finite iterate windows, residual-distance comparisons, and extracted Cauchy modulus before it may read the completion handoff. It receives no Banach fixed point, selected limit, host function equality, quotient completion representative, or ambient completeness beyond the named CompleteMetric$^{\uparrow}$ *row.*

Proof. Project the contraction and iteration rows. The $\mathsf{ContractionMapping}^{\uparrow}$ row supplies the self-map and ratio data, while the $\mathsf{PicardContraction}^{\uparrow}$ row supplies the finite orbit ledger.

Read the complete-metric row next. All residual comparisons in R are distance reads through X, and the exact windows W determine which finite orbit entries are visible to a tolerance request.

The row M is therefore a Cauchy-modulus extraction from finite residual data. The completion handoff K may consume this route, and the endpoint boundary E may be read only after K.

The structural rows preserve the same dependency order. Since no row stores a selected endpoint or host equality, every completion-facing consumer remains confined to the displayed handoff. □

Theorem 3506.4 (ContractiveCauchyOrbit ledger non-escape)**.** *Every public read of an accepted* $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ *packet factors through*

$$X, T, I, W, R, M, K, E, H, C, P, N.$$

In particular, the residual Cauchy-modulus extraction and completion handoff are visible as finite BHist *rows, and no consumer can replace them by an external convergence theorem, a chosen completion point, a quotient representative, countable choice, or host fixed-point equality.*

Proof. Read the carrier definition together with the NameCert obligation theorem. They expose exactly the twelve rows listed in the statement, with finite orbit windows and residual comparisons preceding the modulus row.

Apply Definition 3506.3. Any completion-facing read must pass through the displayed contraction, Picard, complete-metric, window, residual, and modulus route before K and E are available.

The transport, replay, provenance, and naming rows add no analytic coordinate. Therefore a public consumer can only inspect the displayed carrier route, and the excluded host, choice, quotient, and endpoint objects remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ completion read factors through one CompleteMetric row, one ContractionMapping row, one PicardContraction finite orbit ledger, one finite iterate-window exactness row, one residual-distance row, one CauchyConvergenceModulus extraction, one completion handoff, one endpoint boundary, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: contractionmapping, picardcontraction, completemetric, cauchy-convergence-modulus, banachfixedpoint: none is bijective with $\mathsf{ContractiveCauchyOrbit}^{\uparrow}$ because the packet jointly stores the contraction row, Picard orbit ledger, complete-metric distance reads, finite window exactness, residual modulus extraction, completion handoff, endpoint boundary, transport, replay, provenance, and local naming as one finite completion-facing orbit.

Closure status for $\mathsf{NameCert}_{\mathsf{ContractiveCauchyOrbit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractiveCauchyOrbit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3506.1, Definition 3506.2, Definition 3506.3, and Definition 3506.4 seed the finite contraction-orbit route from Picard rows to Cauchy completion handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractiveCauchyOrbit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Banach fixed points, selected limits, quotient completion representatives, host function equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, contraction-row visibility, finite iterate-window exactness, residual Cauchy-modulus extraction, completion handoff, endpoint-boundary separation, transport, replay, provenance, local naming, and ledger non-escape for BEDC.Derived.ContractiveCauchyOrbitUp.

Constructive story: A ContractiveCauchyOrbit$^{\uparrow}$ packet is generated from a complete-metric row, contraction-map row, PicardContraction finite iterate ledger, finite window exactness row, residual-distance row, extracted CauchyConvergenceModulus row, completion handoff, endpoint boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3507

A Concrete Naming Certificate for $\mathsf{CompletionSubsetClosure}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{CompletionSubsetClosure}^{\uparrow}$ packet records the traditional fact that a closed subset of a complete metric completion remains complete, but only as finite BEDC NameCert data. It sits over the complete separable metric surface of chapter 1735, the dense embedding route of chapter 3351, the dense Cauchy embedding packet of chapter 2250, the Polish-space readback of chapter 1490, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a closed-subset completion surface for downstream completion consumers; it is not open-cover compactness, a quotient equality of completed points, countable choice, selected limit extraction, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3507.1 (Completion subset closure carrier)**.** *A* $\mathsf{CompletionSubsetClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, E, D, P, S, W, Q, R, L, H, C, G, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *source row exposing the complete separable metric packet from which the closed subset is read.*
2. *E is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *dense-embedding row naming the completion-facing source image.*
3. *D is the* $\mathsf{DenseCauchyEmbedding}^{\uparrow}$ *handoff row, recording the Cauchy-name route by which subset points are inspected.*
4. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *consumer row, used only after the complete separable and dense embedding rows have been displayed.*
5. *S is the closed-subset ledger, listing subset membership, closedness witnesses, and boundary refusal rows over the completion source.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family used to inspect subset membership and Cauchy approximation rows.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed Cauchy and distance-budget data.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the finite distance and radius comparisons read by the subset closure ledger.*

9. *L is the limit-handoff row, recording that every accepted Cauchy read remaining in S reaches a displayed subset limit row before any downstream completion consumer sees it.*
10. *H records componentwise* hsame *transport for the complete metric source, dense embeddings, closed-subset ledger, stream windows, readback rows, Real seals, limit handoff, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from subset Cauchy reads through $M, E, D, P, S, W, Q, R, L, H$.*
12. *G is the* Pkg *provenance over* $\mathsf{CompletionSubsetClosure}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, MetricCompletionDenseEmbe DenseCauchyEmbedding$^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionSubsetClosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, D, P, S, W, Q, R, L, H, C, G, N$. It has no coordinate for open-cover compactness, quotient equality of completed points, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3507.2 (CompletionSubsetClosure NameCert obligations)**.** *For every accepted* CompletionSubsetClosure$^{\uparrow}$ *carrier $K = (M, E, D, P, S, W, Q, R, L, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionSubsetClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for the complete separable metric source, metric-completion dense embedding, dense Cauchy embedding, Polish-space consumer row, closed-subset ledger, finite stream windows, regular rational readback, Real seal, limit handoff, componentwise transport, displayed replay, provenance, and local naming.*

Every completion-facing read must therefore pass through

$$M \longmapsto E \longmapsto D \longmapsto P \longmapsto S \longmapsto W \longmapsto Q \longmapsto R \longmapsto L \longmapsto (H, C, G, N)$$

before it can treat a Cauchy read in the subset as closed under completion. The route exports no open-cover compactness theorem, no quotient equality of completion classes, no selected limit, no countable-choice schedule, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 3507.1. The rows M, E, D, P expose the complete separable source, dense completion image, dense Cauchy handoff, and Polish consumer boundary before the subset ledger can be read.

Next inspect the closed-subset and finite observation rows. The ledger S is read only through finite windows W, regular rational data Q, and Real seals R, so a subset Cauchy request has a displayed membership and boundary route before a limit row is exposed.

Finally read the structural rows. The limit handoff L is transported by H, replayed by C, sourced by G, and named by N. Since the carrier has no row for open covers, quotient completion equality, selected limits, countable choice, trichotomy, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CompletionSubsetClosureUp.CompletionSubsetClosure namecert obligations`

Theorem 3507.3 (CompletionSubsetClosure dense embedding handoff)**.** *Every accepted* CompletionSubsetClosure$^{\uparrow}$ *packet hands a subset-completion consumer the displayed route*

$\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{DenseCauchyEmbedding}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, StreamNa

The handoff is the finite closed-subset completion route carried by K; it is not a host theorem about all closed subsets of all complete spaces.

Proof. Begin with an accepted packet K. The complete separable source M and dense embedding row E identify the completion surface, while the dense Cauchy row D fixes how subset Cauchy names enter the packet.

The Polish row P is downstream of those completion rows, and the observation rows W, Q, R display the finite reads used by the closed-subset ledger S. Thus the subset-completion consumer sees only the named route through the listed sibling chapters.

Transport, replay, provenance, and local naming preserve that route. No host closed-subset theorem or ambient completion object is introduced by the handoff. □

Theorem 3507.4 (CompletionSubsetClosure nonescape)**.** *Every accepted* $\mathsf{CompletionSubsetClosure}^{\uparrow}$ *completion read remains inside the displayed rows* $M, E, D, P, S, W, Q, R, L, H, C, G, N$*. In particular, the packet cannot export open-cover compactness, quotient equality of completed points, selected limits, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the packet coordinates in order. The completion source, dense embedding, dense Cauchy handoff, and Polish consumer rows are exactly M, E, D, P; the subset boundary is exactly S.

The finite observation data is exactly W, Q, R, and the only completion-facing exit is the displayed limit handoff L. Componentwise transport, replay, provenance, and naming through H, C, G, N do not add new coordinates.

Thus every accepted read is exhausted by the displayed rows, and the refused principles have no carrier position from which they could be exported. □

Falsifiable prediction: Every accepted $\mathsf{CompletionSubsetClosure}^{\uparrow}$ completion read must display complete-separable source data, dense completion embedding data, dense Cauchy embedding data, Polish consumer data, a closed-subset ledger, StreamName windows, RegSeqRat readback, a RealUp seal, a limit handoff, transport, replay, provenance, and local naming before any closed-subset completion claim is public.

Independence witness: complete-separable-metric, metric-completion-dense-embedding, dense-cauchy-embedding, polishspace, streamname, regseqrat, real: $\mathsf{CompletionSubsetClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a closed-subset ledger, finite observation windows, regular readback, Real seals, a limit handoff, transport, replay, provenance, and local naming over the completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionSubsetClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionSubsetClosure}^{\uparrow}$ packet is generated from CompleteSeparableMetricUp source rows, MetricCompletionDenseEmbeddingUp and DenseCauchyEmbeddingUp completion rows, a PolishSpaceUp consumer row, a closed-subset ledger, StreamName windows, RegSeqRat readback, RealUp seals, a limit handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionSubsetClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3507.1, Definition 3507.2, Definition 3507.3, and Definition 3507.4 seed the closed-subset completion route over the L10 completion siblings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionSubsetClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient equality of completed points, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-subset ledger exactness, dense-embedding handoff, limit-handoff non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionSubsetClosureUp.

Chapter 3508

A Concrete Naming Certificate for DnaBoundaryTriggerClosure$^{\uparrow}$

The DnaBoundaryTriggerClosure$^{\uparrow}$ packet realizes the boundary-closure structure of Definition 9462.1306 as finite BEDC NameCert data. It sits over the six boundary-tile coverage packet of chapter 3470, the finite trigger algebra of chapter 3478, the cellular trace window of chapter 3481, and the weak Konig boundary refusal surface of chapter 3482. The packet names boundary-trigger closure for six-tile DNA window rows; it is not a biological code table, a stochastic evolutionary model, an infinite branch selector, a quotient codon semantics, or a host closure oracle.

Definition 3508.1 (DnaBoundaryTriggerClosure carrier)**.** *A* DnaBoundaryTriggerClosure$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, A, T, W, F, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the* SixBoundaryTileCoverage$^{\uparrow}$ *boundary-tile coverage row, exposing the six-tile trigger and coverage-rank data.*
2. *A is the* WindowCoverageTriggerAlgebra$^{\uparrow}$ *finite trigger-algebra row, recording closure of displayed support rows under boundary-trigger operations.*
3. *T is the* CellularWindowTrace$^{\uparrow}$ *trace row, used only to display finite local evolution windows attached to accepted boundary triggers.*
4. *W is the* WeakKonigBoundary$^{\uparrow}$ *refusal row, recording that the closure packet does not export an infinite branch selector or countable-choice schedule.*
5. *F is the finite frontier ledger listing the boundary codons, Q_2 completion faces, stage rows, and pressure rows read from the source vision.*
6. *L is the closure ledger, recording that each accepted boundary-trigger closure step is obtained from displayed six-tile rows, trigger algebra, trace windows, and weak-branch refusals.*
7. *H records componentwise* hsame *transport for boundary-tile coverage, trigger algebra, trace windows, weak-boundary refusals, frontier rows, closure rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a boundary-trigger closure request through B, A, T, W, F, L, H.*
9. *P is the* Pkg *provenance over* DnaBoundaryTriggerClosure$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAl CellularWindowTrace$^{\uparrow}$, WeakKonigBoundary$^{\uparrow}$, *the boundary-closure source vision,* BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, A, T, W, F, L, H, C, P, N$. It has no coordinate for hidden genetic-code semantics, stochastic dynamics, infinite branch choice, quotient codon equality, or a host closure oracle.

Lean4 ✓ `BEDC.Derived.DnaBoundaryTriggerClosureUp.DnaBoundaryTriggerClosureTasteGate single carrier alignment`

Theorem 3508.2 (DnaBoundaryTriggerClosure NameCert obligations)**.** *For every accepted* DnaBoundaryTriggerCl *carrier $K = (B, A, T, W, F, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for six-boundary-tile coverage, window-coverage trigger algebra, cellular window trace, weak Konig boundary refusal, finite frontier rows, closure ledger rows, componentwise transport, displayed replay, provenance, and local naming.*

Every boundary-trigger closure read must therefore route through

$$B \longmapsto A \longmapsto T \longmapsto W \longmapsto F \longmapsto L \longmapsto (H, C, P, N)$$

before it can be consumed as a finite closure packet for DNA window rows. The route exports no biological code table, stochastic dynamics, infinite branch selector, quotient codon equality, or host closure oracle.

Proof. Project the carrier of Definition 3508.1. The rows B, A, T, W expose the four sibling surfaces: six-boundary coverage, trigger algebra, cellular trace, and weak-branch refusal.

The frontier and closure ledgers are finite. The row F records only displayed boundary codons, Q_2 completion faces, stage rows, and pressure rows, while L records closure steps obtained from those rows and the sibling packets.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no hidden semantics, stochastic model, infinite branch selector, quotient equality, or host oracle is present in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 3508.3 (DnaBoundaryTriggerClosure nonescape)**.** *Every accepted* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ *boundary-trigger closure read passes through displayed six-tile boundary rows, finite trigger algebra rows, cellular trace rows, weak-branch refusal rows, frontier rows, closure rows, transport, replay, provenance, and local naming. The packet cannot escape to a biological code table, stochastic dynamics, infinite branch choice, quotient codon equality, or host closure oracle.*

Proof. Read B first. It supplies the six-boundary tile coverage row, so the trigger source is a displayed finite boundary packet rather than an implicit biological table.

Read A, T, W next. The trigger algebra closes only finite support rows, the cellular trace row supplies only finite local windows, and the weak-boundary row records the refusal of infinite branch selection.

The rows F, L, H, C, P, N then bind the frontier, closure, transport, replay, provenance, and naming surface. No further coordinate remains, so an accepted read cannot export any of the refused objects. □

Falsifiable prediction: Every boundary-trigger closure read for $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ must pass through displayed six-tile boundary rows, finite trigger-algebra rows, cellular trace windows, weak-branch refusal rows, frontier rows, closure rows, transport, replay, provenance, and local naming; omitting any displayed six-tile boundary row refutes the packet.

Independence witness: six-boundary-tile-coverage, window-coverage-trigger-algebra, cellular-window-trace, weak-konig-boundary: $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six-tile coverage, finite trigger algebra, cellular trace windows, weak-branch refusal, frontier ledgers, closure ledgers, transport, replay, provenance, and local naming.

The Lean follow-up `BEDC.Derived.DnaBoundaryTriggerClosureUp.TasteGate` supplies explicit $\mathsf{Nontrivial\ DnaBoundaryTriggerClosure}^{\uparrow}$ and $\mathsf{FieldFaithful\ DnaBoundaryTriggerClosure}^{\uparrow}$ instances preserving $B, A, T, W, F, L, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ packet is generated from SixBoundaryTileCoverageUp boundary rows, WindowCoverageTriggerAlgebraUp finite trigger rows, CellularWindowTraceUp finite trace windows, WeakKonigBoundaryUp refusal rows, finite frontier ledgers, closure ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3508.1, Definition 3508.2, and Definition 3508.3 seed the finite boundary-trigger closure packet for six-tile DNA window rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim biological code-table identity, stochastic evolutionary dynamics, infinite branch choice, quotient codon equality, host closure oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, six-tile boundary coverage, trigger-algebra exactness, trace-window handoff, weak-branch refusal, Nontrivial DnaBoundaryTriggerClosureUp, and FieldFaithful DnaBoundaryTriggerClosureUp for BEDC.Derived.DnaBoundaryTriggerClosureUp.

Chapter 3509

A Concrete Naming Certificate for $\mathsf{Ceva}^{\uparrow}$

Following Ceva, the $\mathsf{Ceva}^{\uparrow}$ packet records the finite incidence data for three cevians in a triangle and the concurrence witness that makes the side-intersection rows compatible. It sits beside the affine carrier of chapter 206, the projective incidence boundary of chapter 207, and the bilinear pairing row of chapter 146. The chapter names only triangle vertices, side-incidence rows, cevian rows, concurrence, transport, replay, provenance, and local naming; it does not export a coordinate determinant proof, a host projective plane, or an analytic area computation.

Definition 3509.1 (Ceva carrier)**.** *A* $\mathsf{Ceva}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (T, S, L, X, H, C, P, N)$$

with the following displayed rows:

1. *T is the triangle-vertex row, recording three carried point histories read through the* $\mathsf{AffineSpace}^{\uparrow}$ *and* $\mathsf{ProjectiveSpace}^{\uparrow}$ *source certificates;*
2. *S is the side-incidence row, recording the three side lines and the finite incidence witnesses that place each side between the corresponding vertex pair;*
3. *L is the cevian row, recording one displayed cevian from each triangle vertex to the opposite side-incidence row;*
4. *X is the concurrence witness, recording that the three cevian rows meet at a common projective point;*
5. *H records componentwise* hsame *transport for vertices, side incidences, cevian rows, concurrence, and the bilinear incidence tests used by the local classifier;*
6. *C records displayed* Cont *replay for vertex admission, side construction, cevian attachment, concurrence inspection, and incidence readback;*
7. *P is the* Pkg *provenance over* $\mathsf{Ceva}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{ProjectiveSpace}^{\uparrow}$, $\mathsf{BilinForm}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Ceva}^{\uparrow}}$ *row.*

The carrier contains no coordinate chart, no determinant numerator, no host quotient of points and lines, and no external proof that bypasses the displayed incidence rows.

Lean4 ✓ `BEDC.Derived.CevaUp.TasteGate.CevaTasteGate single carrier alignment`

Theorem 3509.2 (Ceva NameCert obligations)**.** *For the carrier of Definition 3509.1, the local* $\mathsf{NameCert}_{\mathsf{Ceva}^\uparrow}$ *surface consists exactly of carrier admission for* $V = (T, S, L, X, H, C, P, N)$*, triangle-vertex coverage through* T*, side-incidence coverage through* S*, cevian coverage through* L*, concurrence exactness through* X*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. The* $\mathsf{AffineSpace}^\uparrow$*,* $\mathsf{ProjectiveSpace}^\uparrow$*, and* $\mathsf{BilinForm}^\uparrow$ *rows are consumed only as dependency certificates for the displayed incidence packet.*

Lean4 ✓ `BEDC.Derived.CevaUp.CevaCarrier namecert obligations`

Proof. Project the carrier of Definition 3509.1. The vertex row T supplies the three carried point histories, while S records the side incidences they determine inside the affine and projective dependency surfaces.

Read the cevian row L next. Each cevian is attached to one vertex and the opposite side, so the line data cannot be consumed without the side-incidence witnesses already present in S.

The concurrence row X then binds the three cevian rows to one displayed projective point. The bilinear row is used only as the incidence test named by the packet, and the transport and replay rows H and C preserve the same vertices, sides, cevians, and concurrence witness.

Finally P and N source and name the resulting packet. Since the carrier has no further coordinate, these rows exhaust the local $\mathsf{NameCert}_{\mathsf{Ceva}^\uparrow}$ obligations. □

Theorem 3509.3 (Ceva incidence non-escape)**.** *Let*

$$V = (T, S, L, X, H, C, P, N)$$

be an accepted $\mathsf{Ceva}^\uparrow$ *packet. Any consumer that reads a Ceva concurrence conclusion must pass through the triangle-vertex row* T*, the side-incidence row* S*, the cevian row* L*, the concurrence witness* X*, the transport row* H*, the replay row* C*, the provenance row* P*, and the local naming row* N*. No conclusion can be recovered from a coordinate determinant, an unnamed projective-plane quotient, or a bilinear incidence test detached from the displayed side and cevian rows.*

Lean4 ✓ `BEDC.Derived.CevaUp.CevaCarrier incidence nonescape`

Proof. Use the obligation surface of Definition 3509.2. It places triangle vertices, side incidences, cevian rows, and concurrence in one finite packet, with the affine, projective, and bilinear sources appearing only through displayed dependency rows.

If a route omits S, it no longer knows which opposite side each cevian meets. If it omits L, it no longer has the three cevians whose concurrence is being read. If it omits X, it has only side and line data, not a concurrence witness.

The rows H, C, P, N keep the same incidence data under transport, replay, provenance, and local naming. Thus any route bypassing the listed rows exits the $\mathsf{Ceva}^\uparrow$ carrier rather than exporting a BEDC Ceva incidence conclusion. □

Falsifiable prediction: If the concurrence witness row is absent, no accepted $\mathsf{Ceva}^\uparrow$ packet exports a three-cevian concurrence reading.

Independence witness: affinespace, projectivespace, bilinform: the affine-space packet names carried point and translation data without the three side and cevian rows, the projective-space packet names scaling-orbit representatives without the Ceva concurrence witness, and the bilinear-form packet names pairing data without the triangle incidence carrier. None is bijective to $\mathsf{Ceva}^\uparrow$.

Closure status for $\mathsf{NameCert}_{\mathsf{Ceva}\uparrow}$**.**

Constructive story: A $\mathsf{Ceva}^{\uparrow}$ packet is generated from triangle-vertex, side-incidence, cevian, concurrence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Ceva}\uparrow}, \text{obligation})$

Scope closed: Definition 3509.1, Definition 3509.2, and Definition 3509.3 bind the finite incidence packet for triangle vertices, side rows, cevian rows, concurrence, transport, replay, provenance, local naming, and the displayed $\mathsf{Ceva}^{\uparrow}$ carrier exclusions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Ceva}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, coordinate determinant proof, a host projective plane, host projective-plane quotient, quotient equality of point-line incidences, analytic area computation, or bridge-checked standard model.

Upgrade path: Scoped closure requires a Lean carrier and obligation package for the same triangle-vertex, side-incidence, cevian, concurrence, hsame, Cont, Pkg, and NameCert route, including carrier admission, incidence-row stability, concurrence exactness, and nonescape for BEDC.Derived.CevaUp.

Chapter 3510

A Concrete Naming Certificate for $\mathsf{BishopCauchyApproximation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyApproximation}^{\uparrow}$ packet names the finite approximation surface by which a regular Cauchy rational source answers a Real-facing precision request. It sits between the regular rational source of chapter 301, the finite observation interface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, and the finite approximation service of chapter 601. The packet is the L10 human-origin approximation row used by Real and Completion consumers before any quotient stream, selected limit, countable choice, trichotomy, host equality, or ambient completeness principle is available.

Definition 3510.1 (Bishop Cauchy approximation source)**.** *A* $\mathsf{BishopCauchyApproximation}^{\uparrow}$ *source is a finite* BHist *packet*

$$A = (R, n, W, D, V, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational name supplies the Cauchy data.*
2. *n is the unary precision request row. It records the requested approximation depth before any finite window is opened.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at precision n.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same request and window.*
5. *V is the displayed approximation value row read from R through W and checked against D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff. It can be consumed only after R, n, W, D, V have all been displayed.*
7. *H stores componentwise* hsame *transports for the source, request, window, tolerance, value, seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a Real-facing approximation read through R, n, W, D, V and into the seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyApproximation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteCauchyApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyApproximation}^{\uparrow}}$ *row.*

The local classifier compares two sources only through the displayed rows $R, n, W, D, V, E, H, C, P, N$. It has no coordinate for a quotient stream, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyApproximationUp.BishopCauchyApproximationTasteGate single carrier alignment`

Theorem 3510.2 (Bishop Cauchy approximation window handoff)**.** *Let*

$$A = (R, n, W, D, V, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyApproximation}^{\uparrow}$ *source. Every* $\mathsf{Real}^{\uparrow}$*-facing approximation read of A passes through, in order, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row R, the unary precision request n, the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the displayed approximation value V, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff E, with componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support supplied by H, C, P, N. The read exports no quotient stream, selected limit, host equality, countable-choice selector, trichotomy row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the source through Definition 3510.1. The only analytic rows visible to a Real-facing consumer are R, n, W, D, V, E, while H, C, P, N supply transport, replay, provenance, and local naming.

The regular source row is read first. It presents the $\mathsf{RegSeqRat}^{\uparrow}$ Cauchy data as finite packet data, so the consumer has not yet received a Real value, quotient stream, or selected limit.

The precision request and finite window then determine the inspected observation. The row n fixes the requested depth, W opens the corresponding finite $\mathsf{StreamName}^{\uparrow}$ segment, and D records the dyadic tolerance ledger attached to that same finite request.

The displayed value row V is therefore read only after the source, request, window, and tolerance rows are all present. The terminal row E seals the result as Real-facing data, and the support rows H, C, P, N replay exactly that route.

Finally compare with the sibling service of chapter 601. Both packets use the same regular-source, finite-window, dyadic-ledger, and Real-seal order. Since neither route contains a coordinate for quotient streams, selected limits, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no such datum can be exported by the Bishop approximation handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3510.1 and Definition 3510.2 seed the L10 Bishop approximation route from $\mathsf{RegSeqRat}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteCauchyApproximation}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, host equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, precision-window handoff, dyadic tolerance exactness, RealUp seal nonescape, and finite approximation compatibility for BEDC.Derived.BishopCauchyApproximationUp.

Constructive story: A $\mathsf{BishopCauchyApproximation}^{\uparrow}$ packet is generated from a RegSeqRat source row, unary precision request, StreamName finite window, DyadicRatCore tolerance ledger, displayed approximation value, RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3511

A Concrete Naming Certificate for $\mathsf{KakutaniFixedPoint}^{\uparrow}$

Following Kakutani's fixed point theorem and constructive fixed-point readings, the $\mathsf{KakutaniFixedPoint}^{\uparrow}$ packet records only a finite certificate surface for compact convex domains, convex-valued set maps, approximate selector windows, and fixed-point witness ledgers. It sits beside $\mathsf{Compact}^{\uparrow}$ in chapter 60, $\mathsf{ConvexSet}^{\uparrow}$ in chapter 208, $\mathsf{SchauderFixedPoint}^{\uparrow}$ in chapter 1923, $\mathsf{FixedPointIteration}^{\uparrow}$ in chapter 2383, and $\mathsf{Met}^{\uparrow}$ in chapter 57. The packet is a NameCert surface for the fixed-point obligation; it does not import a host choice selector, a full classical compactness theorem, or ambient real completeness.

Definition 3511.1 (Kakutani fixed point carrier)**.** *A* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, G, V, S, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the compact convex domain row, read through the named* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*, and* $\mathsf{Met}^{\uparrow}$ *surfaces.*
2. *G is the set-valued graph row, recording only finite graph windows and their source ledger.*
3. *V is the nonempty compact convex value row for the displayed graph windows.*
4. *S is the approximate selector-window row, listing finite selector approximants and their domain restrictions.*
5. *F is the fixed-point witness ledger, recording approximate self-contact rows and the accepted witness boundary.*
6. *H stores componentwise* hsame *transport for the domain, graph, value, selector, witness, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from domain reads to graph windows, from graph windows to selector windows, and from selector windows to the fixed-point witness ledger.*
8. *P is the* Pkg *provenance over* $\mathsf{KakutaniFixedPoint}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{SchauderFixedPoint}^{\uparrow}$*,* $\mathsf{FixedPointIteration}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KakutaniFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, G, V, S, F, H, C, P, N$. It has no coordinate for a host choice selector, a full classical compactness principle, an ambient real-completeness oracle, or an unrestricted multivalued map.

Lean4 ✓ `BEDC.Derived.KakutaniFixedPointUp.KakutaniFixedPointTasteGate single carrier alignment`

Theorem 3511.2 (Kakutani fixed point NameCert obligations)**.** *For every accepted* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *carrier $K = (D, G, V, S, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KakutaniFixedPoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, compact-convex domain admission through D, finite set-valued graph access through G, nonempty compact convex value admission through V, approximate selector-window admission through S, fixed-point witness ledger admission through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3511.1. The domain, graph, value, selector, and witness coordinates are exactly D, G, V, S, F, so every fixed-point observation enters through those displayed rows.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no additional coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 3511.3 (Kakutani graph-selector nonescape)**.** *Every selector-facing read from an accepted* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *carrier factors through*

$$D, G, V \longmapsto S \longmapsto F$$

together with H, C, P, N. Consequently a consumer may use the displayed $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, *and* $\mathsf{Met}^{\uparrow}$ *interfaces named by the packet, but it receives no host selection function, no unbounded graph oracle, no full classical compactness theorem, and no ambient real-completeness principle.*

Proof. Begin with a selector-facing request. By Definition 3511.1, the request can inspect the compact convex domain row D, the finite set-valued graph row G, and the nonempty compact convex value row V before it reads a selector window.

The selector row S exposes only the displayed approximate selectors and their domain restrictions. The witness ledger F repacks those selector reads as approximate self-contact and fixed-point boundary data.

Finally read H, C, P, N. These rows preserve, replay, source, and name the same displayed data, so none of the excluded host principles can escape through the accepted classifier. □

Theorem 3511.4 (Kakutani convex compact value scope)**.** *The value coordinate V of an accepted* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *carrier is scoped only as a displayed nonempty compact convex value row relative to D and G. It may feed the selector-window route S and the witness ledger F, but it exports no ambient hyperspace compactness theorem, no quotient set-of-points object, no arbitrary selection principle, and no host real-completeness assumption.*

Proof. Use the carrier rows D, G, V from Definition 3511.1. The value row is admitted relative to the displayed domain and graph windows, so its compactness and convexity evidence remains a finite row in the packet.

The only downstream consumers are the selector windows S and the fixed-point witness ledger F. The structural rows H, C, P, N then keep the value evidence tied to the same finite NameCert route rather than an ambient hyperspace or choice construction. □

Theorem 3511.5 (Kakutani Brouwer Schauder handoff)**.** *Every accepted* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *fixed-point read that is later consumed by* $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$, *or* $\mathsf{NashEquilibrium}^{\uparrow}$ *factors first through the compact-convex domain row D, the finite set-valued graph row G, the nonempty compact convex value row V, approximate selector windows S, and the fixed-point witness ledger F of Definition 3511.1. The handoff reaches the Brouwer and Schauder fixed-point surfaces only through those displayed rows together with H, C, P, N; it exports no host choice selector, unrestricted hyperspace compactness theorem, selected fixed point, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or equilibrium/common-fixed-point shortcut.*

Proof. Begin with the carrier and NameCert obligations of Definition 3511.1 and Definition 3511.2. These fix the only admissible rows for the domain, graph, values, selectors, witness ledger, transport, replay, provenance, and local naming.

Next apply Definition 3511.3. A Brouwer or Schauder consumer can read selector data only after D, G, V have been displayed, and the selector window can be repacked into F only as finite approximate self-contact data.

Finally use Definition 3511.4. The value row remains a displayed nonempty compact convex row relative to the graph and domain. Therefore downstream equilibrium or common-fixed-point consumers receive the Brouwer/Schauder handoff through the finite Kakutani route, with no host selector, hyperspace compactness oracle, chosen fixed point, or ambient real-completeness principle. □

Falsifiable prediction: Every $\mathsf{KakutaniFixedPoint}^{\uparrow}$ fixed-point read factors through a compact convex domain row, finite set-valued graph row, nonempty compact convex value row, approximate selector windows, fixed-point witness ledger, transport, continuation, provenance, and local naming.

Independence witness: compact, convexset, schauder-fixed-point, fixed-point-iteration, metric-space: $\mathsf{KakutaniFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a compact convex domain, set-valued graph, nonempty compact convex values, approximate selector windows, fixed-point witness ledger, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KakutaniFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{KakutaniFixedPoint}^{\uparrow}$ packet is generated from finite rows for a compact convex domain, set-valued graph, nonempty compact convex values, approximate selector windows, a fixed-point witness ledger, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KakutaniFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3511.1, Definition 3511.2, Definition 3511.3, Definition 3511.4, and Definition 3511.5 bind the finite Kakutani fixed-point certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KakutaniFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host choice, full classical compactness, ambient real completeness, unrestricted hyperspace compactness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, graph-selector nonescape, convex-compact value scope, and TasteGate field faithfulness for BEDC.Derived.KakutaniFixedPointUp.

Chapter 3512

A Concrete Naming Certificate for $\mathsf{RatCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of the real line as regular Cauchy data over the rationals, the $\mathsf{RatCauchyCompletion}^{\uparrow}$ packet records the finite BEDC interface by which rational rows are read as regular rational Cauchy names and then presented to the real-name seal. It consumes the rational source surface of chapter 37, the Cauchy-modulus tail budget of chapter 292, the finite schedule surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet gives Phase Real and Completion consumers a named rational-Cauchy handoff without quotienting Cauchy names, selecting limits, invoking countable choice, or asserting ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3512.1 (RatCauchyCompletion carrier)**.** *A* $\mathsf{RatCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (R, M, S, Q, D, E, H, K, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Rat}^{\uparrow}$ *source row, recording the rational entries that seed the completion-facing stream.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail row, recording the displayed budget by which two sufficiently late rational observations are forced inside the requested tolerance.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, recording the finite windows through which later consumers request rational approximants.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational sequence visible to the completion corridor.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic budgets, endpoint comparisons, and finite error rows used to check the regularity bounds.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording only the handoff boundary at which the regular rational name may be read as a real-facing name.*
7. *H records componentwise* hsame *transport for the rational source, tail budget, schedule, regular readback, dyadic ledger, seal, continuation, provenance, and local naming rows.*
8. *K records displayed* Cont *routes from rational source rows through tail budgets, schedules, regular readback, dyadic tolerance checks, and the real-seal boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{RatCauchyCompletion}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RatCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, S, Q, D, E, H, K, P, N$. It has no coordinate for quotient-real equality, selected limits, arbitrary Cauchy filters, countable-choice schedules, host completeness, or a theorem that every $\mathsf{Real}^{\uparrow}$ *request is complete.*

Theorem 3512.2 (RatCauchyCompletion NameCert obligations)**.** *For every accepted* $\mathsf{RatCauchyCompletion}^{\uparrow}$ *carrier*

$$C = (R, M, S, Q, D, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RatCauchyCompletion}^{\uparrow}}$ *surface consists exactly of carrier exposure for the rational source row R, Cauchy-modulus tail row M, stream schedule row S, regular rational readback row Q, dyadic tolerance ledger D, real-seal boundary E, componentwise transport row H, continuation row K, package provenance row P, and local naming row N.*

Lean4 ✓ `BEDC.Derived.RatCauchyCompletionUp.TasteGate.RatCauchyCompletionCarrier namecert obligations`

Proof. Carrier exposure is projection from Definition 3512.1. Each row named in the statement is one coordinate of the finite packet, and the definition lists no hidden coordinate for completion beyond those rows.

The rational source and Cauchy-modulus obligations are R and M. The stream and regular-readback obligations are S and Q. The dyadic ledger and real-facing seal obligations are D and E.

Transport, replay, provenance, and local naming are supplied by H, K, P, N. Repacking these coordinates yields the displayed $\mathsf{NameCert}_{\mathsf{RatCauchyCompletion}^{\uparrow}}$ surface, while any claim about quotient equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness remains outside the packet. □

Theorem 3512.3 (RatCauchyCompletion Real seal boundary)**.** *An accepted* $\mathsf{RatCauchyCompletion}^{\uparrow}$ *carrier may hand its regular rational readback row Q and dyadic tolerance ledger D to the* $\mathsf{Real}^{\uparrow}$ *seal row E only through the displayed continuation row K. The handoff preserves the rational-Cauchy interface for Phase Real and Completion consumers, but it does not assert that* $\mathsf{Real}^{\uparrow}$ *is complete, does not choose a quotient representative, and does not manufacture a limit outside the rows $R, M, S, Q, D, E, H, K, P, N$.*

Proof. The only real-facing coordinate of the carrier is E, and the only route into that coordinate is the displayed continuation row K. Thus a consumer reaches the seal boundary by reading the rational source, tail budget, stream schedule, regular rational readback, and dyadic ledger through the packet's finite route.

The carrier definition also lists the negative boundary: no coordinate stores a selected limit, a quotient representative, a countable-choice schedule, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$. Therefore the seal row is a handoff boundary for existing regular rational data, not a proof of completeness of the target interface. □

Theorem 3512.4 (RatCauchyCompletion seal nonescape)**.** *Every accepted* $\mathsf{RatCauchyCompletion}^{\uparrow}$ *carrier reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed rational source row, Cauchy-modulus tail row, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, componentwise transport, displayed replay, provenance, and local NameCert rows. The packet exports no quotient Cauchy name, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 3512.1. Its only Real-facing coordinate is E, and every coordinate before E is one of R, M, S, Q, D together with the structural rows H, K, P, N.

Apply the obligation theorem Definition 3512.2. It exposes the rational source, Cauchy modulus, stream schedule, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming as the whole local NameCert surface.

Now use the handoff theorem Definition 3512.3. The seal row is reachable only through the displayed continuation row after the rational-Cauchy and dyadic rows have been presented.

Therefore a seal read cannot escape to quotient Cauchy names, selected limits, countable-choice schedules, or ambient Real completeness. None of those objects is a carrier coordinate or a local NameCert obligation. □

Closure status for $\mathsf{NameCert}_{\mathsf{RatCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RatCauchyCompletion}^{\uparrow}$ packet is generated from $\mathsf{Rat}^{\uparrow}$ source rows, $\mathsf{CauchyModulus}^{\uparrow}$ tail data, $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RatCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3512.1, Definition 3512.2, Definition 3512.3, and Definition 3512.4 bind the carrier, local NameCert obligations, Real-facing seal boundary, and seal nonescape theorem for the rational-Cauchy completion interface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RatCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove $\mathsf{Real}^{\uparrow}$ completeness, quotient Cauchy equality, selected limits, arbitrary Cauchy-filter completion, countable choice, or a public standard bridge.

Upgrade path: Scoped closure requires Lean encoding of the carrier, the NameCert obligation surface, the Real seal boundary, and the rejection of completeness claims outside the displayed rows.

Chapter 3513

A Concrete Naming Certificate for DyadicDensityRealEmbeddingComparison$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicDensityRealEmbeddingComparison$^{\uparrow}$ packet compares the dyadic-density route of chapter 1484 with the constant dyadic real-name route of chapter 467. It keeps the comparison over the finite rows already exposed by DyadicRatCore$^{\uparrow}$, DyadicDensityReal$^{\uparrow}$, DyadicEmbedding$^{\uparrow}$, RealDyadicEmbedding$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$. The packet is a naming certificate for route agreement at displayed windows, not a construction of host real equality, selected dense points, trichotomy, or completeness of Real$^{\uparrow}$.

Definition 3513.1 (Dyadic-density real embedding comparison carrier)**.** *A* DyadicDensityRealEmbeddingCompariso *carrier is a finite* BHist *packet*

$$K = (D, E, E', S, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicDensityReal$^{\uparrow}$ *density-witness row whose dyadic source is read through the* DyadicRatCore$^{\uparrow}$ *tolerance ledger.*
2. *E is the* DyadicEmbedding$^{\uparrow}$ *constant-name route from the same dyadic source into a stream, a regular rational readback, and a real seal.*
3. *E' is the* RealDyadicEmbedding$^{\uparrow}$ *comparison row that records the Real-facing read of the embedded dyadic name at the displayed window.*
4. *S is the shared* StreamName$^{\uparrow}$ *finite-window row opened by both the density witness and the embedding route.*
5. *R is the shared* RegSeqRat$^{\uparrow}$ *readback row attached to that window.*
6. *Q is the* Real$^{\uparrow}$ *seal row consumed by the comparison.*
7. *H stores componentwise* hsame *transport for the density row, embedding rows, stream window, regular readback, real seal, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from the dyadic source to the density witness, from the same source through the embedding route, and from the common window-readback pair to the* Real$^{\uparrow}$ *seal.*
9. *P stores* Pkg *provenance for* DyadicRatCore$^{\uparrow}$, DyadicDensityReal$^{\uparrow}$, DyadicEmbedding$^{\uparrow}$, RealDyadicEmbedding$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}}$ *row.*
The carrier contains no coordinate for host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ BEDC.Derived.DyadicDensityRealEmbeddingComparisonUp.DyadicDensityRealEmbeddingComparisonTasteGa
single carrier alignment

Theorem 3513.2 (Dyadic-density real embedding comparison NameCert obligations)**.** *For every accepted* $\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}$ *carrier* $K = (D, E, E', S, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}}$ *surface consists of six finite obligation rows:*

1. *carrier admission for the density, embedding, comparison, window, readback, real-seal, transport, continuation, provenance, and local naming rows;*
2. *dyadic-source agreement, stating that the density row D and the embedding row E read the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row;*
3. *window agreement, stating that the comparison opens the same* $\mathsf{StreamName}^{\uparrow}$ *row S for the density read and for the embedded constant name;*
4. *readback agreement, stating that the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *row R is the only rational readback passed to the* $\mathsf{Real}^{\uparrow}$ *seal Q;*
5. *Real-facing comparison, stating that the* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *row E' compares only the displayed density route with the displayed embedding route at the common finite window;*
6. *non-escape, stating that host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness are absent from the carrier.*

Lean4 ✓ BEDC.Derived.DyadicDensityRealEmbeddingComparisonUp.DyadicDensityRealEmbeddingComparisonCarrier
namecert obligations

Proof. Project the accepted carrier. The tuple lists exactly the density row, embedding rows, shared stream window, shared regular readback, real seal, transport, continuation, provenance, and local naming rows available to the classifier.

Dyadic-source agreement is read from the common $\mathsf{DyadicRatCore}^{\uparrow}$ source named by the density and embedding routes. The carrier has one source ledger for the comparison, so the embedded constant name cannot use a separate dyadic point.

Window agreement and readback agreement follow from the shared rows S and R. Both routes must open the same finite $\mathsf{StreamName}^{\uparrow}$ window and pass the same $\mathsf{RegSeqRat}^{\uparrow}$ readback before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

The Real-facing comparison is therefore only the row E'. It records agreement of the two displayed routes at the common finite read, while the transport and continuation rows replay the same packet under componentwise hsame.

Finally inspect the carrier inventory. No row names host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, or ambient completeness, so the six rows exhaust the local NameCert surface. □

Theorem 3513.3 (Dyadic-density real embedding comparison route)**.** *Every accepted* DyadicDensityRealEmbedding
packet compares the density witness route and the constant dyadic embedding route only through the finite spine

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow (\mathsf{DyadicDensityReal}^{\uparrow}, \mathsf{DyadicEmbedding}^{\uparrow}, \mathsf{RealDyadicEmbedding}^{\uparrow}) \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSe}$$

The comparison is a route equality of displayed certificate rows at a common finite window; it does not import host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Start with an accepted packet $K = (D, E, E', S, R, Q, H, C, P, N)$. The density route begins with the $\mathsf{DyadicDensityReal}^{\uparrow}$ row D, and the constant-name route begins with the $\mathsf{DyadicEmbedding}^{\uparrow}$ row E over the same dyadic source.

The comparison row E' is downstream of those two rows. It does not add a new source; it only records the Real-facing comparison after the shared $\mathsf{StreamName}^{\uparrow}$ window S and the shared $\mathsf{RegSeqRat}^{\uparrow}$ readback R have been displayed.

The real seal Q is therefore reached through the same finite read on both sides. Componentwise transport H, continuation replay C, provenance P, and the local name N preserve the packet as a finite BEDC certificate.

Since the carrier provides no row for host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, or ambient completeness, no consumer can replace this finite comparison by an external real-equality or completeness argument. □

Theorem 3513.4 (Dyadic-density real embedding comparison RegSeqRat modulus use)**.** *Every accepted* $\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}$ *packet reads the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *row through the same finite modulus window before comparing the density witness route with the constant dyadic embedding route. In particular, for* $K = (D, E, E', S, R, Q, H, C, P, N)$*, the window row* S *and readback row* R *are consumed before the comparison row* E' *can export agreement to the* $\mathsf{Real}^{\uparrow}$ *seal* Q*.*

Proof. Project the accepted carrier as $K = (D, E, E', S, R, Q, H, C, P, N)$. The carrier has one shared $\mathsf{StreamName}^{\uparrow}$ row S and one shared $\mathsf{RegSeqRat}^{\uparrow}$ readback row R for the density witness route and the constant dyadic embedding route.

Use the shared-window and readback agreement rows from Definition 3513.2. They force both sides of the comparison to open the same finite window and to pass the same regular rational readback before the Real-facing comparison row is consumed.

Apply Definition 3513.3 to identify the comparison spine ending in the $\mathsf{Real}^{\uparrow}$ seal Q. Since the carrier contains no row for host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, or ambient completeness, the shared $\mathsf{RegSeqRat}^{\uparrow}$ window cannot be replaced by any external Real-side principle. □

Theorem 3513.5 (Dyadic-density real embedding comparison non-escape)**.** *The dependency ledger of an accepted* $\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}$ *carrier is exhausted by* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicDensityReal}^{\uparrow}$*,* $\mathsf{DyadicEmbedding}^{\uparrow}$*,* $\mathsf{RealDyadicEmbedding}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. No accepted comparison consumer may add host real equality, a selected dense point, trichotomy, quotient stream equality, arbitrary limit choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness as an implicit dependency.*

Proof. Project the package row P and the local naming row N. They list exactly the finite dependency rows displayed in Definition 3513.1.

Apply Definition 3513.2 for carrier admission, source agreement, window agreement, readback agreement, Real-facing comparison, and non-escape. Then use Definition 3513.3 to identify the only comparison spine consumed by downstream Real-facing readers.

No coordinate remains that could carry an external equality test, a chosen dense point, a trichotomy decision, a quotient-stream equality proof, an arbitrary limit choice, or a completeness

principle. Each such object would therefore be an off-packet dependency, not a row of the accepted comparison certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}$ packet is generated from a DyadicDensityReal density row, a DyadicEmbedding constant-name route, a RealDyadicEmbedding comparison row, shared StreamName and RegSeqRat reads, a Real seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3513.1, Definition 3513.2, Definition 3513.3, and Definition 3513.5 seed the finite comparison packet over dyadic density and dyadic real embedding rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicDensityRealEmbeddingComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, selected dense points, trichotomy, quotient stream equality, arbitrary limit choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source agreement, shared-window agreement, shared-readback agreement, Real-facing comparison, and non-escape for the same finite comparison packet.

Chapter 3514

A Concrete Naming Certificate for $\mathsf{CauchyInterleavingComparison}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyInterleavingComparison}^{\uparrow}$ packet records the finite comparison surface for two interleaved regular-Cauchy names before a completion-facing consumer reads either name as a real-facing object. It sits over the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the convergence-modulus route of chapter 1438, the sequence-limit handoff of chapter 1413, and the terminal real seal of chapter 38. The packet supplies a finite comparison certificate for completion consumers; it is not a quotient of Cauchy names, not a selected representative, and not an ambient completeness principle.

Definition 3514.1 (Cauchy interleaving comparison carrier)**.** *A* $\mathsf{CauchyInterleavingComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, E, O, D, T, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the paired regular-Cauchy source row, storing the two regular rational names whose observations are compared.*
2. *E is the even interleaving window row, exposing the finite observations assigned to the first source.*
3. *O is the odd interleaving window row, exposing the finite observations assigned to the second source.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic comparison budget and endpoint error rows.*
5. *T is the shared tail threshold, read before either interleaving window may be used as a comparison witness.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family that displays the finite window requests routed through T.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback comparison row, reconstructing the regular rational comparison from E, O, D, T, W.*

8. *H records componentwise* hsame *transport for the source, window, tolerance, threshold, readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each completion-facing comparison request through $S, E, O, D, T, W, Q, H, P$*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyInterleavingComparison}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingComparison}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of Cauchy names, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyInterleavingComparisonUp.CauchyInterleavingComparisonTasteGate`
`single carrier alignment`

Theorem 3514.2 (Cauchy interleaving comparison NameCert obligations)**.** *For every accepted* $\mathsf{CauchyInterleavingComparison}^{\uparrow}$ *carrier $K = (S, E, O, D, T, W, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingComp}}$ *surface consists exactly of paired regular-Cauchy source admission, even-window exposure, odd-window exposure, dyadic tolerance exposure, shared tail-threshold exposure, StreamName finite-window exposure, RegSeqRat readback comparison, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 3514.1. Its analytic rows are the paired source S, the even and odd windows E, O, the dyadic ledger D, the shared threshold T, the finite window family W, and the readback comparison row Q.

The NameCert obligations read those rows in the displayed order. The even and odd windows are not independent representatives; they are the two finite faces of the same paired source, controlled by the same dyadic ledger and the same threshold row.

The structural rows H, C, P, N preserve, replay, source, and name the packet. Since the carrier lists no quotient equality, chosen representative, choice selector, trichotomy row, or ambient completeness row, the local certificate surface is exhausted by the displayed finite comparison data. □

Theorem 3514.3 (Cauchy interleaving comparison tail lock)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyInterleavingComparison}^{\uparrow}$ *packet must read the shared threshold row T before inspecting either the even window E or the odd window O. The comparison route is*

$$S \longmapsto D \longmapsto T \longmapsto W \longmapsto E, O \longmapsto Q \longmapsto H, C, P, N,$$

so a downstream $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer receives a single finite tail lock rather than two selected tail representatives.*

Proof. Begin with the NameCert obligations. They place D and T before the window family and before the even–odd observations may be read as comparison evidence.

The $\mathsf{StreamName}^{\uparrow}$ family W then displays the finite requests controlled by the shared threshold. Since both interleaving windows are read through the same T, W pair, a consumer cannot replace the comparison by separate chosen tails for the two sources.

Finally Q repacks the displayed windows as a $\mathsf{RegSeqRat}^{\uparrow}$ readback comparison, and the structural rows preserve that route for $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. Quotient equality, countable choice, trichotomy, selected representatives, and ambient completeness are absent from the carrier and from the local provenance. □

Falsifiable prediction: A $\mathsf{CauchyInterleavingComparison}^{\uparrow}$ consumer that reads an even or odd interleaving window without first reading the shared threshold T refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, cauchyconvergencemodulus, realsequencelimit, real: no listed sibling supplies the whole packet $K = (S, E, O, D, T, W, Q, H, C, P, N)$, because each sibling contributes only tolerance, finite-window, readback, convergence-modulus, limit-handoff, or seal data while this chapter binds the two interleaved windows to one shared comparison threshold.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInterleavingComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyInterleavingComparison}^{\uparrow}$ packet is generated from a paired regular-Cauchy source, even and odd interleaving windows, a DyadicRatCore tolerance ledger, a shared tail threshold, StreamName finite windows, RegSeqRat readback comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyInterleavingComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3514.1, Definition 3514.2, and Definition 3514.3 seed the finite comparison route for interleaved regular-Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyInterleavingComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, even–odd window exposure, shared threshold locking, RegSeqRat readback comparison, transport, replay, provenance, and local naming for BEDC.Derived.CauchyInterleavingComparisonUp.

Chapter 3515

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$ packet records the finite certificate surface for the standard fact that a monotone cofinal subsequence of a regular Cauchy rational name remains regular and presents the same real-name boundary. It consumes the subsequence interface of chapter 381, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal seal surface of chapter 38. The packet is a finite BEDC handoff for Phase Real and Completion consumers; it does not choose a subsequence by countable choice, quotient streams, or invoke ambient completeness.

Definition 3515.1 (RegularCauchySubsequenceStability carrier)**.** *A* $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy packet, carrying the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows and the source finite stream observations.*
2. *T is a monotone-cofinal schedule row, recording the unary reindexing route by which each selected subsequence window is reached from an inspected source window.*
3. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *source and subsequence windows compared by the packet.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying dyadic radii, endpoint comparisons, and the transported regularity budgets.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the subsequence window after transport along T.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary exposed only after the source, schedule, window, dyadic, and readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the source packet, schedule, windows, tolerance ledger, readback row, seal boundary, continuation routes, provenance, and local certificate.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P records the* Pkg *provenance over* $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceStability}^{\uparrow}}$ *row.*
The classifier compares accepted packets only by $S, T, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a choice-selected infinite subsequence, host sequence equality, host real equality, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceStabilityUp.RegularCauchySubsequenceStabilityTasteGate`
`single carrier alignment`
Lean4 (definition) `BEDC.Derived.RegularCauchySubsequenceStabilityUp.RegularCauchySubsequenceStabilityCarri`

Theorem 3515.2 (RegularCauchySubsequenceStability NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$ *carrier*

$$G = (S, T, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceStability}^{\uparrow}}$ *surface consists exactly of the source regular Cauchy rows S, the monotone-cofinal schedule T, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows W, the transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *subsequence readback R, the* $\mathsf{Real}^{\uparrow}$ *seal boundary E, the componentwise transport row H, the continuation replay row C, the package provenance row P, and the local naming row N.*

Proof. Carrier exposure is projection from Definition 3515.1. Each row in the statement is one displayed coordinate of the finite packet, and the definition lists no hidden coordinate for an externally selected subsequence or completion object.

The source and schedule obligations are S and T. The finite-window obligation is W, while the dyadic tolerance and regular rational readback obligations are D and R. These are the rows that express the usual cofinal-subsequence regularity argument inside the BEDC packet.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Repacking these projections yields the displayed $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceStability}^{\uparrow}}$ surface, with no quotient stream, host equality, or ambient completeness datum. □

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceStabilityUp.RegularCauchySubsequenceStabilityCarrier`
`namecert obligations`

Theorem 3515.3 (RegularCauchySubsequenceStability Real seal boundary)**.** *An accepted* RegularCauchySubseque
carrier may expose its $\mathsf{Real}^{\uparrow}$ *seal row E only after the source regular Cauchy data S, the monotone-cofinal schedule T, the finite stream windows W, the transported dyadic tolerance ledger D, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R have been displayed through H and C. Thus cofinal subsequence transport preserves the real-name seal surface as finite BEDC data and does not export quotient streams, a choice-selected subsequence, host sequence equality, or ambient real completeness.*

Proof. Start with an accepted carrier. The seal row E is not a source coordinate; it is reached after the source, schedule, window, dyadic, readback, transport, continuation, provenance, and naming rows have been projected.

Apply the NameCert obligation surface of Definition 3515.2. It identifies the monotone-cofinal schedule, the inspected and selected finite windows, the transported dyadic tolerance ledger, and the regular rational readback as the only data available before the seal boundary.

The ordinary constructive subsequence argument is therefore recorded as carrier projection followed by cofinal schedule transport and finite-window replay. Since the classifier has no coordinate for quotient streams, choice-selected subsequences, host sequence equality, host real equality, or a completeness principle, none of those data can escape through the $\mathsf{Real}^{\uparrow}$ seal row. □

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceStabilityUp.RegularCauchySubsequenceStabilityCarrier`
`real seal boundary`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceStability}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$ packet is generated from source regular Cauchy rows, a monotone-cofinal schedule, finite $\mathsf{StreamName}^{\uparrow}$ windows, transported $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3515.1, Definition 3515.2, and Definition 3515.3 bind the carrier, local NameCert obligations, and Real-facing seal boundary for cofinal regular Cauchy subsequence stability.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove a public standard bridge, quotient stream equality, host sequence equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Scoped closure requires Lean encoding of the carrier, the NameCert obligation surface, the Real seal boundary, and the nonescape boundary for data outside the displayed rows.

DNA hash: `aggregate=sha256:5f957223fdebb99cd0a4300c035bf3311aafd9888c8f99810e0304aa1e677f18;statement=sha256:a7`

Chapter 3516

A Concrete Naming Certificate for $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$

Following Specker's constructive counterexample tradition and Bishop–Bridges constructive analysis, the $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ packet isolates the reusable nonlocated-supremum obstruction behind monotone bounded rational streams. It sits after $\mathsf{SpeckerSequence}^{\uparrow}$ in chapter 1406 and reads only the finite windows supplied by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{LocatedCut}^{\uparrow}$ in chapter 126, chapter 301, chapter 291, chapter 38, and chapter 404. The packet names the obstruction surface; it does not supply Real completeness, a located supremum, trichotomy, quotient stream equality, countable choice, or selected limits.

Definition 3516.1 (Specker sequence boundary carrier)**.** *A* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, D, M, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SpeckerSequence}^{\uparrow}$ *source row naming the monotone bounded rational stream and its nonlocated-supremum boundary.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finite source windows inspected by the boundary packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and bound ledger read from the same selected windows.*
4. *M is the monotone and bounded obstruction ledger recording the displayed comparison and bound data that can be read before any real-facing seal.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational windows certified by S, W, D, M.*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *seal or* $\mathsf{LocatedCut}^{\uparrow}$ *refusal row; it records that the displayed windows may be sealed as finite real readback data, while a located-cut or supremum witness remains external.*
7. *H stores componentwise* hsame *transport for the source, schedule, dyadic ledger, obstruction ledger, regular readback, seal-or-refusal row, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from S, W into D, from D into M, from M into R, and from R into the seal-or-refusal row L.*
9. *P is the* Pkg *provenance over* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SpeckerSequenceBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, W, D, M, R, L, H, C, P, N$. It has no coordinate for a located supremum, a selected limiting real, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SpeckerSequenceBoundaryUp.SpeckerSequenceBoundaryTasteGate single carrier alignment`

Theorem 3516.2 (Specker sequence boundary NameCert obligations)**.** *For every accepted* SpeckerSequenceBounda *carrier $B = (S, W, D, M, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SpeckerSequenceBoundary}^{\uparrow}}$ *surface consists exactly of source admission through S, finite schedule selection through W, dyadic tolerance and bound admission through D, monotone bounded obstruction admission through M, regular rational readback through R, the* $\mathsf{Real}^{\uparrow}$ *seal or* $\mathsf{LocatedCut}^{\uparrow}$ *refusal row L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3516.1. The analytic rows are exactly the Specker source, stream schedule, dyadic ledger, monotone bounded obstruction ledger, regular readback, and seal-or-refusal row.

The structural rows H, C, P, N transport, replay, source, and name those same coordinates. Since the carrier contains no further analytic field, the listed rows exhaust the local NameCert obligations.

The missing fields are also part of the boundary. A located supremum, quotient stream equality, countable-choice selector, trichotomy branch, or selected limit would require an additional coordinate, and no such coordinate is present. □

Theorem 3516.3 (Specker sequence boundary Cauchy readback)**.** *Every Cauchy-facing read from an accepted* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ *carrier factors through*

$$S, W \longmapsto D \longmapsto M \longmapsto R \longmapsto L$$

together with H, C, P, N. The row R exports only the $\mathsf{RegSeqRat}^{\uparrow}$ *window readback certified by the displayed schedule and dyadic ledger, and the row L exports only a finite* $\mathsf{Real}^{\uparrow}$ *seal or a* $\mathsf{LocatedCut}^{\uparrow}$ *refusal boundary.*

Proof. Start with the source route. The $\mathsf{SpeckerSequence}^{\uparrow}$ row S and the $\mathsf{StreamName}^{\uparrow}$ schedule W determine which finite rational windows are inspected.

Read the dyadic and obstruction ledgers next. The row D supplies the tolerance and bound data for those windows, while M records the monotone bounded obstruction information available at the same finite stages.

The regular readback row R is downstream of those data, and the seal-or-refusal row L is downstream of R. Transport, replay, provenance, and local naming through H, C, P, N preserve this route, so no located supremum or selected limiting real is produced by the Cauchy readback. □

Theorem 3516.4 (Specker sequence boundary nonescape)**.** *Every consumer of an accepted* SpeckerSequenceBounda *carrier receives only the finite rows $S, W, D, M, R, L, H, C, P, N$. Consequently the packet may reuse the* $\mathsf{SpeckerSequence}^{\uparrow}$ *nonlocated-supremum obstruction and its* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{LocatedCut}^{\uparrow}$ *interfaces, but it exports no* $\mathsf{Real}^{\uparrow}$ *completeness principle, located supremum, trichotomy, quotient stream equality, countable-choice selector, or selected limit.*

Proof. Use Definition 3516.2 to identify the complete public surface of the accepted packet. All analytic reads pass through the six displayed rows S, W, D, M, R, L.

Use Definition 3516.3 to order those rows. The regular readback and seal-or-refusal row appear only after finite windows, dyadic data, and monotone bounded obstruction data have been displayed.

Finally read the structural rows. Componentwise transport, displayed replay, provenance, and local naming do not add analytic coordinates, so none of the excluded completeness, choice, equality, order-decision, or selected-limit principles can escape from the packet. □

Theorem 3516.5 (Specker sequence boundary LPO separation)**.** *Every consumer reading an accepted* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ *carrier* $B = (S, W, D, M, R, L, H, C, P, N)$ *through the displayed rows* $S, W, D, M, R, L, H, C, P, N$ *receives only the Specker source, finite schedule, dyadic tolerance ledger, monotone bounded obstruction ledger, regular rational readback, seal-or-refusal boundary, transport, continuation, provenance, and local naming data. Such a consumer cannot extract* $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$, $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, *countable choice, trichotomy, or a located supremum unless an external row supplies that principle.*

Proof. Project the carrier of Definition 3516.1. The only analytic rows available to the consumer are S, W, D, M, R, L, and the only structural rows are H, C, P, N.

Apply the Cauchy readback theorem Definition 3516.3. It orders the read through the Specker source, finite schedule, dyadic ledger, monotone bounded obstruction ledger, regular readback, and seal-or-refusal row before any Real-facing conclusion is public.

Now apply nonescape from Definition 3516.4. The carrier has no coordinate for located supremum construction, trichotomy, quotient stream equality, countable choice, selected limits, or ambient Real completeness.

The neighbouring omniscience packets of chapter 5945 and chapter 1977 are therefore only comparison siblings. Without an external row naming one of those principles, the Specker boundary exports the obstruction route and not LPO, LLPO, countable choice, trichotomy, or a located supremum. □

Falsifiable prediction: Every $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ Cauchy-facing read factors through a SpeckerSequence source row, StreamName schedule, DyadicRatCore tolerance ledger, monotone bounded obstruction ledger, RegSeqRat readback, Real seal or LocatedCut refusal row, transport, continuation, provenance, and local naming.

Independence witness: speckersequence, streamname, regseqrat, dyadicratcore, real, located-cut: $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the nonlocated-supremum obstruction route, regular readback, seal-or-refusal boundary, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SpeckerSequenceBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ packet is generated from a $\mathsf{SpeckerSequence}^{\uparrow}$ source row, a $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and bound rows, a monotone bounded obstruction ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal or $\mathsf{LocatedCut}^{\uparrow}$ refusal row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpeckerSequenceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3516.1, Definition 3516.2, Definition 3516.3, Definition 3516.4, and Definition 3516.5 bind the finite nonlocated-supremum obstruction certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpeckerSequenceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, located supremum construction, trichotomy, quotient stream equality, countable choice, selected limits, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, Cauchy readback, nonescape, and TasteGate field faithfulness for BEDC.Derived.SpeckerSequenceBoundaryUp.

Chapter 3517

A Concrete Naming Certificate for $\mathsf{BishopOrderCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopOrderCompletion}^{\uparrow}$ packet records the order-completion face of the real-number construction as finite BEDC NameCert data. It sits after the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the comparison boundary of chapter 1730, the lower and upper cut rows of chapter 1446 and chapter 2087, and the terminal real-name seal of chapter 38. The packet names a constructive order-completion interface; it is not a quotient-cut construction, selected supremum principle, trichotomy oracle, host real equality test, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 3517.1 (Bishop order-completion carrier)**.** *A* $\mathsf{BishopOrderCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, E, B, L, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison-budget ledger used by all lower, upper, and real-seal requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at those dyadic requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R have been displayed.*
5. *B is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *comparison row, read through the located-real comparison surface and tied to the same windows and dyadic budgets.*
6. *L is the LowerReal-style located lower-cut ledger, recording only the displayed inhabited lower observations and downward-use rows available to the packet.*
7. *U is the UpperReal-style located upper-cut ledger, recording only the displayed upper observations and upward-use rows available to the packet.*
8. *H records componentwise* hsame *transport for the tolerance, window, readback, Real seal, comparison, lower-cut, upper-cut, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each order-completion request through $D, S, R, E, B, L, U, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopOrderCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopOrderCompletion}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $D, S, R, E, B, L, U, H, C, P, N$. It has no coordinate for quotient cuts, host supremum objects, selected representatives, trichotomy, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopOrderCompletionUp.TasteGate.BishopOrderCompletionTasteGate single carrier alignment`

Theorem 3517.2 (Bishop order-completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopOrderCompletion}^{\uparrow}$ *carrier $O = (D, S, R, E, B, L, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopOrderCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, DyadicRatCore tolerance exposure, finite StreamName window exposure, RegSeqRat readback, Real seal handoff, BishopRealComparison exposure, LowerReal-style lower-cut exposure, UpperReal-style upper-cut exposure, componentwise transport, displayed continuation replay, package provenance, and local naming. Every order-completion consumer factors through*

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto B \longmapsto (L, U) \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

Proof. Project the carrier of Definition 3517.1. Its real-facing rows are the dyadic tolerance ledger, finite stream windows, regular rational readback, and terminal Real seal.

Read the order rows after the same real-facing route. The comparison row B uses the displayed windows and dyadic budgets, while L and U record the lower and upper located-cut observations available to the packet.

The structural rows then preserve this ordered route. The hsame, Cont, Pkg, and local NameCert rows transport, replay, source, and name the route, and the refused quotient, host-supremum, selected, trichotomy, host-equality, choice, and ambient-completeness objects have no carrier coordinate. □

Theorem 3517.3 (Bishop order-completion located-cut handoff)**.** *Every located lower-or-upper cut read exported by an accepted* $\mathsf{BishopOrderCompletion}^{\uparrow}$ *carrier is downstream of the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{BishopRealComparison}^{\uparrow}$ *comparison row. The handoff exposes the LowerReal-style and UpperReal-style ledgers only as the finite packet $D, S, R, E, B, L, U, H, C, P, N$.*

Proof. Start with the NameCert obligations. They place D, S, R, E before any order-facing row can be consumed.

Next read the comparison boundary. The row B ties lower and upper observations to the same finite windows and dyadic budgets, so the lower and upper ledgers cannot be inspected as independent host cuts.

Finally project L and U. These rows are named only inside the carrier and are preserved by H, C, P, N, so the handoff contains no quotient-cut equality, selected representative, trichotomy branch, host supremum, or ambient completeness coordinate. □

Theorem 3517.4 (Bishop order-completion Cauchy-cut comparison)**.** *For every accepted* $\mathsf{BishopOrderCompletion}^{\uparrow}$ *carrier, the comparison between regular-Cauchy real data and located lower–upper cut data is a single finite route through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BishopRealComparison}^{\uparrow} \longmapsto (\mathsf{LowerReal}^{\uparrow}, \mathsf{UpperR}$$

Thus a Cauchy-facing consumer and a cut-facing consumer read the same packet-local rows $D, S, R, E, B, L, U, H, C$ rather than two unrelated completion principles.

Proof. Read the Cauchy-facing side first. The rows D, S, R, E display the tolerance, window, readback, and Real seal route used by regular-Cauchy consumers.

Read the cut-facing side through the comparison row. The row B is downstream of the same route and supplies the finite comparison request before L and U can expose lower and upper located observations.

The two faces are therefore synchronized by the structural rows. Transport, continuation, provenance, and local naming preserve one packet-local route, while quotient-cut completion, selected supremum, host real equality, trichotomy, countable choice, and ambient Real completeness remain outside the carrier. □

Falsifiable prediction: A claimed $\mathsf{BishopOrderCompletion}^{\uparrow}$ consumer that reaches a lower-cut or upper-cut row without the displayed DyadicRatCore, StreamName, RegSeqRat, Real, and BishopRealComparison rows refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishoprealcomparison, lowerreal, upperreal: no listed sibling supplies the whole $\mathsf{BishopOrderCompletion}^{\uparrow}$ packet, because each sibling contributes only tolerance, window, readback, seal, comparison, or one-sided cut data while this chapter binds all of them with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopOrderCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopOrderCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, RealUp seal, BishopRealComparison row, LowerReal-style and UpperReal-style located cut rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopOrderCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3517.1, Definition 3517.2, Definition 3517.3, and Definition 3517.4 seed the finite order-completion interface joining regular-Cauchy real data to located lower and upper cut rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopOrderCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient cut completion, selected suprema, trichotomy, countable choice, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window exactness, regular readback, RealUp seal handoff, comparison-row stability, located cut handoff, Cauchy-cut comparison, transport, replay, provenance, and local naming for BEDC.Derived.BishopOrderCompletionUp.

Chapter 3518

A Concrete Naming Certificate for $\mathsf{EffectiveCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ packet records the finite precision-to-tail schedule that lets a Cauchy name serve L10 Real and Completion consumers without importing ambient completeness. It sits over the generic modulus schedule of chapter 292, the fast threshold discipline of chapter 1781, the request-to-tail realizer of chapter 1918, the finite-window interface of chapter 126, the regular rational route of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet supplies one displayed schedule row before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reads a seal.

Definition 3518.1 (Effective Cauchy modulus carrier)**.** *An* $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, D, M, T, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row whose observations are opened only through finite windows.*
2. *D is the dyadic precision ledger consumed by the tail estimates and regular rational readbacks.*
3. *M is the effective precision-to-tail modulus row, assigning each displayed precision request a finite tail index.*
4. *T is the tail-index comparison row showing that the selected index is stable under stronger displayed precision requests.*
5. *W is the finite tail-window row opened from S at the index selected by M.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W under the dyadic ledger D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row, exposed only after S, D, M, T, W, Q have been displayed.*
8. *H records componentwise* hsame *transport for the stream, dyadic ledger, effective modulus, tail comparison, window, readback, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a precision request through $S, D, M, T, W, Q, E_H, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{FastCauchyModulus}^{\uparrow}$, $\mathsf{RegularCauchyModulusRealizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, M, T, W, Q, E, H, C, P, N$. It has no coordinate for quotient limits, countable choice, host convergence, trichotomy, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3518.2 (Effective Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ *carrier*

$$X = (S, D, M, T, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCauchyModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for the stream source, dyadic precision ledger, effective modulus row, tail comparison row, finite window, regular readback, Real handoff, transport, replay, provenance, and local naming rows;*
2. *schedule classification, requiring M to be the only precision-to-tail row read by a downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer;*
3. *monotone tail-index stability, requiring T to certify that stronger displayed precision requests never require a weaker tail boundary than the row already exposed by M;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal compatibility, requiring W and Q to be read before the handoff row E exposes a terminal Real seal;*
5. *ledger refusal for quotient limits, countable choice, host convergence, trichotomy, selected representatives, and ambient completeness as local certificate data.*

No effective Cauchy modulus obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic coordinates are exactly the stream source, dyadic ledger, effective modulus, tail comparison, finite window, regular readback, and Real handoff rows.

The schedule classifier is the row M. Since every consumer reaches a tail window only after reading M, no hidden convergence selector or external completeness principle can choose the boundary.

The monotonicity information is stored in T. It relates stronger displayed precision requests to tail indices already chosen by M, so transport through H and replay through C preserve the same schedule.

Finally, the readback and seal are downstream of the finite window. The rows Q and E can expose regular rational and Real-facing data only after S, D, M, T, W have been displayed, and the refused objects have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.EffectiveCauchyModulusUp.EffectiveCauchyModulusCarrier namecert obligations`

Theorem 3518.3 (Effective Cauchy modulus seal route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ *packet factors through*

$$S, D, M, T \longmapsto W \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

The route exports a displayed finite tail schedule and does not export quotient limits, countable choice, host convergence, trichotomy, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier coordinates in order. A precision request first sees the stream and dyadic rows S, D, then the effective modulus and tail-stability rows M, T.

Only after those rows are displayed can the finite window W be opened. The regular rational readback Q and terminal handoff E_H are downstream of that finite window.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no coordinate for the refused principles, the exported object remains the finite schedule-to-window packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchyModulus}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ packet is generated from a StreamName source row, a dyadic precision ledger, an effective precision-to-tail modulus row, a monotone tail-index comparison row, a finite tail-window row, a RegSeqRat readback, a RealUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3518.1, Definition 3518.2, and Definition 3518.3 seed the finite schedule object consumed by L10 StreamName, RegSeqRat, and Real routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, quotient limits, countable choice, host convergence, trichotomy, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, schedule classification, monotone tail-index stability, RegSeqRat and RealUp seal compatibility, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveCauchyModulusUp.

Chapter 3519

A Concrete Naming Certificate for $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$

The $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ packet realizes the MetaCIC audit-map frontier of section 9376.7 as finite BEDC rows. It sits next to the redex frontier, normalization frontier, confluence-audit packet, and decidable-boundary anchors already used by the MetaCIC vision, but it names the smaller object needed by a candidate-mediated reducer: a displayed finite choice surface for which redex rows may be inspected, which normalization and confluence-audit rows are available, and which boundaries remain undecided. The packet consumes the redex-row surface of chapter 1008, the candidate-normalization boundary of chapter 892, the local critical-pair fork surface of chapter 2382, and the beta critical-pair row of chapter 881. The normal-form endpoint row is consumed through chapter 740, while the redex-choice packet keeps subject reduction and global consistency outside the carrier. The packet does not assert global normalization, Church–Rosser, subject reduction for all terms, or a complete MetaCIC semantics.

Definition 3519.1 (MetaCIC redex-choice frontier carrier)**.** *A* $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, N, F, D, B, H, K, L, C, P, Q)$$

with the following displayed rows:

1. *A is the MetaCIC redex row, listing the candidate redexs exposed by the local term-and-context window.*
2. *N is the normalization-frontier row, recording which candidates have a displayed bounded reduction trace.*
3. *F is the confluence-audit row, recording local fork and join checks for the same candidate set.*
4. *D is the decidable-boundary row, recording which redex choices are classified by finite inspection and which remain outside the packet.*
5. *B is the* BHist *replay ledger for the term window, candidate row, trace row, fork row, boundary row, and local naming row.*
6. *H records componentwise* hsame *transport for the redex, normalization, confluence-audit, decidability, replay, continuation, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a term-window request through A, N, F, D, B, H, P, Q.*

8. *L is the* Pkg *provenance over* $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$*, MetaCIC redex rows, normalization-frontier rows, confluence-audit rows, decidable-boundary rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *C records the candidate-choice classifier: it exposes only the redex choices whose A, N, F, D rows are present in the packet.*
10. *P records the local package boundary for Nontrivial and FieldFaithful TasteGate instances to be checked by a later Lean development over the displayed carrier.*
11. *Q is the local* $\mathsf{NameCert}_{\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, N, F, D, B, H, K, L, C, P, Q$. It has no coordinate for global normalization, global confluence, unrestricted redex selection, subject reduction for all terms, quotient syntax, host evaluator soundness, or a completed MetaCIC model.

Lean4 ✓ `BEDC.Derived.MetacicRedexChoiceFrontierUp.MetacicRedexChoiceFrontierTasteGate single carrier alignment`

Theorem 3519.2 (MetaCIC redex-choice frontier NameCert obligations)**.** *For every accepted* $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ *carrier*

$$R = (A, N, F, D, B, H, K, L, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for MetaCIC redex rows, normalization-frontier traces, confluence-audit fork rows, decidable-boundary classifiers, replay, transport, continuation, provenance, candidate-choice, TasteGate boundary, and local naming rows;*
2. *redex-choice classification, requiring the candidate-choice row C to inspect only redexs displayed in A and only boundary outcomes displayed in D;*
3. *normalization-frontier compatibility, requiring every candidate exported by C to carry either the bounded trace row in N or the explicit boundary refusal in D;*
4. *confluence-audit compatibility, requiring every fork exported by C to use the same candidate set as A and the same local fork rows as F;*
5. *TasteGate preparation, requiring the packet to expose the Nontrivial and FieldFaithful instance boundary in P without claiming those Lean instances as paper-side evidence;*
6. *ledger refusal for global normalization, global confluence, unrestricted redex selection, subject reduction for all terms, quotient syntax, host evaluator soundness, and a completed MetaCIC model.*

No redex-choice frontier obligation is stored outside these rows.

Proof. Project the accepted carrier. The term-facing data are the redex row A, the normalization-frontier row N, the confluence-audit row F, the decidable-boundary row D, and the candidate-choice row C.

The candidate classifier cannot inspect a redex outside A, because C is downstream of the displayed redex row. It cannot treat an undecided boundary as decided, because every exported choice must pass through D.

The normalization and confluence rows are tied to the same candidate set. A selected candidate therefore carries the bounded trace information from N and the local fork information from F exactly when those rows are displayed by the packet.

The TasteGate boundary row P records the intended Nontrivial and FieldFaithful instance surface for Lean without adding a marker or treating the instances as verified. The refused global principles have no carrier coordinate, so the NameCert surface remains finite. □

Theorem 3519.3 (MetaCIC redex-choice frontier nonescape)**.** *Every reducer-facing read from an accepted* $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ *packet factors through*

$$A, N, F, D \longmapsto C \longmapsto B, H, K, L, P, Q.$$

The exported object is a finite candidate-mediated frontier for local redex choice, not global normalization, global confluence, unrestricted redex selection, quotient syntax, host evaluator soundness, or a completed MetaCIC model.

Proof. Start with the displayed redex, normalization, confluence-audit, and decidable-boundary rows. These rows are the only inputs to the candidate-choice classifier.

The classifier C exports only the candidates that survive those displayed rows. Replay through B, transport through H, continuation through K, provenance through L, TasteGate boundary through P, and naming through Q preserve the same finite route.

Since no global normalization theorem, global confluence theorem, unrestricted redex selector, quotient syntax object, host evaluator soundness proof, or completed MetaCIC model appears in the carrier, the reducer-facing read cannot escape the finite frontier. □

Theorem 3519.4 (MetaCIC redex-choice frontier candidate-boundary exhaustion)**.** *For every accepted* $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ *carrier*

$$R = (A, N, F, D, B, H, K, L, C, P, Q),$$

each exported candidate choice is exhausted by the displayed A, N, F, D, C *rows before replay, provenance, transport, TasteGate preparation, and local naming are read through* B, H, K, L, P, Q*. No accepted route can import global normalization, global confluence, unrestricted redex selection, quotient syntax, host evaluator soundness, or completed MetaCIC semantics.*

Proof. Begin with the candidate-choice classifier C. By Definition 3519.1, it exports only choices whose redex row A, normalization-frontier row N, confluence-audit row F, and decidable-boundary row D are already displayed.

Apply the nonescape theorem Definition 3519.3. After A, N, F, D and C have been consumed, replay and provenance can only preserve the same finite route through B, H, K, L, P, Q.

The refused global objects have no carrier coordinate. Thus the boundary is exhausted at the candidate-mediated finite rows and remains separate from global normalization, global confluence, unrestricted redex selection, quotient syntax, host evaluator soundness, and completed MetaCIC semantics. □

Theorem 3519.5 (MetaCIC redex-choice candidate-normalization handoff)**.** *Every exported redex choice from an accepted* $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ *packet consumed by a normalization-window or confluence-audit reader must pass through*

$$A, N, F, D, C \longmapsto B, H, K, L, P, Q.$$

The row N *supplies only displayed candidate-normalization evidence, the row* F *supplies only local fork information, and the row* D *preserves undecided boundary rows. The packet refuses global normalization, Church–Rosser, subject reduction for all terms, quotient syntax, host evaluator soundness, and a completed MetaCIC semantics.*

Proof. Start with the NameCert obligations of Definition 3519.2. Redex-choice classification forces C to inspect only redexs in A and boundary outcomes in D, while normalization-frontier and confluence-audit compatibility tie exported candidates to the displayed N and F rows.

The normalization-window reader therefore receives only candidate-normalization evidence from N. The confluence-audit reader receives only local fork information from F, and undecided rows remain recorded by D rather than being converted into global decisions.

Apply Definition 3519.4. Each exported candidate is already exhausted by A, N, F, D, C before replay, transport, continuation, provenance, TasteGate preparation, and local naming are read through B, H, K, L, P, Q.

Finally use Definition 3519.3. The refused global principles and host-side objects have no carrier coordinate, so the handoff cannot assert global normalization, Church–Rosser, subject reduction for all terms, quotient syntax, host evaluator soundness, or a completed MetaCIC semantics. □

Falsifiable prediction: A $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ reducer-facing read factors through displayed MetaCIC redex rows, normalization-frontier traces, confluence-audit fork rows, decidable-boundary classifiers, candidate-choice rows, BHist replay, hsame transport, Cont replay, Pkg provenance, TasteGate boundary rows, and local NameCert data.

Independence witness: metacic-redex, metacic-normalization-frontier, metacic-confluence-audit, metacic-decidable-boundary: $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ is not bijective to any listed anchor because it jointly carries candidate-choice classification, shared redex-boundary routing, Nontrivial and FieldFaithful TasteGate boundaries, replay, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}$ packet is generated from MetaCIC redex rows, normalization-frontier rows, confluence-audit rows, decidable-boundary rows, BHist replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, a candidate-choice classifier, Nontrivial and FieldFaithful TasteGate boundary rows, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3519.1, Definition 3519.2, Definition 3519.3, and Definition 3519.4 seed the finite candidate-mediated redex-choice frontier for MetaCIC audit maps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicRedexChoiceFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global normalization, global confluence, unrestricted redex selection, subject reduction for all terms, quotient syntax, host evaluator soundness, a completed MetaCIC model, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, redex-choice classification, normalization-frontier compatibility, confluence-audit compatibility, Nontrivial and FieldFaithful TasteGate instances, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetacicRedexChoiceFrontierUp.

Chapter 3520

A Concrete Naming Certificate for $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$

Following Bishop and Bridges constructive completion theory, the $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$ packet records the finite route by which a displayed finite coproduct of metric sources is read before any completion-facing or real-facing consumer may inspect the completed object. It sits after the metric-completion surface of chapter 1506, the finite sum carrier of chapter 35, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite coproduct completion handoff, not a quotient completion equality, not a selected limit, not a countable-choice selector, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3520.1 (Metric completion finite-coproduct carrier)**.** *A* $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{MCFC}(I, S, M, W, R, A, J, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row naming the admitted summands.*
2. *S is the* $\mathsf{Sum}^{\uparrow}$ *coproduct row, recording injections, finite case analysis, and the branch classifier.*
3. *M is the family of* $\mathsf{MetricCompletion}^{\uparrow}$ *source rows, one for each admitted branch.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used when a branch request is inspected by a completion consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the branch-local tolerance and distance data.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after W and R have fixed the requested branch data.*
7. *J is the coproduct-completion join row, stating that every accepted consumer first selects a displayed finite branch and then reads the corresponding completion route.*
8. *H records componentwise* hsame *transport for index, sum, completion, window, readback, seal, join, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a coproduct-completion request through I, S, M, W, R, A, J.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{Sum}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, S, M, W, R, A, J, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, infinite coproducts, countable choice, host case analysis outside S, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionFiniteCoproductUp.MetricCompletionFiniteCoproductTasteGate`
`single carrier alignment`

Theorem 3520.2 (Metric completion finite-coproduct NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$ *carrier* $\mathsf{MCFC}(I, S, M, W, R, A, J, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index row,* $\mathsf{Sum}^{\uparrow}$ *coproduct row, branchwise* $\mathsf{MetricCompletion}^{\uparrow}$ *rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, coproduct-completion join, componentwise transport, displayed replay, provenance, and local naming.*

Every obligation is branch-local after the finite case split in S, and every public read must pass through W, R, A before it may expose a completed coproduct branch. No obligation is stored in quotient completion equality, selected representatives, countable choice, infinite coproduct data, host case analysis, or ambient completeness.

Proof. Carrier admission is projection from Definition 3520.1. The tuple displays the finite index row, sum row, branchwise completion rows, numerical readback rows, join row, and structural support.

The finite case split is the row S. Once a branch is selected, the corresponding completion route in M is the only completion-facing source available to a consumer.

The readback rows W, R, A then bind finite observation windows, regular rational tolerance data, and the terminal Real seal to that same branch. The join row J records that this branch-local route is the public coproduct-completion handoff.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for the excluded quotient, choice, host, or ambient-completeness objects, the stated rows exhaust the NameCert obligations. □

Theorem 3520.3 (Metric completion finite-coproduct universal route)**.** *Every consumer that reads a finite coproduct after metric completion, or metric completion after a finite coproduct, factors through the displayed route*

$$\mathsf{Sum}^{\uparrow} \longrightarrow \mathsf{MetricCompletion}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The exported object is the branch classifier named by $I, S, M, W, R, A, J, H, C, P, N$, not a quotient-level universal property and not a selected completed representative.

Proof. Start with the finite index and coproduct rows I, S. They are the only rows that select a branch, so any universal read begins with the displayed finite case split.

For the chosen branch, project the corresponding $\mathsf{MetricCompletion}^{\uparrow}$ row from M. The carrier offers no completed branch outside this family.

Now pass through W, R, A. These rows provide the finite stream window, regular rational readback, and real seal used by the branch consumer.

Apply Definition 3520.2. The join, transport, replay, provenance, and naming rows keep the same route visible, so the consumer receives only the finite universal route and cannot import a quotient completion isomorphism or selected representative. □

Theorem 3520.4 (Metric completion finite-coproduct nonescape)**.** *No accepted* $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$ *consumer can escape from the finite branch route into quotient completion equality, selected limits, countable choice, an infinite coproduct, host-side case analysis, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every exposed claim is read through the same finite packet rows*

$$I, S, M, W, R, A, J, H, C, P, N.$$

Proof. Use Definition 3520.3. It places every completion-coproduct consumer behind the finite branch classifier and the branch-local completion rows.

The numerical boundary is fixed by W, R, A. These rows provide only finite windows, regular rational readback, and a Real seal for the displayed branch.

The support rows J, H, C, P, N join, transport, replay, source, and name the same packet. Because no excluded object occurs as a coordinate of Definition 3520.1, no consumer can export it. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}$ packet is generated from a finite index row, a SumUp coproduct row, branchwise MetricCompletionUp rows, StreamName windows, RegSeqRat readback, a RealUp seal, a coproduct-completion join row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3520.1, Definition 3520.2, Definition 3520.3, and Definition 3520.4 seed the finite coproduct completion route over MetricCompletionUp, SumUp, StreamNameUp, RegSeqRatUp, RealUp, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionFiniteCoproduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, selected limits, countable choice, infinite coproducts, host case analysis, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite branch classification, branchwise completion routing, StreamName and RegSeqRat readback, Real seal exactness, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionFiniteCoproductUp.

Chapter 3521

A Concrete Naming Certificate for $\mathsf{LatentCompletion}^{\uparrow}$

The $\mathsf{LatentCompletion}^{\uparrow}$ packet realizes the finite monotone-path completion witness of Definition 9462.1836 as BEDC NameCert data. It records observed module states, latent prefix states, target-monotone edges, exception rows, and a completion-choice ledger before any consumer may claim coverage of the module-state exception geometry. The observed module-state ledger is consumed through chapter 3470, chapter 3508, and chapter 3478 before the latent-prefix exception rows are read. The packet is a finite completion surface for the two missing monotone squares of Definition 9462.1837; it is not an empirical biological transition model, not a host graph-completion oracle, and not a global state-space completeness claim.

Definition 3521.1 (Latent completion carrier)**.** *A* $\mathsf{LatentCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{LatentCompletion}(O, E, L, D, M, K, H, C, P, N)$$

with the following displayed rows:

1. *O is the observed module-state ledger containing the sampled endpoints and their module-value rows.*
2. *E is the exception ledger for the target-monotone failures represented by table identifiers* 9*,* 14*, and* 28*.*
3. *L is the latent-state row containing one deep-branch prefix and one partial-boundary prefix from Definition 9462.1836.*
4. *D is the directed rewrite-edge row for target-monotone one-module changes.*
5. *M is the monotone-path coverage row verifying that every observed endpoint is reachable after the latent rows are admitted.*
6. *K is the exception-kill row recording that the two latent rows cover the two independent missing squares and no third exception branch is created.*
7. *H records componentwise* hsame *transport for observed states, latent states, rewrite edges, coverage rows, exception rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of a coverage request through O, E, L, D, M, K.*
9. *P is the* Pkg *provenance over* $\mathsf{LatentCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows, with the module-state source tied to Definition 9462.1836.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LatentCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, E, L, D, M, K, H, C, P, N$. It has no coordinate for a continuous biological transition, a complete empirical state space, a graph oracle, unbounded latent search, or a module-state equality principle outside the displayed rows.

Theorem 3521.2 (Latent completion NameCert obligations)**.** *For every accepted* $\mathsf{LatentCompletion}^{\uparrow}$ *carrier* $\mathsf{LatentCompletion}(O, E, L, D, M, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LatentCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for observed module states, exception rows, latent-prefix rows, directed rewrite edges, monotone-path coverage, exception-kill accounting, componentwise transport, displayed replay, provenance, and local naming.*

Every accepted coverage read must identify the two independent missing squares from E, consume the two latent rows in L, rebuild the directed rewrite graph through D, and then expose coverage through M, K, H, C, P, N. No obligation is stored in a host graph-completion oracle, a biological-transition claim, an unbounded latent search, or a complete empirical state space.

Lean4 ✓ `BEDC.Derived.LatentCompletionUp.LatentCompletionTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 3521.1. The tuple displays the observed ledger, exception ledger, latent rows, rewrite edges, coverage row, exception-kill row, and structural support.

The exception analysis is read from E and L. The deep-branch exception rows require one deep prefix, and the partial-boundary exception row requires one partial-boundary prefix.

The coverage route is D, M, K. The directed rewrite row rebuilds target-monotone one-module steps, the coverage row records reachability of the observed endpoints, and the exception-kill row records that no third missing square remains.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no graph oracle, biological transition row, unbounded search row, or complete empirical state-space row, the stated surface exhausts the NameCert obligations. □

Theorem 3521.3 (Latent completion monotone-path coverage)**.** *Every accepted* $\mathsf{LatentCompletion}^{\uparrow}$ *packet covers the finite monotone-path exception geometry by routing each observed endpoint through the displayed rewrite graph after adjoining exactly one deep-branch latent prefix and exactly one partial-boundary latent prefix. The public coverage claim is the finite route*

$$O, E, L, D, M, K, H, C, P, N$$

and it exports no stronger temporal, mechanistic, or empirical completeness claim.

Proof. Start with the observed ledger O and exception ledger E. They identify the endpoints and the three target-monotone failures that must be covered.

Use the latent row L. It supplies one deep-branch prefix for the table-9 and table-14 square and one partial-boundary prefix for the table-28 square.

Now apply the rewrite-edge and coverage rows D, M. These rows rebuild the finite directed graph and record reachability of every observed endpoint from the standard state.

The exception-kill and support rows K, H, C, P, N preserve and name the same coverage route. Since no temporal mechanism or empirical-completeness coordinate is present, the exported conclusion is exactly monotone-path coverage of the finite module-state packet. □

Falsifiable prediction: If either the deep-branch latent prefix or the partial-boundary latent prefix is removed from an accepted $\mathsf{LatentCompletion}^{\uparrow}$ packet, at least one of the table-9, table-14, or table-28 monotone-path exceptions remains uncovered.

Independence witness: six-boundary-tile-coverage, dna-boundary-trigger-closure, window-coverage-trigger-algebra, choice-window-sequence, metacic-redex-choice-frontier: none is bijective to $\mathsf{LatentCompletion}^{\uparrow}$ because this packet binds observed module states, two latent prefix choices, directed rewrite edges, monotone-path coverage, and exception-kill accounting in one NameCert surface.

The Lean follow-up supplies Nontrivial and FieldFaithful TasteGate instances for the accepted latent-completion carrier, so the formal route can distinguish nonempty coverage from faithful preservation of the module-state fields without adding new paper-side rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LatentCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{LatentCompletion}^{\uparrow}$ packet is generated from observed module-state rows, exception rows, two latent-prefix rows, directed rewrite-edge rows, monotone-path coverage, exception-kill accounting, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LatentCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3521.1, Definition 3521.2, and Definition 3521.3 seed the finite monotone-path completion witness over observed module states, latent prefixes, rewrite edges, coverage rows, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LatentCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close empirical biological transition mechanisms, complete state-space sampling, host graph-completion oracles, unbounded latent search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exception splitting, latent-prefix coverage, directed rewrite reachability, exception-kill accounting, TasteGate Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.LatentCompletionUp.

Chapter 3522

A Concrete Naming Certificate for $\mathsf{BoundedFunctionFamily}^{\uparrow}$

Following the bounded-family usage standard in Kelley, *General Topology*, and Bourbaki-style analysis, the $\mathsf{BoundedFunctionFamily}^{\uparrow}$ packet records the finite BEDC surface for a family of continuous maps whose displayed values are controlled by pointwise real bounds and a sup-norm ledger. It sits between the compact-continuity route of chapter 129, the equicontinuity family surface of chapter 413, the Arzela–Ascoli packet of chapter 412, and the real-name boundary of chapter 38. The carrier is a finite BHist packet over $\mathsf{ContinuousMap}^{\uparrow}$ rows, a $\mathsf{CompactMetric}^{\uparrow}$ source row, a $\mathsf{CompleteMetric}^{\uparrow}$ target row, pointwise $\mathsf{Real}^{\uparrow}$ bound rows, a displayed sup-norm ledger, hsame, Cont, Pkg, and a local $\mathsf{NameCert}$ row.

Definition 3522.1 (Bounded function-family carrier)**.** *A* $\mathsf{BoundedFunctionFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, I, M, B, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *surface of chapter 129;*
2. *Y is the complete metric target row, supplying only the displayed target metric and completion-facing name data;*
3. *I is the finite family-index row naming the inspected family members;*
4. *M is the finite list of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, one for each displayed family member from X into Y;*
5. *B is the pointwise* $\mathsf{Real}^{\uparrow}$ *bound ledger, recording for each displayed index and inspected source window the real-name bound read from the value row;*
6. *U is the displayed sup-norm ledger, obtained by comparing the value-distance rows against the finite pointwise bound surface and not by selecting an ambient supremum;*
7. *H stores componentwise* hsame *transport for the source, target, index, map, pointwise-bound, sup-norm, provenance, and name rows;*
8. *C stores the displayed* Cont *replay from compact source inspection through continuous-map values, pointwise real bounds, and the sup-norm ledger;*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedFunctionFamily}^{\uparrow}}$ *row.*
The carrier has no row for an open-cover compactness principle, an ambient function-space topology, a selected supremum, quotient real equality, or a choice-selected subsequence.

Lean4 (definition) `BEDC.Derived.BoundedFunctionFamilyUp.BoundedFunctionFamilyCarrier`
Lean4 ✓ `BEDC.Derived.BoundedFunctionFamilyUp.BoundedFunctionFamilyUpTasteGate single carrier alignment`

Theorem 3522.2 (Bounded function-family NameCert obligations)**.** *For the carrier of Definition 3522.1, the local* $\mathsf{NameCert}_{\mathsf{BoundedFunctionFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for* $F = (X, Y, I, M, B, U, H, C, P, N)$*, compact-source readback through* X*, complete-target readback through* Y*, finite index admission through* I*, continuous-map readback through* M*, pointwise* $\mathsf{Real}^{\uparrow}$ *bound readback through* B*, displayed sup-norm ledger readback through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and terminal naming through* N*.*

Lean4 ✓ `BEDC.Derived.BoundedFunctionFamilyUp.BoundedFunctionFamilyCarrier namecert obligations`

Proof. Project the carrier row by row. The source row X is read through the compact metric certificate, while Y supplies only the complete metric target surface needed by the displayed value distances.

The finite index row I then bounds the family members that can be inspected. Each inspected member is read through a corresponding $\mathsf{ContinuousMap}^{\uparrow}$ row in M, so no ambient function-space topology is introduced.

The pointwise bound row B and the sup-norm ledger U are downstream of the map rows. They compare displayed real-name value distances and record the bound ledger as finite data; they do not choose a supremum in the host real line and do not identify quotient real representatives.

Finally H, C, P, N transport, replay, source, and name the same finite surface. Since no other coordinate occurs in F, these rows exhaust the local NameCert obligations. □

Theorem 3522.3 (Bounded function-family sup-norm route)**.** *Every accepted* $\mathsf{BoundedFunctionFamily}^{\uparrow}$ *packet exports its sup-norm ledger only through*

$$X, Y, I, M, B, U, H, C, P, N.$$

A consumer first reads the compact source row, complete target row, finite family-index row, and displayed continuous-map rows; only then may it read the pointwise $\mathsf{Real}^{\uparrow}$ *bound rows and the finite sup-norm ledger. The route exports no open-cover compactness theorem, ambient function-space topology, selected supremum, quotient real equality, or choice-selected subsequence.*

Lean4 ✓ `BEDC.Derived.BoundedFunctionFamilyUp.BoundedFunctionFamilyCarrier sup norm route`

Proof. Start with the source and target rows. The $\mathsf{CompactMetric}^{\uparrow}$ row X supplies the inspected source windows, and the $\mathsf{CompleteMetric}^{\uparrow}$ row Y supplies the target metric surface without importing a function-space object.

Next read the finite family data. The index row I lists the family members available to the packet, and M attaches each listed member to a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row.

The pointwise real bounds in B are then read against those map values. The sup-norm ledger U is a finite comparison ledger over the displayed values and bounds, so it can be replayed by C and transported by H without selecting an ambient supremum.

The provenance and local name rows P, N close the packet. Because the carrier contains no open-cover, ambient topology, quotient equality, or subsequence-selector coordinate, the listed rows exhaust every sup-norm read available to downstream Arzela–Ascoli and equicontinuity consumers. □

Theorem 3522.4 (Bounded function-family sup-norm non-escape)**.** *Any Arzela–Ascoli, equicontinuity, or compact-continuity consumer using the* $\mathsf{BoundedFunctionFamily}^{\uparrow}$ *sup-norm ledger must read exactly*

$$X, Y, I, M, B, U, H, C, P, N.$$

Consequently it cannot replace U by an ambient function-space topology, selected supremum, quotient real equality, or choice-selected subsequence. The only available sup-norm data are the displayed pointwise $\mathsf{Real}^{\uparrow}$ *bound comparisons, the finite family-index and continuous-map rows, structural transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 3522.1. The rows available to a sup-norm consumer are precisely $X, Y, I, M, B, U, H, C, P, N$, with U positioned after the compact source, complete target, finite index, continuous-map, and pointwise-bound rows.

Apply Definition 3522.2 to identify the local certificate obligations and Definition 3522.3 to force every sup-norm read through the displayed route.

No additional carrier coordinate remains after those rows are exhausted. Thus an Arzela–Ascoli, equicontinuity, or compact-continuity consumer cannot import an ambient function-space topology, selected supremum, quotient real equality, or choice-selected subsequence in place of U. □

Lean4 ✓ `BEDC.Derived.BoundedFunctionFamilyUp.BoundedFunctionFamilySupNormNonescape`

Falsifiable prediction: An accepted $\mathsf{BoundedFunctionFamily}^{\uparrow}$ consumer that reads a sup-norm ledger without the displayed finite family-index row, continuous-map rows, pointwise $\mathsf{Real}^{\uparrow}$ bound rows, and structural hsame, Cont, Pkg, and NameCert rows refutes the carrier surface.

Independence witness: compactmetric, equicontinuityfamily, arzelaascoli, real: no listed sibling jointly carries the compact source, complete target, finite continuous-map family, pointwise real-bound ledger, displayed sup-norm route, transport, replay, provenance, and local name rows of $F = (X, Y, I, M, B, U, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedFunctionFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedFunctionFamily}^{\uparrow}$ packet is generated from a compact metric source row, complete metric target row, finite family-index row, continuous-map rows, pointwise RealUp bound rows, displayed sup-norm ledger, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedFunctionFamily}^{\uparrow}}$, seed)

Scope closed: Definition 3522.1, Definition 3522.2, Definition 3522.3, and Definition 3522.4 bind the finite bounded-family carrier and its displayed sup-norm ledger route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedFunctionFamily}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, ambient function-space topology, selected suprema, quotient real equality, choice-selected subsequences, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuous-map readback, pointwise bound exactness, displayed sup-norm replay, structural transport, provenance, and local naming for BEDC.Derived.BoundedFunctionFamilyUp.

Chapter 3523

A Concrete Naming Certificate for CauchyCompletionApartness$^{\uparrow}$

Following Bishop and Bridges on constructive metric completion and apartness, the CauchyCompletionApartness$^{\uparrow}$ packet records the positive separation boundary for completed Cauchy names without passing through quotient representatives. It is a Real-and-Completion neighbour of the universal completion route in chapter 2319, the apartness completion surface of chapter 1567, the separated metric classifier in chapter 1411, the regular rational readback of chapter 301, and the finite stream window interface of chapter 126.

Definition 3523.1 (Cauchy completion apartness carrier)**.** *A* CauchyCompletionApartness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (U, R, S, W, E, G, H, C, P, N)$$

with the following displayed rows:

1. *U is the* CauchyCompletionUniversalProperty$^{\uparrow}$ *completion source row, exposing the completed Cauchy-name request before any apartness read is attempted.*
2. *R is the* RegSeqRat$^{\uparrow}$ *regular rational readback row attached to the Cauchy name and to the requested tolerance budget.*
3. *S is the* StreamName$^{\uparrow}$ *finite-window row through which the compared Cauchy names are inspected.*
4. *W is the* Real$^{\uparrow}$ *witness-seal row reached only after the regular readback and stream-window rows have been displayed.*
5. *E is the* SeparatedMetric$^{\uparrow}$ *zero-distance classifier handoff that identifies when a completed comparison must collapse to the separated metric boundary.*
6. *G is the* RealApartnessCompletion$^{\uparrow}$ *positive-gap row, recording apartness by a displayed completed-real gap rather than by an external representative choice.*
7. *H records componentwise* hsame *transport for the completion source, readback, windows, real seal, separatedness handoff, apartness gap, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an apartness request through U, R, S, W, E, G.*
9. *P is the* Pkg *provenance over* CauchyCompletionApartness$^{\uparrow}$, CauchyCompletionUniversalProperty$^{\uparrow}$, RealApartnessCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionApartness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, R, S, W, E, G, H, C, P, N$. It has no coordinate for quotient-stream equality, selected representatives, host real equality, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Theorem 3523.2 (Cauchy completion apartness NameCert obligations)**.** *For every accepted* CauchyCompletionApa *carrier*

$$A = (U, R, S, W, E, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionApartness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the completion source, regular readback, stream-window, real-seal, separatedness, apartness-gap, transport, replay, provenance, and local naming rows;*
2. *completion-source exposure, requiring an apartness request to pass through the displayed* CauchyCompletionUniver *row U before any completed comparison is read;*
3. *regular-window readback, requiring R and S to be the only numerical and stream observation route before the* $\mathsf{Real}^{\uparrow}$ *seal row W is reached;*
4. *separatedness handoff, requiring zero-distance collapse to be read only through the displayed* $\mathsf{SeparatedMetric}^{\uparrow}$ *row E;*
5. *apartness-gap exposure, requiring positive separation to be read only through the* $\mathsf{RealApartnessCompletion}^{\uparrow}$ *row G after U, R, S, W, E have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport through H and displayed replay through C to preserve the same route;*
7. *ledger non-escape, excluding quotient representatives, selected limits, host equality, trichotomy, countable choice, ambient completeness, Lean verification, and bridge checking from the packet.*

No NameCert obligation is stored outside these rows.

```
Lean4✓  BEDC.Derived.CauchyCompletionApartnessUp.TasteGate.CauchyCompletionApartnessCarrier
namecert obligations
```

Proof. Carrier admission is projection from Definition 3523.1. The accepted packet exposes exactly the completion source, regular readback, finite windows, real seal, separatedness row, apartness-gap row, and structural rows.

The completion-facing route begins at U. The regular rational row R and stream-window row S then supply the only finite observation data available before the real seal W is read.

Separatedness and apartness are two downstream readings of the same displayed route. The row E records the separated metric handoff for zero-distance collapse, while G records the positive-gap apartness completion row.

Finally H, C, P, N transport, replay, source, and name the same carrier. Since the carrier has no coordinate for quotient representatives, host equality, trichotomy, choice, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 3523.3 (Cauchy completion apartness separatedness handoff)**.** *Every separatedness or apartness read of an accepted* $\mathsf{CauchyCompletionApartness}^{\uparrow}$ *carrier*

$$A = (U, R, S, W, E, G, H, C, P, N)$$

must factor through the finite route

$$U \longmapsto R, S, W \longmapsto E, G \longmapsto H, C, P, N.$$

Consequently a consumer receives only the displayed completion source, regular rational readback, finite stream windows, real seal, separated-metric handoff, apartness-completion gap, componentwise transport, continuation replay, provenance, and local name. It receives no quotient representative, selected limit, host real equality, trichotomy split, countable-choice schedule, or ambient completeness theorem.

Proof. Start with a separatedness or apartness read of the carrier. Projection exposes U first, so the read begins from the displayed universal completion row rather than from a quotient representative of the completed Cauchy name.

The numerical read then passes through R, S, W. The regular rational row and finite stream-window row fix the inspected data before the real seal is available.

The comparison boundary is exactly E, G. Zero-distance collapse is handled by the separated metric row E, and positive separation is handled by the apartness-completion gap row G.

The structural rows H, C, P, N preserve and name only that finite route. Because no excluded coordinate appears in the carrier, the handoff cannot export quotient representatives, selected limits, host real equality, trichotomy, choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionApartness}^{\uparrow}$ packet is generated from a CauchyCompletionUniversalProperty source row, RegSeqRat readback, StreamName windows, a RealUp seal row, a SeparatedMetric handoff, a RealApartnessCompletion positive-gap row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3523.1, Definition 3523.2, and Definition 3523.3 seed the finite apartness route for completed Cauchy names over displayed completion, readback, window, separatedness, gap, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host real equality, real trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-source exposure, regular-window readback, separatedness handoff, apartness-gap exposure, classifier stability, consumer nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionApartnessUp.

Chapter 3524

A Concrete Naming Certificate for $\mathsf{BishopRegularCutEquivalence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularCutEquivalence}^{\uparrow}$ packet records the finite comparison certificate by which located Dedekind cut language and regular Cauchy real names meet inside the existing $\mathsf{LocatedReal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ routes. It is a NameCert reconstruction over the concrete rows of chapter 1933, chapter 436, chapter 301, chapter 291, and chapter 38.

The packet is deliberately finite. It records a displayed cut row, a located-real enclosure row, a regular rational readback, a dyadic bracket ledger, and a terminal real seal, but it does not add quotient reals, trichotomy, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 3524.1 (Bishop regular-cut equivalence carrier)**.** *A* $\mathsf{BishopRegularCutEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (C, L, R, D, Q, H, T, P, N)$$

with the following visible rows:

1. *C is a displayed Dedekind or located cut row whose lower and upper sides are read as positive and negative rational evidence rather than as quotient-real data;*
2. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row that records the finite located interval information associated to the cut row C;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the located enclosures, giving the regular Cauchy name visible to completion consumers;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket ledger that records the dyadic lower and upper rational brackets used to compare the cut and regular-name presentations;*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from R through the existing real-name route;*
6. *H stores the displayed* hsame *transports for C, L, R, D, Q;*
7. *T stores the displayed* Cont *routes that replay the cut-to-enclosure, enclosure-to-readback, bracket-compatibility, and real-seal handoffs;*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCutEquivalence}^{\uparrow}}$ *row for the finite comparison packet.*

The carrier predicate is $\mathsf{BishopRegularCutEquivalencePacket}(E)$*. Its public rows are exactly the displayed cut, located enclosure, regular-rational readback, dyadic bracket ledger, real seal, transports, provenance, and local naming row.*

Theorem 3524.2 (Bishop regular-cut equivalence NameCert obligations)**.** *For the carrier*

$$E = (C, L, R, D, Q, H, T, P, N)$$

of Definition 3524.1, the local $\mathsf{NameCert}_{\mathsf{BishopRegularCutEquivalence}^{\uparrow}}$ *surface has five obligations:*

1. *carrier admission for the displayed finite packet;*
2. *bracket and readback compatibility, requiring the* $\mathsf{DyadicRatCore}^{\uparrow}$ *brackets in* D *to support both the located cut row* C *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*;*
3. *located-real handoff, requiring the enclosure row* L *to be the only route from* C *to* R*;*
4. *classifier transport, requiring accepted carriers to compare only through the displayed* hsame *and* Cont *routes in* H, T *together with the package row* P*;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring every real-facing read through* Q *to factor through* C, L, R, D, H, T, P, N *and no outside quotient, trichotomy, choice, or completeness datum.*

Lean4 ✓ `BEDC.Derived.BishopRegularCutEquivalenceUp.TasteGate.BishopRegularCutEquivalenceCarrier namecert obligations`

Proof. Carrier admission is projection from the finite packet E. The rows list the cut display, located enclosure, regular readback, dyadic bracket ledger, real seal, transports, provenance, and local naming certificate as one visible history.

Bracket and readback compatibility is the joint routing condition on D and R. The same dyadic bracket ledger that locates the cut side also supplies the rational bounds used by the regular Cauchy readback, so the comparison has no hidden quotient-real coordinate.

The located-real handoff is the row L. Any passage from the cut row C to the regular name R must pass through the displayed located enclosure, and any transported comparison must replay through H, T with provenance P.

Finally the real-facing row Q is a terminal seal, not a new completeness principle. Since Q is reached only after the displayed cut, enclosure, readback, bracket, transport, package, and local certificate rows have been consumed, the packet exports the finite comparison surface and no stronger real-analysis principle. □

Theorem 3524.3 (Bishop regular-cut equivalence located-real handoff)**.** *For every accepted* $\mathsf{BishopRegularCutEquiv}$ *carrier*

$$E = (C, L, R, D, Q, H, T, P, N),$$

the public comparison between the located cut row C *and the regular Cauchy row* R *factors through the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row* L *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket ledger* D*. The* $\mathsf{Real}^{\uparrow}$ *seal row* Q *may be consumed only after that finite route has been replayed through* H, T, P, N*.*

Consequently the packet gives a finite L10 comparison certificate between Bishop located cuts and regular Cauchy real names without asserting Dedekind completeness, quotient-real extensionality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3524.1. The row C is the displayed cut surface, L is the located enclosure row attached to it, and R is the regular rational readback.

Apply Definition 3524.2. The bracket and readback obligation forces D to be the shared finite dyadic ledger for both sides of the comparison, while the located-real handoff obligation prevents a direct jump from C to R.

The classifier transport obligation then carries the same route through H, T, P, N. The real-seal nonescape obligation leaves Q as the terminal consumer of that route, so no unlisted quotient, trichotomy, choice, or completeness datum can be read from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCutEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCutEquivalence}^{\uparrow}$ packet is generated from a displayed located cut row, a $\mathsf{LocatedReal}^{\uparrow}$ enclosure row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ bracket ledger, a terminal $\mathsf{Real}^{\uparrow}$ seal, displayed hsame and Cont transports, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCutEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3524.1, Definition 3524.2, and Definition 3524.3 bind the finite comparison surface between Bishop located cuts and regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCutEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, quotient reals, trichotomy, choice principles, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: The next paper grade is a checked finite carrier theorem for the cut, located-enclosure, regular-readback, dyadic-bracket, and real-seal rows.

Chapter 3525

A Concrete Naming Certificate for $\mathsf{DyadicToleranceLadder}^{\uparrow}$

Following Bishop and Bridges' constructive use of rational tolerances, the $\mathsf{DyadicToleranceLadder}^{\uparrow}$ packet records the finite ladder of dyadic requests used by Real and Completion consumers before any completed real object is exposed. It sits on the dyadic arithmetic core of chapter 291, the finite request-window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the tail-budget packet of chapter 379. The packet gives downstream Real and Completion chapters one reusable source object for the tolerances 2^{-n}, their halving route, and their finite handoff to regular-rational windows.

Definition 3525.1 (DyadicToleranceLadder carrier)**.** *A* $\mathsf{DyadicToleranceLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, Q, E, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, recording dyadic numerators, denominators, comparison rows, and the visible tolerance term* 2^{-n}*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request-window row, recording the finite list of precision indices at which a consumer asks for tolerances.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational window row, recording the rational readback surface that consumes the requested dyadic tolerances.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary row, recording only the terminal handoff at which the tolerance ladder can be read by a real-facing consumer.*
5. *T is the* $\mathsf{DyadicTailBound}^{\uparrow}$ *row, recording the finite tail-budget comparison that treats successive ladder entries as shrinking tolerance requests.*
6. *H records componentwise* hsame *transport for the dyadic endpoint, window, regular-rational, real-seal, tail-bound, continuation, provenance, and naming rows.*
7. *C records displayed* Cont *routes from dyadic endpoints through finite windows, regular-rational readback, tail-bound comparisons, and the real-seal boundary.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicToleranceLadder}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicTailBound}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicToleranceLadder}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, Q, E, T, H, C, P, N$. It has no coordinate for quotient stream equality, trichotomy on real names, selected limits, countable-choice schedules, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DyadicToleranceLadderUp.DyadicToleranceLadderTasteGate single carrier alignment`

Theorem 3525.2 (DyadicToleranceLadder NameCert obligations)**.** *For every accepted* $\mathsf{DyadicToleranceLadder}^{\uparrow}$ *carrier*

$$L = (D, S, Q, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicToleranceLadder}^{\uparrow}}$ *surface consists exactly of carrier exposure for the dyadic endpoint row D, finite request-window row S, regular-rational readback row Q, real-seal boundary E, tail-bound comparison row T, componentwise transport row H, continuation row C, package provenance row P, and local naming row N.*

Proof. Carrier exposure is projection from Definition 3525.1. Each row named in the statement is one coordinate of the finite packet, and the definition lists no hidden coordinate for a completed real object.

The dyadic endpoint and request-window obligations are D and S. The regular-rational readback and real-facing boundary obligations are Q and E, while the shrinking tolerance budget is the row T.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Repacking these rows gives the displayed $\mathsf{NameCert}_{\mathsf{DyadicToleranceLadder}^{\uparrow}}$ surface, with quotient stream equality, trichotomy, selected limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness outside the packet. □

Theorem 3525.3 (DyadicToleranceLadder monotone halving)**.** *Let $L = (D, S, Q, E, T, H, C, P, N)$ be an accepted* $\mathsf{DyadicToleranceLadder}^{\uparrow}$ *carrier. If two requested indices m, n are both displayed in the finite* $\mathsf{StreamName}^{\uparrow}$ *window S and m is the successor request after n, then the tolerance read from D at m is routed through the same dyadic endpoint row as one halving of the tolerance read at n, and the comparison is consumed by T before Q or E can export the request.*

Proof. The only dyadic endpoint row in the carrier is D, so both displayed requests are read from the same dyadic arithmetic surface. The successor relation is visible only as part of the finite window S, not as an external sequence choice.

The halving comparison is the role of the tail-bound row T. It consumes the two displayed endpoint reads before the regular-rational window Q is opened, so the comparison cannot be replaced by an unrecorded real-order argument.

After T records the comparison, the readback row Q and the seal boundary E may consume the tolerance request. The route therefore remains a finite ladder through $D, S, T, Q, E, H, C, P, N$, and it exports no quotient stream equality, trichotomy, selected limit, countable-choice schedule, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicToleranceLadder}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicToleranceLadder}^{\uparrow}$ packet is generated from dyadic endpoint rows, finite StreamName request windows, RegSeqRat readback windows, Real seal boundaries, DyadicTailBound comparison rows, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicToleranceLadder}^{\uparrow}}$, seed)

Scope closed: Definition 3525.1, Definition 3525.2, and Definition 3525.3 bind the finite dyadic tolerance ladder, its local NameCert surface, and its monotone halving route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicToleranceLadder}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove Real$^{\uparrow}$ completeness, quotient stream equality, trichotomy, selected limits, countable choice, or a public standard bridge.

Upgrade path: Scoped closure requires Lean encoding of the carrier, the local NameCert obligation surface, and the monotone halving route over the displayed dyadic and regular-rational rows.

Chapter 3526

A Concrete Naming Certificate for $\mathsf{NestedClosedBall}^{\uparrow}$

Following Bishop and Bridges and the Cantor-style nested closed ball criterion, the $\mathsf{NestedClosedBall}^{\uparrow}$ packet records explicit nested closed ball completion data as finite NameCert rows. It sits beside the metric-completion carrier of chapter 1506, the complete-metric service of chapter 128, the Cauchy-filter evidence of chapter 333, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a displayed descending ball route rather than a host completeness theorem, a quotient completion, or a choice-selected center.

Definition 3526.1 (Nested closed ball carrier)**.** *A* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, K, F, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row naming the ambient completion request before any ball center is read.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row available only as a displayed limit-service dependency, not as an independent selector.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *filter row generated by the descending family of closed balls.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspecting the indexed balls and their center approximations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the inspected center and radius data.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger, recording the dyadic shrink schedule, containment witnesses, and late-radius comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, S, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the completion source, complete-metric service, filter, windows, readback, dyadic ledger, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a nested-ball request through M, K, F, S, R, D, E.*
10. *P is the* Pkg *provenance over* $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedClosedBall}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, selected limits, quotient completions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.TasteGate.NestedClosedBallTasteGate single carrier alignment`

Theorem 3526.2 (Nested closed ball NameCert obligations)**.** *For every accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier*

$$B = (M, K, F, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedClosedBall}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric-completion source, displayed complete-metric service, Cauchy-filter row, finite stream windows, regular rational readback, dyadic diameter ledger, terminal real seal, componentwise transport, displayed continuation replay, package provenance, and local naming. Every nested-ball read is therefore routed through $M, K, F, S, R, D, E, H, C, P, N$, and no obligation is stored outside those rows.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallNameCertObligations`

Proof. Carrier admission is projection from Definition 3526.1. The packet displays the completion source, the complete-metric service, the Cauchy filter generated by the nested balls, the finite windows, the rational readback, and the dyadic diameter ledger before the real seal can be consumed.

The constructive nested-ball content is the route through F, S, R, D. The filter row records the descending family, the stream row exposes only finite indexed windows, the regular rational row reads center and radius data, and the dyadic row records the shrink and containment comparisons.

The structural rows H, C, P, N transport, replay, source, and name exactly that route. Since the carrier contains no open-cover compactness row, selected limit, quotient completion, countable-choice schedule, ambient real-completeness row, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 3526.3 (Nested closed ball Cauchy-center route)**.** *Every center read exported by an accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hs}$$

Equivalently, a consumer may inspect the descending closed-ball family only through the displayed Cauchy-filter row, finite stream windows, regular rational readback, dyadic shrink ledger, and terminal real seal; it receives no open-cover compactness theorem, selected limit, quotient completion, countable-choice schedule, independent real-completeness witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the accepted carrier and project the rows M, K, F, S, R, D, E. The metric-completion and complete-metric rows provide the surrounding completion service, while the Cauchy-filter row is the only entry point for the descending closed-ball family.

The center data are then inspected through finite windows. The stream row S exposes finite ball indices, the regular rational row R reads the center and radius approximants, and the dyadic ledger D records the shrink and containment comparisons needed for a Cauchy-center route.

Finally the real seal E and the structural rows H, C, P, N preserve the same route for public consumers. Because no excluded coordinate occurs in the carrier, the handoff cannot export open-cover compactness, selected limits, quotient completions, countable choice, or ambient real completeness. □

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallCauchyCenterRoute`

Theorem 3526.4 (Nested closed ball RegSeqRat center extraction)**.** *Every accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *packet whose displayed diameters refine through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows yields a* $\mathsf{RegSeqRat}^{\uparrow}$*-facing center readback through the* $\mathsf{StreamName}^{\uparrow}$ *finite windows before the* $\mathsf{Real}^{\uparrow}$ *seal is available. The extracted readback uses the nested closed-ball carrier row, the local NameCert obligations, and the Cauchy-center route to expose only the finite center schedule, dyadic shrink comparisons, and regular-rational handoff.*

Proof. Begin with the carrier of Definition 3526.1. Its rows S, R, D are the only finite-window, regular-rational, and dyadic tolerance coordinates available before the terminal real seal.

Apply the local obligations of Definition 3526.2. The NameCert surface requires the Cauchy-filter row, finite windows, regular rational readback, and dyadic diameter ledger to be admitted together, so a displayed diameter refinement through D cannot bypass S or R.

Use the Cauchy-center route of Definition 3526.3. The nested finite-ball chain is inspected through S, its center and radius approximants are read through R, and the dyadic shrink comparisons in D provide the tolerance control needed for a center readback.

The structural rows H, C, P, N preserve this route under transport and replay. Since E is downstream of S, R, D, the packet yields the $\mathsf{RegSeqRat}^{\uparrow}$-facing center readback before any $\mathsf{Real}^{\uparrow}$ seal is consumed. □

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallRegSeqRatCenterExtraction`

Theorem 3526.5 (Nested closed ball diameter-tail stability)**.** *For every accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier*

$$B = (M, K, F, S, R, D, E, H, C, P, N),$$

the dyadic diameter ledger D is stable under later $\mathsf{StreamName}^{\uparrow}$ *windows S and under the componentwise* hsame *and* Cont *transport rows H, C. Every later ball read therefore keeps the displayed containment witness and shrink comparison before the* $\mathsf{Real}^{\uparrow}$ *seal E is consumed.*

The packet exports no selected center, quotient completion, choice witness, or ambient completeness object through this stability route.

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallCarrier diameter tail stability`

Proof. Project the diameter, stream, transport, and replay rows D, S, H, C from the accepted carrier. The dyadic ledger records the shrink comparisons and containment witnesses before the terminal seal is available.

Use the Cauchy-filter row F to keep tail membership in the descending closed-ball family. Later stream windows in S inspect only finite indexed balls already covered by this filter row, so no later read can replace the displayed containment ledger.

The regular rational row R supplies the scheduled center and radius reads attached to those windows. Its center readback is downstream of the dyadic ledger, so the same shrink comparison remains attached to the later window.

Finally, H transports the completion source, filter, stream windows, readback, dyadic ledger, and seal componentwise, while C replays the same nested-ball route. Thus every later ball read preserves containment and diameter control before E is consumed. Since the carrier has no selected-center, quotient-completion, choice, or ambient-completeness coordinate, the stability theorem exports none. □

Theorem 3526.6 (Nested closed ball obligation package)**.** *The carrier of Definition 3526.1, the local obligations of Definition 3526.2, and the Cauchy-center route of Definition 3526.3 jointly form the exact obligation package consumed by later metric-completion and complete-metric chapters. The package consists of the metric-completion source row, complete-metric service row, Cauchy-filter row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{NestedClosedBall}^{\uparrow}}$ *row.*

It supplies no open-cover compactness, selected limit, quotient completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallObligationPackage`

Proof. Start with the carrier of Definition 3526.1. Its displayed tuple is precisely the list of metric-completion, complete-metric, Cauchy-filter, stream-window, regular-rational, dyadic, real-seal, transport, replay, provenance, and naming rows.

Apply Definition 3526.2. This identifies the local NameCert surface with admission and replay through exactly those rows, with no obligation stored outside the packet.

Finally apply Definition 3526.3. Every center read factors through the same finite route, so later metric-completion and complete-metric consumers receive one obligation package and no open-cover compactness, selected limit, quotient completion, countable-choice schedule, or ambient real-completeness witness. □

Theorem 3526.7 (Nested closed ball consumer nonescape)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$*-,* $\mathsf{CompleteMetric}^{\uparrow}$*-, or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *packet must read exactly the displayed route*

$$M, K, F, S, R, D, E, H, C, P, N$$

before using any nested-ball endpoint. The consumer may use the selected center only through the finite windows, regular-rational readback, dyadic diameter ledger, Cauchy-filter route, terminal real seal, componentwise transport, displayed replay, provenance, and local NameCert rows of that packet.

Consequently selected centers, quotient completions, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ *completeness cannot escape the packet boundary.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallConsumerNonescape`

Proof. Start with the carrier of Definition 3526.1. Its displayed tuple is the only accepted source for a nested-ball endpoint, and the local obligations of Definition 3526.2 identify the NameCert surface with the rows $M, K, F, S, R, D, E, H, C, P, N$.

Apply the Cauchy-center route of Definition 3526.3. Any center read used by a metric-completion, complete-metric, or real-facing consumer must pass through the Cauchy-filter row F, the stream windows S, the regular-rational readback row R, and the dyadic ledger D before the terminal seal E is available.

Use the RegSeqRat extraction of Definition 3526.4 and the diameter-tail stability of Definition 3526.5. They keep later endpoint reads attached to the same finite windows, regular readback, dyadic shrink comparisons, and transport and replay rows.

Finally apply the obligation package of Definition 3526.6. The package is exactly the displayed route consumed by downstream completion chapters, so no consumer obtains a separate selected center, quotient completion, countable-choice schedule, open-cover compactness theorem, or ambient real-completeness witness outside the packet. □

Theorem 3526.8 (Nested closed ball kernel scope binding)**.** *Every scoped read of an accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier*

$$B = (M, K, F, S, R, D, E, H, C, P, N)$$

binds M *to* $\mathsf{MetricCompletion}^{\uparrow}$*,* K *to* $\mathsf{CompleteMetric}^{\uparrow}$*,* F *to* $\mathsf{CauchyFilter}^{\uparrow}$*,* S *to* $\mathsf{StreamName}^{\uparrow}$*,* R *to* $\mathsf{RegSeqRat}^{\uparrow}$*,* D *to* $\mathsf{DyadicRatCore}^{\uparrow}$*,* E *to* $\mathsf{Real}^{\uparrow}$*, and* H, C, P, N *respectively to* BHist *transport by* hsame*, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{NestedClosedBall}^{\uparrow}}$ *row. No scoped consumer can reinterpret one of these rows as an open-cover compactness object, a selected endpoint, a quotient completion, a countable-choice schedule, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallKernelScopeBinding`

Proof. Project the carrier of Definition 3526.1. Its displayed tuple already assigns the completion, complete-metric, filter, stream, regular-rational, dyadic, real-seal, transport, replay, provenance, and naming roles to the rows $M, K, F, S, R, D, E, H, C, P, N$.

Apply the obligation package of Definition 3526.6 and the consumer nonescape theorem Definition 3526.7. These results force every downstream completion, complete-metric, or real-facing read to consume the same displayed route before any endpoint is used.

Use the RegSeqRat extraction of Definition 3526.4 together with the diameter-tail stability of Definition 3526.5. They keep finite windows, center readback, dyadic shrink comparisons, and later tail reads attached to their original rows under hsame transport and Cont replay. Thus the scoped read binds the rows to the named kernel objects and has no coordinate for the excluded host-level objects. □

Theorem 3526.9 (Nested closed ball public NameCert export)**.** *The carrier of Definition 3526.1, the obligation package of Definition 3526.6, the consumer nonescape theorem Definition 3526.7, the RegSeqRat extraction of Definition 3526.4, the diameter-tail stability theorem Definition 3526.5, and the kernel scope binding of Definition 3526.8 assemble the public* $\mathsf{NameCert}_{\mathsf{NestedClosedBall}^{\uparrow}}$ *export for the nested-ball completion route.*

The exported surface is exactly the finite route through $M, K, F, S, R, D, E, H, C, P, N$*. It refuses open-cover compactness, selected limits, quotient completions, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallPublicNameCertExport`

Proof. Start with the carrier and the obligation package. They identify the displayed rows $M, K, F, S, R, D, E, H, C$ as the metric-completion source, complete-metric service, Cauchy-filter row, stream windows, regular rational readback, dyadic diameter ledger, real seal, transport, replay, provenance, and local naming route.

Use consumer nonescape together with RegSeqRat extraction. Any completion-facing or real-facing read must pass through the finite windows, regular readback, dyadic shrink ledger, Cauchy-filter route, terminal seal, transport, replay, provenance, and local NameCert rows before it can use an endpoint.

Apply diameter-tail stability and kernel scope binding. Later ball reads keep the same containment and shrink comparisons under hsame transport and Cont replay, and each row remains bound to its displayed kernel role.

Thus the public export is the finite nested-ball completion route named by the local certificate. Since the carrier has no coordinate for open-cover compactness, selected limits, quotient completions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects is exported. □

Theorem 3526.10 (Nested closed ball public completion surface)**.** *Every accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier exposes the finite nested-ball completion route as a public consumer surface through the rows*

$$M, K, F, S, R, D, E, H, C, P, N.$$

The surface is public exactly as a displayed completion interface: M names the metric-completion source, K the complete-metric service, F the nested Cauchy-filter row, S finite ball windows, R regular rational center readback, D dyadic diameter control, E the terminal real seal, and H, C, P, N the transport, replay, provenance, and local naming rows. It exposes no selected limit, no ambient completeness theorem, no quotient completion, no countable-choice schedule, and no open-cover compactness object.

Proof. Start with the public NameCert export of Definition 3526.9. It already packages the carrier, obligation package, nonescape theorem, center extraction, diameter-tail stability, and kernel scope binding as one public route.

Read the exported rows objectwise. The completion source, complete-metric service, nested filter, finite windows, regular readback, dyadic ledger, real seal, transport, replay, provenance, and local naming entries are exactly $M, K, F, S, R, D, E, H, C, P, N$.

Finally apply consumer nonescape and kernel scope binding. They keep every downstream completion or real-facing read on the displayed route, so the public surface exports only the finite nested-ball completion interface and none of the excluded host-level objects. □

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallPublicCompletionSurface`

Theorem 3526.11 (Nested closed ball separated uniqueness handoff)**.** *Let $B = (M, K, F, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{NestedClosedBall}^{\uparrow}$ *carrier whose public completion surface is read through the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *service row K. Any two endpoint reads obtained from the same accepted packet can be compared only through a* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *separated comparison route as in chapter 5983. The handoff uses the same nested-filter row F, stream windows S, regular readback R, dyadic diameter ledger D, terminal seal E, transport H, replay C, provenance P, and local name N; it exports no selected center, quotient completion point, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.NestedClosedBallUp.NestedClosedBallSeparatedUniquenessHandoff`

Proof. Start with the carrier and obligation package of Definition 3526.1 and Definition 3526.6. They identify $M, K, F, S, R, D, E, H, C, P, N$ as the only rows available before a nested-ball endpoint can be read.

Use consumer nonescape and the public NameCert export, Definition 3526.7 and Definition 3526.9. These keep both endpoint reads inside the same displayed completion route and prevent either read from becoming a selected host center or quotient representative.

Now apply the public completion surface of Definition 3526.10. Since the surface exposes K only as the displayed $\mathsf{CompleteMetric}^{\uparrow}$ service row, any comparison between two endpoint reads must be delegated to the separated uniqueness route of chapter 5983. The structural rows H, C, P, N preserve the same packet identity, so the comparison cannot import ambient $\mathsf{Real}^{\uparrow}$ completeness or host equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedClosedBall}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NestedClosedBall}^{\uparrow}$ packet is generated from a MetricCompletion source row, a CompleteMetric service row, a CauchyFilter nested-ball row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore diameter

ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{NestedClosedBall}^{\uparrow}}$, publicClosed)

Scope closed: Definition 3526.9 and Definition 3526.10 bind the public nested-ball completion route over the displayed rows $M, K, F, S, R, D, E, H, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\mathsf{NestedClosedBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient completions, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification and bridge checking require the public completion surface to be mirrored by a checked target and a standard bridge.

Chapter 3527

A Concrete Naming Certificate for $\mathsf{RealBoundedInterval}^{\uparrow}$

Bishop–Bridges constructive real analysis treats a bounded interval by endpoint evidence and finite approximation data rather than by an ambient compact set. The $\mathsf{RealBoundedInterval}^{\uparrow}$ packet records that endpoint interval as finite BEDC NameCert data over the real-name seal of chapter 38, the regular rational readback of chapter 301, the finite window surface of chapter 126, the dyadic endpoint-order ledger of chapter 291, the located endpoint route of chapter 1709, and the bracketing surface of chapter 1807. It names a closed finite endpoint packet for downstream Real and Completion consumers; it is not open-cover compactness, a Heine–Borel theorem, a selected point of the interval, a quotient interval, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3527.1 (Real bounded interval carrier)**.** *A* $\mathsf{RealBoundedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, D, S, T, R, Q, B, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint* $\mathsf{Real}^{\uparrow}$ *seal rows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-order ledger recording the displayed finite evidence that the lower endpoint precedes the upper endpoint at the requested tolerance.*
3. *S and T are finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which the endpoint names are observed before any interval read is exported.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the paired endpoint windows.*
5. *Q is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row tying the endpoint seals, dyadic order ledger, and readback route to a located interval surface.*
6. *B is the* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *row giving the finite bracket consumed by Real and Completion-facing readers.*
7. *H records componentwise* hsame *transport for endpoint seals, endpoint-order evidence, windows, readback, located interval, bracket, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded-interval request through $L, U, D, S, T, R, Q, B, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealBoundedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{FiniteBracketingInterval}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealBoundedInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, Heine–Borel compactness, selected points, quotient intervals, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealBoundedIntervalUp.RealBoundedIntervalTasteGate single carrier alignment`

Theorem 3527.2 (Real bounded interval NameCert obligations)**.** *For every accepted* $\mathsf{RealBoundedInterval}^{\uparrow}$ *carrier*

$$I = (L, U, D, S, T, R, Q, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealBoundedInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the two endpoint* $\mathsf{Real}^{\uparrow}$ *seals,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-order evidence, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{LocatedRealInterval}^{\uparrow}$ *located endpoint row,* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *bracket row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Every bounded-interval consumer must therefore read $L, U, D, S, T, R, Q, B, H, C, P, N$ in the displayed route, and no obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 3527.1. The projection exposes exactly the two endpoint seals, the endpoint-order ledger, the two finite windows, readback, located interval, bracket, and structural rows.

The endpoint-order obligation is read from D. The finite-window obligation is read from S, T, and the regular rational readback obligation is read from R before either the located interval row Q or the bracket row B is available.

Componentwise transport is supplied by H, and continuation replay is supplied by C. The provenance and local naming rows P, N attach the same finite route to the packet, so there is no separate host interval, quotient interval, selected point, compactness, or completeness coordinate from which a consumer could read additional data. □

Theorem 3527.3 (Real bounded interval endpoint seal route)**.** *Every endpoint read of an accepted* $\mathsf{RealBoundedInterval}^{\uparrow}$ *packet factors through the paired* $\mathsf{Real}^{\uparrow}$ *seals L, U, the endpoint-order ledger D, the finite windows S, T, and the regular rational readback R before the located interval row Q and bracket row B are consumed. The route exports no host real equality, quotient interval equality, selected endpoint representative, trichotomy row, open-cover compactness proof, Heine–Borel theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an endpoint-facing consumer and project the route C. The only endpoint rows are L, U, and the only order witness attached to them is the dyadic ledger D.

The consumer then reads the finite windows S, T and the regular rational readback R. Those rows provide the displayed approximation surface needed by the located interval and bracketing rows.

Finally Q and B package the endpoint surface for interval readers. Since the carrier contains no host equality, quotient interval, selected representative, compactness theorem, or completeness coordinate, the endpoint seal route is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealBoundedInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealBoundedInterval}^{\uparrow}$ packet is generated from two RealUp endpoint seals, a DyadicRatCore endpoint-order ledger, paired StreamName finite windows, RegSeqRat readback, LocatedRealInterval and FiniteBracketingInterval rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealBoundedInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3527.1, Definition 3527.2, and Definition 3527.3 seed the finite endpoint interval route over real seals, dyadic order evidence, finite windows, regular readback, located interval rows, and bracketing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealBoundedInterval}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, Heine–Borel compactness, selected interval points, quotient intervals, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order evidence, finite-window readback, located interval handoff, bracketing handoff, endpoint seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealBoundedIntervalUp.

Chapter 3528

A Concrete Naming Certificate for $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$

Following Stieltjes, Jordan, and the Bishop–Bridges constructive reading of bounded variation, this packet records only the finite boundary by which a $\mathsf{BoundedVariation}^{\uparrow}$ integrator supplies interval-jump rows to $\mathsf{RiemannStieltjes}^{\uparrow}$ and $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ consumers. It sits after the partition-variation ledger of chapter 398, the tagged-sum handoff of chapter 1637, the regulated Cauchy readback of chapter 2351, the regular rational surface of chapter 301, the dyadic endpoint core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite interval-jump boundary; it is not a variation measure, a Lebesgue integration object, a quotient of host functions, a selected limit, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 3528.1 (Stieltjes measure boundary carrier)**.** *A* $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, \Pi, J, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row naming the integrator only through displayed finite partition-variation data.*
2. *Π is the displayed interval partition, including ordered endpoints, interval cells, and the refinement witnesses on which boundary reads are requested.*
3. *J is the endpoint-jump* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, recording the finite left and right endpoint differences attached to the cells of Π.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes those jump rows at the requested rational windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, Π, J, R have been displayed.*
6. *H records componentwise* hsame *transport for the bounded-variation source, partition, jump ledger, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from bounded-variation partition reads to interval jumps, from jumps to regular rational readback, and from readback to the* $\mathsf{Real}^{\uparrow}$ *seal.*
8. *P is the* Pkg *provenance over* $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{StieltjesMeasureBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, \Pi, J, R, E, H, C, P, N$. It has no coordinate for measure completion, Lebesgue integration, a host function quotient, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.StieltjesMeasureBoundaryUp.StieltjesMeasureBoundaryTasteGate single carrier alignment`

Theorem 3528.2 (Stieltjes measure boundary NameCert obligations)**.** *For every accepted* StieltjesMeasureBoundar *carrier*

$$S = (B, \Pi, J, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StieltjesMeasureBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{BoundedVariation}^{\uparrow}$ *source, displayed interval-partition exposure through Π, endpoint-jump exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger J,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 3528.1. The source row B is already the finite partition-variation object of chapter 398, so the boundary packet begins from displayed partition data rather than from a completed variation measure.

The interval and jump obligations are the rows Π and J. The partition cells provide the only endpoint pairs that may be inspected, and the dyadic ledger records the corresponding finite endpoint differences through chapter 291.

The readback and seal obligations are downstream. The regular rational route of chapter 301 consumes J through R, and the real-name route of chapter 38 consumes R through E. Transport, replay, provenance, and local naming are exactly H, C, P, N, leaving no hidden measure, quotient, choice, selected-limit, or completeness row. □

Theorem 3528.3 (Stieltjes boundary bounded-variation handoff)**.** *Every* $\mathsf{RiemannStieltjes}^{\uparrow}$ *or* $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$ *packet receives the integrator boundary only through the displayed route*

$$\mathsf{BoundedVariation}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{StieltjesMeasureBoundary}^{\uparrow}}.$$

Concretely, the consumer must read the bounded-variation source B, the interval partition Π, the endpoint-jump ledger J, and the regular rational readback R before any $\mathsf{Real}^{\uparrow}$ *seal E is visible.*

Proof. Start with the bounded-variation source. By chapter 398, that source exposes partition data and dyadic variation ledgers, not a variation measure or a host function quotient.

The boundary carrier refines the source to endpoint jumps on the displayed partition. The cells of Π determine the finite list of endpoint pairs, and the ledger J records their dyadic jump reads.

Now pass to consumers. The $\mathsf{RiemannStieltjes}^{\uparrow}$ route of chapter 1637 and the $\mathsf{RegulatedCauchyIntegral}^{\uparrow}$ route of chapter 2351 may consume only the displayed regular readback and seal rows R, E together with H, C, P, N. Thus the handoff is the listed finite route, with no channel for measure completion, Lebesgue integration, selected limits, countable choice, or ambient real completeness. □

Theorem 3528.4 (Stieltjes boundary Real seal non-escape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* StieltjesMeasureBoundar *carrier is available only after the bounded-variation source row, displayed interval partition, endpoint-jump* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been read. The seal exposes the same*

finite interval-jump boundary and exports no measure completion, Lebesgue integration object, host function quotient, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the seal coordinate of Definition 3528.1. The row E is downstream from B, Π, J, R and is transported or replayed only by the structural rows H and C.

Apply Definition 3528.2. It identifies the bounded-variation source, partition exposure, dyadic jump ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows as the complete local certificate surface.

Apply Definition 3528.3. Every integration-facing read must pass through the same finite jump route before the seal is visible. Since none of the excluded objects is a carrier coordinate, the $\mathsf{Real}^{\uparrow}$ seal cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{StieltjesMeasureBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$ packet is generated from a BoundedVariation source row, a displayed interval partition, endpoint-jump DyadicRatCore ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StieltjesMeasureBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3528.1, Definition 3528.2, Definition 3528.3, and Definition 3528.4 seed the finite Stieltjes boundary by which bounded-variation interval jumps are read by Riemann–Stieltjes and regulated Cauchy integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StieltjesMeasureBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure completion, Lebesgue integration, host function quotients, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-jump exactness, regular readback, bounded-variation handoff, Real-seal non-escape, transport and replay stability, provenance non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.StieltjesMeasureBoundaryUp.

Chapter 3529

A Concrete Naming Certificate for $\mathsf{BanachContraction}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{BanachContraction}^{\uparrow}$ packet records the fixed-point route as finite displayed data from the contraction map and Picard orbit surfaces to the complete-metric endpoint boundary. It consumes $\mathsf{ContractionMapping}^{\uparrow}$ from chapter 1418, $\mathsf{PicardIteration}^{\uparrow}$ from chapter 2359, $\mathsf{MetricCompletion}^{\uparrow}$ from chapter 1506, and $\mathsf{SeparatedMetric}^{\uparrow}$ from chapter 1411. The packet also reads the complete-metric row of chapter 128, regular rational readback through chapter 301, and the terminal real-name boundary of chapter 38; it does not claim quotient completions, selected representatives, host function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3529.1 (BanachContraction carrier)**.** *A* $\mathsf{BanachContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, I, M, Q, S, E, H, C, P, N)$$

whose coordinates are exactly:

1. K*, the accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *row displaying the self-map graph, contraction bound, one-step Picard comparison, and fixed-point readiness surface;*
2. I*, the* $\mathsf{PicardIteration}^{\uparrow}$ *row displaying the finite orbit, residual-distance ledger, Cauchy-modulus extraction, and regular-sequence handoff;*
3. M*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *row, read only as the endpoint-admission surface for the Picard Cauchy data;*
4. Q*, the regular-Cauchy and readback route through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal used by endpoint-facing consumers;*
5. S*, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *uniqueness row, consumed only after the two endpoint reads expose zero distance through the displayed metric row;*
6. E*, the endpoint seal row naming the fixed-point candidate as the result of the completion route rather than as a selected host point;*
7. H*, componentwise* hsame *transport for contraction data, Picard iterates, complete-metric endpoint rows, readback rows, separatedness rows, endpoint seals, replay rows, provenance, and local naming;*

8. *C, displayed* Cont *replay from contraction admission through Picard iteration, Cauchy readback, complete-metric endpoint admission, separated uniqueness, and endpoint sealing;*
9. *P, the* Pkg *provenance row over* $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N, the local* $\mathsf{NameCert}_{\mathsf{BanachContraction}^{\uparrow}}$ *row.*

The carrier names the constructive Banach contraction route. It has no coordinate for quotient completion equality, selected representatives, host fixed-point equality, host function extensionality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BanachContractionUp.BanachContractionTasteGate single carrier alignment`

Theorem 3529.2 (BanachContraction NameCert obligations)**.** *For an accepted* $\mathsf{BanachContraction}^{\uparrow}$ *carrier $B = (K, I, M, Q, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachContraction}^{\uparrow}}$ *surface consists exactly of contraction-map admission, Picard-iteration admission, complete-metric endpoint visibility, regular-Cauchy and Real readback visibility, separated uniqueness visibility, endpoint-seal stability, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 3529.1.*

Proof. Project the carrier. The rows K, I, M, Q, S, E are the only mathematical coordinates, and the rows H, C, P, N are the only structural coordinates available to the local certificate.

The contraction and Picard obligations come from chapter 1418 and chapter 2359. They expose the self-map graph, contraction bound, finite orbit ledger, residual comparisons, and Cauchy-modulus handoff before any endpoint row is inspected.

The completion and readback obligations come next. The complete-metric row M admits the Cauchy data to an endpoint-facing surface, while Q records the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback path used by consumers of that endpoint.

Finally S, E, H, C, P, N bind uniqueness, endpoint sealing, transport, replay, provenance, and naming to the same displayed rows. Since no excluded object is a coordinate of B, the NameCert surface exports only the constructive Banach contraction packet. □

Theorem 3529.3 (BanachContraction Cauchy orbit route)**.** *Every endpoint-facing read of an accepted* $\mathsf{BanachContraction}^{\uparrow}$ *carrier first consumes the contraction row K and the Picard row I, then the complete-metric row M, then the readback route Q through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *and only afterward the endpoint seal E. Thus the Cauchy iteration route is the displayed finite chain*

$$\mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto (\mathsf{RegSeqRat}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{Real}^{\uparrow}) \longmapsto E.$$

No read may replace this chain by quotient completion equality, a selected limit representative, countable choice, host function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with K. The contraction row supplies only the finite self-map graph, rational contraction bound, one-step Picard comparison, and fixed-point readiness boundary.

Next consume I. The Picard row generates the finite orbit ledger, residual-distance comparisons, Cauchy-modulus extraction, and regular handoff, so the read has Cauchy data before it asks for an endpoint.

The complete-metric row M is then the only endpoint-admission coordinate. The readback row Q records how the admitted endpoint is inspected through regular rational windows, the metric-completion surface, and the terminal real seal.

The endpoint seal E is downstream of those rows. Because the carrier includes no quotient completion, representative selector, choice schedule, host function equality, or ambient real-completeness coordinate, the displayed route is the whole Cauchy iteration route. □

Theorem 3529.4 (BanachContraction Picard tail modulus)**.** *Every accepted* $\mathsf{BanachContraction}^{\uparrow}$ *orbit read must pass through the* $\mathsf{PicardIteration}^{\uparrow}$ *finite orbit row, residual-distance row,* $\mathsf{CauchyModulus}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{CompleteMetric}^{\uparrow}$ *row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before the unique fixed-point seal can be read. Equivalently, the fixed-point consumer may inspect the separated uniqueness row only after the Picard tail modulus has been routed through the displayed regular rational completion boundary.*

Proof. Apply Definition 3529.3. It forces every endpoint-facing read through the contraction row, Picard row, complete-metric row, readback route, and endpoint seal before any fixed-point endpoint is consumed.

Now read the Picard row through Definition 2359.5. The finite orbit ledger and residual-distance row determine the $\mathsf{CauchyModulus}^{\uparrow}$ row, and that row is the source of the $\mathsf{RegSeqRat}^{\uparrow}$ handoff exposed to completion-facing consumers.

Finally apply Definition 3529.5. The separated uniqueness seal is downstream of the endpoint route, so it cannot be read before the Picard finite orbit, residual-distance ledger, modulus handoff, regular rational boundary, complete-metric row, and terminal real seal have all been displayed. □

Theorem 3529.5 (BanachContraction unique fixed-point seal)**.** *For an accepted* $\mathsf{BanachContraction}^{\uparrow}$ *carrier* $B = (K, I, M, Q, S, E, H, C, P, N)$*, uniqueness of the fixed-point endpoint is exported only through the separated zero-distance route* S *after both compared endpoint reads have passed through* K, I, M, Q, E *and the structural rows* H, C, P, N*. The exported uniqueness is classifier equality inside the displayed* $\mathsf{SeparatedMetric}^{\uparrow}$ *surface, not host equality of points, quotient equality of completion names, a selected representative, trichotomy, or ambient completeness.*

Proof. Take two endpoint-facing reads of the same carrier. By Definition 3529.3, each read must expose the contraction row, Picard row, complete-metric row, readback route, and endpoint seal before any uniqueness comparison is available.

Apply the separatedness row S. It compares the two endpoint reads only after the displayed zero-distance witness is routed through the $\mathsf{SeparatedMetric}^{\uparrow}$ surface; this is the same kind of classifier route isolated in chapter 1411.

Transport and replay are componentwise through H and C, while P and N record provenance and local naming for the same finite packet. These rows do not add a host equality, quotient equality, representative selector, trichotomy principle, or ambient completeness theorem.

Therefore the fixed-point seal is unique only in the displayed local classifier sense. The carrier records the constructive endpoint route and its separated uniqueness boundary, not a host-level fixed-point object. □

Falsifiable prediction: Every accepted $\mathsf{BanachContraction}^{\uparrow}$ read factors through one ContractionMapping row, one PicardIteration row, one CompleteMetric row, one RegSeqRat/MetricCompletion/Real readback route, one SeparatedMetric uniqueness row, one endpoint seal, hsame transport, Cont replay, Pkg provenance, and NameCert row before any fixed-point endpoint is consumed.

Independence witness: contractionmapping, picard-iteration, completemetric, metriccompletion, separatedmetric, regseqrat, real: none is bijective with $\mathsf{BanachContraction}^{\uparrow}$ because the packet jointly stores the contraction route, Picard Cauchy iteration, completion endpoint admission, readback route, separated uniqueness seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachContraction}^{\uparrow}$ packet is generated from a ContractionMapping row, a PicardIteration row, a CompleteMetric endpoint row, a RegSeqRat/MetricCompletion/Real readback route, a SeparatedMetric uniqueness row, an endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3529.1, Definition 3529.2, Definition 3529.3, and Definition 3529.5 seed the finite constructive Banach contraction fixed-point route over the existing contraction, Picard, completion, readback, and separatedness packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, selected representatives, host fixed-point equality, host function extensionality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, contraction-map visibility, Picard-iteration visibility, complete-metric endpoint visibility, readback exactness, separated uniqueness routing, endpoint-seal stability, transport, replay, provenance, and local naming.

Chapter 3530

A Concrete Naming Certificate for $\mathsf{PeanoExistence}^{\uparrow}$

Following Peano and Bishop and Bridges, the $\mathsf{PeanoExistence}^{\uparrow}$ packet records constructive local ODE existence data without uniqueness as finite NameCert rows. It consumes the real endpoint discipline of chapter 38, the continuous vector-field surface of chapter 130, and the displayed ODE source of chapter 193. The packet names an interval-window, vector-field, Euler-polygon, and compact-containment route; it does not name a Lipschitz modulus, a unique flow, a maximal solution, host compactness, or a choice-selected path.

Definition 3530.1 (Peano existence carrier)**.** *A* $\mathsf{PeanoExistence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, V, W, E, Q, M, H, C, G, N)$$

with the following displayed rows:

1. *I is the interval source row, binding the initial time, initial state, local radius, and finite rational time window through the* $\mathsf{Ode}^{\uparrow}$ *source surface.*
2. *V is the* $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field row, read on the displayed time-state window and classified only through its continuous-map graph and modulus ledgers.*
3. *W is the closed* $\mathsf{Real}^{\uparrow}$ *interval and state-window row that bounds the Euler-polygon construction before any solution read is exported.*
4. *E is the finite Euler polygon approximation ledger, including step windows, endpoint approximants, and local slope reads from V.*
5. *Q is the compact-containment row, recording that every displayed polygon segment remains in the certified window W.*
6. *M is the modulus row used to compare nearby polygon windows and to pass from finite polygon data to a Cauchy-style local solution row.*
7. *H records componentwise* hsame *transport for interval sources, vector-field rows, real windows, polygon ledgers, containment rows, modulus rows, replay rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from the ODE request through I, V, W, E, Q, M.*
9. *G is the* Pkg *provenance over* $\mathsf{PeanoExistence}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{PeanoExistence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for uniqueness, Lipschitz dependence, a selected maximal solution, ambient host compactness, or a choice principle.

Lean4 ✓ `BEDC.Derived.PeanoExistenceUp.TasteGate.PeanoExistenceTasteGate single carrier alignment`

Theorem 3530.2 (Peano existence NameCert obligations)**.** *For every accepted* $\mathsf{PeanoExistence}^{\uparrow}$ *carrier*

$$P = (I, V, W, E, Q, M, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PeanoExistence}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval source row, continuous vector-field row, real closed window row, Euler polygon approximation ledger, compact-containment row, modulus row, componentwise transport, displayed continuation replay, package provenance, and local naming. Every local existence read is therefore routed through* $I, V, W, E, Q, M, H, C, G, N$.

Proof. Project the accepted carrier of Definition 3530.1. The interval source I fixes the ODE request, V supplies the displayed continuous vector-field read, and W supplies the real closed window in which the construction is inspected.

The approximation content is carried by E, Q, M. Euler polygons in E provide finite stepwise approximants, Q keeps every inspected polygon segment inside the recorded window, and M gives the finite comparison ledger needed for a Cauchy-style local solution read.

The structural rows H, C, G, N transport, replay, package, and name exactly that finite route. Since the carrier has no coordinate for uniqueness, Lipschitz dependence, maximal-extension selection, host compactness, or choice, the NameCert surface cannot export any of those objects. □

Definition 3530.3 (Peano interval trap carrier)**.** *The Peano interval trap inside a* $\mathsf{PeanoExistence}^{\uparrow}$ *carrier is the displayed subpacket*

$$(I, V, W, E, Q, M)$$

consisting of the closed $\mathsf{Real}^{\uparrow}$ *time-state window named by I and W, the continuous vector-field row V, the Euler polygon ledger E, the compact-containment row Q, and the modulus comparison row M. It records only the finite data used to keep polygon approximants inside the source packet before a local solution row is exported.*

Theorem 3530.4 (Peano interval trap obligations)**.** *Every accepted local-existence read of a* $\mathsf{PeanoExistence}^{\uparrow}$ *packet must pass through the interval source I, the continuous vector-field row V, the closed* $\mathsf{Real}^{\uparrow}$ *time-state window W, the Euler polygon ledger E, the compact-containment row Q, and the modulus handoff M before it can export a solution row. Thus the interval trap obligations are exactly the finite rows displayed in Definition 3530.3, together with the transport, replay, provenance, and local naming rows of Definition 3530.1.*

Proof. Begin with the carrier of Definition 3530.1. The interval source I and vector-field row V are the only rows that provide the ODE request and continuous slope reads, while W is the only closed Real window in which the finite construction is inspected.

The Euler polygon ledger E gives the finite approximants. The compact-containment row Q checks each displayed segment against the same source window, and the modulus row M supplies the comparison handoff needed before a local solution read can be exported.

Rows H, C, G, N do not add another analytic source. They transport, replay, record provenance, and name the same interval trap. Therefore every accepted local-existence read must expose I, V, W, E, Q, M before the solution row is public. □

Theorem 3530.5 (Peano existence scoped primitive route)**.** *Every accepted local-existence read of a* $\mathsf{PeanoExistence}^{\uparrow}$ *carrier factors through the exact primitive route*

$\mathsf{Ode}^{\uparrow}$ *interval source* $\to$ $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field row* $\to$ $\mathsf{Real}^{\uparrow}$ *closed window* $\to$ *Euler polygon ledger* $\to$ *compac*

Thus the scoped read exposes precisely the interval source, vector-field, closed-window, polygon, containment, modulus, transport, replay, provenance, and local naming rows of Definition 3530.1. It exports no Lipschitz uniqueness, selected maximal solution, host compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier $P = (I, V, W, E, Q, M, H, C, G, N)$ of Definition 3530.1. The only analytic entrance rows are the $\mathsf{Ode}^{\uparrow}$ interval source I, the $\mathsf{ContinuousMap}^{\uparrow}$ vector-field row V, and the closed $\mathsf{Real}^{\uparrow}$ window W.

Apply Definition 3530.2. It identifies the local $\mathsf{NameCert}_{\mathsf{PeanoExistence}^{\uparrow}}$ surface with the displayed carrier rows and records that every local-existence read is routed through $I, V, W, E, Q, M, H, C, G, N$.

Apply Definition 3530.4. The finite solution-producing part of the route is exactly the Euler polygon ledger E, compact-containment row Q, and modulus handoff M before transport, replay, provenance, and local naming are consumed.

Since the carrier definition has no coordinate for Lipschitz uniqueness, a selected maximal solution, host compactness, countable choice, or ambient Real completeness, none of those objects can be exported by the scoped primitive route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PeanoExistence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PeanoExistence}^{\uparrow}$ packet is generated from an $\mathsf{Ode}^{\uparrow}$ interval source row, a $\mathsf{ContinuousMap}^{\uparrow}$ vector-field row, a closed $\mathsf{Real}^{\uparrow}$ time-state window, Euler polygon approximation ledgers, compact-containment and modulus rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PeanoExistence}^{\uparrow}}$, obligation)

Scope closed: Definition 3530.1, Definition 3530.2, Definition 3530.3, and Definition 3530.4 expose the constructive local existence obligations over displayed ODE, continuous-map, real-window, Euler-polygon, containment, modulus, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PeanoExistence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim uniqueness, Lipschitz dependence, selected maximal solutions, host compactness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding these obligations to their exact primitive routes for interval sources, continuous vector fields, closed Real windows, Euler polygon ledgers, compact-containment rows, modulus handoffs, transport, replay, provenance, and local naming.

Chapter 3531

A Concrete Naming Certificate for $\mathsf{LocatedCompletionFunctor}^{\uparrow}$

Following Bishop and Bridges on located constructive metric completions and Kelley on functorial completion discipline, the $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ packet records the finite route by which a located metric-space presentation is sent to its completion-facing regular-name surface. It sits after the located real boundary of chapter 1933, the metric-completion carrier of chapter 1506, the universal-property witness of chapter 2319, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the displayed functorial handoff used by L10 completion consumers; it is not a quotient completion theorem, not a selected host limit, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3531.1 (Located completion functor carrier)**.** *A* $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{LocatedCompletionFunctor}(L, M, U, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *or located metric-source row exposing the positive-apartness and approximation data that make Cauchy requests decidable as finite located reads.*
2. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier row naming the completion-facing object surface, without quotienting Cauchy names.*
3. *U is the* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *row recording the displayed universal-property handoff for uniformly continuous maps already routed through finite data.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the completion object is presented through regular rational names.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located, completion, universal-property, and regular rational rows have been displayed.*
6. *F is the functorial action row, naming how source maps are transported to completion-facing maps through L, M, U, R, E.*
7. *H records componentwise* hsame *transport for the located source, completion carrier, universal-property handoff, regular rational readback, Real seal, functorial action, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a located source request through the completion, universal-property, regular rational, Real-seal, and functorial-action rows.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedCompletionFunctor}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, M, U, R, E, F, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, countable-choice schedules, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge data.

Lean4 ✓ `BEDC.Derived.LocatedCompletionFunctorUp.LocatedCompletionFunctorTasteGate single carrier alignment`

Theorem 3531.2 (Located completion functor NameCert obligations)**.** *For every accepted* LocatedCompletionFunc *carrier* $\mathsf{LocatedCompletionFunctor}(L, M, U, R, E, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission for the located source, metric-completion carrier, Cauchy-completion universal-property handoff, regular rational readback, Real seal, functorial action, componentwise transport, displayed replay, provenance, and local naming rows.*

Every completion-facing consumer must read the route

$$L, M, U, R, E, F, H, C, P, N$$

before treating a located map as a completion map. The route exports no quotient completion theorem, selected host limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge datum.*

Proof. Carrier admission is projection from Definition 3531.1. The accepted tuple displays the located source row, completion carrier, universal-property row, regular rational readback, Real seal, functorial action, and structural support.

The completion-facing read begins with L and M. These rows expose located input data and the completion object surface before any map action is available.

Next read U, R, E, F. The universal-property row supplies the finite handoff discipline, the regular rational and Real rows name the target readback boundary, and the functorial action row records the transported map only after those rows are present.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since no quotient equality, selected limit, choice schedule, trichotomy row, host real equality, Real completeness theorem, Lean verification row, or bridge datum is present in the carrier, none can become a local NameCert obligation. □

Theorem 3531.3 (Located completion functor Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ *packet reaches the Real-facing handoff only through the displayed located source row, metric-completion row, Cauchy-completion universal-property row, regular rational readback row, Real seal row, and functorial-action row of Definition 3531.1. In particular, the handoff is a finite NameCert route for located completion data, not a quotient completion, selected host limit, countable-choice construction, trichotomy principle, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer. The consumer-facing evidence is the displayed carrier, so the located source, completion object, universal-property handoff, readback, seal, and functorial action are the only rows it may inspect.

The regular rational and Real rows are downstream. The consumer reaches R and E only after L, M, U have fixed the located completion route and before F packages the transported map.

The support rows H, C, P, N carry the same route through transport, replay, provenance, and local naming. No coordinate supplies quotient completion equality, a selected limit, countable choice, trichotomy, host equality, ambient Real completeness, Lean verification, or bridge checking. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ packet factors a Real-facing completion read through one located source row, one MetricCompletion row, one CauchyCompletionUniversalProperty handoff, one RegSeqRat readback, one RealUp seal, one functorial-action row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: located-real, metric-completion, cauchy-completion-universal-property, regseqrat, real: $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the located source, completion carrier, universal-property handoff, regular rational readback, Real seal, and functorial action as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3531.1, Definition 3531.2, and Definition 3531.3 seed the finite located-completion functor route over located source rows, metric-completion carriers, universal-property handoffs, regular rational readback, Real seals, functorial action, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-source exactness, completion-carrier handoff, universal-property consumption, RegSeqRat and Real handoff, functorial-action exactness, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompletionFunctorUp.

Constructive story: A $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ packet is generated from a located source row, a MetricCompletion row, a CauchyCompletionUniversalProperty handoff, a RegSeqRat readback row, a RealUp seal row, a functorial-action row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3532

A Concrete Naming Certificate for $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ packet records the finite surface at which a located regular rational sequence exposes the modulus windows consumed by Phase Real and Completion classifiers. It sits after the dyadic tolerance core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the located Cauchy representation route of chapter 4070, and the terminal real-name seal of chapter 38. The packet is a carrier for displayed located-modulus data, not a quotient completion, a selected limit, a countable-choice schedule, a trichotomy oracle, or an ambient completeness principle.

Definition 3532.1 (RegSeqRat located-modulus carrier)**.** *A* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, L, \mu, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance query row.*
2. *L is the* $\mathsf{LocatedCauchyRepresentation}^{\uparrow}$ *located regular-sequence row.*
3. *μ is the displayed modulus row assigning finite stream windows to the tolerance queries admitted by Q.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposed by μ.*
5. *D is the dyadic decision ledger binding the tolerance query to the displayed window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row at the window named by W.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal reached after the located regular-sequence readback.*
8. *H stores componentwise* hsame *transport for $Q, L, \mu, W, D, R, E, C, P, N$.*
9. *C stores displayed* Cont *replay from tolerance request to modulus window, regular readback, locatedness row, and real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedCauchyRepresentation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatLocatedModulus}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $Q, L, \mu, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit representative, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegSeqRatLocatedModulusUp.TasteGate.RegSeqRatLocatedModulusTasteGate single carrier alignment`

Theorem 3532.2 (RegSeqRat located-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegSeqRatLocatedMod}$ *carrier $M = (Q, L, \mu, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatLocatedModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, located-modulus exposure, finite-window stability,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise transport, displayed continuation replay, package provenance, local naming, and ledger refusal for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3532.1. The accepted packet first exposes the tolerance query Q, the located regular-sequence row L, and the displayed modulus row μ.

The modulus row opens only the finite $\mathsf{StreamName}^{\uparrow}$ window W and the dyadic decision ledger D attached to that request. The rational readback row R is then read at the displayed window, and the terminal real-name seal E is reached only after this finite route has been replayed.

Transport and continuation are exhausted by H and C, while P and N record provenance and local naming. Since the carrier has no further coordinate, no accepted packet can import quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 3532.3 (RegSeqRat located-modulus finite-window stability)**.** *Every* $\mathsf{LocatedCauchyRepresentation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ *packet factors through $Q, L, \mu, W, D, R, E, H, C, P, N$ before any consumer-visible located read is exported. The handoff therefore exposes the located modulus as a finite window discipline over regular rational readback and terminal real-name sealing, not as quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier as $M = (Q, L, \mu, W, D, R, E, H, C, P, N)$. A $\mathsf{LocatedRegSeqRat}^{\uparrow}$ consumer must read the located row L together with the displayed modulus row μ before it can export a locatedness response.

A $\mathsf{RegSeqRat}^{\uparrow}$ consumer reaches rational data only through the finite window W named by μ and the readback row R bound to that window. The dyadic ledger D records which tolerance request was served, so the read cannot be replaced by an unbounded stream equality or by an arbitrary limit choice.

A $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal E only after the same window and readback route has been replayed by C and transported by H. The remaining rows P and N certify provenance and local naming, so the handoff contains no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness. □

Theorem 3532.4 (RegSeqRat located-modulus located row exhaustion)**.** *For an accepted* $\mathsf{RegSeqRatLocatedModul}$ *carrier $M = (Q, L, \mu, W, D, R, E, H, C, P, N)$, every located read exported to* $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *is exhausted by exactly the located row L, the displayed modulus row μ, the finite windows W, the dyadic decision ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{Real}^{\uparrow}$ *seal E, the componentwise transport row H, the displayed replay row C, the provenance row P, and the local naming row N. No exported located read factors through quotient stream equality, selected limits, countable choice, trichotomy, host equality, or ambient completeness.*

Proof. Project the carrier of Definition 3532.1. The located export has no coordinates other than $Q, L, \mu, W, D, R, E, H, C, P, N$, and its consumer-visible located row is L together with the displayed modulus row μ.

Use the finite-window stability theorem Definition 3532.3. A $\mathsf{LocatedCauchyRepresentation}^{\uparrow}$ consumer reads L and μ before exporting locatedness; a $\mathsf{RegSeqRat}^{\uparrow}$ consumer reaches data through W, D, R; and a $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal E only after transport and replay through H and C.

The remaining rows P and N source and name this same route. Since the carrier definition contains no quotient stream equality, selected-limit representative, countable-choice schedule, trichotomy oracle, host equality coordinate, or ambient completeness witness, the listed rows exhaust every exported located read. □

Theorem 3532.5 (RegSeqRat located-modulus Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ *carrier* $M = (Q, L, \mu, W, D, R, E, H, C, P, N)$ *passes in order through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance query* Q*, the* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *row* L*, the displayed modulus row* μ*, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows* W*, the dyadic decision ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. No* $\mathsf{Real}^{\uparrow}$*-facing read bypasses this route by quotient stream equality, selected limits, countable choice, trichotomy, host equality, or ambient completeness.*

Proof. Project the carrier from Definition 3532.1. The only Real-facing rows in the packet are the displayed tolerance, locatedness, modulus, window, ledger, readback, seal, transport, replay, provenance, and naming rows.

Apply the finite-window stability theorem Definition 3532.3 to force every $\mathsf{Real}^{\uparrow}$ consumer through $Q, L, \mu, W, D, R, E, H, C, P, N$ before a consumer-visible seal is exported.

Apply the located-row exhaustion theorem Definition 3532.4. It rules out additional coordinates for quotient stream equality, selected limits, countable choice, trichotomy, host equality, or ambient completeness, so the displayed order is the full Real route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegSeqRatLocatedModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance query, a LocatedRegSeqRat row, a displayed modulus row, StreamName finite windows, a dyadic decision ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegSeqRatLocatedModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3532.1, Definition 3532.2, Definition 3532.3, and Definition 3532.5 seed the finite located-modulus route from regular rational sequence data to Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegSeqRatLocatedModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-modulus exposure, finite-window stability, RegSeqRat readback, RealUp seal routing, and ledger refusal for BEDC.Derived.RegSeqRatLocatedModulusUp.

Chapter 3533

A Concrete Naming Certificate for $\mathsf{MorseTheory}^{\uparrow}$

Following Milnor on Morse theory, the $\mathsf{MorseTheory}^{\uparrow}$ packet records the finite certificate surface by which critical-point data, Hessian signatures, local chart rows, gradient-flow incidence, and filtration boundary rows are read as one displayed Morse-theory name. It sits after the charted carrier of chapter 96, the derivative observation rows of chapter 122, the scalar comparison seal of chapter 38, the tangent-fibre bookkeeping of chapter 210, and the fibrewise metric rows of chapter 133. The packet names a local finite Morse certificate; it is not a host smooth-function space, not a Sard or transversality theorem, not a handle-decomposition completeness theorem, and not a cobordism classification principle.

Definition 3533.1 (Morse theory carrier)**.** *A* $\mathsf{MorseTheory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, D, R, T, G, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Manifold}^{\uparrow}$ *charted source row naming the local carrier on which the Morse data are read.*
2. *F is the displayed function row, exposing only the finite function-name observations used by the certificate.*
3. *D is the* $\mathsf{Derivative}^{\uparrow}$ *first- and second-derivative observation row attached to F over the charted source.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar comparison row used for critical values, local height comparisons, and finite ordering tests.*
5. *T is the* $\mathsf{VectorBundle}^{\uparrow}$ *tangent-fibre row over X, carrying the finite source for Hessian and flow-incidence reads.*
6. *G is the* $\mathsf{RiemannianMetric}^{\uparrow}$ *metric row used to read gradient-flow incidence only after X, T, D have been displayed.*
7. *L is the local Morse ledger row: critical-point admission, nondegenerate Hessian signature, index tag, finite flow-incidence boundary, and filtration boundary are recorded here as finite observations.*

8. *H records componentwise* hsame *transport for the chart, function, derivative, scalar, tangent-fibre, metric, ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through chart admission, derivative readback, real comparison, tangent-fibre transport, metric readback, and Morse ledger inspection.*
10. *P is the* Pkg *provenance over* $\mathsf{MorseTheory}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VectorBundle}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MorseTheory}^{\uparrow}}$ *row.*

The carrier exports Morse-theory reads only through $X, F, D, R, T, G, L, H, C, P, N$. It has no coordinate for a host function space, global transversality, Sard regular-value selection, complete handle decomposition, cobordism classification, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.MorseTheoryUp.MorseTheoryTasteGate single carrier alignment`

Theorem 3533.2 (Morse theory NameCert obligations)**.** *For every accepted* $\mathsf{MorseTheory}^{\uparrow}$ *carrier*

$$M = (X, F, D, R, T, G, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MorseTheory}^{\uparrow}}$ *surface consists exactly of charted manifold admission, displayed function rows, derivative readback, real scalar comparison, tangent-fibre bookkeeping, Riemannian metric readback, local Morse ledger inspection, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Every critical-point, index, or flow-incidence read exported by the packet must factor through

$\mathsf{Manifold}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VectorBundle}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

Proof. Project the accepted carrier. The charted source is row X, the displayed function observations are row F, derivative readback is row D, real comparison is row R, tangent-fibre bookkeeping is row T, and metric readback is row G.

The Morse-specific content is confined to row L. It records critical-point admission, nondegenerate Hessian signature, index tag, finite flow-incidence boundary, and filtration boundary only after the chart, derivative, scalar, tangent, and metric rows are available.

The structural rows H, C, P, N transport, replay, source, and name exactly that displayed route. Since no row stores Sard regular values, transversality, complete handle decompositions, cobordism classification, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{MorseTheory}^{\uparrow}$ critical-point, index, or flow-incidence read factors through displayed $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VectorBundle}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, provenance, transport, replay, and local NameCert rows.

Independence witness: manifold, derivative, real, vectorbundle, riemannianmetric: the Manifold packet records charted carriers without Morse functions, the Derivative packet records derivative observations without critical-index ledgers, the Real packet records scalar comparison without tangent flow incidence, the VectorBundle packet records fibres without a fibrewise metric read, and the RiemannianMetric packet records metric rows without Morse ledger data. None is bijective to $\mathsf{MorseTheory}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{MorseTheory}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MorseTheory}^{\uparrow}$ packet is generated from Manifold chart rows, displayed function observations, Derivative first- and second-derivative reads, Real scalar comparisons, VectorBundle tangent-fibre rows, RiemannianMetric

metric reads, a local Morse ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MorseTheory}\uparrow}$, seed)

Scope closed: Definition 3533.1 and Definition 3533.2 seed the finite Morse-theory certificate over chart, function, derivative, scalar, tangent, metric, ledger, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MorseTheory}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Sard theory, transversality, handle decomposition completeness, cobordism classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, critical-point ledger exposure, Hessian signature exactness, index tagging, finite flow-incidence routing, filtration boundary routing, and a Lean carrier/obligation formalization for BEDC.Derived.MorseTheoryUp.

Chapter 3534

A Concrete Naming Certificate for $\mathsf{HyperbolicHorocycle}^{\uparrow}$

Following classical hyperbolic geometry in the Poincare disk, the $\mathsf{HyperbolicHorocycle}^{\uparrow}$ packet realizes the boundary-tangent horocycle rows requested by chapter 9463 as finite NameCert data. It sits after the disk-coordinate carrier of chapter 377, the metric-read surface of chapter 3474, the boundary-fixed transport route of chapter 3500, and the geodesic metric carrier of chapter 2213. The packet names a displayed horocycle certificate rather than a host circle model, a completed ideal-boundary quotient, a global geodesic foliation, or a physical observer trajectory.

Definition 3534.1 (Hyperbolic horocycle carrier)**.** *A* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, M, B, G, T, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row for the finite source observations.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same disk data.*
3. *B is the boundary-anchor row, recording the displayed ideal boundary point only as a finite boundary-facing observation.*
4. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *incidence row used to compare tangent geodesic directions near the boundary anchor.*
5. *T is the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *transport row preserving the boundary anchor during admissible disk transport.*
6. *L is the horocycle ledger row: boundary tangency, constant hyperbolic-distance readback relative to the anchored geodesic family, and finite incidence compatibility are recorded here.*
7. *H records componentwise* hsame *transport for disk, metric, boundary, geodesic, transport, ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through disk admission, metric readback, boundary anchoring, geodesic incidence, boundary-fixed transport, and horocycle ledger inspection.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTranspo}$ $\mathsf{GeodesicMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycle}^{\uparrow}}$ *row.*

The carrier exports horocycle reads only through $D, M, B, G, T, L, H, C, P, N$. It has no coordinate for a host Euclidean circle, quotient ideal boundary, global horocycle foliation, selected geodesic representative, physical observer motion, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.HyperbolicHorocycleUp.HyperbolicHorocycleTasteGate single carrier alignment`

Theorem 3534.2 (Hyperbolic horocycle NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *carrier*

$$Q = (D, M, B, G, T, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycle}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, hyperbolic-metric readback, boundary-anchor admission, geodesic-incidence readback, boundary-fixed transport compatibility, horocycle ledger inspection, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Every boundary-tangent horocycle read exported by the packet must factor through

$$\mathsf{UnitDisk}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{PoincareBoundaryFixedTransport}^{\uparrow},\ \mathsf{GeodesicMetric}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Name}$$

Proof. Project the accepted carrier. The disk surface is row D, the hyperbolic metric read is row M, the boundary anchor is row B, the geodesic incidence read is row G, and the boundary-fixed transport route is row T.

The horocycle-specific content is row L. It records boundary tangency, constant hyperbolic-distance readback relative to the anchored geodesic family, and finite incidence compatibility only after the disk, metric, boundary, geodesic, and transport rows have been displayed.

The structural rows H, C, P, N preserve and name that route. Since the carrier contains no host Euclidean circle, quotient ideal boundary, global horocycle foliation, selected geodesic representative, physical observer motion, Lean verification, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicHorocycle}^{\uparrow}$ boundary-tangent read factors through displayed $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, provenance, transport, replay, and local NameCert rows.

Independence witness: unitdisk, hyperbolic-metric, poincare-boundary-fixed-transport, geodesic-metric: the UnitDisk packet records disk coordinates without hyperbolic tangency, the HyperbolicMetric packet records metric reads without a boundary anchor ledger, the PoincareBoundaryFixedTransport packet records fixed-boundary transport without horocycle incidence, and the GeodesicMetric packet records geodesic metric data without a boundary-tangent horocycle row. None is bijective to $\mathsf{HyperbolicHorocycle}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycle}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicHorocycle}^{\uparrow}$ packet is generated from UnitDisk disk-coordinate rows, HyperbolicMetric metric reads, a boundary-anchor row, GeodesicMetric incidence, PoincareBoundaryFixedTransport compatibility, a horocycle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicHorocycle}^{\uparrow}}$, seed)

Scope closed: Definition 3534.1 and Definition 3534.2 seed the finite horocycle certificate over disk, metric, boundary, geodesic, transport, ledger, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicHorocycle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Euclidean circle models, ideal-boundary quotient equality, global horocycle foliations, selected geodesic representatives, physical observer motion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk admission, metric readback, boundary anchoring, geodesic incidence, boundary-fixed transport compatibility, horocycle ledger exactness, and a Lean carrier/obligation formalization for BEDC.Derived.HyperbolicHorocycleUp.

Chapter 3535

A Concrete Naming Certificate for $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$

Following Baire and Oxtoby, the $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ packet records the textbook complete-metric Baire argument as finite BEDC NameCert rows rather than as an ambient host theorem. It sits over the dense-open schedule of chapter 1542, the Cauchy-thread and limit-service row of chapter 128, the metric carrier rows of chapter 57, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the surface on which a Baire dense-open construction can be inspected before any countable-choice selector, host intersection, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim is available.

Definition 3535.1 (CompleteMetricBaireSurface carrier)**.** *A* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, K, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open schedule row, listing the finite dense-open requests and the predecessor-ball refinements made visible to the packet.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-thread row, exposing only the displayed center sequence, radius shrinkage, and limit-service handoff used by the dense-open route.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *carrier row, naming the distance, ball classifier, and metric comparison data consumed by B and K.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the schedule, centers, radii, and requested tolerances are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational center and radius data visible before the terminal seal.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the schedule, Cauchy thread, metric carrier, finite windows, and rational readback have been displayed.*
7. *H records componentwise* hsame *transport for the dense-open schedule, complete-metric thread, metric carrier, finite windows, rational readback, real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the same dense-open, Cauchy-thread, metric, window, readback, and seal route.*
9. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricBaireSurface}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for countable choice, host intersections, open-cover compactness, selected limit points, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CompleteMetricBaireSurfaceUp.CompleteMetricBaireSurfaceTasteGate single carrier alignment`

Theorem 3535.2 (Baire-category complete-metric NameCert surface)**.** *For every accepted* CompleteMetricBaireSur *carrier*

$$U = (B, K, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteMetricBaireSurface}^{\uparrow}}$ *surface exposes exactly the Baire dense-open schedule, complete-metric Cauchy thread, metric carrier rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Every complete-metric Baire read is routed through $B, K, M, S, R, E, H, C, P, N$, and no obligation is stored outside those rows.*

Proof. Project the accepted carrier of Definition 3535.1. The rows B, K, M, S, R, E are the only analytic rows available to a consumer: dense-open schedule, Cauchy-thread service, metric carrier, finite windows, rational readback, and terminal real seal.

The Baire-category content is read first through B. Each dense-open request and predecessor-ball refinement is displayed as finite schedule data, then the complete-metric row K carries the Cauchy thread built from those refinements.

The numerical and metric observations are constrained by M, S, R, E. The metric carrier supplies distance and ball comparisons, the stream row supplies finite inspection windows, the regular rational row reads center and radius data, and the real seal is reached only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no coordinate for countable choice, host intersections, open-cover compactness, selected limit points, ambient real completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 3535.3 (Complete metric Baire surface nested-ball route)**.** *Let $U = (B, K, M, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *carrier. A finite dense-open schedule displayed by B together with the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy service displayed by K determines a nested closed ball route whose radii are readable through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and whose limit request is sealed through* $\mathsf{Real}^{\uparrow}$ *only after the corresponding* $\mathsf{StreamName}^{\uparrow}$ *windows S have been displayed. The route is transported, replayed, sourced, and named only by H, C, P, N.*

Proof. Consume the dense-open schedule in B. Each finite request exposes the predecessor-ball refinement data that the Baire surface records before any host intersection or choice selector is available.

Choose the displayed ball rows from that finite schedule and read their metric comparisons through M. The complete-metric row K then supplies the Cauchy thread and limit-service handoff for the same displayed nested ball route.

The numerical observations pass through S and R. The stream windows display the center and radius observations, and the regular rational readback makes the radii available without adding a selected limit point.

Finally use the Real seal nonescape already built into Definition 3535.2. The seal row E is downstream from the dense-open schedule, complete-metric thread, metric carrier, stream windows, and rational readback, while H, C, P, N preserve that route without adding countable choice, host intersections, open-cover compactness, selected limit points, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 3535.4 (CompleteMetricBaireSurface open-density thread)**.** *Let*

$$U = (B, K, M, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *carrier. Every dense-open schedule read from B must expose the complete-metric Cauchy thread K, metric row M,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and* $\mathsf{Real}^{\uparrow}$ *seal E before a Baire consumer may inspect the terminal route. The exposed thread is transported, replayed, sourced, and named only by H, C, P, N, and it exports no selected generic point, countable-choice schedule, host intersection, open-cover compactness, selected limit point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3535.1. The dense-open schedule B and Cauchy thread K are coordinates of the same packet, so a consumer cannot read the schedule as an external countable-choice object.

Use the NameCert surface of Definition 3535.2. It makes $B, K, M, S, R, E, H, C, P, N$ the complete visible route for every complete-metric Baire read, with no obligation stored outside those rows.

Compose with the nested-ball route of Definition 3535.3. The metric row M, finite windows S, rational readback R, and seal row E must be exposed before the terminal route can be inspected.

Finally close by carrier exhaustion. The structural rows H, C, P, N preserve the same route, while the excluded generic point, choice schedule, host intersection, compactness, selected limit, and ambient completeness endpoints have no carrier coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricBaireSurface}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricBaireSurface}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3535.1 and Definition 3535.2 seed the complete-metric Baire surface over dense-open schedules, Cauchy-thread rows, metric carriers, finite windows, rational readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricBaireSurface}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, host intersections, open-cover compactness, selected limit points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exposure, complete-metric Cauchy-thread exactness, finite-window readback, rational center readback, real sealing, and nonescape for BEDC.Derived.CompleteMetricBair

Constructive story: A $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ packet is generated from a BaireCategory dense-open schedule, a CompleteMetric Cauchy thread, MetricSpace carrier rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3536

A Concrete Naming Certificate for $\mathsf{BaireSpaceCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Oxtoby's Baire-space presentation, the $\mathsf{BaireSpaceCompleteness}^{\uparrow}$ packet records the usual complete ultrametric structure on Baire space as finite NameCert rows. It reads finite prefix-cylinder data from $\mathsf{BaireSpace}^{\uparrow}$ in chapter 334, routes Cauchy-thread convergence through $\mathsf{CompleteMetric}^{\uparrow}$, exposes windows through $\mathsf{StreamName}^{\uparrow}$, reads rational tolerances through $\mathsf{RegSeqRat}^{\uparrow}$, and seals endpoint distances only through $\mathsf{Real}^{\uparrow}$. The downstream complete-metric Baire surface of chapter 3535 can therefore consume a direct Baire-space completeness object instead of an implicit host completeness assertion.

Definition 3536.1 (BaireSpaceCompleteness carrier)**.** *A* $\mathsf{BaireSpaceCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (B, K, S, R, E, H, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder row, including the displayed stream schedule, finite prefix windows, prefix classifier, and local cylinder transport.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-thread row for the usual ultrametric in which the distance between two streams is bounded by the first displayed prefix disagreement.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite observations of the Cauchy thread and its limit stream are inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for dyadic tolerances and prefix-length bounds used by the ultrametric estimates.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint distances, reached only after B, K, S, R have been displayed.*
6. *H records componentwise* hsame *transport for prefix cylinders, Cauchy-thread rows, stream windows, rational readback, and real endpoint seals.*
7. *P is the* Pkg *provenance over* $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireSpaceCompleteness}^{\uparrow}}$ *row naming the displayed completeness packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for a choice-selected branch, host sequence equality, quotient completion, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3536.2 (BaireSpaceCompleteness NameCert obligations)**.** *For every accepted* $\mathsf{BaireSpaceCompleteness}^{\uparrow}$ *carrier* $C = (B, K, S, R, E, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireSpaceCompleteness}^{\uparrow}}$ *surface consists exactly of the prefix-cylinder admission row, the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-thread route, the* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *dyadic tolerance readback, the* $\mathsf{Real}^{\uparrow}$ *endpoint-distance seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from Definition 3536.1. The Baire-space row B supplies only finite prefix-cylinder data, while K records the Cauchy-thread service for the ultrametric route.

The observation rows are then forced by S and R. A consumer reads finite stream windows through $\mathsf{StreamName}^{\uparrow}$ and reads dyadic tolerance bounds through $\mathsf{RegSeqRat}^{\uparrow}$ before it can inspect any endpoint distance.

Finally the endpoint seal is the row E, and the structural rows H, P, N only transport, source, and name the displayed route. Since none of these coordinates contains a branch selector, host equality, quotient completion, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no such obligation is exported. □

Theorem 3536.3 (BaireSpaceCompleteness Cauchy-thread route)**.** *Let* $C = (B, K, S, R, E, H, P, N)$ *be an accepted* $\mathsf{BaireSpaceCompleteness}^{\uparrow}$ *packet. Every Cauchy thread in the usual Baire-space ultrametric is read through the finite prefix-cylinder row of* B*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *route* K*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback* R *before its endpoint distance is sealed through* E*. The route is transported, replayed, sourced, and named only by* H, P, N*.*

Proof. Start with the prefix-cylinder surface of chapter 334. It exposes finite stream prefixes and their cylinder classifier before any completed stream or host topology is available.

Apply the complete-metric route through K. A Cauchy-thread request is therefore routed through the displayed $\mathsf{CompleteMetric}^{\uparrow}$ service rather than through a quotient completion or selected limit operation.

The finite observations are read through S and the dyadic tolerance bounds through R. Only after those rows are displayed does the endpoint-distance row E seal the resulting real-valued estimate. The transport, replay, provenance, and local naming rows preserve this order, matching the downstream complete-metric Baire surface of chapter 3535. □

Theorem 3536.4 (Baire finite-prefix cylinder induction)**.** *Let* $C = (B, K, S, R, E, H, P, N)$ *be an accepted* $\mathsf{BaireSpaceCompleteness}^{\uparrow}$ *packet, and let* Λ *be a finite replay ledger whose entries refine the displayed* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder row by one finite prefix-cylinder observation at a time. Induction on* Λ *preserves the invariant that the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-thread route is read through the same* $\mathsf{BaireSpace}^{\uparrow}$ *prefix surface* B*,* $\mathsf{StreamName}^{\uparrow}$ *window row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal* E*. Thus every finite prefix-cylinder refinement ledger exports the same Baire-space completeness route and no selected branch, quotient completion, host stream equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness premise.*

Proof. For the empty ledger, use Definition 3536.3. The accepted carrier already routes the Cauchy thread through B, K, S, R, E, H, P, N, so the invariant holds with no additional prefix-cylinder observation.

For the induction step, assume the invariant for a finite replay ledger Λ and extend it by one displayed prefix-cylinder observation. The new observation only refines the finite prefix row inside B; it does not create a new Cauchy-thread row, stream-window row, rational-tolerance row, or endpoint seal.

Reuse the same finite observation and tolerance rows. The $\mathsf{StreamName}^{\uparrow}$ row S reads the extended prefix window, the $\mathsf{RegSeqRat}^{\uparrow}$ row R reads the same dyadic tolerance scale, and K keeps the Cauchy-thread route inside $\mathsf{CompleteMetric}^{\uparrow}$ before E seals the endpoint distance.

The structural rows H, P, N transport, source, and name the extended replay ledger without adding any carrier coordinate. Therefore each finite ledger prefix preserves the displayed route, and induction over Λ gives the stated cylinder-refinement invariant. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireSpaceCompleteness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireSpaceCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3536.1, Definition 3536.2, and Definition 3536.3 seed the finite NameCert route for the usual complete ultrametric on Baire space.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireSpaceCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host sequence equality, quotient completion, choice-selected branches, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-cylinder projection, Cauchy-thread convergence routing, finite observation readback, rational tolerance readback, endpoint-distance sealing, and ledger nonescape for BEDC.Derived.BaireSpaceCompletenessUp.

Constructive story: A $\mathsf{BaireSpaceCompleteness}^{\uparrow}$ packet is generated from BaireSpace prefix cylinders, a CompleteMetric Cauchy-thread row, StreamName finite windows, RegSeqRat tolerance readback, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3537

A Concrete Naming Certificate for $\mathsf{MeasurableSpace}^{\uparrow}$

Following Caratheodory and Bourbaki measure theory, the $\mathsf{MeasurableSpace}^{\uparrow}$ packet records the carrier-level interface that pairs an underlying point row with a displayed measurable-event family before any measure, probability, Borel, or measurable-map consumer reads it. It sits between the sigma-algebra closure surface of chapter 5186, the generated-event boundary of chapter 3384, the measure rows of chapter 92, the probability rows of chapter 184, and the preimage ledger of chapter 3461. The packet names measurable-space data as finite BEDC rows; it is not a host powerset, completed measurable universe, quotient event algebra, countable-choice selector, or ambient measure object.

Definition 3537.1 (MeasurableSpace carrier)**.** *A* $\mathsf{MeasurableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, A, B, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying point-carrier row whose events are being named.*
2. *A is the* $\mathsf{SigmaAlgebra}^{\uparrow}$ *event-family row over X, including empty-event, complement, and countable-union closure readback.*
3. *B is the optional* $\mathsf{BorelSet}^{\uparrow}$ *generated-event row used when the measurable space is read from a topological or real-facing source.*
4. *E is the public event classifier, reading event membership and event comparison only through A and, when present, B.*
5. *H records componentwise* hsame *transport for the carrier, sigma-algebra, Borel, event-classifier, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a measurable-event request through X, A, B, E and then to the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{MeasurableSpace}^{\uparrow}$, $\mathsf{SigmaAlgebra}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{MeasurableFunction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MeasurableSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host powerset, completed sigma-algebra, quotient event equality, countable-choice enumeration of events, ambient measure, or external measurable-space instance.

Lean4 ✓ `BEDC.Derived.MeasurableSpaceUp.MeasurableSpaceTasteGate single carrier alignment`

Theorem 3537.2 (MeasurableSpace NameCert obligations)**.** *For every accepted* $\mathsf{MeasurableSpace}^{\uparrow}$ *carrier* $M = (X, A, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MeasurableSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for* X*, sigma-algebra admission for* A*, generated-event compatibility for* B *when a Borel source is present, event-classifier visibility for* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Every obligation routes through the sibling rows of $\mathsf{SigmaAlgebra}^{\uparrow}$*,* $\mathsf{BorelSet}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, and* $\mathsf{MeasurableFunction}^{\uparrow}$ *before any downstream measurable-object read is public.*

Proof. Project the carrier of Definition 3537.1. The point row X supplies the underlying carrier, while A supplies the sigma-algebra closure rows that make event reads measurable.

When the source is Borel-facing, read the generated-event row B through chapter 3384. The event classifier E is then constrained to the same displayed event family, so it cannot leave the packet for a host powerset or completed measurable universe.

The structural rows H, C, P, N transport, replay, source, and name exactly this packet. Since no coordinate names quotient event equality, countable-choice enumeration, ambient measure data, or an external measurable-space instance, the listed rows exhaust the local NameCert obligations. □

Theorem 3537.3 (MeasurableSpace sigma-algebra handoff)**.** *Every* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*, or* $\mathsf{MeasurableFunction}^{\uparrow}$ *consumer that cites an accepted* $\mathsf{MeasurableSpace}^{\uparrow}$ *carrier must first read the* $\mathsf{SigmaAlgebra}^{\uparrow}$ *row* A*, the generated* $\mathsf{BorelSet}^{\uparrow}$ *row* B *when present, and the event classifier* E *over the same point row* X*. Thus measures receive measurable events before assigning values, probability spaces receive the same event family before normalization, and measurable functions receive source and target event families before reading preimage ledgers.*

The handoff exports no host powerset, completed sigma-algebra, quotient event algebra, countable-choice event selector, ambient measure completion, or hidden measurable-map carrier.

Proof. Start with the sigma-algebra row. By chapter 5186, event admission, complement, and countable-union closure are displayed inside the $\mathsf{SigmaAlgebra}^{\uparrow}$ packet before measure-facing rows consume them.

Next route generated events through chapter 3384 when the measurable space is Borel-sourced. The same event classifier E is used by chapter 92 and chapter 184, so value and normalization rows cannot precede measurable-event exposure.

Finally apply the preimage discipline of chapter 3461. A measurable-map consumer reads source and target event families before the preimage ledger, so the measurable-space handoff is a source interface for measurable functions rather than a hidden host function space or completed measure object. □

Falsifiable prediction: A $\mathsf{MeasurableSpace}^{\uparrow}$ consumer that assigns a measure value, probability normalization, or measurable-function preimage without first reading the displayed $\mathsf{SigmaAlgebra}^{\uparrow}$ row A and event classifier E refutes the carrier surface.

Independence witness: sigma-algebra, borelset, measure, probspace, measurable-function: no listed sibling supplies the full eight-row packet $M = (X, A, B, E, H, C, P, N)$, because each sibling contributes only closure, generation, value, normalization, or preimage data while this chapter binds the measurable-space carrier with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MeasurableSpace}^{\uparrow}}$**.**

Constructive story: A MeasurableSpace$^{\uparrow}$ packet is generated from an underlying carrier row, a sigma-algebra event-family row, an optional Borel generated-event row, an event classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MeasurableSpace}^{\uparrow}}$, seed)

Scope closed: Definition 3537.1, Definition 3537.2, and Definition 3537.3 seed the finite measurable-space interface consumed by measure, probability, and measurable-function rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MeasurableSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure construction, probability normalization, random variables, completed sigma-algebras, quotient event algebras, countable-choice event selectors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sigma-algebra admission, Borel compatibility, event-classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.MeasurableSpaceUp.

Chapter 3538

A Concrete Naming Certificate for $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$

Following Bishop and Bridges' constructive finite-subcover treatment for compact intervals, the $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$ packet records the BEDC route that turns a located closed interval cover request into a displayed finite subcover through finite nets and positive-radius data. It sits over the located interval finite-net surface of chapter 1808, the compact-cover radius route of chapter 2301, the finite-net interval-cover packet of chapter 3471, the terminal real-name seal of chapter 38, and the dyadic tolerance rows of chapter 291. The packet names a located finite-subcover certificate; it does not claim unrestricted open-cover Heine–Borel compactness, selected subcovers from arbitrary covers, countable choice, quotient interval equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Its subcover read uses chapter 3471 and the located interval finite-net sibling as mandatory predecessors before any retained witness can reach the $\mathsf{Real}^{\uparrow}$ seal.

Definition 3538.1 (Located Heine–Borel subcover carrier)**.** *A* $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, F, L, H, R, D, E, T, C, P, N)$$

with the following displayed rows:

1. *I is the located closed interval source row, exposing endpoint names, endpoint order, and locatedness only as finite* $\mathsf{Real}^{\uparrow}$ *histories.*
2. *F is the* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *finite-net row, listing the mesh scale and finite interval net used by the cover request.*
3. *L is the* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *positive-radius row attached to the displayed finite cover or pointwise radius family.*
4. *H is the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *sibling row that records the finite-net interval-cover route over the same interval, net, radius, dyadic, and real-seal data.*
5. *R is the retained-subcover row, listing exactly the finitely many cover witnesses selected by the displayed net and radius checks.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording mesh width, radius slack, endpoint containment, and finite neighborhood comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint, radius, and coverage reads.*

8. *T records componentwise* hsame *transport for the interval source, finite-net row, radius row, finite-net sibling row, retained-subcover row, dyadic ledger, real seal, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from a located cover request through $I, F, L, H, R, D, E, T, P, N$.*

10. *P is the* Pkg *provenance over* LocatedHeineBorelSubcover$^{\uparrow}$, LocatedClosedIntervalFiniteNet$^{\uparrow}$, LebesgueNumberLem HeineBorelFiniteNet$^{\uparrow}$, Real$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{LocatedHeineBorelSubcover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, L, H, R, D, E, T, C, P, N$. It has no coordinate for arbitrary open covers, unrestricted Heine–Borel compactness, selected subcover functionals, quotient interval representatives, countable choice, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedHeineBorelSubcoverUp.LocatedHeineBorelSubcoverTasteGate single carrier alignment`

Theorem 3538.2 (Located Heine–Borel subcover NameCert obligations)**.** *For every accepted* LocatedHeineBorelSubcover$^{\uparrow}$ *carrier*

$$S = (I, F, L, H, R, D, E, T, C, P, N),$$

the local NameCert$_{\text{LocatedHeineBorelSubcover}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the located interval source, finite-net row, positive-radius row, finite-net sibling row, retained-subcover row, dyadic ledger, real seal, transport, replay, provenance, and local naming rows;*

2. *located interval exposure, requiring every cover request to display I and the finite-net row F before any retained cover witness is inspected;*

3. *radius compatibility, requiring L and D to record the positive-radius and dyadic slack checks that allow listed net points to control nearby interval points;*

4. *finite-subcover exactness, requiring R to list only cover witnesses reached through the finite net, radius ledger, and* HeineBorelFiniteNet$^{\uparrow}$ *sibling route;*

5. *real-seal non-escape, requiring E to be downstream of the located interval, finite-net, radius, retained-subcover, and dyadic rows;*

6. *structural preservation through T, C, P, N and refusal of arbitrary open-cover compactness, unrestricted Heine–Borel, selected subcover functionals, quotient interval representatives, countable choice, host real equality, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No located finite-subcover obligation is stored outside these rows.

Proof. Project the carrier of Definition 3538.1. The analytic rows are exactly the located interval source I, finite-net row F, positive-radius row L, finite-net sibling row H, retained-subcover row R, dyadic ledger D, and terminal real seal E.

The cover request first exposes I and F. The packet therefore reads a located interval and a displayed finite net before it can inspect any cover witness, so the route cannot start from an arbitrary open-cover selector.

The radius step is finite. The row L supplies the positive radius ledger, while D records the mesh-width and endpoint-slack comparisons that transfer a witness at a listed net point to nearby interval points.

The retained row R is downstream of F, L, H, D. Hence every retained cover witness is tied to the same finite-net route already named by chapter 3471, and the terminal seal E is reached only after those finite checks have been displayed.

Transport, replay, provenance, and local naming preserve this finite surface. Since the refused objects have no carrier coordinate, the local certificate exports only the located finite-subcover route. □

Theorem 3538.3 (Located Heine–Borel finite-net route)**.** *Every located cover read from an accepted* $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longmapsto \mathsf{LebesgueNumberLemma}^{\uparrow} \longmapsto \mathsf{HeineBorelFiniteNet}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Re}$$

The exported object is the retained finite subcover row R over $I, F, L, H, D, E, T, C, P, N$, not an unrestricted open-cover Heine–Borel principle.

Proof. Begin with an accepted carrier $S = (I, F, L, H, R, D, E, T, C, P, N)$. The located interval and finite net are exposed by I and F, the positive-radius ledger is L, and the already displayed finite-net cover route is H.

The retained-subcover row R may be read only after those rows. Its witnesses are checked by the dyadic ledger D and then sealed by E, so the exported finite subcover is a displayed BEDC packet row rather than a host-level choice operation.

Replay through C, transport through T, provenance through P, and naming through N keep the same route. No arbitrary open cover, unrestricted compactness theorem, quotient interval representative, countable-choice row, or ambient completeness coordinate is available to bypass it. □

Theorem 3538.4 (Located Heine–Borel subcover sibling route)**.** *Any accepted read of a* $\mathsf{LocatedHeineBorelSubcover}$ *retained subcover row must pass through chapter 3471 and the located interval finite-net sibling before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Equivalently, in the carrier $S = (I, F, L, H, R, D, E, T, C, P, N)$, the row R is readable only after the displayed finite-net row F and the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *sibling row H have exposed the same interval, radius, dyadic, and cover-witness surface.*

Proof. Project the carrier of Definition 3538.1. The located interval finite-net row is F, the finite-net sibling row is H, and the retained-subcover row is R.

Apply Definition 3538.2. Its located interval exposure and finite-subcover exactness clauses require every retained witness to be downstream of F, L, H, D before the real-seal row E is available.

Finally apply Definition 3538.3. The displayed route places $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ between the positive-radius row and the dyadic/Real seal, so a located subcover consumer cannot read R by bypassing either sibling. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedHeineBorelSubcover}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$ packet is generated from a located closed interval source, a LocatedClosedIntervalFiniteNet row, a LebesgueNumberLemma positive-radius ledger, a HeineBorelFiniteNet sibling row, retained finite subcover witnesses, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedHeineBorelSubcover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3538.1, Definition 3538.2, and Definition 3538.3 seed the located finite-subcover route over interval nets, positive-radius ledgers, finite-net cover rows, dyadic tolerances, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedHeineBorelSubcover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted open-cover Heine–Borel compactness, arbitrary subcover selection, countable choice, quotient interval equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located interval exposure, radius compatibility, finite-subcover exactness, real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedHeineBorelSubcover

Chapter 3539

A Concrete Naming Certificate for MetaCICTypedNormalizationAudit$^{\uparrow}$

The MetaCICTypedNormalizationAudit$^{\uparrow}$ packet realizes the candidate-mediated typed-normalization route of chapter 9383 as finite BEDC rows. It sits beside the normalization audit packet of chapter 750, the candidate-evidence strong-normalization route of chapter 758, the Pi-application adequacy route of chapter 907, and the normalization frontier of chapter 892. The packet names the closed typed term, candidate evidence, Pi and application adequacy, no-infinite-reduction projection, frontier refusal, transport, replay, provenance, and local naming rows needed for an audit citation. It does not claim evidence-free strong normalization for every closed typed MetaCIC term, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluation soundness, or completed closed consistency.

Definition 3539.1 (MetaCIC typed-normalization audit carrier)**.** *A* MetaCICTypedNormalizationAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, K, S, P, R, Q, F, H, C, G, N)$$

with the following displayed rows:

1. *T is the closed typed term row, exposing the empty-context term, type, and closedness checks read by the normalization audit map.*
2. *K is the candidate-evidence row, carrying the reducibility candidate, closed-candidate, or candidate-set membership evidence consumed by the closed typed term projection.*
3. *S is the strong-normalization projection row, recording the candidate-mediated route from K to the displayed strong-normalization witness for T.*
4. *P is the Pi adequacy row, exposing Pi-candidate and neutral-normal evidence only when the inspected term route requires it.*
5. *R is the application adequacy row, exposing function-side Pi evidence, argument candidate evidence, and the application-candidate handoff.*
6. *Q is the no-infinite-reduction row, recording the projection from strong normalization to absence of infinite beta chains along the same candidate-mediated route.*
7. *F is the frontier row, retaining the boundary named by* MetaCICNormalizationFrontier$^{\uparrow}$ *when the requested read would erase candidate evidence or subject-reduction obligations.*

8. *H records componentwise* hsame *transport for the closed typed term, candidate evidence, SN projection, Pi route, application route, no-infinite-reduction row, frontier row, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a typed-normalization audit request through $T, K, S, P, R, Q, F, H, G, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$*, chapter 9383, chapter 750, chapter 758, chapter 907, chapter 892,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, S, P, R, Q, F, H, C, G, N$. It has no coordinate for evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, erased candidate evidence, or completed closed consistency.

Theorem 3539.2 (MetaCIC typed-normalization audit NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$ *carrier*

$$A = (T, K, S, P, R, Q, F, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the closed typed term row, candidate-evidence row, SN projection row, Pi adequacy row, application adequacy row, no-infinite-reduction row, frontier row, transport, replay, provenance, and local naming rows;*
2. *candidate gate exactness, requiring every SN projection in S to read candidate, closed-candidate, or candidate-set evidence from K before it can read the closed typed term row T as normalized;*
3. *Pi and application adequacy compatibility, requiring P and R to be consumed only as typed route data for the same candidate-mediated term window;*
4. *no-infinite-reduction compatibility, requiring Q to be downstream of S and to reuse the same candidate evidence rather than introducing a separate termination source;*
5. *frontier retention, requiring F to remain visible whenever a requested read would erase candidate evidence, subject-reduction obligations, confluence boundaries, or the normalization audit map's conditional interface;*
6. *structural preservation through H, C, G, N and refusal of evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, erased candidate evidence, completed closed consistency, Lean verification, and bridge checking.*

No typed-normalization audit obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.MetaCICTypedNormalizationAuditUp.MetaCICTypedNormalizationAuditNameCertObligations`

Proof. Project the carrier of Definition 3539.1. Its typed-normalization data are exactly the closed typed term row T, candidate-evidence row K, SN projection row S, Pi row P, application row R, no-infinite-reduction row Q, and frontier row F.

The candidate gate is first. A closed typed term can be read as strongly normalizing only after K supplies the candidate, closed-candidate, or candidate-set membership evidence consumed by the audit map.

The Pi and application rows refine that same route. The row P supplies Pi-candidate and neutral-normal data when the term route requires it, while R supplies function, argument, and application-candidate evidence for application cases. Neither row can replace the candidate gate.

The no-infinite-reduction row Q is downstream of S. It inherits the same candidate-mediated strong-normalization witness and therefore cannot introduce a separate global termination theorem.

The frontier row F remains visible for rejected readings. Transport, replay, provenance, and local naming preserve the listed rows, so the packet refuses evidence-free normalization, unrestricted subject reduction, global confluence, host evaluation soundness, quotient syntax equality, and closed consistency outside the displayed carrier. □

Theorem 3539.3 (MetaCIC typed-normalization substitution route)**.** *Every closed typed normalization read from an accepted* $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$ *packet factors through the finite route*

$$T \longmapsto K \longmapsto S \longmapsto (P, R) \longmapsto Q \longmapsto F.$$

The exported route is candidate-mediated typed-normalization audit data over $A = (T, K, S, P, R, Q, F, H, C, G, N)$*, not a theorem that every closed typed MetaCIC term normalizes without supplied candidate evidence.*

Proof. Start with a closed typed term read. The row T exposes the typed and closed term window, but it does not by itself carry a normalization theorem.

The next row is K. It supplies the candidate evidence used by S to project strong normalization for that same closed typed term. The Pi and application rows P, R are read only as adequacy data for this candidate-mediated route.

The row Q then projects no-infinite-reduction along the same strong-normalization path. If a consumer asks for a reading that drops the candidate evidence or erases subject-reduction and confluence boundaries, the frontier row F records that refusal.

Thus every accepted read remains inside the displayed finite carrier and cannot be reread as evidence-free normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluation soundness, or completed closed consistency. □

Falsifiable prediction: Every $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$ closed typed normalization read factors through displayed closed typed term data, candidate evidence, candidate-mediated strong-normalization projection, Pi adequacy rows, application adequacy rows, no-infinite-reduction projection, frontier retention, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: metacicnormalizationaudit, candidate-evidence-sn-route, pi-application-adequacy-route, metacicnormalizationfrontier: $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the closed typed term row, candidate gate, SN projection, Pi route, application route, no-infinite-reduction route, frontier retention, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$ packet is generated from a closed typed term row, candidate-evidence row, candidate-mediated strong-normalization projection, Pi adequacy row, application adequacy row, no-infinite-reduction row, normalization-frontier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3539.1, Definition 3539.2, and Definition 3539.3 seed the finite candidate-mediated typed-normalization audit route over closed typed term, candidate, Pi, application, no-infinite-reduction, and frontier rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICTypedNormalizationAudit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close evidence-free strong normalization for every closed typed MetaCIC term, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate gate exactness, Pi and application adequacy compatibility, no-infinite-reduction compatibility, frontier retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICTypedNormalizationAuditUp.

Chapter 3540

A Concrete Naming Certificate for $\mathsf{LocatedCompletionCriterion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ packet records the traditional located criterion by which completion-facing consumers recognize a displayed Cauchy name as admitted by finite tolerance windows. It sits after the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the metric-completion carrier of chapter 1506, and the located complete-metric service of chapter 3349. The packet names the criterion route used by L10 Real and Completion consumers; it is not a quotient completion, selected limit, countable-choice schedule, trichotomy principle, host equality test, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 3540.1 (Located completion criterion carrier)**.** *A* $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, E, M, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, endpoint comparisons, and error-budget rows inspected by the criterion.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the requested observations of the Cauchy name and the local locatedness tests attached to those observations.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational sequence obtained from the displayed windows and dyadic budgets.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been exposed.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier row that records the completion-facing object surface for the same displayed Cauchy name.*
6. *L is the* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *service row, recording the located complete-metric limit service available for accepted regular Cauchy point names.*
7. *H records componentwise* hsame *transport for the dyadic tolerance ledger, stream windows, regular readback, Real seal, metric-completion carrier, located complete-metric service, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a criterion request through D, S, R, E, M, L.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCompletionCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{LocatedCompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, M, L, H, C, P, N$. It has no coordinate for quotient Cauchy equality, selected representatives, countable choice, host real equality, trichotomy, or completeness outside the displayed located complete-metric service.

Lean4 ✓ `BEDC.Derived.LocatedCompletionCriterionUp.LocatedCompletionCriterionTasteGate single carrier alignment`

Theorem 3540.2 (Located completion criterion NameCert obligations)**.** *For every accepted* LocatedCompletionCrit *carrier $K = (D, S, R, E, M, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance ledger, finite stream windows, regular rational readback, terminal Real seal, metric-completion carrier, located complete-metric service, componentwise transport, displayed continuation replay, package provenance, and local naming rows.*

Every completion-facing consumer must read the finite route

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto M \longmapsto L \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before treating the Cauchy name as admitted by the located completion criterion.

Proof. Project the carrier of Definition 3540.1. The accepted packet displays exactly the dyadic tolerance, stream-window, regular readback, Real seal, metric-completion, located complete-metric, transport, replay, provenance, and naming rows.

The analytic criterion begins with D and S. The dyadic ledger supplies the requested tolerance budget, and the stream row supplies the finite observations and locatedness tests made at that budget.

The readback and completion handoff are downstream. The row R repacks the inspected windows as regular rational data, the row E seals the Real-facing name, and the rows M and L expose only the displayed metric-completion and located complete-metric service attached to the same route.

Finally H, C, P, N preserve, replay, source, and name that route. Since the carrier contains no quotient equality, selected representative, countable-choice schedule, host equality test, trichotomy row, or ambient completeness coordinate, none of those objects belongs to the local NameCert obligations. □

Theorem 3540.3 (Located completion criterion Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ *packet reaches the terminal seal and completion-facing service only through the dyadic tolerance ledger D, finite* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E,* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier M,* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *service row L, componentwise transport H, displayed replay C, provenance P, and local name N.*

The route exports a located criterion for displayed completion data, not a quotient completion, selected host limit, countable-choice construction, host equality test, trichotomy principle, or ambient completeness theorem for all $\mathsf{Real}^{\uparrow}$ *names.*

Proof. Start with a completion-facing or Real-facing consumer. The only terminal Real coordinate in the carrier is E, and the only completion-facing rows are M and L.

The consumer must first inspect D, S, R. The dyadic tolerances, finite windows, and regular rational readback are the displayed data that make the criterion located before the seal is exposed.

After the seal, M and L record the metric-completion surface and located complete-metric service attached to the same displayed Cauchy name. The support rows H, C, P, N can transport and replay this path, but they cannot add quotient completion equality, selected limits, countable choice, host equality, trichotomy, or ambient completeness because none of those coordinates is present in the accepted carrier. □

Theorem 3540.4 (Located completion criterion sequential closure)**.** *Let $K = (D, S, R, E, M, L, H, C, P, N)$ be an accepted* $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ *carrier. Any Real-facing sequential-closure read of K must pass through the dyadic tolerance windows in D, the finite* $\mathsf{StreamName}^{\uparrow}$ *observations in S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in R, the* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier row M, the* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *service row L, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, with transport, replay, provenance, and local naming supplied only by H, C, P, N.*

Consequently the accepted carrier admits a Real-facing read only as a finite tolerance-window route. It does not export quotient completion equality, a selected limit, countable choice, trichotomy, host real equality, or an ambient completeness theorem for all displayed names.

Proof. Read the carrier through Definition 3540.1. The only rows available for sequential closure are $D, S, R, E, M, L, H, C, P, N$, and the finite observation route begins with the dyadic tolerance ledger and stream windows.

Apply the Real seal route of Definition 3540.3. That theorem forces every Real-facing or completion-facing consumer to reach E, M, L only after D, S, R have been exposed.

The closure read is therefore finite at every stage. The dyadic ledger supplies the tolerance windows, the stream row supplies the inspected observations, the regular rational row supplies readback, and the metric-completion and located complete-metric rows supply the completion-facing service before the terminal Real seal is consumed.

Finally H, C, P, N preserve the same route without adding coordinates. Since the carrier definition contains no quotient completion, selected limit, countable-choice schedule, trichotomy row, host equality test, or ambient completeness field, the sequential-closure read cannot export any of those non-claims. □

Theorem 3540.5 (Located completion criterion terminal seal exhaustion)**.** *Let $K = (D, S, R, E, M, L, H, C, P, N)$ be an accepted* $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ *carrier. Any Real-facing completion read from K exhausts exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{StreamName}^{\uparrow}$ *observations S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E,* $\mathsf{MetricCompletion}^{\uparrow}$ *carrier M,* $\mathsf{LocatedCompleteMetric}^{\uparrow}$ *service row L, componentwise transport H, displayed replay C, provenance P, and local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionCriterion}^{\uparrow}}$ *row N. It has no remaining coordinate for selected limits, quotient equality, host equality, countable choice, trichotomy, or ambient completeness.*

Proof. Apply the NameCert obligations of Definition 3540.2. They identify the displayed rows $D, S, R, E, M, L, H, C, P, N$ as the exact local certificate surface for an accepted carrier.

Use the Real seal route of Definition 3540.3. It forces every Real-facing or completion-facing consumer to pass through the dyadic ledger, stream windows, regular readback, terminal Real seal, metric-completion carrier, located complete-metric service, transport, replay, provenance, and local naming rows.

Finally apply sequential closure, Definition 3540.4. The completion read remains finite at each stage and cannot acquire coordinates absent from the carrier. Therefore exhausting the listed rows exhausts the accepted terminal-seal route. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ consumer factors a completion-facing read through one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal, one $\mathsf{MetricCompletion}^{\uparrow}$ carrier, one $\mathsf{LocatedCompleteMetric}^{\uparrow}$ service row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, metriccompletion, located-complete-metric: $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries tolerance inspection, finite windows, regular readback, Real sealing, metric-completion admission, and located complete-metric service as one criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompletionCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3540.1, Definition 3540.2, and Definition 3540.3 seed the finite located completion criterion route over dyadic tolerance ledgers, stream windows, regular rational readback, Real seals, metric-completion carriers, located complete-metric service, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompletionCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, StreamName window inspection, RegSeqRat readback, Real seal handoff, MetricCompletion carrier admission, LocatedCompleteMetric service, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompletionCriterionUp.

Constructive story: A $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, a MetricCompletion carrier, a LocatedCompleteMetric service row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3541

A Concrete Naming Certificate for $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$

Following Bishop–Bridges and Bourbaki-style constructive Cauchy-space grounding, the RegularCauchySequenceSpa packet records rate-controlled families of regular rational Cauchy names before any completion or equality quotient is read. It sits after the broader Cauchy-name surface of chapter 406, the finite schedule rows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite interface for regular-rate sequence-space consumers; it is not a proof that $\mathsf{Real}^{\uparrow}$ is complete, not a quotient of Cauchy streams, and not a selected limiting representative.

Definition 3541.1 (RegularCauchySequenceSpace carrier)**.** *A* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, \rho, \sigma, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is a finite family of* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence rows.*
2. *ρ is the regular-rate ledger assigning dyadic Cauchy budgets to the rows of F.*
3. *σ is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that chooses the inspected sequence and finite window.*
4. *W records the finite common-window data used by the scheduled family inspection.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the requested regularity budget.*
6. *Q is the surrounding* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *row through which the same family can be read as a Cauchy-name-space object.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, ρ, σ, W, D, Q have been displayed.*
8. *H stores componentwise* hsame *transport for the family, rate ledger, schedule, window, tolerance, Cauchy-space, and real-seal rows.*
9. *C stores displayed* Cont *replay from finite rate requests to scheduled windows, regular rational readback, the CauchySequenceSpace handoff, and the terminal Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, \rho, \sigma, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySequenceSpaceUp.RegularCauchySequenceSpaceTasteGate single carrier alignment`

Theorem 3541.2 (RegularCauchySequenceSpace NameCert obligations)**.** *For every accepted* RegularCauchySequen *carrier $R = (F, \rho, \sigma, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, regular-rate ledger exposure, scheduled finite-window stability,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness,* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise transport, displayed continuation replay, package provenance, local naming, and refusal of quotient streams, selected limits, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Carrier admission is projection from Definition 3541.1. The accepted packet exposes the regular rational family F, the regular-rate ledger ρ, the schedule σ, the finite window row W, and the dyadic tolerance row D before any Cauchy-space or Real-facing consumer can read the packet.

The Cauchy-name-space handoff is then forced through Q. The surrounding $\mathsf{CauchySequenceSpace}^{\uparrow}$ row can consume the same family, schedule, and tolerance data, but it receives them only as displayed rows of this finite carrier.

Finally the terminal seal E is downstream of F, ρ, σ, W, D, Q and is transported only by H and replayed only by C. The provenance row P and local naming row N close the certificate surface, while the absence of any additional carrier coordinate excludes quotient streams, selected limits, countable choice, host real equality, ambient completeness, Lean verification, and bridge checking. □

Theorem 3541.3 (RegularCauchySequenceSpace real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *carrier factors through the displayed route*

$$F, \rho, \sigma, W, D, Q, E, H, C, P, N.$$

Thus the consumer first reads regular rational sequence data, then a regular-rate dyadic budget, then a scheduled finite window, then the $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff, and only then the terminal real-name seal. The route exports no quotient of Cauchy names, no selected limiting representative, no host real equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Lean4 ✓ `BEDC.Derived.RegularCauchySequenceSpaceUp.RegularCauchySequenceSpaceRealHandoff`

Proof. Begin with an accepted carrier $R = (F, \rho, \sigma, W, D, Q, E, H, C, P, N)$. The only regular sequence data available to a consumer are the rows F and ρ, and the only finite observation channel is the schedule and window pair σ, W together with the dyadic tolerance row D.

Use Definition 3541.2. It binds regular-rate exposure, scheduled window stability, readback, and tolerance exactness to the same finite packet.

The Cauchy-space read reaches Q only after those rows have been displayed, and the Real-facing read reaches E only after Q has been exposed. Since the carrier definition lists no quotient, selected limit, host real equality, or ambient completeness coordinate, every $\mathsf{Real}^{\uparrow}$ consumer route is exhausted by the displayed rows. □

Theorem 3541.4 (RegularCauchySequenceSpace rate-ledger stability)**.** *Let $R = (F, \rho, \sigma, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *carrier. Any classifier-preserving replacement of the family row F, regular-rate ledger ρ, schedule σ, and finite window row W preserves the same dyadic tolerance row D, the same* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff row Q, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal row E whenever the replacement remains inside the local classifier determined by H, C, P, N.*

Thus a consumer may not replace the displayed rate ledger by quotient stream equality, selected limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. The stable route remains the finite row sequence*

$$F, \rho, \sigma, W, D, Q, E, H, C, P, N.$$

Proof. Project the carrier rows from Definition 3541.1. The rows F, ρ, σ, W are the only family, rate, schedule, and finite-window data available to the local classifier.

Apply Definition 3541.2. It identifies regular-rate ledger exposure, scheduled finite-window stability, tolerance exactness, CauchySequenceSpace handoff, and Real seal routing as obligations over the same displayed carrier.

Now apply Definition 3541.3. Real-facing consumers see only the displayed route through D, Q, E after the replacement has preserved the classifier on F, ρ, σ, W. Since quotient stream equality, selected limits, host real equality, and ambient completeness are not carrier coordinates, the replacement preserves the same tolerance, handoff, and terminal seal rows rather than substituting any of those refused objects. □

Theorem 3541.5 (RegularCauchySequenceSpace tail-zero route)**.** *Let $R = (F, \rho, \sigma, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *carrier. If the regular-rate ledger ρ carries an explicit dyadic tail-to-zero modulus, then every* $\mathsf{Real}^{\uparrow}$*-facing consumer still factors through*

$$F, \rho, \sigma, W, D, Q, E, H, C, P, N.$$

The tail-zero conclusion is a displayed rate-ledger read over ρ, D, Q, E; it is not a selected limit, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Project the carrier rows from Definition 3541.1. The family F, rate ledger ρ, schedule σ, window W, dyadic row D, CauchySequenceSpace handoff Q, and Real seal E are the only data available before the structural rows transport and name the packet.

Apply Definition 3541.2. It binds regular-rate exposure, scheduled finite-window stability, regular rational readback, dyadic tolerance exactness, the CauchySequenceSpace handoff, and the Real seal to the same displayed packet.

Now apply Definition 3541.3 and Definition 3541.4. The Real-facing route remains the finite row sequence above, and the tail-to-zero modulus remains a rate-ledger entry rather than a selected limit or quotient-stream coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ packet is generated from a finite regular rational sequence family, a regular-rate dyadic ledger, scheduled finite stream windows, dyadic tolerance rows, a CauchySequenceSpace handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySequenceSpace}^{\uparrow}}$, seed)

Scope closed: Definition 3541.1, Definition 3541.2, Definition 3541.3, and Definition 3541.4 seed the finite regular-rate sequence-space route from regular rational families to Real-facing handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySequenceSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient Cauchy-name equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, regular-rate ledger exposure, scheduled finite-window stability, tolerance exactness, CauchySequenceSpace handoff, RealUp seal routing, and non-escape for BEDC.Derived.RegularCauchySe

Chapter 3542

A Concrete Naming Certificate for $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$

Following Bishop and Bridges and Kelley on constructive completions and dense embeddings, the $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ packet records the finite dense-source face used by the Cauchy completion universal-property route. It sits between the universal-property surface of chapter 2319, the metric dense-image packet of chapter 3351, the regular-Cauchy dense route of chapter 1453, the Real admission route of chapter 3389, the regular rational source of chapter 301, the stream-window source of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet lets universal-property, completion-functor, and Real-completion consumers cite a dense source without importing quotient completion, selected limits, countable choice, or ambient real completeness.

Definition 3542.1 (CauchyCompletionDensitySource carrier)**.** *A* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (U, M, J, R, W, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *consumer row that reads the dense source before any extension or uniqueness row is available.*
2. *M is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *row, exposing the source metric, completion carrier, dense image, separated comparison, uniform handoff, and regular rational readback used by metric completion consumers.*
3. *J is the* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *row, recording the regular Cauchy rational source-to-completion route.*
4. *R is the* $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$ *row, recording the admission of the same regular Cauchy source into the* $\mathsf{Real}^{\uparrow}$ *seal.*
5. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational name and its displayed modulus discipline.*
6. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source only at requested stages.*
7. *S is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording precision budgets, slack rows, and finite comparison data before the* $\mathsf{Real}^{\uparrow}$ *seal is read.*

8. *H records componentwise* hsame *transport for $U, M, J, R, W, Q, S, C, P, N$.*
9. *C records displayed* Cont *replay from dense-source requests through the metric dense image, regular Cauchy route, Real admission route, source windows, dyadic tolerance ledger, transport, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$*, the eight sibling chapters named above,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionDensitySource}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for quotient representatives, selected completion limits, selected real representatives, countable choice, trichotomy, host equality of completion classes, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionDensitySourceUp.CauchyCompletionDensitySourceTasteGate`
`single carrier alignment`

Theorem 3542.2 (CauchyCompletionDensitySource NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *carrier $D = (U, M, J, R, W, Q, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionDen}}$ *surface consists exactly of carrier admission for the universal-property consumer row, metric dense-image row, regular Cauchy dense route, Real admission route, RegSeqRat source, StreamName finite windows, DyadicRatCore tolerance ledger, componentwise transport, displayed replay, provenance, and local naming. A completion universal-property consumer must read M, J, R, W, Q, S as dense-source evidence before it can consume the extension and uniqueness rows of U.*

Proof. Project the carrier of Definition 3542.1. The tuple displays the universal-property consumer row, metric dense-image row, regular Cauchy dense route, Real admission route, regular rational source, stream windows, dyadic tolerance ledger, transport, replay, provenance, and local naming row.

The dense-source evidence is finite and source-facing. The metric dense-image row supplies the completion-side dense embedding, the regular Cauchy route supplies the rational source discipline, the Real admission route records the terminal seal, and the RegSeqRat, StreamName, and DyadicRatCore rows expose only requested source observations and tolerance budgets.

The universal-property row U is downstream of those rows. Its extension and uniqueness reads therefore consume displayed dense-source evidence rather than quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient completeness. □

Theorem 3542.3 (CauchyCompletionDensitySource universal route)**.** *Every universal-property, completion-functor, or* $\mathsf{Real}^{\uparrow}$*-completion consumer of an accepted* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *packet factors through the finite route*

$\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{RealCauchyDenseEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, S

The exported object is a dense-source packet. It is not a quotient completion, a selected limit operator, a countable-choice principle, a host equality comparison, or an ambient real-completeness theorem.

Proof. Begin with the local obligations of Definition 3542.2. Any consumer reaching the universal-property row must first read the metric dense image, regular Cauchy dense route, Real admission route, regular rational source, finite stream windows, and dyadic tolerance ledger.

The sibling packets determine the route. The metric dense-image row gives completion-facing density, the regular Cauchy dense route gives the source discipline, the Real admission route gives

the seal handoff, and the RegSeqRat, StreamName, and DyadicRatCore rows give finite observation and tolerance data.

Transport, replay, provenance, and local naming preserve the same displayed route. Since the carrier contains no row for quotient representatives, selected limits, countable choice, host equality, or ambient real completeness, the universal route exports only the dense-source packet. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ consumer that reaches a universal-property extension or uniqueness read while omitting the metric dense image, regular Cauchy dense route, Real admission route, RegSeqRat source, StreamName windows, DyadicRatCore tolerance ledger, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: cauchy-completion-universal-property, metric-completion-dense-embedding, regular-cauchy-dense-embedding, real-cauchy-dense-embedding, regseqrat, streamname, dyadicratcore, real: no listed sibling is bijective with $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ because the packet jointly carries dense-source evidence, universal-property consumption, completion-facing dense image data, regular rational source discipline, finite windows, dyadic tolerance accounting, Real-seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionDensitySource}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ packet is generated from a universal-property consumer row, a metric dense-image row, a regular Cauchy dense route, a Real admission route, a RegSeqRat source row, finite StreamName windows, a DyadicRatCore tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDensitySource}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3542.1, Definition 3542.2, and Definition 3542.3 seed the dense-source face consumed by constructive Cauchy completion universal-property routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDensitySource}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, countable choice, trichotomy, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source exactness, metric dense-image handoff, regular Cauchy source readback, Real-seal handoff, finite-window and tolerance accounting, transport replay, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchyCompletionDensitySourceUp.

Chapter 3543

A Concrete Naming Certificate for $\mathsf{SeparatedCompletionReflection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ packet records the finite reflection boundary where separated zero-distance evidence is allowed to feed completion uniqueness. It sits between the separated metric classifier of chapter 1411, the complete-limit rows of chapter 128, the metric distance surface of chapter 57, the terminal real-name seal of chapter 38, and the regular-Cauchy comparison route of chapter 1412. The packet names a reflection route for completion consumers without importing quotient completion, selected representatives, trichotomy, countable choice, or a claim that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 3543.1 (SeparatedCompletionReflection carrier)**.** *A* $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, S, C, E, Z, H, K, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier and the metric-distance witness surface that completion reads may inspect.*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier row, read only after the metric distance witness has been displayed.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *pair of completion-limit rows for a single regular Cauchy point name, including the displayed limit modulus and convergence-distance ledgers.*
4. *E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route binding the two completion-limit reads to the same finite regular-Cauchy window data.*
5. *Z is the* $\mathsf{Real}^{\uparrow}$ *zero-distance read of the metric-distance witness between the two displayed completion limits.*
6. *H records componentwise* hsame *transport for M, S, C, E, Z, K, P, N.*
7. *K records displayed* Cont *replay from finite Cauchy windows to completion limits, from those limits to a metric-distance witness, and from the real zero-distance row to the separated classifier.*
8. *P is the* Pkg *provenance over* $\mathsf{SeparatedCompletionReflection}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflection}^{\uparrow}}$ *row.*

The carrier is a reflection surface: it records how already displayed separated zero-distance evidence is consumed by completion uniqueness. It has no quotient-completion object, no representative selector, no trichotomy row, no countable-choice schedule, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SeparatedCompletionReflectionUp.SeparatedCompletionReflectionTasteGate`
`single carrier alignment`

Theorem 3543.2 (SeparatedCompletionReflection NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ *carrier* $R = (M, S, C, E, Z, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflection}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the* $\mathsf{Met}^{\uparrow}$ *source row, the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance classifier, the paired* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route, the* $\mathsf{Real}^{\uparrow}$ *zero-distance read, componentwise transport, continuation replay, provenance, and local naming;*
2. *completion-window exactness, requiring the two completion-limit reads in C to be compared only through the finite-window route E before any endpoint classifier is inspected;*
3. *zero-distance exactness, requiring the metric-distance witness from M to pass through the* $\mathsf{Real}^{\uparrow}$ *row Z before the separated classifier S is consumed;*
4. *transport and replay stability, requiring* hsame *transport through H and* Cont *replay through K to preserve the same order E, M, Z, S under local naming;*
5. *ledger visibility, requiring P and N to expose only the displayed rows and to refuse quotient completion, selected representatives, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3543.1. Its fields give exactly the metric source, separated classifier, complete-limit pair, Cauchy comparison route, real zero-distance read, and structural support rows named in the first obligation.

For completion-window exactness, read C through E. The two limit rows are thereby tied to the same regular-Cauchy window data before the metric-distance witness is formed, so no quotient completion or selected representative can supply an alternate comparison.

For zero-distance exactness, the metric row M supplies the distance witness, Z reads that witness at zero through the $\mathsf{Real}^{\uparrow}$ seal, and only then may S export the separated classifier. The transport and replay rows H, K preserve this same order componentwise.

The final obligation is the provenance inventory. Since P and N name only the rows listed in the carrier, the local certificate cannot expose trichotomy, countable choice, a quotient completion carrier, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 3543.3 (SeparatedCompletionReflection route)**.** *Every completion-uniqueness consumer of an accepted* $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Concretely, the consumer must first read the paired complete-limit rows C, then the finite-window comparison route E, then the metric-distance witness from M, then the $\mathsf{Real}^{\uparrow}$ *zero-distance row Z, and only afterward the separated classifier row S with support from H, K, P, N. The exported conclusion is completion uniqueness as a local separated-classifier route, not quotient completion equality, a selected limit, host equality, trichotomy, countable choice, or an ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the paired $\mathsf{CompleteMetric}^{\uparrow}$ limit rows in C. The comparison route E binds them to the same regular Cauchy point name through finite windows before any endpoint comparison is available.

Next form the displayed metric-distance witness using M. The real-valued zero-distance read Z is then the only row that turns that witness into data consumable by a separated classifier.

Finally apply the $\mathsf{SeparatedMetric}^{\uparrow}$ row S and carry the result through H, K, P, N. Transport, replay, provenance, and local naming do not add analytic coordinates; they only preserve and name the displayed route. Since the carrier contains no quotient-completion, selected-representative, trichotomy, countable-choice, or ambient-completeness field, the consumer route has no escape from the stated boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ packet is generated from a MetricUp source row, a SeparatedMetricUp zero-distance classifier, paired CompleteMetricUp limit rows, a CauchySequenceEquivalenceUp comparison route, a RealUp zero-distance read, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3543.1, Definition 3543.2, and Definition 3543.3 seed the completion-reflection boundary over separated zero-distance evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionReflection}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.SeparatedCompletionReflectionUp.SeparatedCompletionReflectionTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, quotient completion, selected representatives, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-window exactness, zero-distance exactness, transport replay, provenance, and local naming for BEDC.Derived.SeparatedCompletionReflectionUp.

Chapter 3544

A Concrete Naming Certificate for $\mathsf{ConvergentNet}^{\uparrow}$

Following Moore–Smith and Kelley, the $\mathsf{ConvergentNet}^{\uparrow}$ packet records ordinary convergent-net evidence as finite BEDC naming data. It sits over the directed-index substrate of chapter 1607, beside the Cauchy-tail surface of chapter 589, and before the convergence boundary of chapter 1521 and chapter 1561. The same finite route is readable by the completion consumers in chapter 1473 and chapter 1506, without turning convergence into a quotient of nets, a selected host limit, countable choice, or an ambient completeness assertion.

Definition 3544.1 (ConvergentNet carrier)**.** *A* $\mathsf{ConvergentNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, V, T, L, M, C, H, K, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index-window row, naming the inspected indices, tail windows, and displayed upper-window witnesses.*
2. *V is the net-value row over the indices displayed by D.*
3. *T is the convergence-test row, recording the finite neighborhoods, entourages, or metric tolerances that the packet actually inspects.*
4. *L is the displayed boundary row toward which the packet tests convergence, read only as finite naming data.*
5. *M is the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *boundary row that packages the same directed-window, value, test, and boundary evidence.*
6. *C is the optional* $\mathsf{CauchyNet}^{\uparrow}$ *tail row consumed by completion-facing readers that need Cauchy evidence.*
7. *H records componentwise* hsame *transport for the directed-window, value, test, boundary, convergence, Cauchy-tail, continuation, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from directed windows through net values, tests, boundary reads, Moore–Smith convergence, optional Cauchy-tail evidence, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{ConvergentNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MooreSmithConvergence}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConvergentNet}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient nets, selected host limits, countable-choice selectors, cofinal choice functions, host equality of boundary points, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ConvergentNetUp.ConvergentNetTasteGate single carrier alignment`

Theorem 3544.2 (ConvergentNet NameCert obligations)**.** *For every accepted* $\mathsf{ConvergentNet}^{\uparrow}$ *carrier* $G = (D, V, T, L, M, C, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConvergentNet}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed directed index windows, net values, convergence tests, boundary row, Moore–Smith row, Cauchy-tail row, transport, continuation, provenance, and local naming;*
2. *directed-window coverage, requiring every convergence test in T to be attached to a tail window displayed by D;*
3. *value exposure, requiring each accepted test to inspect only net values displayed by V;*
4. *boundary exposure, requiring L to be read only after D, V, T have been displayed;*
5. *Moore–Smith packaging, requiring M to preserve the same finite route before any completion-facing consumer reads it;*
6. *completion handoff readiness, requiring the optional Cauchy-tail row C before* $\mathsf{CauchyNetLimit}^{\uparrow}$*,* $\mathsf{UniformCompletion}^{\uparrow}$*, or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumes the packet;*
7. *ledger refusal, excluding quotient nets, selected host limits, countable choice, cofinal choice, host equality of limits, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 3544.1. The tuple exposes directed windows, net values, convergence tests, a boundary row, the Moore–Smith convergence row, the optional Cauchy-tail row, and the structural rows H, K, P, N.

Directed-window coverage and value exposure are forced by the continuation row K. A convergence test is replayed first through D, then through V, and only then reaches T and the boundary row L.

The Moore–Smith row M packages the same displayed route. If a completion-facing reader also needs Cauchy evidence, it must consume the row C before the route can be handed to $\mathsf{CauchyNetLimit}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, or $\mathsf{MetricCompletion}^{\uparrow}$.

Since the carrier has no coordinate for quotient nets, selected limits, choice operators, host equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3544.3 (ConvergentNet Cauchy handoff)**.** *Let $G = (D, V, T, L, M, C, H, K, P, N)$ be an accepted* $\mathsf{ConvergentNet}^{\uparrow}$ *packet. Any completion-facing consumer that reads G as Cauchy-directed evidence must first display the* $\mathsf{DirectedSet}^{\uparrow}$ *index substrate D, the net-value row V, the convergence-test row T, the boundary row L, the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *row M, and then the* $\mathsf{CauchyNet}^{\uparrow}$ *tail row C. The handoff preserves the finite directed-net route toward chapter 1561, chapter 1473, and chapter 1506, and exports no quotient net, selected limit, countable-choice selector, cofinal-choice operator, host equality, or ambient completeness principle.*

Proof. Start from a completion-facing read of the packet. Carrier admission gives the directed-window substrate D and the values V, but no completion consumer is visible before the convergence tests and boundary row have been replayed.

Use the continuation row K. It routes the read through D, V, T, L and then into the Moore–Smith row M, so the convergence evidence remains a finite directed-net display.

For a Cauchy-directed completion consumer, the row C is the required tail-evidence handoff. After C is displayed, the same finite route can be consumed by the directed-net limit, uniform-completion, or metric-completion surface.

The omitted coordinates are exactly the forbidden exits: quotient nets, selected limits, countable choice, cofinal choice, host equality, and ambient completeness. Hence the handoff preserves only the displayed finite route. □

Theorem 3544.4 (ConvergentNet completion-consumer boundary)**.** *Let $G = (D, V, T, L, M, C, H, K, P, N)$ be an accepted* $\mathsf{ConvergentNet}^{\uparrow}$ *packet. Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of G must read the* $\mathsf{DirectedSet}^{\uparrow}$ *row D, the net-value row V, the convergence-test row T, the boundary row L, the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *row M, and the optional* $\mathsf{CauchyNet}^{\uparrow}$ *tail-evidence row C in that order before any completion-facing handoff is available. The consumer receives only the finite route named by $D, V, T, L, M, C, H, K, P, N$ and receives no selected host limit, quotient net, countable-choice selector, cofinal-choice operator, host equality of boundary points, or ambient completeness principle.*

Proof. Project the carrier of Definition 3544.1. The only rows visible to a completion consumer are the directed-window row D, the value row V, the test row T, the boundary row L, the Moore–Smith row M, the optional Cauchy-tail row C, and the structural rows H, K, P, N.

Use Definition 3544.2. Its directed-window coverage, value exposure, boundary exposure, and Moore–Smith packaging clauses force the read order D, V, T, L, M before any completion-facing consumer can see convergence evidence.

Then apply Definition 3544.3. A metric-completion or uniform-completion consumer that needs Cauchy-directed evidence must next read C, so the completion-facing route is the displayed finite route through D, V, T, L, M, C.

Since the carrier omits selected host limits, quotient nets, choice operators, host equality, and ambient completeness, no completion consumer can bypass this order or turn the convergence packet into a selected limit object. □

Theorem 3544.5 (ConvergentNet limit handoff)**.** *Let $G = (D, V, T, L, M, C, H, K, P, N)$ be an accepted* $\mathsf{ConvergentNet}^{\uparrow}$ *packet. Every accepted limit read of G must expose the* $\mathsf{DirectedSet}^{\uparrow}$ *row D, the net-value row V, the convergence-test row T, the boundary row L, the* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *row M, the optional* $\mathsf{CauchyNet}^{\uparrow}$ *row C, componentwise transport H, continuation replay K, provenance P, and the local* $\mathsf{NameCert}_{\mathsf{ConvergentNet}^{\uparrow}}$ *row N before any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer can read the packet as completion-facing data. The read exports the Moore–Smith boundary only through this finite row order and exports no quotient net, selected host limit, countable-choice selector, cofinal-choice operator, host equality of boundary points, or ambient completeness principle.*

Proof. Apply Definition 3544.2. Its carrier admission and exposure clauses display exactly $D, V, T, L, M, C, H, K, P,$ while its ledger refusal excludes quotient nets, selected limits, choice operators, host equality, and ambient completeness.

The limit-facing part is the Moore–Smith boundary row. Boundary exposure and Moore–Smith packaging force a read through D, V, T, L, M before the packet can be treated as a convergent-net boundary.

For completion consumers, apply Definition 3544.3. The optional Cauchy-tail row C is the only displayed Cauchy-directed handoff, and it is read after the Moore–Smith route rather than as a separate completion object.

Finally, use Definition 3544.4. It states that $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{UniformCompletion}^{\uparrow}$ consumers receive only the finite route named by the carrier rows, so the accepted limit read is exactly the Moore–Smith boundary row plus the listed structural support before completion consumption. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConvergentNet}^{\uparrow}}$.

Constructive story: A $\mathsf{ConvergentNet}^{\uparrow}$ packet is generated from a DirectedSet index-window row, net values, convergence tests, a displayed boundary row, Moore–Smith convergence data, optional CauchyNet tail evidence, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvergentNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3544.1, Definition 3544.2, Definition 3544.3, Definition 3544.4, and Definition 3544.5 seed the finite convergent-net surface between directed index data, Moore–Smith convergence, limit handoff, and completion-consumer handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvergentNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected host limits, countable choice, cofinal choice, host equality of boundary points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-window coverage, value exposure, boundary exposure, Moore–Smith packaging, Cauchy handoff, provenance, and ledger refusal for the same finite packet.

Chapter 3545

A Concrete Naming Certificate for $\mathsf{MedianClosure}^{\uparrow}$

The $\mathsf{MedianClosure}^{\uparrow}$ packet realizes the coordinatewise-majority closure surface of Definition 9462.1319 and Definition 9462.1320 as finite NameCert data. It records the reassigned support, the majority-saturation row, inactive-corner readback, f-vector ledger, and maximal-cell ledger for the 20-codon WNR∪CUN carrier. It sits beside the sibling finite-structure packets in chapter 2309, chapter 349, and chapter 112, but is not bijective with them because it carries the coordinatewise-majority saturation row.

Definition 3545.1 (MedianClosure carrier)**.** *A* $\mathsf{MedianClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, M, I, F, X, H, C, P, N)$$

with the following displayed rows:

1. *S is the reassigned support row, naming the* 13 *codons of the source support $\mathcal{R}$.*
2. *M is the coordinatewise-majority saturation row, displaying exactly the* 20 *codons of* $\mathrm{WNR} \cup \mathrm{CUN}$ *as the median closure of S.*
3. *I is the inactive-corner readback row, displaying the seven codons in* $\mathrm{Med}(\mathcal{R}) \setminus \mathcal{R}$ *and the four codons in* $\mathrm{Med}(\mathcal{R}) \setminus \overline{\mathcal{R}}$.
4. *F is the f-vector ledger for $K(\mathrm{Med}(\mathcal{R}))$, displaying* $(20, 38, 26, 8, 1, 0, \ldots)$.
5. *X is the maximal-cell ledger, displaying the* WNR 4*-cube, the* CUN 2*-cube, and the listed bridge cells from the source vision.*
6. *H records componentwise* hsame *transport for support, median saturation, inactive-corner, f-vector, maximal-cell, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from support through coordinatewise-majority saturation, inactive-corner readback, f-vector ledger, maximal-cell ledger, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{MedianClosure}^{\uparrow}$, $\mathsf{HellyTheorem}^{\uparrow}$, $\mathsf{Trie}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MedianClosure}^{\uparrow}}$ *row.*

The carrier contains no coordinate for the full Q_6 convex hull, no Helly theorem, no cubical homology package, no trie dictionary order, and no abstract finite-set equality outside the displayed codon rows.

Theorem 3545.2 (MedianClosure NameCert obligations)**.** *For every accepted* $\mathsf{MedianClosure}^{\uparrow}$ *carrier* $Q = (S, M, I, F, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MedianClosure}^{\uparrow}}$ *surface consists exactly of support admission through* S*, coordinatewise-majority saturation through* M*, inactive-corner readback through* I*, f-vector exposure through* F*, maximal-cell exposure through* X*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.MedianClosureUp.MedianClosureTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3545.1. The support row, median-saturation row, inactive-corner row, f-vector ledger, maximal-cell ledger, and structural rows are explicit coordinates of the same finite BHist packet.

The continuation row C fixes the order of reads. A consumer first sees the reassigned support S, then the coordinatewise-majority saturation row M, and only then the inactive-corner, f-vector, and maximal-cell rows.

Transport, provenance, and local naming preserve that same route. Since the carrier omits convex-hull completion, Helly theorem data, cubical homology, trie order, and abstract finite-set equality, the listed rows exhaust the local NameCert surface. □

Theorem 3545.3 (MedianClosure vision realization)**.** *Every accepted* $\mathsf{MedianClosure}^{\uparrow}$ *packet realizes the median-closure claims of Definition 9462.1319, Definition 9462.1320, Definition 9462.1321, Definition 9462.1323, and Definition 9462.1324 as one finite NameCert surface. In particular, the displayed closure-size row rejects any carrier whose median-saturation row is not the* 20*-codon set* $\mathrm{WNR} \cup \mathrm{CUN}$*.*

Proof. Read the support row S and the median-saturation row M. By carrier admission, M is the displayed coordinatewise-majority closure of the reassigned support and has the 20 codons $\mathrm{WNR} \cup \mathrm{CUN}$.

The inactive-corner row I and f-vector row F are downstream of M, so their readback is tied to the same displayed closure rather than to an independent finite set.

The maximal-cell row X uses that same closure to expose the WNR and CUN cells and their bridge cells. Therefore any carrier with a different median closure cannot satisfy the local NameCert route. □

Falsifiable prediction: The $\mathsf{MedianClosure}^{\uparrow}$ closure-size row rejects any carrier whose displayed median closure is not the 20-codon $\mathrm{WNR} \cup \mathrm{CUN}$ set.

Independence witness: helly theorem, cubical finite-support chapters, trie, finset: none is bijective with $\mathsf{MedianClosure}^{\uparrow}$ because this carrier alone binds the coordinatewise-majority saturation row to the inactive-corner readback, f-vector ledger, and maximal-cell ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{MedianClosure}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MedianClosure}^{\uparrow}$ packet is generated from the reassigned support row, coordinatewise-majority saturation, inactive-corner readback, f-vector ledger, maximal-cell ledger, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MedianClosure}^{\uparrow}}$, seed)

Scope closed: Definition 3545.1, Definition 3545.2, and Definition 3545.3 seed the finite median-closure packet for the 20-codon $\mathrm{WNR} \cup \mathrm{CUN}$ carrier.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MedianClosure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the full Q_6 convex hull, Helly theorem content, cubical homology, trie ordering, abstract finite-set equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked support admission, majority saturation, inactive-corner readback, f-vector exposure, maximal-cell exposure, provenance, and ledger refusal for the same finite packet.

Chapter 3546

A Concrete Naming Certificate for $\mathsf{RegularCauchyReal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyReal}^{\uparrow}$ packet presents a real number by regular Cauchy rational data with an explicit finite tolerance route before any quotient, selected limit, or ambient completeness principle is read. It sits on the finite observation surface of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, the Cauchy-convergence handoff of chapter 1509, and the terminal real-name seal of chapter 38. The packet names the non-quotient regular Cauchy route used by L10 Real and Completion consumers; it does not assert that every Cauchy object has a chosen limit.

Definition 3546.1 (RegularCauchyReal carrier)**.** *A* $\mathsf{RegularCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule listing the rational observations opened for each displayed tolerance request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic error rows, comparison bounds, and late-window inequalities.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled stream windows and dyadic tolerance ledger.*
4. *K is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *handoff row, checking that the displayed regular readback satisfies the finite convergence criterion exposed to completion consumers.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, Q, K have all been displayed.*
6. *H records componentwise* hsame *transport for the stream schedule, dyadic ledger, regular readback, convergence handoff, Real seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a regular-Cauchy-real request through S, D, Q, K, and E.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRealUp.RegularCauchyRealTasteGate single carrier alignment`

Theorem 3546.2 (RegularCauchyReal NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReal}^{\uparrow}$ *carrier*

$$R = (S, D, Q, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyReal}^{\uparrow}}$ *surface consists exactly of carrier admission, finite stream-window exposure, dyadic tolerance exactness, regular rational readback, Cauchy-convergence handoff, Real-seal routing, componentwise transport, displayed replay, provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 3546.1. The accepted packet exposes the stream schedule S, dyadic tolerance ledger D, regular readback Q, convergence handoff K, terminal Real seal E, and structural rows H, C, P, N.

The obligation rows are then read in order. The finite windows of chapter 126 supply the observations, the dyadic comparisons of chapter 291 supply the tolerance ledger, and the readback surface of chapter 301 packages them as regular rational data.

The convergence and seal rows close the route without adding an ambient limit. The handoff through chapter 1509 exposes only the displayed criterion row K, and the Real seal of chapter 38 is reached only through E.

Finally H and C transport and replay the same coordinates, while P and N record provenance and local naming. Since no additional coordinate is present, the certificate surface exports none of the excluded quotient, choice, completeness, host-equality, verification, or bridge data. □

Theorem 3546.3 (RegularCauchyReal Real seal route)**.** *Every Real-facing read exported by an accepted* $\mathsf{RegularCauchyReal}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, Q, K \longmapsto E$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Thus a consumer receives scheduled stream windows, dyadic tolerance rows, regular rational readback, and the Cauchy-convergence handoff before any Real seal is visible.*

Proof. Start with an accepted carrier $R = (S, D, Q, K, E, H, C, P, N)$. By Definition 3546.2, the only Real-facing row is E, and it is downstream of the displayed stream, dyadic, regular-readback, and convergence rows.

The route cannot skip the finite observation stage because S is the only coordinate containing opened stream windows. It cannot skip the tolerance stage because D is the only coordinate containing dyadic comparison and late-window information.

The regular readback and convergence handoff are also forced. The row Q is the sole $\mathsf{RegSeqRat}^{\uparrow}$ readback, while K is the sole $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ handoff available to a completion consumer.

Transport, replay, provenance, and local naming preserve the same route. Since H, C, P, N have no quotient, selected-limit, countable-choice, or ambient-completeness coordinate, every Real-facing read reaches E only through the displayed route. □

Theorem 3546.4 (RegularCauchyReal seal factorization)**.** *Every accepted* $\mathsf{RegularCauchyReal}^{\uparrow}$ *Real seal factors through the L10 four-object route*

$$\mathsf{StreamName}^{\uparrow}(S) \longmapsto \mathsf{DyadicRatCore}^{\uparrow}(D) \longmapsto \mathsf{RegSeqRat}^{\uparrow}(Q) \longmapsto \mathsf{CauchyConvergenceCriterion}^{\uparrow}(K) \longmapsto \mathsf{Real}^{\uparrow}(E)$$

before any consumer can expose the terminal $\mathsf{Real}^{\uparrow}$ *row. The factorization is carried by the same* H, C, P, N *support rows of the carrier, and it supplies no quotient equality of Cauchy names, no selected limit, no host real equality, and no ambient completeness principle.*

Proof. Project the accepted carrier $R = (S, D, Q, K, E, H, C, P, N)$ through Definition 3546.1. The rows S, D, Q, K, E are the only analytic rows available to a Real-facing consumer.

The sibling route is ordered by the carrier itself. The finite windows of chapter 126 are read from S, the tolerance comparisons of chapter 291 are read from D, and the regular rational readback of chapter 301 is read from Q.

Apply Definition 3546.3 and Definition 3546.5. The first theorem forces every Real-facing read through S, D, Q, K before E, while the second identifies K as the displayed Cauchy-convergence handoff rather than an ambient completeness theorem.

Finally use the support rows H, C, P, N. They transport, replay, source, and name exactly the displayed route, so the terminal $\mathsf{Real}^{\uparrow}(E)$ seal has no coordinate from which quotient equality, selected limits, host real equality, or ambient completeness could be recovered. □

Theorem 3546.5 (RegularCauchyReal Cauchy-criterion handoff)**.** *Every completion-facing request for an accepted* $\mathsf{RegularCauchyReal}^{\uparrow}$ *carrier reads the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row* K *only after the stream schedule* S*, dyadic tolerance ledger* D*, and regular rational readback* Q *have been displayed. The handoff therefore supplies a finite criterion witness, not an ambient proof that an arbitrary Cauchy object has a chosen Real limit.*

Proof. Project the carrier rows of Definition 3546.1. The row K is listed after S, D, Q and is defined as the convergence handoff for that displayed regular readback.

The sibling routes determine the inputs to K. The schedule row S gives the finite inspected windows, the dyadic ledger D supplies the tolerance comparisons, and the regular rational row Q packages those reads into the source expected by the convergence criterion.

Thus a completion-facing consumer cannot read K as a standalone completeness principle. The only accepted handoff is the displayed finite route through S, D, Q, K, transported by H, replayed by C, and named by P, N. □

Theorem 3546.6 (RegularCauchyReal Cauchy-modulus source lock)**.** *Every accepted* $\mathsf{RegularCauchyReal}^{\uparrow}$ *packet must read its displayed Cauchy modulus or convergence budget before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row can be sealed as* $\mathsf{Real}^{\uparrow}$*. Concretely, any Real-facing consumer of*

$$R = (S, D, Q, K, E, H, C, P, N)$$

must expose the $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *budget row* K*, with the same source discipline as the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *interface, before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed.*

Proof. Project the rows $S, D, Q, K, E, H, C, P, N$ from Definition 3546.1. The stream schedule S is the only row exposing finite observations, and D is the only row exposing dyadic tolerance and late-window comparisons.

The readback row Q is therefore source-locked to S and D. The convergence row K records the displayed Cauchy budget for that readback, matching the modulus-source role of chapter 292 while staying inside the carrier rows already present in the packet.

Only after S, D, Q, K have been read can the terminal row E serve as the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The seal is not an independent limit selector; it is downstream of the StreamName, DyadicRatCore, RegSeqRat, and Cauchy-budget route.

Finally H, C, P, N transport, replay, source, and name this same route. Since the carrier contains no selected limit, quotient stream equality, countable-choice row, host equality, or ambient completeness coordinate, no such datum can enter the Real seal. □

Theorem 3546.7 (RegularCauchyReal non-escape)**.** *An accepted* $\mathsf{RegularCauchyReal}^{\uparrow}$ *carrier exports no quotient stream equality, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, host real equality, Lean verification, or bridge credential. Every exported read is confined to* $S, D, Q, K, E, H, C, P, N$.

Proof. Use the carrier definition to enumerate the available coordinates. They are exactly the stream schedule, dyadic ledger, regular readback, convergence handoff, Real seal, transport, replay, provenance, and local naming rows.

The obligation theorem identifies the NameCert surface with those same rows. Any proposed exported read must therefore be one of the displayed coordinates or a structural transport of them through H and C.

None of the displayed coordinates stores quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real completeness, host real equality, Lean verification, or bridge data. Hence no such datum can escape from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3546.1, Definition 3546.2, Definition 3546.3, Definition 3546.5, Definition 3546.6, and Definition 3546.7 seed the non-quotient regular Cauchy real-name packet over displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyRealUp.RegularCauchyRealTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, dyadic tolerance exactness, regular rational readback, convergence handoff, Real-seal routing, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.RegularCauchyRealUp.

Constructive story: A $\mathsf{RegularCauchyReal}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ handoff, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3547

A Concrete Naming Certificate for $\mathsf{GDeltaSet}^{\uparrow}$

Following Kechris and Engelking on Polish spaces and descriptive set theory, the $\mathsf{GDeltaSet}^{\uparrow}$ packet records the traditional countable-intersection-of-open-sets interface as finite BEDC NameCert data. It sits over the complete separable metric source of chapter 1490, the generated-set boundary of chapter 3384, the countable-base discipline of chapter 1901, and the indexed density surface of chapter 1566. The packet names the route by which Polish and Borel consumers inspect a displayed open-row schedule without importing a host subset, selected enumeration, classical complement closure, ambient countable choice, or a standard descriptive-set theorem.

Definition 3547.1 (GDeltaSet carrier)**.** *A* $\mathsf{GDeltaSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, B, S, W, O, H, C, L, N)$$

with the following displayed rows:

1. *P is the Polish and second-countable source row. It exposes the* $\mathsf{PolishSpace}^{\uparrow}$ *complete-separable metric packet, the* $\mathsf{SecondCountable}^{\uparrow}$ *base row, and the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *indexed-density handoff visible to the current consumer.*

2. *B is the* $\mathsf{BorelSet}^{\uparrow}$ *row that receives the generated-set handoff after the displayed open schedule has been inspected.*

3. *S is the countable open-row schedule. Each finite prefix names the open rows whose intersection is being offered, together with the schedule position and the source row over which the open row is read.*

4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It records exactly the schedule positions, base-cell indices, density indices, and finite query windows visible before the consumer reads the Borel row.*

5. *O is the open-set readback row, carrying the displayed open classifier, local basis witness, and source compatibility proof for every open row inspected through S and W.*

6. *H records componentwise* hsame *transport for the Polish source, Borel row, open schedule, stream windows, open readback, continuation replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a Polish or Borel query through P, S, W, O before the generated-set row B is consumed.*

8. *L is the* Pkg *provenance over* $\mathsf{GDeltaSet}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{SecondCountable}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{GDeltaSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, B, S, W, O, H, C, L, N$. It has no coordinate for host subsets, chosen countable enumerations, ambient countable choice, quotient set equality, classical complement closure, or standard descriptive-set transfer theorems.

Lean4 ✓ `BEDC.Derived.GDeltaSetUp.GDeltaSetTasteGate single carrier alignment`

Theorem 3547.2 (GDeltaSet NameCert obligations)**.** *For every accepted* $\mathsf{GDeltaSet}^{\uparrow}$ *carrier* $G = (P, B, S, W, O, H, C, L, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GDeltaSet}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Polish and second-countable source row, Borel row, open-row schedule, finite windows, open readback, transport, replay, provenance, and local naming;*
2. *countable schedule exposure, requiring every inspected intersection stage to appear as a displayed finite prefix of S before it reaches B;*
3. *finite-window stability, requiring each schedule position, base-cell index, density index, and query window to be read through W;*
4. *open-row readback, requiring each open component to pass through the classifier and local-basis data stored in O over the same source row P;*
5. *Borel and Polish handoff, requiring the generated-set row B to consume only the displayed route through P, S, W, O;*
6. *componentwise transport, requiring H to preserve the source, schedule, windows, open readback, Borel row, replay, provenance, and local name together;*
7. *continuation replay, requiring C to replay the same ordered route before any Polish or Borel consumer receives the packet;*
8. *provenance, requiring L to name exactly the displayed sibling packets and BEDC kernel rows used by the carrier;*
9. *local naming, requiring N to certify only the rows P, B, S, W, O, H, C, L;*
10. *ledger refusal, excluding host countable choice, quotient set equality, selected enumerations, host subsets, classical complement closure, and ambient descriptive-set theorems.*

No $\mathsf{GDeltaSet}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Project the carrier of Definition 3547.1. The tuple displays exactly the Polish and second-countable source row, Borel row, countable open-row schedule, finite stream windows, open readback row, transport, replay, provenance, and local naming.

The schedule exposure and finite-window obligations are read through S and W. A consumer sees only a finite prefix of the countable open schedule, and each schedule position, base-cell index, density index, and query window is inspected through the same displayed stream-window row.

Open-row readback is forced by O over the source row P. Thus each open component is tied to the Polish, second-countable, and indexed-density data before the generated-set row B can be consumed.

Finally H, C, L, N transport, replay, source, and name the same route. Since no listed row stores a host subset, chosen enumeration, countable-choice selector, quotient set equality, classical

complement closure, or standard descriptive-set theorem, the enumerated obligations exhaust the local NameCert surface. □

Theorem 3547.3 (GDeltaSet Polish-Borel handoff)**.** *Every Polish or Borel consumer of an accepted* $\mathsf{GDeltaSet}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{PolishSpace}^{\uparrow},\ \mathsf{SecondCountable}^{\uparrow},\ \mathsf{CountableDenseSubset}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{BorelSet}^{\uparrow}.$$

More precisely, the consumer first reads the source row P, then the schedule and finite windows S, W, then the open-row readback O, and only then the generated-set row B. The exported object is a finite NameCert packet for the displayed countable open-row route; it is not a host subset, a chosen enumeration, a classical complement-closure proof, an ambient standard descriptive-set theorem, or a quotient set equality.

Proof. Begin with a Polish or Borel consumer of the accepted packet. Carrier admission provides the source row P, but no generated-set read is available until the open schedule and window rows have been displayed.

Replay the continuation row C. The read moves through S and W, so every countable-intersection stage is consumed only as a finite visible prefix with finite schedule, base-cell, density, and query observations.

The open readback row O then ties the visible open components back to the Polish and second-countable source. After that readback, the Borel row B receives the generated-set handoff.

The remaining rows H, L, N preserve, source, and name the same route. Therefore every consumer factors through the displayed schedule, window, and open-row route, with no host subset, chosen enumeration, classical complement closure, standard descriptive-set theorem, or quotient set equality exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GDeltaSet}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GDeltaSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3547.1, Definition 3547.2, and Definition 3547.3 seed the finite GDeltaSet route over Polish, second-countable, countable-dense, StreamName, open-readback, Borel, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GDeltaSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subsets, selected countable enumerations, countable choice, quotient set equality, classical complement closure, standard descriptive-set theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, countable schedule exposure, finite-window stability, open-row readback, Polish-Borel handoff, transport, replay, provenance, local naming, and ledger refusal for BEDC.Derived.GDeltaSetUp.

Constructive story: A $\mathsf{GDeltaSet}^{\uparrow}$ packet is generated from a Polish and second-countable source row, a BorelSet row, a countable open-row schedule, finite StreamName windows, open-set readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3548

A Concrete Naming Certificate for $\mathsf{ClosedBallCompactness}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{ClosedBallCompactness}^{\uparrow}$ packet records the theorem-facing finite certificate that every displayed closed ball in a proper metric carrier is compact. It sits between the closed-ball membership surface of chapter 1451, the proper-metric witness of **??**, the nested-ball completion route of chapter 3526, the compact-metric certificate of chapter 129, and the total-bounded plus complete-metric route through chapter 127 and chapter 128. The packet names the finite closed-ball compactness handoff only; it is not an open-cover compactness theorem, not a host Heine–Borel proof, not an arbitrary properness oracle, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 3548.1 (Closed-ball compactness carrier)**.** *A* $\mathsf{ClosedBallCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (B, P, N, K, T, M, R, H, D, Q, A)$$

with the following displayed rows:

1. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row naming the center, radius, metric source, and closed membership comparison.*
2. *P is the* $\mathsf{ProperMetric}^{\uparrow}$ *row whose displayed closed-ball family contains the same center-radius window.*
3. *N is the* $\mathsf{NestedClosedBall}^{\uparrow}$ *route available for Cauchy-center and descending-ball handoff reads.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *witness row attached to the displayed closed ball.*
5. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row exposed by the compact metric witness.*
6. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-service row exposed by the compact metric witness and by the proper-metric completion handoff.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row for center, radius, distance, and compactness-window comparisons.*
8. *H records componentwise* hsame *transport for the closed-ball, proper-metric, nested-ball, compact-metric, totally-bounded, complete-metric, real-readback, replay, provenance, and naming rows.*
9. *D records displayed* Cont *replay from a closed-ball compactness request through B, P, N, K, T, M, R.*

10. *Q is the* Pkg *provenance over* ClosedBallCompactness$^{\uparrow}$, MetricClosedBall$^{\uparrow}$, ProperMetric$^{\uparrow}$, NestedClosedBall$^{\uparrow}$, CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *A is the local* NameCert$_{\text{ClosedBallCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their displayed transports, their continuation routes, provenance, and local naming. It has no coordinate for open covers, selected subcovers, quotient metric points, a host compactness theorem, arbitrary properness beyond the shown ball, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.ClosedBallCompactnessUp.ClosedBallCompactnessTasteGate single carrier alignment`

Theorem 3548.2 (Closed-ball compactness NameCert obligations)**.** *For every accepted* ClosedBallCompactness$^{\uparrow}$ *carrier*

$$C = (B, P, N, K, T, M, R, H, D, Q, A),$$

the local NameCert$_{\text{ClosedBallCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric closed-ball row, proper-metric row, nested-ball route, compact-metric witness, totally-bounded row, complete-metric row, real-readback row, componentwise transport, displayed continuation replay, package provenance, and local naming; center-radius compatibility between B and the closed-ball family displayed by P; compact witness exactness through K; finite-net and complete-limit exposure through T and M; and ledger refusal for open-cover compactness, selected subcovers, quotient metric points, host compactness, arbitrary properness outside the displayed ball, and ambient* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 3548.1. The accepted packet displays the closed-ball row, the proper-metric source, the nested-ball route, the compact witness, the total-bounded and complete-metric witnesses, the real readback, and the structural rows.

Center-radius compatibility is forced before compactness is read. The row B names the closed-ball membership comparison, and P exposes the same center-radius window in its displayed proper-metric family, so a consumer cannot switch to another ball.

Compact witness exactness is the route through K. The finite-net face T and the limit-service face M are read only after K has named the compact metric witness attached to B.

The structural rows H, D, Q, A transport, replay, source, and name the same route. Since no excluded coordinate occurs in the carrier, open-cover compactness, selected subcovers, quotient point equality, host compactness, arbitrary properness outside the displayed ball, and ambient real completeness cannot enter the local NameCert surface. □

Theorem 3548.3 (Closed-ball compactness nested-ball handoff)**.** *Every nested-ball or completion-facing consumer of an accepted* ClosedBallCompactness$^{\uparrow}$ *carrier reads the closed ball through*

MetricClosedBall$^{\uparrow}$, ProperMetric$^{\uparrow}$, NestedClosedBall$^{\uparrow}$, CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, CompleteMetric$^{\uparrow}$

The handoff therefore exposes the displayed closed-ball membership row, the proper-metric compact witness, the nested-ball Cauchy-center route, the finite-net face, and the complete-metric face, and it exports no open-cover compactness proof or choice-selected center.

Proof. Begin with the accepted carrier $C = (B, P, N, K, T, M, R, H, D, Q, A)$. The closed-ball request first reads B and the matching proper-metric row P.

The nested-ball route N is then available only as a displayed handoff. It supplies the descending-ball and Cauchy-center route used by completion consumers, while K supplies the compact metric witness attached to the same closed ball.

Finally T, M, R, H, D, Q, A expose the finite-net, limit-service, real-readback, transport, replay, provenance, and naming rows. Because the carrier has no selector coordinate, the consumer receives no open-cover compactness proof and no choice-selected center. □

Theorem 3548.4 (Closed-ball compactness nonescape)**.** *Every public read of an accepted* $\mathsf{ClosedBallCompactness}^{\uparrow}$ *packet factors through the carrier of Definition 3548.1 and the obligations of Definition 3548.2. In particular, the packet can export compactness for the displayed closed ball only as the route*

$$B, P, N, K, T, M, R, H, D, Q, A,$$

and cannot export open-cover compactness, a selected finite subcover, quotient equality of metric points, a host Heine–Borel theorem, arbitrary properness beyond the displayed center-radius window, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The rows B, P, N, K, T, M, R are the only mathematical rows available before structural replay, and the rows H, D, Q, A are the only transport, continuation, provenance, and naming rows.

Apply Definition 3548.2. The local NameCert surface requires the closed-ball row, proper-metric row, nested-ball route, compact witness, total-bounded face, complete-metric face, and real-readback face to be admitted together.

Any public compactness read must therefore pass through the same finite tuple. Since the tuple has no coordinate for the excluded objects, those objects cannot escape through the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBallCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedBallCompactness}^{\uparrow}$ packet is generated from a MetricClosedBall row, ProperMetric closed-ball family row, NestedClosedBall route, CompactMetric witness, TotallyBounded finite-net row, CompleteMetric limit-service row, RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBallCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3548.1, Definition 3548.2, Definition 3548.3, and Definition 3548.4 seed the theorem-facing finite compactness certificate for displayed proper-metric closed balls.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBallCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient metric points, host Heine–Borel compactness, arbitrary properness beyond displayed closed balls, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, center-radius compatibility, compact witness exactness, nested-ball handoff, finite-net and complete-limit exposure, nonescape, and TasteGate field faithfulness for BEDC.Derived.ClosedBallCompactnessUp.

Chapter 3549

A Concrete Naming Certificate for $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$

Following the finite-net proof of compact uniform continuity in chapter 9237, the $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ packet records the residual triangle-estimate surface that remains after a compact source, continuous-map pointwise modulus, and uniform-modulus candidate have already been displayed. It sits over the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the metric triangle estimate packet of chapter 1159, and the uniform-modulus consumer of chapter 369. The packet names the final source-and-target triangle ledger only; it is not a compactness theorem, not a pointwise-modulus selector, not a finite-net constructor, and not a host proof of Heine–Cantor.

Definition 3549.1 (Compact-source triangle estimate carrier)**.** *A* $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, U, E, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the finite-net coverage and located-distance comparisons for the compact source metric.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise modulus and graph evaluations are inspected on the same compact source.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *candidate row produced by the finite-net lower-bound route.*
4. *E is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *residual row, recording the source triangle estimate around a selected net center and the target triangle estimate for the two image points.*
5. *S is the finite center-radius ledger that ties the selected compact-source probe to the pointwise modulus radius and to the uniform-modulus precision.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger for the epsilon-third, half-radius, and lower-bound inequalities used by E.*
7. *L is the local nonescape ledger saying that the estimate consumes only the displayed compact source, continuous-map graph, uniform-modulus candidate, triangle-estimate row, and rational comparisons.*
8. *H records componentwise* hsame *transport for the compact source, continuous map, uniform-modulus candidate, triangle estimate, center-radius ledger, rational comparison ledger, nonescape ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-uniform-continuity request through* K, F, U, E, S, R, L.
10. *P is the* Pkg *provenance over* $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactSourceTriangleEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an open cover, an external finite subset, a selected point outside the displayed probe row, a host supremum norm, or an independent Heine–Cantor theorem.

Lean4 ✓ `BEDC.Derived.CompactSourceTriangleEstimateUp.CompactSourceTriangleEstimateTasteGate`
`single carrier alignment`

Theorem 3549.2 (Compact-source triangle estimate NameCert obligations)**.** *For every accepted* $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ *carrier*

$$T = (K, F, U, E, S, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactSourceTriangleEstimate}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, continuous-map row, uniform-modulus candidate, metric triangle estimate, finite center-radius ledger, rational comparison ledger, local nonescape ledger, componentwise transport, displayed continuation replay, package provenance, and local naming; compact-source compatibility between K and the source row of F; triangle-estimate exactness through E; rational-bound exactness through R; and refusal of open covers, external finite subsets, hidden point selectors, host norms, and independent Heine–Cantor reasoning.*

Proof. Carrier admission is projection from Definition 3549.1. The accepted packet displays the compact source, continuous map, uniform-modulus candidate, triangle estimate, center-radius ledger, rational comparisons, and structural rows.

Compact-source compatibility is read first. The compact row K and continuous-map row F name the same source metric before any center-radius estimate in S can be consumed.

The residual estimate is the row E. It combines the source triangle comparison around the displayed compact-net center with the target triangle comparison for the two image points, while R records the epsilon-third and radius inequalities used by that comparison.

The rows L, H, C, P, N record nonescape, transport, replay, provenance, and naming. Since no excluded coordinate appears in the carrier, the packet cannot export an open cover, external finite subset, hidden selector, host norm, or independent Heine–Cantor proof. □

Theorem 3549.3 (Compact-source triangle estimate UniformModulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ *packet must read the compact source, continuous-map graph, uniform-modulus candidate, metric triangle estimate, finite center-radius ledger, rational comparison ledger, and nonescape ledger before it reads the structural rows*

$$H, C, P, N.$$

Consequently the consumer receives a final compact-source triangle residual over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, *and* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, *rather than a new compactness or continuity principle.*

Proof. Start with the accepted carrier $T = (K, F, U, E, S, R, L, H, C, P, N)$. The uniform-modulus consumer can read U only after K and F have identified the compact source and graph surface.

The estimate then passes through S, R, E. The center-radius ledger ties the selected compact-source probe to the pointwise-modulus radius and uniform precision, the rational ledger records the required inequalities, and the metric triangle estimate row supplies the source and target triangle steps.

The nonescape ledger L and structural rows H, C, P, N preserve the same route. Thus the handoff is a residual triangle-estimate packet for an already displayed compact-uniform route, not an additional source of compactness or continuity data. □

Falsifiable prediction: Every accepted $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ read must expose a $\mathsf{CompactMetric}^{\uparrow}$ source row, a $\mathsf{ContinuousMap}^{\uparrow}$ graph row over the same source, a $\mathsf{UniformModulus}^{\uparrow}$ candidate row, a $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ residual row, finite center-radius and rational comparison ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuousmap, uniformmodulus, metric-triangle-uniform-estimate: $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ is not bijective to any listed sibling because it binds the final compact-source triangle residual after the finite-net and pointwise-modulus data have already been displayed.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactSourceTriangleEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactSourceTriangleEstimate}^{\uparrow}$ packet is generated from a CompactMetric source row, ContinuousMap graph row, UniformModulus candidate row, MetricTriangleUniformEstimate residual row, finite center-radius ledger, RatUp comparison ledger, local nonescape ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactSourceTriangleEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3549.1, Definition 3549.2, and Definition 3549.3 seed the final compact-source triangle residual consumed by the compact-uniform-continuity route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactSourceTriangleEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compactness, pointwise continuity, finite-net construction, selected centers outside displayed probes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source compatibility, triangle-estimate exactness, rational-bound exactness, UniformModulus handoff, nonescape, and TasteGate field faithfulness for BEDC.Derived.CompactSourceT

Chapter 3550

A Concrete Naming Certificate for $\mathsf{RealLineConnected}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealLineConnected}^{\uparrow}$ packet records the finite connectedness surface of the real line as interval-chain and intermediate-value data visible before any host topological connectedness theorem is invoked. It sits over the real-name boundary of chapter 38, the interval connectedness route of chapter 1462, the intermediate-value bisection route of chapter 1402, the graph and modulus rows of chapter 130, and the dyadic tolerance ledger of chapter 291. The chapter names a constructive real-line connectedness packet for later continuous-image and completion consumers; it does not claim open-cover compactness, real trichotomy, quotient stream equality, selected paths, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3550.1 (Real line connected carrier)**.** *A* $\mathsf{RealLineConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, J, V, F, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *line-source row, exposing only terminal real-name reads through displayed finite windows;*
2. *J is the* $\mathsf{ConnectedInterval}^{\uparrow}$ *interval-chain row, recording the finite chain of located interval segments used by a connectedness consumer;*
3. *V is the* $\mathsf{IntermediateValue}^{\uparrow}$ *sign-route row attached to the interval-chain handoff;*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and modulus row inspected by continuous-image consumers of the line route;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the interval-chain, bisection, and finite-window requests;*
6. *W is the finite observation-window row opened by D before any real-line connectedness read is exported;*
7. *Q is the regular rational readback row attached to the same windows;*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after J, V, F, D, W, Q have been displayed;*
9. *H stores componentwise* hsame *transport for the real-source, interval-chain, intermediate-value, continuous-map, dyadic, window, readback, seal, replay, provenance, and local naming rows;*

10. *C stores displayed* Cont *replay through the same rows;*
11. *P is the* Pkg *provenance over* $\mathsf{RealLineConnected}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ConnectedInterval}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineConnected}^{\uparrow}}$ *row.*

The carrier has no coordinate for host open-cover connectedness, trichotomy, quotient stream equality, a selected path object, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RealLineConnectedUp.RealLineConnectedTasteGate single carrier alignment`

Theorem 3550.2 (Real line connected NameCert obligations)**.** *For every accepted* $\mathsf{RealLineConnected}^{\uparrow}$ *carrier*

$$L = (R, J, V, F, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineConnected}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real-source, interval-chain, intermediate-value, continuous-map, dyadic, finite-window, readback, terminal-seal, transport, replay, provenance, and local naming rows;*
2. *interval-chain visibility, requiring every connectedness read to pass through J before a continuous-image or completion consumer can inspect the terminal seal;*
3. *intermediate-value routing, requiring each separation-refusal read along the chain to cite V and its finite bisection route;*
4. *continuous-map handoff, requiring downstream image consumers to use F only after the same interval-chain and intermediate-value rows have been displayed;*
5. *dyadic-window exactness, requiring the tolerance row D, window row W, and readback row Q to name the same finite request before E is exported;*
6. *nonescape from host open-cover connectedness, trichotomy, quotient stream equality, selected path objects, host real equality, and ambient completeness.*

No $\mathsf{RealLineConnected}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 3550.1. The tuple lists the real-source, interval-chain, intermediate-value, continuous-map, dyadic, finite-window, readback, terminal-seal, transport, replay, provenance, and local naming rows.

Interval-chain visibility is read from J. A connectedness consumer must inspect the finite $\mathsf{ConnectedInterval}^{\uparrow}$ chain before it can treat the real line as connected data.

Intermediate-value routing is read from V. The only separation-refusal information available to the packet is the finite intermediate-value sign route attached to the displayed interval chain.

Continuous-map handoff is read from F. A continuous-image consumer therefore receives graph and modulus data only after the line-source, interval-chain, and intermediate-value rows have already been displayed.

Dyadic-window exactness is read from D, W, Q, E. The dyadic tolerance opens the finite window, the readback row names the regular rational data in that window, and the terminal seal exports the same request as $\mathsf{Real}^{\uparrow}$ data.

Finally H, C, P, N transport, replay, source, and name only the displayed packet. Since the carrier contains no host open-cover connectedness, trichotomy, quotient stream equality, selected path object, host real equality, or ambient completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 3550.3 (Real line connected interval-chain handoff)**.** *Every continuous-image or completion-facing read exported by an accepted* $\mathsf{RealLineConnected}^{\uparrow}$ *packet factors through*

$$\mathsf{ConnectedInterval}^{\uparrow} \longmapsto \mathsf{IntermediateValue}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route uses the displayed rows $J, V, F, D, W, Q, E, H, C, P, N$ *of Definition 3550.1. It exports no host open-cover connectedness theorem, trichotomy principle, quotient stream equality, selected path object, host real equality, or ambient completeness claim.*

Proof. Start with an accepted carrier $L = (R, J, V, F, D, W, Q, E, H, C, P, N)$. The source connectedness row is J, so any real-line connectedness read begins with the displayed $\mathsf{ConnectedInterval}^{\uparrow}$ chain rather than with a host connected-subset assertion.

Read the separation-refusal surface through V. This intermediate-value row records the finite bisection and sign-route data used by the chain; no trichotomy or selected separator is available.

Read the downstream continuous-map surface through F. The graph and modulus rows are attached to the same chain and sign-route data, so continuous-image consumers cannot bypass the interval-chain handoff.

Finally read the dyadic and real-name boundary through D, W, Q, E. The dyadic tolerance opens the finite window, the readback row presents the regular rational data, and the terminal seal exports the Real-facing datum.

The remaining rows H, C, P, N preserve the same displayed route. Since no row names open-cover compactness, quotient stream equality, selected paths, host real equality, or ambient completeness, every continuous-image or completion-facing read remains inside the finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineConnected}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3550.1, Definition 3550.2, and Definition 3550.3 seed the finite real-line connectedness route through interval chains, intermediate-value rows, continuous-map rows, dyadic windows, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineConnected}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealLineConnectedUp.RealLineConnectedTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host open-cover connectedness, trichotomy, quotient stream equality, selected path objects, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, interval-chain visibility, intermediate-value routing, continuous-map handoff, dyadic-window exactness, and Real seal nonescape for BEDC.Derived.RealLineConnectedUp.

Constructive story: A $\mathsf{RealLineConnected}^{\uparrow}$ packet is generated from a Real source row, ConnectedInterval chain row, IntermediateValue sign route, ContinuousMap graph and modulus row, DyadicRatCore tolerance ledger, finite observation windows, regular readback, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3551

A Concrete Naming Certificate for $\mathsf{CauchyProductMetric}^{\uparrow}$

Following Bishop–Bridges on metric products and regular Cauchy names, the $\mathsf{CauchyProductMetric}^{\uparrow}$ packet records the finite product-metric surface used by two displayed CauchyProduct rows before any host product metric or Real completeness principle is available. It sits beside the product route of chapter 464, the metric carrier surface of chapter 57, the regular rational readback of chapter 301, the scheduled window layer of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is the regular-Cauchy specialization consumed by chapter 424 when the product-distance ledger is read as a metric packet, and by chapter 1506 when paired Cauchy windows are passed to completion-facing consumers. The packet gives downstream Real, metric, and Cauchy-completion consumers a non-quotient product-distance certificate over displayed rows only.

Definition 3551.1 (CauchyProductMetric carrier)**.** *A* $\mathsf{CauchyProductMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, R, W_L, W_R, Q_L, Q_R, D, \Delta, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two accepted* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows. Each row supplies a finite product-name route rather than host product equality.*
2. *W_L and W_R are the paired* $\mathsf{StreamName}^{\uparrow}$ *window rows inspected on the left and right product names.*
3. *Q_L and Q_R are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the two displayed window pairs.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-distance ledger. It records coordinate tolerances, the product-distance radius, the comparison budget, and the displayed error allowance used by the packet.*
5. *Δ is the* $\mathsf{Met}^{\uparrow}$ *distance row, read only through the displayed product windows, regular rational readbacks, and dyadic ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the product-distance read.*
7. *H records componentwise* hsame *transport for the CauchyProduct rows, stream windows, regular readbacks, dyadic ledger, metric row, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a product-metric request through $L, R, W_L, W_R, Q_L, Q_R, D, \Delta, E$.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyProductMetric}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, W_L, W_R, Q_L, Q_R, D, \Delta, E, H, C, P, N$. It has no coordinate for host product metrics, quotient stream equality, selected product limits, trichotomy, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyProductMetricUp.CauchyProductMetricTasteGate single carrier alignment`

Theorem 3551.2 (CauchyProductMetric NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductMetric}^{\uparrow}$ *carrier $M = (L, R, W_L, W_R, Q_L, Q_R, D, \Delta, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{CauchyProduct}^{\uparrow}$ *rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-distance ledger,* $\mathsf{Met}^{\uparrow}$ *distance row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, local naming, and refusal of host product metrics, quotient stream equality, selected product limits, trichotomy, detached real carriers, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 3551.1. The accepted packet exposes exactly the two CauchyProduct rows, paired stream windows, regular rational readbacks, dyadic product-distance ledger, metric row, Real seal, and structural rows.

The product-distance ledger is downstream of the displayed windows and readbacks. Thus D cannot be read before W_L, W_R, Q_L, Q_R have fixed the finite CauchyProduct observations.

The metric and Real rows are then forced through Δ and E. The distance row reads only the displayed dyadic ledger, and the seal row records the resulting product-distance value without adding a second carrier.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host product metrics, quotient stream equality, selected limits, trichotomy, detached real carriers, or ambient completeness, the listed obligations exhaust the local certificate surface. □

Theorem 3551.3 (CauchyProductMetric projection stability)**.** *Let $M = (L, R, W_L, W_R, Q_L, Q_R, D, \Delta, E, H, C, P,$ be an accepted* $\mathsf{CauchyProductMetric}^{\uparrow}$ *packet. Any projection-facing metric consumer that reads the left or right coordinate distance must factor through the same* $\mathsf{CauchyProduct}^{\uparrow}$ *source row, the same* $\mathsf{StreamName}^{\uparrow}$ *window row, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-distance ledger, and the same structural rows H, C, P, N. Projection reads may forget the unused coordinate, but they cannot introduce a host product metric, a quotient stream, a selected limit, or an independent real carrier.*

Proof. Start with a projection-facing read of the accepted packet. The only coordinate data exposed by the carrier are L, R together with their displayed window and regular readback rows.

For the left projection, the read passes through L, W_L, Q_L and then through the shared dyadic ledger D. For the right projection, the same argument uses R, W_R, Q_R and the same ledger.

The metric row Δ and Real seal E are downstream of this ledger. Forgetting one coordinate therefore removes data from the displayed packet, but it does not create a new metric source or a new Real-facing endpoint.

The structural rows H, C, P, N preserve exactly this projected route. The omitted coordinates in Definition 3551.1 rule out host product metrics, quotient streams, selected limits, and detached real carriers. □

Lean4 ✓ `BEDC.Derived.CauchyProductMetricUp.CauchyProductMetricProjectionStability`

Theorem 3551.4 (CauchyProductMetric Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyProductMetric}^{\uparrow}$ *packet must first display the finite route*

$$\mathsf{CauchyProduct}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

through the rows $L, R, W_L, W_R, Q_L, Q_R, D, \Delta, E, H, C, P, N$*. The Real seal is a product-distance seal for this displayed route only; it exports no host product metric, no quotient product of Cauchy streams, no selected product limit, no trichotomy row, no detached real carrier, and no ambient completeness witness.*

Proof. Begin with a Real-facing read. Carrier admission makes the two CauchyProduct rows visible, but no Real seal is available before the paired stream windows and regular readbacks have been displayed.

The dyadic ledger D records the product-distance budget attached to those windows. The metric row Δ can only read this ledger, so it cannot import a host product metric or a separate distance object.

The seal E is reached after Δ, and the continuation row C replays the same route for downstream Real, metric, or completion-facing consumers. The transport and provenance rows keep the endpoint tied to $L, R, W_L, W_R, Q_L, Q_R, D, \Delta$.

Thus the consumer receives exactly the finite product-distance route named by the local certificate. All quotient, selection, trichotomy, detached-carrier, host-metric, and ambient-completeness exits are outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductMetric}^{\uparrow}$ packet is generated from two CauchyProduct source rows, paired StreamName windows, RegSeqRat readbacks, a DyadicRatCore product-distance ledger, a MetricUp distance row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3551.1, Definition 3551.2, Definition 3551.3, and Definition 3551.4 seed the finite product-metric route from CauchyProduct rows through displayed windows, regular readbacks, dyadic product-distance ledgers, metric rows, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host product metrics, quotient stream equality, selected product limits, trichotomy, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-distance ledger exactness, projection stability, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductMetricUp.

Chapter 3552

A Concrete Naming Certificate for $\mathsf{RegularCauchySpaceMorphism}^{\uparrow}$

Following Bishop and Bridges on uniformly continuous maps between Cauchy presentations, the $\mathsf{RegularCauchySpaceMorphism}^{\uparrow}$ packet records the finite morphism surface between regular Cauchy sequence spaces before any completion equality or limiting representative is read. It sits after the source-space surface of chapter 3541, the finite window source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the Cauchy-name-space packet of chapter 406, and the completion-functor route of chapter 423. The packet is the L10 finite morphism interface consumed by completion-functor and Real-facing handoff chapters; it is not a proof of ambient completeness, quotient equality of streams, selected limits, or host equality of real names.

Definition 3552.1 (RegularCauchySpaceMorphism carrier)**.** *A* $\mathsf{RegularCauchySpaceMorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, T, A, W, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *row, including the source regular rational family, rate ledger, finite schedule, dyadic tolerance route, CauchySequenceSpace handoff, and Real seal.*
2. *T is the target* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *row, carrying the same visible sequence-space structure for the codomain presentation.*
3. *A is the finite-window action row assigning each accepted source window request to a displayed target window request.*
4. *W is the dyadic budget ledger recording the input precision, output precision, and finite modulus rows used by A.*
5. *D is the classifier-transport row, binding source acceptance to target acceptance through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *sibling routes.*
6. *H records componentwise* hsame *transport for source space, target space, action, budget ledger, classifier transport, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from each morphism request through the source finite window, action row, dyadic budget ledger, target finite window, target CauchySequenceSpace handoff, and target Real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySpaceMorphism}^{\uparrow}$, $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySpaceMorphism}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, A, W, D, H, C, P, N$. It has no coordinate for quotient stream equality, selected source or target limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySpaceMorphismUp.RegularCauchySpaceMorphismTasteGate single carrier alignment`

Theorem 3552.2 (RegularCauchySpaceMorphism NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySpaceMorphism}^{\uparrow}$ *carrier $M = (S, T, A, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySpaceMorphism}^{\uparrow}}$ *surface consists exactly of carrier admission, source-target compatibility, finite-window exactness, rate-ledger preservation, classifier transport, non-escape, displayed replay, provenance, and local naming.*

Source-target compatibility requires both S and T to be accepted $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *packets. Finite-window exactness requires A to transform only displayed source windows into displayed target windows. Rate-ledger preservation requires W to expose the dyadic input and output budget rows before any target seal is read. Classifier transport requires D to preserve the visible source and target classifiers through the same sibling routes named in the carrier. Non-escape refuses quotient stream equality, selected limits, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as certificate data.*

Proof. Project the carrier of Definition 3552.1. The rows S and T supply the source and target regular Cauchy sequence spaces, while A supplies only a displayed finite-window action between them.

Next read the dyadic budget and classifier transport rows. The budget ledger W records the precision rows consumed by the action, and D binds acceptance of the source and target windows through the named StreamName, RegSeqRat, DyadicRatCore, CauchySequenceSpace, and Real sibling routes.

Finally attach H, C, P, N. These rows preserve and replay the same finite morphism packet, so every local naming obligation is exhausted by the displayed tuple. Since the tuple has no quotient, selected-limit, countable-choice, host-equality, completeness, verification, or bridge coordinate, the refused objects cannot be exported by the NameCert surface. □

Theorem 3552.3 (RegularCauchySpaceMorphism finite-window exactness)**.** *Every accepted* RegularCauchySpaceM *read is exhausted by the displayed source and target regular Cauchy sequence-space rows, the finite-window action row, the dyadic budget ledger, classifier transport, componentwise transport, replay, provenance, and local naming:*

$$S, T, A, W, D, H, C, P, N.$$

Thus the morphism exports a finite L10 action between regular Cauchy sequence spaces. It exports no quotient stream equality, selected source limit, selected target limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted carrier $M = (S, T, A, W, D, H, C, P, N)$. The only source-space and target-space data available to the consumer are the displayed rows S and T, each read as a $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ packet.

Use Definition 3552.2. It places the action A behind finite windows and places the precision behavior behind the dyadic ledger W and classifier transport row D.

The structural rows H, C, P, N then transport, replay, source, and name only this route. No remaining coordinate can supply quotient stream equality, selected limits, countable choice, host real equality, or ambient real completeness, so every accepted morphism read is finite-window exact in the displayed sense. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySpaceMorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySpaceMorphism}^{\uparrow}$ packet is generated from source and target RegularCauchySequenceSpaceUp rows, a finite-window action, a dyadic budget ledger, classifier transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySpaceMorphism}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3552.1, Definition 3552.2, and Definition 3552.3 seed the finite morphism surface between regular Cauchy sequence spaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySpaceMorphism}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-target compatibility, finite-window exactness, rate-ledger preservation, classifier transport, non-escape, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.RegularCauchySpaceMorphismUp.

Chapter 3553

A Concrete Naming Certificate for $\mathsf{MetricCompletionComparison}^{\uparrow}$

Following Bishop and Bridges and Kelley on constructive metric completions, the $\mathsf{MetricCompletionComparison}^{\uparrow}$ packet records the finite comparison route by which two dense completions of the same metric source are read as the same completion surface. It sits after the universal-property surface of chapter 2319, the dense-source row of chapter 3542, the metric dense-image packet of chapter 3351, the regular Cauchy sequence-space packet of chapter 3541, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names constructive uniqueness of dense metric completions through displayed comparison rows; it is not a quotient representative theorem, not a selected-limit operator, not countable choice, and not an ambient completeness assertion for $\mathsf{Real}^{\uparrow}$.

Definition 3553.1 (MetricCompletionComparison carrier)**.** *A* $\mathsf{MetricCompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, D, E_0, E_1, S, R, W, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *row used twice, once to extend the first dense embedding into the second completion and once in the opposite direction.*
2. *D is the* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *row that fixes the common dense source before either comparison map is read.*
3. *E_0 and E_1 are* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *rows for the two displayed dense completions of the same metric source.*
4. *S is the* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *row recording the common regular Cauchy sequence-space interface inspected by both completions.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite regular rational windows of S.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule shared by the source, the two dense embeddings, and the comparison maps.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the precision budgets used to compare the two completion reads.*

8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* D, E_0, E_1, S, R, W, Q *have been displayed.*
9. *H records componentwise* hsame *transport for the dense-source, dense-embedding, sequence-space, readback, window, tolerance, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the two comparison directions and of the round-trip reads through the same finite rows.*
11. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionComparison}^{\uparrow}$*, the eight sibling chapters named above,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, D, E_0, E_1, S, R, W, Q, A, H, C, P, N$ and their displayed replay paths. It has no coordinate for quotient representatives, selected Cauchy limits, host equality of completion classes, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricCompletionComparisonUp.MetricCompletionComparisonTasteGate single carrier alignment`

Theorem 3553.2 (MetricCompletionComparison NameCert obligations)**.** *For every accepted* MetricCompletionCo*
carrier $K = (U, D, E_0, E_1, S, R, W, Q, A, H, C, P, N)$, the local $\mathsf{NameCert}_{\mathsf{MetricCompletionComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the universal-property row, common dense-source row, paired dense embeddings, regular Cauchy sequence-space row, regular rational readback, stream-window schedule, dyadic tolerance ledger, terminal real seal, componentwise transport, displayed replay, provenance, and local naming. The two comparison directions must read the same D, S, R, W, Q, A rows before either round-trip read is accepted.*

Proof. Project the carrier of Definition 3553.1. The rows $D, E_0, E_1, S, R, W, Q, A$ display the common source, the paired dense embeddings, the regular Cauchy sequence-space interface, the finite readback windows, the dyadic tolerances, and the terminal real-name seal.

Apply the universal-property row U in the two displayed directions. The first use extends E_0 across the dense source into the second completion surface, and the second use extends E_1 back across the same dense source. Both uses are forced to read the same dense-source, sequence-space, regular-readback, stream-window, tolerance, and seal rows.

The structural rows H, C, P, N then preserve, replay, source, and name that finite route. Since the carrier contains no row for quotient representatives, selected limits, host equality, countable choice, trichotomy, or ambient real completeness, no additional NameCert obligation can be projected from the packet. □

Theorem 3553.3 (MetricCompletionComparison universal route)**.** *Every constructive comparison between the two dense completions named by an accepted* $\mathsf{MetricCompletionComparison}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MetricCompletionDenseEmbedding}^{\uparrow},\ \mathsf{CauchyCompletionDensitySource}^{\uparrow},\ \mathsf{RegularCauchySequenceSpace}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}$$

The exported result is the displayed pair of comparison maps with finite round-trip evidence on the common dense source. It is not a quotient-completion equality proof, a selected representative, a selected limiting operator, a countable-choice principle, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the obligation surface of Definition 3553.2. A completion-comparison consumer must first read the paired dense-embedding rows E_0, E_1 and the common dense-source row D.

The finite observation route is then fixed by S, R, W, Q, A. The regular Cauchy sequence-space row supplies the shared source discipline, the regular rational and stream-window rows supply the inspected finite windows, the dyadic row supplies the precision ledger, and the real seal is reached only after those rows are displayed.

Finally use the two universal-property reads stored in U. They produce comparison maps in both directions and check the round-trip evidence only on the displayed dense source. Transport and replay through H and C, with provenance and local naming through P, N, preserve the same route and export no excluded host-side principle. □

Theorem 3553.4 (MetricCompletionComparison triangle route)**.** *Let two accepted* $\mathsf{MetricCompletionComparison}^{\uparrow}$ *packets compare a first dense completion surface to a middle dense completion surface and the same middle surface to a third dense completion surface over one displayed dense metric source. Then every completion-facing read from the first surface to the third surface factors through the two comparison packets in sequence: the common* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *row, the* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *row, the relevant* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *rows, the shared* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and the two local* $\mathsf{NameCert}_{\mathsf{MetricCompletionComparison}^{\uparrow}}$ *rows.*

The composite route exports only the finite comparison read obtained by passing through the middle surface. It exports no quotient representative, selected limit, host equality of completions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 3553.2 to the first-to-middle packet and again to the middle-to-third packet. The two projections expose the same obligation surface: dense source, universal-property row, dense embeddings, regular Cauchy sequence-space interface, regular rational readback, stream windows, dyadic tolerance ledger, real seal, transport, replay, provenance, and local naming.

Next apply Definition 3553.3 to each comparison packet. The first application gives the route from the first completion surface to the middle surface, while the second gives the route from the middle surface to the third surface. Both routes are constrained to read the displayed dense source and the same universal-property discipline before any completion-facing read is accepted.

Compose the displayed routes along the middle completion surface, using the shared dense-source and universal-property rows as the overlap. The componentwise hsame row transports the common finite rows across the overlap, and the Cont row replays the two comparison reads in sequence without adding a new observation coordinate.

The carrier of Definition 3553.1 has no field for quotient representatives, selected limits, host equality of completion classes, countable choice, or ambient real completeness. Therefore the composite route can export only the finite first-to-third comparison read assembled from the two displayed packets. □

Falsifiable prediction: Every accepted $\mathsf{MetricCompletionComparison}^{\uparrow}$ consumer that reaches a comparison map or round-trip read while omitting the common dense-source row, either dense-embedding row, the regular Cauchy sequence-space row, the RegSeqRat readback, the StreamName windows, the DyadicRatCore tolerance ledger, the Real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: cauchy-completion-universal-property, cauchy-completion-density-source, metric-completion-dense-embedding, regular-cauchy-sequence-space, regseqrat, streamname, dyadicratcore, real: no listed sibling is bijective with $\mathsf{MetricCompletionComparison}^{\uparrow}$ because the packet

jointly carries paired dense embeddings, a common dense source, two universal-property comparison directions, shared finite sequence-space readback, tolerance accounting, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionComparison}^{\uparrow}$ packet is generated from a CauchyCompletionUniversalProperty row, a CauchyCompletionDensitySource row, two MetricCompletionDenseEmbedding rows, a RegularCauchySequenceSpace row, RegSeqRat readback, StreamName windows, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3553.1, Definition 3553.2, Definition 3553.3, and Definition 3553.4 seed the finite comparison route for constructive uniqueness of dense metric completions over a common source.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected representatives, selected limits, countable choice, trichotomy, host equality of completion classes, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired dense-embedding exposure, common dense-source exactness, two universal-property comparison directions, round-trip evidence on the displayed source, finite readback and tolerance accounting, Real-seal routing, transport replay, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.MetricCompletionComparisonUp.

Chapter 3554

A Concrete Naming Certificate for $\mathsf{BaireTwoFunction}^{\uparrow}$

Following Baire and classical descriptive set theory, the $\mathsf{BaireTwoFunction}^{\uparrow}$ packet records the successor step from Baire-one real-valued maps to pointwise limits of Baire-one approximants as finite BEDC NameCert data. It sits over the $\mathsf{BaireOneFunction}^{\uparrow}$ surface of chapter 1604, the finite schedules of chapter 126, the regular rational readback of chapter 301, and the terminal real-value seal of chapter 38. The packet names only the displayed approximation ladder and its finite read route; it is not a host function-space quotient, a selected limiting function, a measurability theorem, or an ambient completeness assertion.

Definition 3554.1 (BaireTwoFunction carrier)**.** *A* $\mathsf{BaireTwoFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, A, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BaireOneFunction}^{\uparrow}$ *approximation-ladder row, listing the Baire-one packets whose pointwise observations are being inspected.*
2. *A is the finite ladder-admission row, naming the displayed source points, approximation indices, and precision requests visible to the successor packet.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite approximation windows opened for each displayed request.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational windows obtained from the selected Baire-one observations.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Baire-one ladder, displayed schedule, and regular rational readback have been replayed.*
6. *H records componentwise* hsame *transport for the Baire-one ladder, finite admission row, schedule windows, rational readback, real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a pointwise successor request through the Baire-one ladder, the stream schedule, the rational readback, the real seal, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{BaireTwoFunction}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireTwoFunction}^\uparrow}$ *row.*

The carrier has no coordinate for a host space of Baire-two functions, an arbitrary selected approximating ladder, quotient equality of real names, full Borel hierarchy closure, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.BaireTwoFunctionUp.TasteGate.BaireTwoFunctionTasteGate single carrier alignment`

Theorem 3554.2 (BaireTwoFunction NameCert obligations)**.** *For every accepted* $\mathsf{BaireTwoFunction}^\uparrow$ *carrier* $T = (B, A, S, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireTwoFunction}^\uparrow}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Baire-one approximation ladder, ladder-admission row, schedule windows, rational readback, real seal, componentwise transport, displayed continuation, provenance, and local naming rows;*
2. *Baire-one ladder exposure, requiring every successor observation to pass first through a displayed* $\mathsf{BaireOneFunction}^\uparrow$ *row in B;*
3. *schedule exactness, requiring every approximation request to use only the finite* $\mathsf{StreamName}^\uparrow$ *windows named by S after the ladder-admission row A is displayed;*
4. *readback exactness, requiring the value read to pass through the* $\mathsf{RegSeqRat}^\uparrow$ *row Q before the* $\mathsf{Real}^\uparrow$ *seal R is available;*
5. *transport and replay stability, requiring H and C to preserve the same route B, A, S, Q, R componentwise;*
6. *ledger refusal, excluding host function-space quotients, selected limiting functions, arbitrary ladder choice, quotient equality of real names, full Borel hierarchy closure, and ambient* $\mathsf{Real}^\uparrow$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 3554.1. The rows B, A, S, Q, R are the only analytic rows available to a consumer, and H, C, P, N are the only structural rows attached to them.

The successor step begins with the Baire-one ladder B. The admission row A fixes the displayed source points, approximation indices, and precision requests before any schedule window can be opened.

The schedule and readback rows then force the finite route. A request reads the $\mathsf{StreamName}^\uparrow$ windows in S, checks the selected observations through the $\mathsf{RegSeqRat}^\uparrow$ row Q, and reaches the $\mathsf{Real}^\uparrow$ seal R only after those rows have been replayed.

Transport, continuation, provenance, and local naming preserve exactly this route. Since no carrier coordinate stores a host function space, selected limiting function, arbitrary ladder choice, quotient real equality, full Borel hierarchy closure, or ambient real completeness, the listed rows exhaust the NameCert surface. □

Theorem 3554.3 (BaireTwoFunction Baire-one handoff)**.** *Every* $\mathsf{BaireOneFunction}^\uparrow$ *approximation consumed by an accepted* $\mathsf{BaireTwoFunction}^\uparrow$ *packet is read before the* $\mathsf{StreamName}^\uparrow$ *schedule,* $\mathsf{RegSeqRat}^\uparrow$ *readback, and* $\mathsf{Real}^\uparrow$ *seal. Thus every successor value exported by the packet factors through*

$$B, A, S, Q \longmapsto R.$$

The handoff exposes a finite pointwise successor route from Baire-one data to real seals and exports no host function-space quotient, selected limiting function, arbitrary ladder selector, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a consumer of the value seal R. By carrier admission, R is downstream of the same packet that contains the Baire-one ladder B, the admission row A, the schedule S, and the readback row Q.

Replay the continuation row C. The consumer first reads a displayed $\mathsf{BaireOneFunction}^{\uparrow}$ approximation from B, then uses A to identify the pointwise request and the finite approximation window available to the packet.

The schedule row S selects only those displayed windows, and the regular rational row Q reads the selected observations before R is exposed. Componentwise transport by H preserves this order for every accepted carrier.

The provenance and local naming rows contain no host function-space quotient, selected limiting function, arbitrary ladder selector, quotient real equality, or ambient completeness coordinate. Hence the exported successor value is only the displayed finite Baire-one handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireTwoFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireTwoFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3554.1, Definition 3554.2, and Definition 3554.3 seed the finite Baire-two successor packet over Baire-one ladders, finite schedules, rational readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireTwoFunction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BaireTwoFunctionUp.TasteGate.BaireTwoFunctionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host function-space quotients, selected limiting functions, arbitrary ladder choice, quotient equality of real names, full Borel hierarchy closure, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Baire-one ladder exposure, schedule exactness, rational readback exactness, real-seal nonescape, transport stability, provenance, and ledger refusal for BEDC.Derived.BaireTwoFunctionUp.

Constructive story: A $\mathsf{BaireTwoFunction}^{\uparrow}$ packet is generated from a BaireOneFunction approximation ladder, finite request admission, StreamName schedule windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3555

A Concrete Naming Certificate for $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$

The $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$ packet realizes the Alexander-dual trigger and blocker algebra of subsection 9462.28.21 as finite BEDC NameCert data. It sits over the finite $\mathsf{Bool}^{\uparrow}$ tag discipline of chapter 32, the finite observation interface of chapter 1007, the DNA boundary-tile carrier of chapter 3393, the six-tile coverage packet of chapter 3470, the boundary-trigger closure packet of chapter 3508, and the finite coverage-trigger algebra of chapter 3478. The packet names the blocker-dual surface as finite rows; it is not a polynomial-ring oracle, stochastic biological model, quotient codon semantics, infinite trigger search, or hidden Alexander-duality principle.

Definition 3555.1 (AlexanderDualTriggerAlgebra carrier)**.** *An* $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, T, I, U, L, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the boundary-tile carrier row read through* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *and* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$.
2. *T is the trigger row recording the finite coordinate supports whose full-trigger behavior is visible.*
3. *I is the inactive-face row recording the complements that remain blocked by a missed coordinate.*
4. *U is the blocker-dual cover row, carrying the four displayed dual generator faces and their finite lcm-degree ledger.*
5. *L is the* $\mathsf{Bool}^{\uparrow}$ *and finite-observation ledger that tags present, absent, trigger, blocker, active, and inactive faces without importing host truth values.*
6. *R is the transport row from boundary tiles through* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ *and* WindowCoverageTriggerAlgeb *to the displayed blocker-dual cover.*
7. *H records componentwise* hsame *transport for boundary tiles, trigger rows, inactive faces, blocker-dual cover rows, finite tags, algebra transport, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from each dual-trigger read through B, T, I, U, L, R, H.*
9. *P is the* Pkg *provenance over* $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{FiniteObservationInterface}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, WindowCoverageTriggerA *the Alexander-dual trigger source vision,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, T, I, U, L, R, H, C, P, N$. It has no coordinate for host polynomial equality, ambient monomial ideals, stochastic evolutionary dynamics, quotient codon equality, infinite trigger search, or a hidden duality oracle.

Theorem 3555.2 (AlexanderDualTriggerAlgebra NameCert obligations)**.** *For every accepted* AlexanderDualTrigger *carrier $A = (B, T, I, U, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}}$ *surface consists exactly of boundary-tile admission, trigger-row exposure, inactive-face exposure, blocker-dual cover exactness, finite Bool and observation tagging, algebra transport, componentwise transport, displayed replay, provenance, and local naming.*

The blocker-dual cover row U is accepted only when its trigger and blocker faces are read through the displayed B, T, I, L, R route. Any consumer that attempts to read Alexander-dual data without those rows, or that replaces them by host polynomial equality, an ambient ideal, quotient codon semantics, stochastic dynamics, infinite search, or a hidden duality oracle, leaves the accepted packet surface.

Proof. Project the carrier of Definition 3555.1. The rows B, T, I, U, L, R expose the boundary-tile source, trigger supports, inactive faces, blocker-dual cover, finite tag ledger, and transport from the boundary-trigger algebra.

The cover row is finite. It records only the four displayed dual generator faces and their lcm-degree ledger, with $\mathsf{Bool}^{\uparrow}$ and finite-observation rows marking which faces are present, absent, active, inactive, triggering, or blocking.

Finally H, C, P, N preserve the same displayed route. Since no host polynomial equality, ambient ideal, stochastic model, quotient codon equality, infinite search, or hidden duality oracle is a carrier coordinate, the local NameCert obligations are exactly the listed finite rows. □

Theorem 3555.3 (AlexanderDualTriggerAlgebra blocker-duality nonescape)**.** *Every accepted* AlexanderDualTrigge *read factors through displayed trigger, blocker, inactive-face, dual-cover, transport, replay, provenance, and local* NameCert *rows:*

$$B, T, I, U, L, R, H, C, P, N.$$

In particular, a dual-trigger consumer cannot replace the blocker-duality row by the $\mathsf{Bool}^{\uparrow}$ *tag discipline alone, by finite observation alone, by boundary closure alone, by trigger-hypergraph reliability alone, by universal coverage-trigger algebra alone, or by any host polynomial-ring equality.*

Proof. Read the boundary source first. The row B supplies the boundary tiles and coverage rows, while T and I separate visible trigger supports from inactive faces.

Next read the blocker-dual data. The row U carries the dual-cover faces, and L records the finite Bool and observation tags needed to distinguish trigger, blocker, active, and inactive positions.

The algebra transport R then ties those rows to the boundary-trigger closure and coverage-trigger algebra siblings. The structural rows H, C, P, N preserve the same route, so no sibling alone can absorb the blocker-duality coordinate and no host polynomial equality can be exported. □

Falsifiable prediction: Every accepted $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$ read factors through displayed trigger, blocker, inactive-face, dual-cover, transport, replay, provenance, and local NameCert rows; omitting any of those rows refutes the packet.

Independence witness: bool, finite-observation-budget-selector, dna-boundary-trigger-closure, trigger-hypergraph-reliability, universal-coverage-trigger-algebra: no listed sibling is bijective with $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$ because the packet jointly carries trigger rows, blocker rows, inactive-face rows, dual-cover rows, finite tag ledgers, algebra transport, replay, provenance, and local

naming. A bijection preserving only finite tags, observation budgets, boundary closure, reliability, or coverage-trigger closure cannot preserve the blocker-duality row U together with the inactive-face row I.

The Lean follow-up `BEDC.Derived.AlexanderDualTriggerAlgebraUp.TasteGate` supplies explicit Nontrivial AlexanderDualTriggerAlgebra$^{\uparrow}$ and FieldFaithful AlexanderDualTriggerAlgebra$^{\uparrow}$ instances preserving $B, T, I, U, L, R, H, C, P, N$ as separate displayed fields.

Closure status for NameCert$_{\text{AlexanderDualTriggerAlgebra}^{\uparrow}}$.

Constructive story: An AlexanderDualTriggerAlgebra$^{\uparrow}$ packet is generated from boundary-tile rows, trigger rows, inactive-face rows, blocker-dual cover rows, finite Bool and observation ledgers, algebra transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{AlexanderDualTriggerAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 3555.1, Definition 3555.2, and Definition 3555.3 seed the finite Alexander-dual trigger and blocker NameCert packet.

Formal verification: FormalStatus(NameCert$_{\text{AlexanderDualTriggerAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host polynomial equality, ambient monomial ideals, stochastic biological dynamics, quotient codon equality, infinite trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trigger-row exposure, blocker-dual cover exactness, inactive-face accounting, finite tag and observation ledgers, algebra transport, Nontrivial AlexanderDualTriggerAlgebraUp, and FieldFaithful AlexanderDualTriggerAlgebraUp for BEDC.Derived.AlexanderDualTriggerAlgebraUp.

Chapter 3556

A Concrete Naming Certificate for $\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}$

Following Moore–Smith and Kelley, the $\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}$ packet records the finite criterion by which a directed Cauchy net exposes a convergence-facing subnet route without adding a selected subnet object or a choice principle. It sits over the directed-index surface of chapter 1607, the Moore–Smith carrier of chapter 3403, the Cauchy-net surface of chapter 589, the convergence interface of chapter 1667, the regular-rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a NameCert boundary for the L10 completion route: it records directed tails, Cauchy windows, subnet witnesses, and Real-facing readback rows, not a quotient of nets or an ambient compactness theorem.

Definition 3556.1 (Moore–Smith Cauchy subnet criterion carrier)**.** *A* $\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, M, A, W, B, N, S, G, Y, R, H, C, P, L)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index row naming finite vertices, preorder comparisons, and upper-window witnesses.*
2. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *row exposing directed net values and the tail ledger consumed by the criterion.*
3. *A is the* $\mathsf{CauchyNet}^{\uparrow}$ *row recording the common-window Cauchy evidence read on the same directed surface.*
4. *W is the cofinal subnet-window row, listing the finite tail requests and their displayed upper refinements.*
5. *B is the subnet bound row, recording how each requested late window in M is met by a later displayed witness in W.*
6. *N is the* $\mathsf{NetConvergence}^{\uparrow}$ *consumer row that reads the subnet route only after D, M, A, W, B have been displayed.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule for finite observation windows along the accepted subnet route.*
8. *G is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the scheduled observations.*

9. *Y is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those stream windows and dyadic tolerances.*
10. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, G, Y are displayed.*
11. *H records componentwise* hsame *transport for all criterion rows.*
12. *C records displayed* Cont *replay through the same directed-tail and readback route.*
13. *P is the* Pkg *provenance over* $\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
14. *L is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}}$ *row.*

The carrier has no coordinate for a globally chosen subnet, quotient-net equality, countable choice, an ambient compactness theorem, or host-level real completeness.

Lean4 ✓ `BEDC.Derived.MooreSmithCauchySubnetCriterionUp.MooreSmithCauchySubnetCriterionTasteGate`
`single carrier alignment`

Theorem 3556.2 (Moore–Smith Cauchy subnet criterion NameCert obligations)**.** *For an accepted carrier $Q = (D, M, A, W, B, N, S, G, Y, R, H, C, P, L)$ of Definition 3556.1, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCauchySubnetCr}}$ *surface consists exactly of carrier admission, directed-index exposure, Moore–Smith tail exposure, Cauchy-window exposure, cofinal subnet-window evidence, subnet-bound compatibility, NetConvergence handoff, StreamName scheduling, DyadicRatCore tolerance comparison, RegSeqRat readback, Real seal exposure, componentwise transport, displayed route replay, provenance, and local naming.*

Proof. Carrier admission projects the finite packet of Definition 3556.1. The directed evidence is stored in D, M, A, W, B, so the criterion first reads the index row, Moore–Smith net row, Cauchy-net row, cofinal subnet windows, and subnet bounds.

The convergence-facing handoff is then N. By chapter 1667, a convergence consumer reads only displayed directed-tail evidence before it reaches filter or Real-facing rows.

The Real-facing part is S, G, Y, R. The StreamName, DyadicRatCore, RegSeqRat, and Real chapters supply finite observation windows, dyadic tolerances, regular-rational readback, and the terminal seal, so the packet does not need a hidden completed limit.

Finally H, C, P, L transport, replay, name, and certify exactly those rows. Since no other coordinate is present, the listed obligations exhaust the local NameCert surface. □

Theorem 3556.3 (Moore–Smith directed-tail handoff)**.** *Every* $\mathsf{NetConvergence}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DirectedSet}^{\uparrow},\ \mathsf{MooreSmithNet}^{\uparrow},\ \mathsf{CauchyNet}^{\uparrow} \longmapsto W, B \longmapsto \mathsf{NetConvergence}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{R}$$

The route supplies directed tails, Cauchy common-window evidence, subnet-window refinements, and finite readback rows only through the displayed carrier. It does not export a selected subnet function, quotient net, countable-choice selector, ambient compactness statement, or host-level completeness witness.

Proof. Start with the directed rows D, M, A. The $\mathsf{DirectedSet}^{\uparrow}$ row names upper-window witnesses, the $\mathsf{MooreSmithNet}^{\uparrow}$ row names the net-value and tail ledger, and the $\mathsf{CauchyNet}^{\uparrow}$ row names common-window evidence on that same directed surface.

The subnet criterion is the displayed pair W, B. The row W records the finite cofinal windows, while B records that each requested late Moore–Smith window is met by a later displayed witness.

The handoff to $\mathsf{NetConvergence}^{\uparrow}$ reads only after these rows are present. The downstream Real-facing rows S, G, Y, R are then the finite StreamName, DyadicRatCore, RegSeqRat, and Real seal route.

Transport, replay, provenance, and naming through H, C, P, L preserve the same carrier. Thus every accepted consumer factors through the displayed directed-tail handoff, and the excluded subnet-selection, quotient, choice, compactness, and host-completeness routes have no export row. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}$ packet is generated from directed indices, a Moore–Smith net row, a CauchyNet row, cofinal subnet windows, subnet-bound compatibility, a NetConvergence handoff, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3556.1, Definition 3556.2, and Definition 3556.3 seed the finite directed-tail subnet criterion used by L10 completion and compactness-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithCauchySubnetCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subnets, quotient nets, countable choice, compactness, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, directed-index exposure, Moore–Smith tail exposure, Cauchy-window exposure, cofinal-window compatibility, convergence handoff, Real-facing readback, transport preservation, and local naming for the displayed criterion packet.

Chapter 3557

A Concrete Naming Certificate for $\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}$

Following Moore–Smith and Kelley-style net convergence, the $\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}$ packet records the standard completeness criterion that every displayed Cauchy net on the metric surface has a displayed convergence endpoint. It sits beside the Moore–Smith net carrier of chapter 3403, the Cauchy-net surface of chapter 589, the convergence interface of chapter 1667, the completeness row of chapter 128, and the Cauchy-subnet criterion of chapter 3556. The packet is a finite completion-facing NameCert route: it names directed tails, Cauchy evidence, endpoint convergence, regular-rational readback, and the terminal real seal without asserting countable choice, quotient equality, or an ambient host-completeness oracle.

Definition 3557.1 (Moore–Smith completeness criterion carrier)**.** *A* $\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, M, A, N, E, K, S, G, R, Y, H, C, P, L)$$

with the following displayed rows:

1. *D is the directed Moore–Smith index row, exposing finite comparison windows and common upper-window witnesses before any Cauchy request is read.*
2. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *row over D, recording net values, tail windows, and the directed route consumed by the criterion.*
3. *A is the* $\mathsf{CauchyNet}^{\uparrow}$ *evidence row, recording the common-window Cauchy estimates on the same Moore–Smith directed surface.*
4. *N is the* $\mathsf{NetConvergence}^{\uparrow}$ *endpoint row, exposing the displayed candidate endpoint and the convergence windows that the Cauchy evidence hands to the consumer.*
5. *E is the endpoint-admission row, recording that the endpoint inspected by N is the same completion-facing object read by the net consumer.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completeness row, used only as the displayed service that accepts the Cauchy-net evidence and returns the endpoint convergence row.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule for finite observation windows along the Cauchy and convergence reads.*

8. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream windows and the displayed convergence estimates.*
9. *R is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the scheduled Cauchy and endpoint estimates.*
10. *Y is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the stream, regular-rational, and dyadic rows have been displayed.*
11. *H records componentwise* hsame *transport for the directed surface, Moore–Smith net row, Cauchy evidence, convergence endpoint, completeness row, readback rows, routes, provenance, and local naming.*
12. *C records displayed* Cont *replay through the same Cauchy-net-to-convergence route.*
13. *P is the* Pkg *provenance over* $\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
14. *L is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}}$ *row.*

The carrier has no coordinate for countable choice, quotient equality of nets, a selected family of limits, an ambient host-completeness oracle, or completeness of $\mathsf{Real}^{\uparrow}$ *outside the displayed readback route.*

Theorem 3557.2 (Moore–Smith completeness criterion NameCert obligations)**.** *For an accepted carrier $Q = (D, M, A, N, E, K, S, G, R, Y, H, C, P, L)$ of Definition 3557.1, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCompletenessCri}}$ *surface consists exactly of carrier admission, directed Moore–Smith index exposure, net-value and tail exposure, CauchyNet evidence, NetConvergence endpoint admission, endpoint compatibility, CompleteMetric service exposure, StreamName scheduling, RegSeqRat readback, DyadicRatCore tolerance comparison, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission projects the finite packet of Definition 3557.1. The directed and net rows D, M must be visible before the Cauchy row A can be inspected.

The endpoint-facing rows are N, E, K. The $\mathsf{CompleteMetric}^{\uparrow}$ service row K accepts the displayed CauchyNet evidence and exposes the $\mathsf{NetConvergence}^{\uparrow}$ endpoint row N, while E records that the same endpoint is read by the convergence consumer.

The numerical readback rows are S, G, R, Y. They provide finite stream windows, regular-rational readback, dyadic tolerance comparisons, and the terminal real-name seal for the displayed convergence estimates.

Finally H, C, P, L transport, replay, source, and name the same rows. Because no other coordinate occurs in the carrier, no NameCert obligation can appeal to countable choice, quotient equality, a selected family of limits, an ambient host-completeness oracle, or a separate $\mathsf{Real}^{\uparrow}$ completeness principle. □

Theorem 3557.3 (Moore–Smith completeness criterion Cauchy-net handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}$ *packet that starts from a displayed* $\mathsf{CauchyNet}^{\uparrow}$ *row must factor through*

$$\mathsf{MooreSmithNet}^{\uparrow},\ \mathsf{CauchyNet}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{NetConvergence}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicR}$$

The handoff supplies endpoint convergence as finite NameCert data and exports no countable-choice selector, quotient equality of nets, selected family of limits, ambient host-completeness oracle, or standalone $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the Moore–Smith and Cauchy rows. The row M records the directed net windows, and A records the common-window Cauchy estimates on the same directed surface.

The completeness service is the displayed row K. It can be read only after M and A are present, and it returns the endpoint-facing convergence row N together with the endpoint compatibility row E.

The readback route is finite. Rows S, G, R, Y record the observation windows, regular-rational estimates, dyadic tolerance comparisons, and terminal real-name seal attached to the endpoint convergence data.

Transport, replay, provenance, and local naming through H, C, P, L preserve this route. The excluded choice, quotient, selected-limit-family, host-completeness, and standalone real-completeness principles have no export row in the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}$ packet is generated from directed Moore–Smith net rows, CauchyNet evidence, NetConvergence endpoint rows, a CompleteMetric service row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparisons, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3557.1, Definition 3557.2, and Definition 3557.3 seed the finite Moore–Smith criterion by which displayed Cauchy-net evidence hands a convergence endpoint to completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithCompletenessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient equality of nets, selected families of limits, ambient host-completeness, standalone $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, directed-net exposure, CauchyNet evidence, CompleteMetric service exposure, NetConvergence endpoint compatibility, finite readback routing, transport preservation, and local naming for the displayed criterion packet.

Chapter 3558

A Concrete Naming Certificate for $\mathsf{ReassignmentSupportCompression}^{\uparrow}$

The $\mathsf{ReassignmentSupportCompression}^{\uparrow}$ packet realizes the codon reassignment support compression branch of the DNA six-bit boundary tile analysis as finite NameCert data. The support row is read through the six-bit codon window of chapter 2234 and the boundary-tile coverage surface of chapter 3470; the compression packet therefore consumes those displayed coordinate and coverage rows before it names motif and prime-cover data. It packages the displayed 13-codon support, five-motif formula, seven prime implicants, and unique five-motif prime cover from Definition 9462.1274 through finite transport and replay rows, rather than treating the support as a host-side Boolean simplification oracle.

Falsifiable prediction: Every accepted $\mathsf{ReassignmentSupportCompression}^{\uparrow}$ read factors through displayed codon support, motif-expansion, prime-implicant, minimal-cover, transport, replay, provenance, and local NameCert rows.

Independence witness: codon-six-bit-window, stopcodonzeckendorfsuffix, codon-transition-matrix, bitvector: none is bijective to $\mathsf{ReassignmentSupportCompression}^{\uparrow}$ because this packet simultaneously binds the reassigned 13-codon support, five-motif expansion, seven prime implicants, unique minimum prime cover, transport, replay, provenance, and local naming rows. The six-bit window carrier supplies coordinates without the support theorem; the Zeckendorf suffix row names a stop-codon boundary; the transition matrix records table movement; and a raw bitvector lacks motif and cover obligations.

Definition 3558.1 (ReassignmentSupportCompression carrier)**.** *A* $\mathsf{ReassignmentSupportCompression}^{\uparrow}$ *carrier is a finite packet*

$$K = (S, M, I, U, H, C, P, N)$$

with the following visible rows:

1. *S is the displayed reassigned support row containing exactly the* 13 *codons of Definition 9462.1275;*
2. *M is the five-motif expansion row recording* CUN, AGR, UNA, WWA, *and* UAR *as the support formula;*
3. *I is the prime-implicant row recording exactly the seven maximal exact subcubes of Definition 9462.1280;*
4. *U is the minimal-cover row recording the unique five-prime cover of Definition 9462.1281;*

5. *H stores componentwise* hsame *transport for the support, motif, prime-implicant, minimal-cover, provenance, and local naming rows;*
6. *C stores the displayed* Cont *replay route from codon support to motif expansion, from motif expansion to prime implicants, and from prime implicants to the minimum-cover row;*
7. *P is the* Pkg *provenance over the DNA six-bit boundary tile source rows,* BHist, hsame, Cont, *and* NameCert*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ReassignmentSupportCompression}^{\uparrow}}$ *row.*

The carrier contains no host Boolean minimizer, no unbounded codon-table oracle, no genetic-code semantics beyond the displayed reassignment support, and no quotient identifying support lists with motif certificates.

Theorem 3558.2 (ReassignmentSupportCompression NameCert obligations)**.** *Every accepted* ReassignmentSuppo *packet satisfies the following finite obligations:*

1. *carrier admission exposes the support, motif, prime-implicant, minimal-cover, transport, replay, provenance, and NameCert rows of Definition 3558.1;*
2. *support exactness identifies S with the displayed* 13*-codon reassigned support and rejects any added or omitted codon;*
3. *motif expansion identifies M with the five IUPAC motifs whose union is the same support;*
4. *prime-cover compression identifies I with the seven prime implicants and U with the unique five-prime cover;*
5. *nonescape prevents a consumer from replacing the displayed rows by a host minimizer, a raw bitvector equality, a transition-matrix equivalence, a stop-codon suffix rule, or an unbounded codon-table oracle.*

Lean4 ✓ `BEDC.Derived.ReassignmentSupportCompressionUp.ReassignmentSupportCompressionNameCertObligations`

Proof. Project the carrier rows of Definition 3558.1. The support row S is the only entry point for codon membership, and the continuation row C replays it first into the five-motif row M.

Next replay M through the finite prime-implicant enumeration row I. This preserves exactly the displayed maximal exact subcubes because every admitted implicant is checked against the already fixed support row.

Finally project the minimal-cover row U from I. The package, transport, replay, and local naming rows carry no additional semantic oracle, so a consumer cannot bypass the finite support, motif, prime-implicant, and cover rows. The Lean follow-up will provide ‘Nontrivial ReassignmentSupportCompressionUp‘ and ‘FieldFaithful ReassignmentSupportCompressionUp‘ in ‘lean4/BEDC/Derived/ReassignmentSupportCompressionUp/TasteGate.lean‘. □

Theorem 3558.3 (ReassignmentSupportCompression sibling lattice)**.** *Every accepted* ReassignmentSupportCompre *consumer must read the codon six-bit window of chapter 2234, the stop-codon Zeckendorf suffix surface of chapter 1374, the codon transition matrix of chapter 2245, and the bitvector carrier of chapter 346 before treating the five-motif row M and the prime-cover rows I, U as support-compression data.*

Thus the packet is read as a horizontal lattice over displayed codon coordinates, stop-boundary suffixes, transition rows, and finite bitvector surfaces. It cannot be consumed as an isolated Boolean minimization certificate, a raw support bitvector, a stop-codon suffix rule, or a transition-matrix equivalence.

Proof. Project the carrier of Definition 3558.1. The support row S is already tied to displayed codon membership, and the packet's provenance row names the DNA six-bit boundary tile source rows before the motif row is replayed.

Read the sibling surfaces in order. The codon six-bit window supplies the coordinate surface, the stop-codon Zeckendorf suffix supplies the stop-boundary comparison row, the codon transition matrix supplies table-movement visibility, and the bitvector carrier supplies the finite support encoding boundary.

Only after those sibling rows are visible can the consumer interpret M, I, U as support-compression rows. Since the carrier contains no host Boolean minimizer, raw bitvector equality, isolated suffix rule, or transition-matrix quotient, the five-motif and prime-cover rows remain downstream of the sibling lattice. □

Closure status for $\mathsf{NameCert}_{\mathsf{ReassignmentSupportCompression}\uparrow}$.

Constructive story: A $\mathsf{ReassignmentSupportCompression}^{\uparrow}$ packet is generated from the reassigned codon support, five-motif expansion, seven-prime-implicant surface, unique minimum prime cover, componentwise transport, displayed replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReassignmentSupportCompression}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3558.1 and Definition 3558.2 seed the finite support-compression route for the reassignment support branch.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReassignmentSupportCompression}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a checked Lean certificate, genetic-code semantics outside the displayed support, host Boolean minimization, table-transition completeness, or biological causality.

Upgrade path: Obligation closure requires checked carrier admission, support exactness, motif expansion, prime-implicant enumeration, minimum-cover uniqueness, and nonescape from host minimizers.

Chapter 3559

A Concrete Naming Certificate for $\mathsf{TopologicalClosure}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{TopologicalClosure}^{\uparrow}$ packet records closure of a displayed subset through finite neighbourhood evidence. It sits after the metric closure certificate of chapter 3342, the metric source of chapter 57, the topology surface of chapter 88, the finite ball discipline of $\mathsf{MetricBall}^{\uparrow}$, and the terminal real-name seal of chapter 38. The packet names a topological closure interface for BEDC neighbourhood reads; it is not a host closure operator, not a powerset completion, not quotient equality, not open-cover compactness, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 3559.1 (TopologicalClosure carrier)**.** *A* $\mathsf{TopologicalClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, x, U, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row naming the finite neighbourhood request surface.*
2. *S is the displayed subset row whose closure is being tested.*
3. *x is the candidate point row, readable only through the same neighbourhood requests.*
4. *U is the neighbourhood-hit ledger, pairing each displayed neighbourhood of x with a retained source witness from S.*
5. *B is the optional* $\mathsf{MetricBall}^{\uparrow}$ *refinement row when the topology is read through metric balls.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the retained neighbourhood and witness observations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for metric radii and witness distances when a metric refinement is present.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the neighbourhood, ball, window, and readback rows have been displayed.*
9. *H records componentwise* hsame *transport for the topology, subset, candidate, neighbourhood ledger, metric-ball refinement, windows, readback, and Real seal rows.*
10. *C records displayed* Cont *replay from neighbourhood requests to source witnesses, through optional metric balls, finite windows, regular readback, and the Real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{TopologicalClosure}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{MetricClosure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{TopologicalClosure}^{\uparrow}}$ *row.*

The classifier accepts only packets whose topology row, subset row, candidate point, neighbourhood-hit ledger, optional metric-ball refinement, finite windows, rational readbacks, Real seal, transport, replay, provenance, and local naming are all displayed. It has no coordinate for a host closure operator, arbitrary open-set quantification, powersets, quotient equality, countable choice, or ambient completion of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.TopologicalClosureUp.TopologicalClosureTasteGate single carrier alignment`

Theorem 3559.2 (TopologicalClosure NameCert obligations)**.** *For every accepted* $\mathsf{TopologicalClosure}^{\uparrow}$ *carrier* $K = (T, S, x, U, B, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TopologicalClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for the ambient topology row, displayed subset row, candidate point row, neighbourhood-hit ledger, optional metric-ball refinement, StreamName windows, RegSeqRat readback, RealUp sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public closure read must pass through those rows before it can consume the candidate point as closure evidence.*

Proof. Project the accepted carrier to the displayed rows $T, S, x, U, B, W, R, E, H, C, P, N$. The topology, subset, and candidate rows give the only admissible source data for a closure read.

The ledger row U binds each neighbourhood request around x to a retained source witness from S. When the topology is read metrically, the row B refines that same request through finite $\mathsf{MetricBall}^{\uparrow}$ data before the window row W and readback row R are exposed.

Finally E, H, C, P, N seal, transport, replay, source, and name the same displayed packet. Since no row stores a host closure operator, a powerset, quotient equality, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the NameCert obligations are exhausted by the listed rows. □

Theorem 3559.3 (TopologicalClosure metric neighbourhood route)**.** *Every* $\mathsf{MetricClosure}^{\uparrow}$ *or metric-topology consumer of an accepted* $\mathsf{TopologicalClosure}^{\uparrow}$ *packet reads a candidate closure point through the finite route*

$$T, S, x, U, B, W, R, E, H, C, P, N.$$

The consumer receives a topology row, displayed subset row, candidate point, neighbourhood-hit ledger, metric-ball refinement, finite StreamName windows, RegSeqRat readbacks, RealUp seal, transport, replay, provenance, and local naming. It receives no ambient closure operator, arbitrary open-set family, quotient-set equality, selected convergent net, or RealUp completeness theorem.

Proof. Start with a metric-neighbourhood consumer. The carrier exposes the candidate point x only together with the common topology row T and source subset row S, so the consumer cannot detach the candidate from the displayed neighbourhood interface.

Use the ledger U to align each neighbourhood read with a source witness. The metric-ball row B, finite window row W, regular rational row R, and Real seal E then give the same finite evidence surface used by the $\mathsf{MetricClosure}^{\uparrow}$ packet of chapter 3342.

The rows H, C, P, N preserve that route under transport, replay, provenance, and naming. Thus the handoff is the finite topological closure surface itself, not a stronger host closure, selected net, powerset, quotient, or completeness principle. □

Falsifiable prediction: Every $\mathsf{TopologicalClosure}^{\uparrow}$ public read factors through a Topology row, a displayed subset row, a candidate point row, a neighbourhood-hit ledger, optional MetricBall refinement, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed continuation, package provenance, and local naming.

Independence witness: topology, metric, metric-closure, streamname, regseqrat, real: $\mathsf{TopologicalClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a neighbourhood-hit ledger, optional metric-ball refinement, finite windows, rational readbacks, Real sealing, transport, replay, provenance, and local naming for closure evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{TopologicalClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{TopologicalClosure}^{\uparrow}$ packet is generated from a Topology row, displayed subset row, candidate point, neighbourhood-hit ledger, optional MetricBall refinement, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TopologicalClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3559.1, Definition 3559.2, and Definition 3559.3 seed the finite topological closure interface for displayed neighbourhood evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TopologicalClosure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.TopologicalClosureUp.TopologicalClosureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host topological closure operators, arbitrary open-set families, selected convergent nets, quotient equality, $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood-hit stability, metric-ball refinement, StreamName and RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TopologicalClosureUp.

Chapter 3560

A Concrete Naming Certificate for $\mathsf{UniformSpaceCompletion}^{\uparrow}$

Following Bourbaki–Kelley uniform-space completion practice, the $\mathsf{UniformSpaceCompletion}^{\uparrow}$ packet records the finite route by which a uniform entourage source admits Cauchy-filter or Cauchy-net data, passes through dense-source and separated-reflection rows, and reaches a completion seal without turning the seal into quotient classes. It sits after the uniform entourage surface of chapter 339, the Cauchy filter surface of chapter 333, the generic completion packet of chapter 95, the metric comparison route of chapter 3553, the finite stream-window discipline of chapter 126, the regular rational source of chapter 301, and the terminal real-name seal of chapter 38. The packet names the L10 completion handoff as displayed NameCert data; it is not a quotient completion theorem, not a selected-limit operator, not countable choice, not trichotomy, not host equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3560.1 (UniformSpaceCompletion carrier)**.** *A* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, F, D, S, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the uniform entourage source row, read from the* $\mathsf{UniformSpace}^{\uparrow}$ *interface before any Cauchy or completion demand is accepted.*
2. *F is the Cauchy filter or Cauchy net row, exposing exactly the finite entourage tests used by the completion consumer.*
3. *D is the dense-source embedding row, recording the source-to-completion handoff that lets original points enter the completion surface.*
4. *S is the separated reflection row, forcing indistinguishable Cauchy data to pass through a displayed separated interface before the completion seal is read.*
5. *E is the completion seal row, recording the accepted completion name after U, F, D, S have all been displayed.*
6. *H records componentwise* hsame *transport for the uniform source, Cauchy row, dense-source row, separated-reflection row, completion seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from Cauchy demands through the uniform source, dense-source handoff, separated reflection, and completion seal.*

8. *P is the* Pkg *provenance over* $\mathsf{UniformSpaceCompletion}^{\uparrow}$*, the seven sibling chapters named above,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformSpaceCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, D, S, E, H, C, P, N$ and their displayed replay paths. It has no coordinate for quotient representatives, selected limits, countable choice, trichotomy, host equality of completion classes, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformSpaceCompletionUp.UniformSpaceCompletionTasteGate single carrier alignment`

Theorem 3560.2 (UniformSpaceCompletion NameCert obligations)**.** *For every accepted* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *carrier $K = (U, F, D, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformSpaceCompletion}^{\uparrow}}$ *surface consists exactly of five completion-facing obligations: carrier admission for the displayed finite packet; uniform-Cauchy exactness of the F row against the entourage source U; dense-source handoff through D; separated-reflection non-escape through S before the seal is consumed; and completion-seal stability through E, H, C, P, N. Every completion consumer must read those five rows in that order before it can export a completion name.*

Proof. Project the carrier of Definition 3560.1. The packet first displays the uniform entourage source U and the Cauchy row F, so the Cauchy demand is tested only against named finite entourages rather than against an ambient host uniformity.

The dense-source and separated-reflection rows then control the handoff. The row D records how original source data enters the completion surface, and S records that indistinguishable Cauchy data cannot escape the displayed separated interface before the completion seal is read.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Because the carrier has no row for quotient completion classes, selected limits, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those principles can be projected as a NameCert obligation. □

Falsifiable prediction: Every accepted $\mathsf{UniformSpaceCompletion}^{\uparrow}$ consumer that reaches a completion seal while omitting the uniform entourage source, Cauchy filter or net row, dense-source embedding row, separated-reflection row, completion-seal row, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: uniformspace, cauchyfilter, completion, metric-completion-comparison, streamname, regseqrat, real: no listed sibling is bijective with $\mathsf{UniformSpaceCompletion}^{\uparrow}$ because the packet jointly carries a uniform entourage source, Cauchy filter or net exactness, dense-source handoff, separated-reflection non-escape, completion seal stability, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformSpaceCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformSpaceCompletion}^{\uparrow}$ packet is generated from a uniform entourage source row, a Cauchy filter or Cauchy net row, a dense-source embedding row, a separated-reflection row, a completion seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformSpaceCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 3560.1 and Definition 3560.2 seed the finite L10 uniform completion route over uniform source, Cauchy exactness, dense-source handoff, separated reflection, seal stability, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformSpaceCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion classes, selected limits, countable choice, trichotomy, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-Cauchy exactness, dense-source handoff, separated-reflection non-escape, completion-seal stability, transport replay, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.UniformSpaceCompletionUp.

Chapter 3561

A Concrete Naming Certificate for $\mathsf{RegularCauchySubspace}^{\uparrow}$

Following Bishop and Bridges on subspaces of constructive metric spaces, the $\mathsf{RegularCauchySubspace}^{\uparrow}$ packet names regular Cauchy rational data whose accepted reads remain inside a displayed subspace predicate before any quotient equality, selected limit, or ambient completeness service is exposed. It sits on the regular rational readback of chapter 301, the finite-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, and the classifier discipline of chapter 1820. The packet is a finite NameCert surface for subspace-restricted regular Cauchy names; it is not a quotient real, not a selected limit, and not an assertion that the ambient space is complete.

Definition 3561.1 (RegularCauchySubspace carrier)**.** *A* $\mathsf{RegularCauchySubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (Q, S, D, A, K, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular rational readback inspected by the subspace consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that opens only the windows needed to test the displayed subspace route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic bounds, window radii, and comparison rows consumed by Q and S.*
4. *A is the displayed subspace predicate row; it records the finite acceptance evidence that the inspected regular Cauchy name is read inside the named subspace.*
5. *K is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row, used only to compare accepted displayed names through their regular readback, tolerance ledger, and subspace predicate evidence.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after Q, S, D, A, K have all been displayed.*
7. *H records componentwise* hsame *transport for the regular readback, finite windows, dyadic ledger, subspace predicate, classifier, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a subspace-restricted regular Cauchy request through S, D, Q, A, K and then to the Real seal E.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubspace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubspace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, S, D, A, K, E, H, C, P, N$. The carrier has no coordinate for quotient real equality, a selected limit, an ambient completeness theorem, a host real equality predicate, countable choice, or an external subspace oracle.

Lean4 ✓ `BEDC.Derived.RegularCauchySubspaceUp.RegularCauchySubspaceTasteGate single carrier alignment`

Theorem 3561.2 (RegularCauchySubspace NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubspace}^{\uparrow}$ *carrier*

$$U = (Q, S, D, A, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubspace}^{\uparrow}}$ *surface consists exactly of carrier admission, regular rational readback, finite StreamName window exposure, DyadicRatCore tolerance exactness, displayed subspace-predicate evidence, CauchyEquivalenceSetoid classifier transport, Real-seal routing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 3561.1. The accepted packet exposes the regular readback Q, finite windows S, dyadic ledger D, subspace predicate evidence A, classifier row K, terminal Real seal E, and structural rows H, C, P, N.

The finite observation route is forced before the subspace predicate can be consumed. The $\mathsf{StreamName}^{\uparrow}$ schedule supplies the inspected windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger supplies the tolerance comparisons, and the $\mathsf{RegSeqRat}^{\uparrow}$ row packages those observations as the regular rational name to which A applies.

Classifier transport is then read only through K and H. The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ row compares accepted displayed names through the same regular readback, tolerance ledger, and subspace predicate evidence; componentwise hsame preserves those coordinates without adding a quotient real equality row.

Finally, the Real seal E is downstream of Q, S, D, A, K, while C, P, N only replay, source, and name the same route. Since the carrier has no coordinate for selected limits, ambient completeness, host real equality, countable choice, or an external subspace oracle, the local NameCert exports none of those objects. □

Theorem 3561.3 (RegularCauchySubspace inherited modulus route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchySubspace}^{\uparrow}$ *carrier inherits its regular Cauchy modulus only through the finite route*

$$S, D, Q, A, K, E, H, C, P, N.$$

Thus the consumer reads StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, displayed subspace evidence, the CauchyEquivalenceSetoid classifier, and the terminal Real seal in that order. It receives no quotient equality for Cauchy names, no selected representative, no ambient completeness service, and no detached subspace-membership oracle.

Proof. Project the accepted carrier $U = (Q, S, D, A, K, E, H, C, P, N)$. The only windows and tolerance data available to a consumer are S and D, and the only regular Cauchy readback attached to them is Q.

The subspace restriction is not a separate oracle. It is the displayed predicate row A applied to the same regular readback route, so every accepted subspace-facing read passes through the same finite windows and dyadic tolerance ledger.

The classifier row K transports accepted names only after Q, S, D, A have been displayed. The terminal seal E is therefore a Real-facing endpoint of this packet, not a selected ambient limit.

The structural rows H, C, P, N preserve and name the route. Because no quotient equality, selected representative, ambient completeness service, or detached membership oracle is present among the displayed coordinates, none can be exported by composing the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubspace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3561.1, Definition 3561.2, and Definition 3561.3 seed the finite subspace-restricted regular Cauchy NameCert packet over displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular readback, subspace-predicate stability, classifier transport, Real-seal routing, replay stability, provenance, local naming, and non-escape for BEDC.Derived.RegularCauchySubspaceUp.

Constructive story: A $\mathsf{RegularCauchySubspace}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, displayed subspace-predicate evidence, a $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3562

A Concrete Naming Certificate for $\mathsf{MetricReflectionSandwich}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{MetricReflectionSandwich}^{\uparrow}$ packet records the standard constructive route that reads a separated metric surface through a metric embedding, lands it in a completion surface, and checks that the dense embedding row preserves the same finite distance evidence. It sits on the metric carrier of chapter 57, the separation witness of chapter 1411, the embedding rows of chapter 3339, the completion surface of chapter 1506, the dense completion discipline of chapter 3351, and the terminal scalar seal of chapter 38. The packet is a finite NameCert consumer for the metric-reflection route; it is not a quotient completion, not a selected-representative theorem, not a choice principle, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 3562.1 (MetricReflectionSandwich carrier)**.** *A* $\mathsf{MetricReflectionSandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, M, Q, E, C, D, R, H, T, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row whose distances are inspected.*
2. *M is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row, exposing the finite zero-distance separation evidence for the same source.*
3. *Q is the* $\mathsf{MetricEmbedding}^{\uparrow}$ *row, read as a distance-preserving route out of X rather than as a host function equality.*
4. *E is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row naming the completion-facing target surface.*
5. *C is the* $\mathsf{DenseEmbedding}^{\uparrow}$ *row showing that the embedded source rows are dense in the displayed completion target.*
6. *D is the dyadic distance ledger used by the metric, embedding, completion, and density rows.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *distance seal reached only after X, M, Q, E, C, D have all been displayed.*
8. *H records componentwise* hsame *transport for metric distances, separation evidence, embedding rows, completion rows, dense embedding rows, dyadic comparisons, Real sealing, replay, provenance, and local naming.*
9. *T records displayed* Cont *replay from a source-distance read through the embedding and completion rows to the dense target read.*

10. *P is the* Pkg *provenance over* $\mathsf{MetricReflectionSandwich}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricEmbedding}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{DenseEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricReflectionSandwich}^{\uparrow}}$ *row.*

The classifier accepts only packets whose separated metric, metric embedding, completion, dense embedding, dyadic distance ledger, Real seal, transport, replay, provenance, and local naming rows are displayed together. It has no coordinate for quotient completion, selected representatives, countable choice, host metric equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.MetricReflectionSandwichUp.MetricReflectionSandwichTasteGate single carrier alignment`

Theorem 3562.2 (MetricReflectionSandwich NameCert obligations)**.** *For every accepted* MetricReflectionSandwich *carrier $S = (X, M, Q, E, C, D, R, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricReflectionSandwich}^{\uparrow}}$ *surface consists exactly of carrier admission, separated-metric exposure, metric-embedding distance preservation, completion-row routing, dense-embedding readback, dyadic distance-ledger exactness, Real distance sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 3562.1. The accepted packet exposes the source metric, separation row, embedding row, completion target, dense embedding row, dyadic ledger, Real seal, and structural rows as finite coordinates.

The route through the sandwich is forced by those coordinates. A source-distance read starts at X, is separated by M, passes through the distance-preserving row Q, lands in the completion row E, and is reread through the dense embedding row C.

The remaining rows keep the route finite. The ledger D supplies the distance comparisons, R seals only those displayed comparisons as Real-facing data, and H, T, P, N transport, replay, source, and name the same packet. Since no row stores quotient completion, selected representatives, countable choice, host equality, or ambient Real completeness, the NameCert surface exports none of those objects. □

Theorem 3562.3 (MetricReflectionSandwich completion route)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricReflectionSandwich}^{\uparrow}$ *carrier reads the source separated metric through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{MetricEmbedding}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{DenseEmbedding}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},$$

The consumer receives a displayed metric source, separation evidence, distance-preserving embedding, completion target, dense embedding readback, dyadic distance ledger, Real distance seal, transport, replay, provenance, and local naming. It receives no quotient completion, selected representative, countable-choice schedule, detached host metric equality, or ambient Real-completeness theorem.

Proof. Begin with the carrier and apply Definition 3562.2. The completion-facing reader can inspect only the displayed rows of the packet.

The source metric is not read directly by the completion target. It first passes through the separated metric row and the metric embedding row, so the completion consumer sees the same finite distance data under the embedding route.

The dense embedding row then rereads the embedded source inside the completion surface. Dyadic comparisons and the Real seal are downstream of the displayed metric and embedding

rows, while transport, replay, provenance, and local naming preserve that order. Therefore the completion route is exactly the finite sandwich route, with no quotient completion, selected representative, choice, host equality, or ambient Real completeness exported. □

Falsifiable prediction: An accepted $\mathsf{MetricReflectionSandwich}^{\uparrow}$ completion consumer that reaches $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{DenseEmbedding}^{\uparrow}$ without first reading the displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricEmbedding}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows refutes the carrier surface.

Independence witness: metric, separatedmetric, metricembedding, metriccompletion, denseembedding, dyadicratcore, real: $\mathsf{MetricReflectionSandwich}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the separated source metric, embedding, completion target, dense readback, dyadic distance ledger, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricReflectionSandwich}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricReflectionSandwich}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3562.1, Definition 3562.2, and Definition 3562.3 seed the finite metric-reflection route between separated metric, metric embedding, completion, dense embedding, dyadic distance, Real seal, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricReflectionSandwich}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host metric equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-metric exposure, metric-embedding preservation, completion routing, dense-embedding readback, dyadic distance exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricReflectionSandwichUp.

Constructive story: A $\mathsf{MetricReflectionSandwich}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ source row, a $\mathsf{SeparatedMetric}^{\uparrow}$ row, a $\mathsf{MetricEmbedding}^{\uparrow}$ route, a $\mathsf{MetricCompletion}^{\uparrow}$ target, a $\mathsf{DenseEmbedding}^{\uparrow}$ readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3563

A Concrete Naming Certificate for $\mathsf{ConvexConjugate}^{\uparrow}$

Following Rockafellar and Boyd–Vandenberghe, the $\mathsf{ConvexConjugate}^{\uparrow}$ packet names the Fenchel–Legendre conjugate surface by finite primal rows, dual rows, pairing evaluations, epigraph rows, and displayed supremum budgets. It sits over the convex-set, vector-space, real-name, and real-order interfaces of chapter 208, chapter 47, chapter 38, and section 38.3, and it supplies the conjugacy handoff consumed by chapter 321. The packet records conjugate data as BEDC carrier rows; it does not import host convex analysis, selected suprema, quotient function spaces, choice selectors, or ambient completeness.

Definition 3563.1 (Convex conjugate carrier)**.** *A* $\mathsf{ConvexConjugate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, V, P, D, E, S, H, C, Q, N)$$

with the following displayed rows:

1. *F is the primal convex functional row, read through a displayed* $\mathsf{ConvexSet}^{\uparrow}$ *epigraph boundary.*
2. *V is the dual-vector row over the visible* $\mathsf{VecSpace}^{\uparrow}$ *dependency surface.*
3. *P is the pairing-evaluation row that records the finite bilinear read used by the conjugate comparison.*
4. *D is the domain and epigraph admission row tying the primal functional to the visible convex-set carrier.*
5. *E is the extended-value comparison row, read through* $\mathsf{Real}^{\uparrow}$ *and the real-order interface.*
6. *S is the supremum-budget row listing the finite inspected witnesses and the budget that prevents escape to a host supremum.*
7. *H stores componentwise* hsame *transport for the primal row, dual vector, pairing row, epigraph row, comparison row, supremum budget, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from primal and dual reads to pairing evaluations, from pairing evaluations to epigraph comparisons, and from those comparisons to the budgeted conjugate row.*
9. *Q is the* Pkg *provenance over* $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConvexConjugate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, V, P, D, E, S, H, C, Q, N$. It has no coordinate for a host supremum operator, quotient function space, choice-selected maximizer, ambient dual-space completion, or external conjugacy theorem.

Lean4 ✓ `BEDC.Derived.ConvexConjugateUp.ConvexConjugateTasteGate single carrier alignment`

Theorem 3563.2 (Convex conjugate NameCert obligations)**.** *For every accepted* $\mathsf{ConvexConjugate}^{\uparrow}$ *carrier* $K = (F, V, P, D, E, S, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConvexConjugate}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, classifier stability under componentwise* hsame *transport, epigraph transport through the visible* $\mathsf{ConvexSet}^{\uparrow}$ *dependency, supremum-budget nonescape through* S*, and ledger visibility through the replay and provenance rows* C, Q, N*. Every conjugate read must pass through the primal functional row, dual-vector row, pairing evaluation row, epigraph row, extended-value comparison row, and displayed budget before a Fenchel-facing consumer can inspect it.*

Proof. Project the carrier of Definition 3563.1. Its visible coordinates are exactly $F, V, P, D, E, S, H, C, Q, N$, so carrier admission and classifier comparison are componentwise on those rows.

The epigraph and comparison clauses route every primal functional read through $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the real-order interface before it can be paired with the dual row. Transport by H and replay by C preserve that displayed route.

The row S is the only supremum-facing coordinate. Since the carrier has no host supremum, quotient function space, or selected maximizer field, the budgeted ledger S, C, Q, N is the entire local NameCert surface available to downstream consumers. □

Theorem 3563.3 (Convex conjugate Fenchel handoff)**.** *Every* $\mathsf{FenchelDuality}^{\uparrow}$ *consumer that reads conjugacy through an accepted* $\mathsf{ConvexConjugate}^{\uparrow}$ *carrier receives only the displayed packet route*

$$F, V, P, D, E, S \longmapsto H, C, Q, N.$$

The consumer reads primal functionals, dual vectors, pairings, epigraphs, extended-value comparisons, and supremum budgets through the $\mathsf{ConvexConjugate}^{\uparrow}$ *packet, and receives no host supremum, quotient function space, choice selector, ambient completeness theorem, or external Fenchel conjugacy principle.*

Proof. Use Definition 3563.2. It places every conjugate-facing read on the carrier rows F, V, P, D, E, S before the structural rows H, C, Q, N can replay or source the answer.

Now pass to the Fenchel-facing consumer. The consumer may cite the $\mathsf{FenchelDuality}^{\uparrow}$ packet only after the displayed conjugate rows have been read, so conjugacy enters as a finite BEDC row rather than as an analytic operation in the host language.

The excluded host objects are absent from Definition 3563.1. Therefore the handoff supplies exactly the packet route and no selected supremum, quotient-function value, choice witness, completeness theorem, or external duality theorem. □

Falsifiable prediction: Every $\mathsf{ConvexConjugate}^{\uparrow}$ consumer reads conjugacy through a primal functional row, dual-vector row, pairing-evaluation row, epigraph row, extended-value comparison row, supremum-budget row, transport, continuation replay, provenance, and local naming.

Independence witness: convexset, vecspace, real, realalgorder, fenchelduality: $\mathsf{ConvexConjugate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries primal functional data, dual-vector data, pairing evaluation, epigraph comparison, a displayed supremum budget, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConvexConjugate}^{\uparrow}}$.

Constructive story: A $\mathsf{ConvexConjugate}^{\uparrow}$ packet is generated from a primal convex functional row, a dual-vector row, a pairing-evaluation row, epigraph and extended-value comparison rows, a displayed supremum budget, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvexConjugate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3563.1, Definition 3563.2, and Definition 3563.3 bind the finite Fenchel–Legendre conjugate certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvexConjugate}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ConvexConjugateUp.ConvexConjugateTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host convex analysis, selected suprema, quotient function spaces, choice selectors, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, supremum-budget nonescape, Fenchel handoff, and TasteGate field faithfulness for BEDC.Derived.ConvexConjugateUp.

$\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ is routed through chapter 38, chapter 301, and the apartness sibling surface before the L10 completion-facing dependency rows are consumed.

Chapter 3564

A Concrete Naming Certificate for LocatedApartnessRealBridge$^{\uparrow}$

Following Bishop and Bridges, the LocatedApartnessRealBridge$^{\uparrow}$ packet records the finite comparison route by which located-radius readback and positive apartness evidence can be consumed together without promoting the result to classical real order. It sits between the located-real surface of **??**, the Cauchy real apartness surface of chapter 1881, the real apartness order bridge of chapter 1905, and the cotransitivity route of chapter 1788. The packet is a constructive comparison bridge for Real and Completion consumers; it is not a trichotomy theorem, quotient-real equality principle, host real equality test, selected-limit operator, or completeness claim.

Definition 3564.1 (Located apartness real bridge carrier)**.** *A* LocatedApartnessRealBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (L_0, L_1, R_0, R_1, A, O, T, H, C, P, N)$$

with the following displayed rows:

1. *L_0 and L_1 are accepted* LocatedReal$^{\uparrow}$ *endpoint packets whose finite located-radius windows are being compared.*
2. *R_0 and R_1 are the located-radius readback rows, each exposing a* StreamName$^{\uparrow}$ *window, a* RegSeqRat$^{\uparrow}$ *readback, and a* DyadicRatCore$^{\uparrow}$ *radius ledger before any terminal* Real$^{\uparrow}$ *seal is inspected.*
3. *A is the positive apartness witness row, read through the* CauchyRealApartness$^{\uparrow}$ *surface and tied to the same endpoint windows.*
4. *O is the order-facing bridge row supplied by* RealApartnessOrderBridge$^{\uparrow}$*, used only after A has exposed positive apartness.*
5. *T is the cotransitivity route row, pointing to the existing* ApartnessCotransitivity$^{\uparrow}$ *surface when a third displayed real name is inspected.*
6. *H records componentwise* hsame *transport for the endpoint packets, readbacks, apartness witness, order bridge, cotransitivity route, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located-apartness bridge request through $L_0, L_1, R_0, R_1, A, O, T, H, P, N$.*
8. *P is the* Pkg *provenance over* LocatedApartnessRealBridge$^{\uparrow}$, LocatedReal$^{\uparrow}$, CauchyRealApartness$^{\uparrow}$, RealApartnessOrderBridge$^{\uparrow}$, ApartnessCotransitivity$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedApartnessRealBridge}^{\uparrow}}$ *row.*
The classifier admits exactly the finite packet in which located-radius readback and apartness evidence share the displayed endpoint windows. It has no coordinate for real trichotomy, quotient equality, host real equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking.

Theorem 3564.2 (Located real apartness cotransitive bridge)**.** *For every accepted* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *carrier*

$$J = (L_0, L_1, R_0, R_1, A, O, T, H, C, P, N),$$

any comparison read that uses the located-radius readbacks R_0, R_1 together with the positive apartness witness A reaches a Real-facing consumer only through the existing apartness-cotransitivity surface. More precisely, the read first opens the two $\mathsf{LocatedReal}^{\uparrow}$ *endpoint packets, then the shared finite readback route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

then the $\mathsf{CauchyRealApartness}^{\uparrow}$ *witness, then the* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *order-facing handoff, and finally the* $\mathsf{ApartnessCotransitivity}^{\uparrow}$ *row T when a third real name is present. The export is finite constructive comparison evidence only. It exports no trichotomy, quotient real equality, host real equality, selected limit, countable-choice branch selection, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or completion principle.*

Proof. Project the carrier of Definition 3564.1. The endpoint information is exactly the two located real packets L_0, L_1 and the two finite located-radius readbacks R_0, R_1.

The apartness row is opened only after those finite readbacks are visible. Thus A is tied to the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ route as the endpoint data.

The order-facing handoff is downstream of apartness. The row O may expose the order bridge supplied by $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, but it receives positive separation from A and cannot introduce an equality test or a trichotomy branch.

When a third real name is inspected, the route must pass through T. That row is precisely the cotransitivity surface of $\mathsf{ApartnessCotransitivity}^{\uparrow}$, so the consumer receives a displayed cotransitive apartness route rather than a classical comparison principle.

The remaining rows H, C, P, N transport, replay, package, and name the same finite route. Since the carrier lists no quotient equality, host equality, selected limit, choice, or completeness row, none can be exported by the local certificate. □

Theorem 3564.3 (Located apartness real bridge NameCert obligations)**.** *For every accepted* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *carrier*

$$J = (L_0, L_1, R_0, R_1, A, O, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedApartnessRealBridge}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *endpoint admission for the two* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint packets L_0, L_1;*
2. *located-radius readback for R_0, R_1, each displaying the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *route attached to its endpoint;*
3. *positive apartness witness admission for the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *row A;*

4. *order-facing handoff for the* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *row* O*, read only after* A *has exposed positive apartness;*
5. *cotransitivity routing for the* $\mathsf{ApartnessCotransitivity}^{\uparrow}$ *row* T *when a third displayed real name is inspected;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* H, C, P, N*.*

These rows export only the displayed constructive comparison route. They do not assert real trichotomy, quotient real equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the carrier of Definition 3564.1. The endpoint and readback obligations are exactly the rows L_0, L_1, R_0, R_1, so the local certificate admits only displayed located endpoints and finite radius-readback data.

The apartness and order rows are A and O. The carrier orders them so that the $\mathsf{CauchyRealApartness}^{\uparrow}$ witness is exposed before the $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ handoff can be consumed.

Apply Definition 3564.2. It reads the same endpoint, readback, apartness, and order rows as the consumer-facing route, and it sends any third-name comparison through the cotransitivity row T.

The remaining rows H, C, P, N transport, replay, package, and name that route. Since the carrier has no coordinate for trichotomy, quotient equality, host equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Theorem 3564.4 (Located apartness real two-way separation)**.** *An accepted* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *carrier exposes* $\mathsf{Real}^{\uparrow}$ *separation reads only through the displayed located-apartness row* A *and its endpoint readbacks* L_0, L_1, R_0, R_1*. Conversely, it exposes located-apartness reads only through the terminal* $\mathsf{Real}^{\uparrow}$ *seal route carried by* R_0, R_1 *together with the bridge transport, replay, provenance, and naming rows* H, C, P, N*.*

Proof. Project the carrier $J = (L_0, L_1, R_0, R_1, A, O, T, H, C, P, N)$ from Definition 3564.1. The Real-facing data are the two located endpoints and their radius-readback rows, while the positive separation data are confined to the apartness witness row A.

Apply the NameCert obligations of Definition 3564.3. They require endpoint admission, located-radius readback, positive apartness admission, order-facing handoff, cotransitivity routing, and structural replay to be read as the same finite packet.

In the Real-facing direction, a separation read reaches the endpoint seal only after the displayed apartness row has tied the endpoints to positive evidence. In the apartness-facing direction, a consumer of A receives only the endpoint $\mathsf{Real}^{\uparrow}$ seal route plus H, C, P, N; the carrier exports no trichotomy, quotient equality, host equality, selected limit, countable-choice branch, or ambient completeness coordinate. □

Theorem 3564.5 (Located apartness real nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *read that exports an order-facing handoff still factors through the positive apartness row* A *and the cotransitivity route* T*. Consequently the handoff cannot export a three-way comparison branch, quotient-real equality, host real equality, or a detached order comparison outside*

$$L_0, L_1, R_0, R_1, A, O, T, H, C, P, N.$$

Proof. Project the carrier $J = (L_0, L_1, R_0, R_1, A, O, T, H, C, P, N)$ from Definition 3564.1. The order-facing row is O, and it is listed downstream of the positive apartness witness A rather than as an independent trichotomy or equality coordinate.

Apply Definition 3564.2. It forces any third-name comparison to pass through the cotransitivity row T after the endpoint readbacks and the positive apartness row have been displayed.

Apply Definition 3564.3 and Definition 3564.4. These obligations keep O downstream of A and keep all Real-facing separation reads attached to the endpoint readbacks R_0, R_1.

The remaining rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate records a three-way comparison branch, quotient-real equality, host real equality, or detached order comparison, none can be exported by an accepted read. □

Theorem 3564.6 (Located apartness real bridge completion forward route)**.** *Any L10 completion consumer, in particular the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *consumer of chapter 1639, that reads located apartness from an accepted* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *carrier*

$$J = (L_0, L_1, R_0, R_1, A, O, T, H, C, P, N)$$

must pass through the located-radius readbacks R_0, R_1*, the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *surface* A*, the* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *compatibility row* O*, and the* $\mathsf{ApartnessCotransitivity}^{\uparrow}$ *row* T *before it consumes any completion-facing comparison. The route exports constructive comparison evidence only; it exports no trichotomy, quotient-real equality, selected limit, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or completion principle outside the displayed rows.*

Proof. Project the endpoint and readback rows from Definition 3564.1. The completion-facing consumer first sees the two located endpoints and their finite radius readbacks, so the comparison begins with visible $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ data.

Apply Definition 3564.2. It opens the Cauchy real apartness witness after the readbacks, then routes the positive evidence through the order-facing bridge and the cotransitivity surface whenever a third name is inspected.

Use Definition 3564.3 and Definition 3564.4. These keep located-apartness evidence and Real-facing separation tied to the same finite packet before any completion-facing comparison is consumed.

Since the carrier has no coordinate for trichotomy, quotient equality, selected limits, host equality, choice, completeness, or an independent completion principle, the forward route is exactly the displayed located-radius, apartness, order-bridge, and cotransitivity handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedApartnessRealBridge}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedApartnessRealBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3564.1 and Definition 3564.2 seed the finite constructive comparison route over located-real endpoints, located-radius readbacks, Cauchy apartness, the real-apartness order bridge, and apartness cotransitivity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedApartnessRealBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close real trichotomy, quotient real equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-radius readback stability, Cauchy apartness handoff, order-bridge compatibility, cotransitivity routing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedApartnessRealBridgeUp.

Constructive story: A $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ packet is generated from two located-real endpoints, two located-radius readbacks, a positive Cauchy real apartness witness, a real-apartness order bridge row, an apartness-cotransitivity route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Lemma 3564.7 (Located apartness real bridge sibling dependency route)**.** *Every accepted* LocatedApartnessRealBri *read consumes the located endpoint rows of* **??***, the positive Cauchy apartness evidence of chapter 1881, the order-facing handoff rows of chapter 1905, and the cotransitivity routing of chapter 1788 before the local bridge name is inspected.*

Proof. Project the carrier of Definition 3564.1. The endpoint rows L_0, L_1 are located-real packets, so their finite located-radius windows are read through the sibling $\mathsf{LocatedReal}^{\uparrow}$ surface.

The positive separation row A is then read through $\mathsf{CauchyRealApartness}^{\uparrow}$, and the order-facing row O is downstream of that apartness evidence. If a third displayed real name is present, the row T routes the comparison through $\mathsf{ApartnessCotransitivity}^{\uparrow}$.

The structural rows H, C, P, N transport, replay, package, and name this same route. Since the carrier has no additional dependency coordinate, every local bridge read factors through exactly the listed sibling chapters. □

Lemma 3564.8 (Located apartness real bridge forward lattice)**.** *Every downstream Real and Completion consumer of a* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *packet reads the local bridge only after the located-real, Cauchy-apartness, order-bridge, and cotransitivity sibling surfaces of Definition 3564.7 have been exposed. In particular, a handoff to the separated-completion route of chapter 1612 may consume the bridge as finite apartness-routing data, but not as quotient-real equality, trichotomy, countable choice, or a selected completion limit.*

Proof. Project the dependency route already recorded in Definition 3564.7. The local bridge has no independent downstream coordinate before the located endpoint rows, positive Cauchy apartness evidence, order-facing handoff rows, and cotransitivity routing have been read.

A separated-completion consumer may therefore receive only the finite bridge packet produced by those sibling surfaces. The consumer obtains a displayed Real and Completion handoff, while the excluded host principles remain outside the carrier. □

Lemma 3564.9 (Located apartness real bridge Cauchy setoid route)**.** *Every located-apartness read exported by an accepted* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *packet to a completion or separated-setoid consumer must pass through* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier route before it can be used as apartness evidence. The exported evidence is the finite L10 readback chain through chapter 38, chapter 301, chapter 126, chapter 291, and chapter 1820; it is not quotient-real equality, a selected completion representative, host order data, or ambient completeness.*

Proof. Project the carrier of Definition 3564.1. The located-radius readbacks are R_0, R_1, and each exposes the stream-name window, regular-rational readback, dyadic-radius ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal before any apartness row is consumed.

Use Definition 3564.3. The positive apartness row A is tied to those same endpoint windows, so a completion or separated-setoid consumer cannot detach the apartness witness from the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route.

Now route the completion-facing read through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ classifier. The setoid classifier is the sibling surface that records equality-compatible Cauchy comparison before a completion consumer may reuse the apartness evidence.

The structural rows H, C, P, N only transport, replay, source, and name this route. Since no row stores quotient-real equality, selected completion representatives, host order data, or ambient completeness, the L10 chain is nonescaping. □

Chapter 3565

A Concrete Naming Certificate for $\mathsf{LocatedApartnessCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedApartnessCompletion}^{\uparrow}$ packet records a completion-facing carrier in which located real windows and apartness evidence are displayed before any completion read is allowed to leave the finite BEDC ledger. It sits after the generic apartness-completion boundary of chapter 1787, the located-apartness real bridge of chapter 3564, the located real carrier of **??**, the positive-separation surface of chapter 304, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The carrier names a finite located-apartness completion route only; it does not assert Real completeness, trichotomy, quotient equality, countable choice, open-cover compactness, or host-selected limits.

Definition 3565.1 (Located apartness completion carrier)**.** *A* $\mathsf{LocatedApartnessCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, U, V, G, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ApartnessCompletion}^{\uparrow}$ *boundary row exposing the separated completion route.*
2. *B is the* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *row binding the completion boundary to located real apartness data.*
3. *U is the source* $\mathsf{LocatedReal}^{\uparrow}$ *row whose finite windows are inspected by the completion read.*
4. *V is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-separation row used to keep equality information apartness-facing.*
5. *G is the located gap row recording that the inspected endpoint windows have a displayed positive dyadic separation whenever apartness is consumed.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the finite completion and apartness windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for positive gaps, radii, and comparison cells.*
9. *E is the optional* $\mathsf{Real}^{\uparrow}$ *seal row, present only after the located, apartness, stream, regular-rational, and dyadic rows have been displayed.*

10. *H records componentwise* hsame *transport for all source, bridge, window, readback, tolerance, seal, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay of the same finite route.*
12. *P is the* Pkg *provenance over* LocatedApartnessCompletion$^{\uparrow}$, ApartnessCompletion$^{\uparrow}$, LocatedApartnessRealBridge$^{\uparrow}$, LocatedReal$^{\uparrow}$, ApartnessReal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{LocatedApartnessCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, U, V, G, S, R, D, E, H, C, P, N$. It has no coordinate for Real completeness, trichotomy, quotient equality, countable choice, open-cover compactness, or host-selected limits.

Lean4 ✓ `BEDC.Derived.LocatedApartnessCompletionUp.LocatedApartnessCompletionTasteGate single carrier alignment`

Theorem 3565.2 (Located apartness completion NameCert obligations)**.** *For every accepted* LocatedApartnessCompletion$^{\uparrow}$ *carrier $L = (A, B, U, V, G, S, R, D, E, H, C, P, N)$, the local* NameCert$_{\text{LocatedApartnessCor}}$ *surface consists exactly of apartness-completion boundary exposure through A; located-apartness real bridge exposure through B; located real source exposure through U; positive-separation exposure through V; located gap exposure through G; finite window, regular readback, and dyadic tolerance exposure through S, R, D; optional Real sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the accepted carrier. The displayed tuple contains precisely the apartness-completion boundary, located-apartness bridge, located real source, positive-separation row, located gap row, finite windows, regular readback, dyadic tolerance ledger, optional seal, transport, replay, provenance, and local name.

The NameCert obligations are read in the same order. Rows A and B expose the completion boundary and bridge before U, V, G make the located real and apartness evidence available. Rows S, R, D then bind every consumer observation to finite windows, regular rational readback, and dyadic tolerance data before the optional Real seal E can be inspected.

The structural rows H, C, P, N transport, replay, source, and name only those displayed rows. Since the carrier has no coordinate for Real completeness, trichotomy, quotient equality, countable choice, open-cover compactness, or host-selected limits, the listed rows exhaust the local obligation surface. □

Theorem 3565.3 (Located apartness completion apartness route)**.** *Every apartness-facing completion read of an accepted* LocatedApartnessCompletion$^{\uparrow}$ *carrier factors through the route*

$$A, B, U, V, G, S, R, D \longmapsto H, C, P, N.$$

Thus positive separation is consumed only as displayed ApartnessReal$^{\uparrow}$ *evidence attached to located* LocatedReal$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks, and* DyadicRatCore$^{\uparrow}$ *tolerance rows, not as a host trichotomy or a quotient equality test.*

Proof. Read the apartness source of the completion route first. The generic boundary row A and the bridge row B identify the completion-facing apartness route before any located real endpoint is inspected.

Rows U, V, G then display the located real window, the positive-separation evidence, and the dyadic gap row. Rows S, R, D keep the same observation finite by naming the stream schedule, regular rational readback, and dyadic tolerance ledger.

The transport, replay, provenance, and naming rows H, C, P, N preserve that route without adding a host comparison coordinate. Hence the consumer receives apartness only through the displayed rows and cannot read trichotomy or quotient equality from the packet. □

Theorem 3565.4 (Located apartness completion nonescape)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{LocatedApartnessCompletion}^{\uparrow}$ *carrier must pass through* A, B, U, V, G, S, R, D *before it may inspect the optional seal row* E *or the structural rows* H, C, P, N*. Consequently the packet exports no Real completeness principle, host-selected limit, open-cover compactness argument, countable-choice schedule, trichotomy decision, or quotient equality of completed names.*

Proof. Start from any downstream consumer. Carrier projection gives only the ordered rows $A, B, U, V, G, S, R, D, E, H, C, P, N$.

The optional Real seal is downstream of the located-apartness data. A read must first display the apartness-completion boundary, located-apartness bridge, located real source, apartness evidence, located gap, stream window, regular rational readback, and dyadic tolerance ledger.

After that finite route is displayed, E, H, C, P, N can seal, transport, replay, package, and name the same data. None of these rows stores completeness, selected limits, open-cover compactness, countable choice, trichotomy, or quotient equality, so those objects cannot escape through the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedApartnessCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedApartnessCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3565.1, Definition 3565.2, Definition 3565.3, and Definition 3565.4 seed the finite located-apartness completion route over ApartnessCompletion, LocatedApartnessRealBridge, LocatedReal, ApartnessReal, StreamName, RegSeqRat, DyadicRatCore, optional Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedApartnessCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, trichotomy, quotient equality, countable choice, open-cover compactness, host-selected limits, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, bridge exposure, located real and apartness route stability, finite readback discipline, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedApartnessCompletion

Constructive story: A $\mathsf{LocatedApartnessCompletion}^{\uparrow}$ packet is generated from an ApartnessCompletion boundary row, a LocatedApartnessRealBridge row, a LocatedReal source row, an ApartnessReal positive-separation row, a located gap row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, an optional RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ hub reads its bounded candidate row through chapter 719 and the MetaCIC normalization frontier, so the socket is a visible sibling dependency rather than an isolated kernel float.

Chapter 3566

A Concrete Naming Certificate for NormalizationCandidateSocket$^{\uparrow}$

The NormalizationCandidateSocket$^{\uparrow}$ packet realizes the candidate-mediated normalization evidence of chapter 9383 as a finite socket object. It sits beside the critical-path packet of chapter 765, the normalization frontier of chapter 892, the confluence audit packet of chapter 735, and the normal-form consistency seal of chapter 740. The packet separates candidate rows from closed-candidate rows and candidate-set rows, records the Pi and App adequacy surfaces, and keeps no-infinite-reduction exports downstream of supplied candidate evidence. It is not an unconditional closed-term strong-normalization theorem.

The socket consumes the MetaCIC candidate-normalization handoff through the candidate-set surface of chapter 2320 and the closed candidate route of chapter 5351. Its subject-reduction boundary is the four-row discharge socket of chapter 719; the local packet may hand candidate-mediated normalization data toward that boundary, but it does not replace the beta, application, lambda, or Pi preservation rows.

Definition 3566.1 (Normalization candidate socket carrier)**.** *A* NormalizationCandidateSocket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, K, D, E, A, B, I, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the closed typed MetaCIC term window, exposing the empty-context term, type, and closedness checks available to the audit map.*
2. *K is the reducibility candidate row, carrying the candidate predicate and its strong-normalization consequence.*
3. *D is the closed-candidate row, carrying closedness together with candidate evidence.*
4. *E is the candidate-set membership row, carrying membership, soundness, and beta-closure data.*
5. *A is the application adequacy row, recording the function-side Pi evidence, argument candidate evidence, and application candidate handoff.*
6. *B is the Pi adequacy row, recording Pi-candidate and neutral-normal evidence consumed by typed application routes.*
7. *I is the no-infinite-reduction row, downstream of the candidate-mediated strong-normalization projection.*

8. *F is the frontier row, retaining the refusal of any read that asks for closed-term strong normalization after deleting K, D, or E.*
9. *H records componentwise* hsame *transport for the term window, candidate row, closed-candidate row, candidate-set row, App adequacy row, Pi adequacy row, no-infinite-reduction row, frontier row, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a normalization-candidate socket request through $M, K, D, E, A, B, I, F, H,$*
11. *P is the* Pkg *provenance over* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$*, chapter 9383, chapter 765, chapter 892, chapter 735, chapter 740,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{NormalizationCandidateSocket}^{\uparrow}}$ *row.*

The classifier compares accepted sockets only through $M, K, D, E, A, B, I, F, H, C, P, N$. It has no coordinate for global closed-term strong normalization, evidence-erased candidate projection, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Theorem 3566.2 (Normalization candidate socket boundary)**.** *For every accepted* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *carrier*

$$S = (M, K, D, E, A, B, I, F, H, C, P, N),$$

the local socket exports closed typed strong-normalization and no-infinite-reduction evidence only through at least one of the candidate rows K, D, E. Application adequacy A and Pi adequacy B are admissible only as route data for that same candidate-mediated socket. Any consumer missing the candidate row, the closed-candidate row, or the candidate-set row reaches F and cannot export closed-term strong normalization from this packet.

Proof. Read the carrier of Definition 3566.1. The closed term window M is present, but the socket does not attach strong normalization directly to M.

The candidate rows are the gate. A read may use K as reducibility candidate evidence, D as closed-candidate evidence, or E as candidate-set membership evidence. The strong-normalization export is downstream of one of these rows.

The adequacy rows refine the same gate. The application row A and Pi row B supply route data for function, argument, Pi, and neutral cases, but neither row replaces candidate evidence.

The no-infinite-reduction row I is downstream of the candidate-mediated strong-normalization projection. If a consumer omits K, D, E or asks to erase them, the frontier row F records the refusal.

Transport, replay, provenance, and local naming preserve this row order through H, C, P, N. Because no global normalization, unrestricted subject-reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed consistency row occurs in the carrier, the socket cannot export one. □

Theorem 3566.3 (Normalization candidate socket candidate-erasure refusal)**.** *Let $S = (M, K, D, E, A, B, I, F, H,$ be an accepted* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *carrier. Any consumer that keeps the closed typed term window M but deletes all candidate evidence rows K, D, E cannot export the no-infinite-reduction row I from this packet. Such a consumer must reach the frontier refusal row F. The App adequacy row A and Pi adequacy row B remain route data for candidate-mediated reads; they are not substitutes for reducibility candidate, closed-candidate, or candidate-set evidence.*

Proof. Project the carrier of Definition 3566.1. The closed typed term window M is a visible socket input, but the carrier does not attach no-infinite-reduction evidence directly to M.

Apply Definition 3566.2. That boundary places closed typed strong-normalization and no-infinite-reduction exports downstream of at least one of K, D, E.

Now delete all three candidate evidence rows. With K, D, E absent, the consumer has no displayed reducibility candidate, closed-candidate, or candidate-set membership route from which I can be replayed.

The adequacy rows do not close the gap. App adequacy A and Pi adequacy B organize function, argument, Pi, and neutral routes once candidate evidence is present, but neither row supplies candidate evidence on its own. Therefore the only available response is the frontier row F, and the packet refuses the evidence-erased no-infinite-reduction export. □

Theorem 3566.4 (Normalization candidate socket MetaCIC diamond route)**.** *Every diamond-residual consumer of an accepted* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *carrier*

$$S = (M, K, D, E, A, B, I, F, H, C, P, N)$$

must first read the candidate rows K, D, E, the adequacy rows A, B, the no-infinite-reduction row I, and the frontier row F before citing chapter 4061. The MetaCIC diamond residual budget may consume the socket only after those candidate-mediated rows are visible; it cannot read a closed typed term window M as a premise-free normalization endpoint.

Proof. Project the socket carrier of Definition 3566.1. The rows relevant to a diamond-residual consumer are displayed as K, D, E, A, B, I, F inside the same finite packet.

Use Definition 3566.2. It places closed typed strong-normalization and no-infinite-reduction exports downstream of at least one candidate evidence row among K, D, E.

Use Definition 3566.3. It shows that deleting K, D, E while retaining M forces the frontier refusal row F, so the diamond-residual consumer cannot treat the closed term window alone as normalization evidence.

The adequacy rows A and B remain route data for candidate-mediated App and Pi reads, and I remains downstream of the same candidate evidence. Therefore the sibling route to chapter 4061 is available only after K, D, E, A, B, I, F are visible in the socket. □

Theorem 3566.5 (Normalization candidate socket forward dependency)**.** *Every forward discharge consumer of an accepted* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *carrier*

$$S = (M, K, D, E, A, B, I, F, H, C, P, N)$$

must expose the candidate rows K, D, E, the adequacy rows A, B, the no-infinite-reduction row I, the frontier row F, and then the forward-socket ledger of chapter 3387 before exporting a downstream socket read. The forward ledger is therefore downstream of visible candidate evidence, not a replacement for reducibility, closed-candidate, candidate-set, App adequacy, Pi adequacy, or frontier rows.

Proof. Project the carrier of Definition 3566.1. The forward discharge consumer can inspect only the displayed rows $M, K, D, E, A, B, I, F, H, C, P, N$.

Use Definition 3566.2. It places any strong-normalization or no-infinite-reduction export downstream of the candidate rows K, D, E and keeps App and Pi adequacy in the rows A, B.

Use Definition 3566.3. If the consumer deletes K, D, E while keeping the closed term window M, the route reaches the frontier refusal F and cannot export I.

Only after K, D, E, A, B, I, F are visible may the consumer cite chapter 3387. The forward-socket ledger records the downstream socket read, while H, C, P, N transport, replay, source, and name the same candidate-mediated packet. □

The socket is a consumer-side sibling of chapter 2320, chapter 5351, and chapter 719. It may route candidate-mediated normalization toward residual or discharge consumers only while keeping the candidate rows K, D, E, the adequacy rows A, B, the no-infinite-reduction row I, and the frontier row F visible.

Falsifiable prediction: Any consumer missing candidate, closed-candidate, or candidate-set rows in a $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ packet cannot export closed-term strong normalization from that packet.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacicconfluenceauditpacket, normalformconsistencyseal: $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries candidate, closed-candidate, candidate-set, App adequacy, Pi adequacy, no-infinite-reduction, frontier, transport, replay, provenance, and local naming rows.

Lean TasteGate coverage for this packet must provide Nontrivial and FieldFaithful instances for the candidate row family, the closed-candidate row family, the candidate-set row family, and the socket classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{NormalizationCandidateSocket}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalizationCandidateSocket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3566.1 and Definition 3566.2 seed the finite candidate-mediated normalization socket over candidate, closed-candidate, candidate-set, App adequacy, Pi adequacy, no-infinite-reduction, and frontier rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalizationCandidateSocket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global closed-term strong normalization, evidence-erased candidate projection, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate gate exactness, App and Pi adequacy compatibility, no-infinite-reduction routing, frontier refusal, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.NormalizationCandidateSocketUp.

Constructive story: A $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ packet is generated from one closed typed MetaCIC term window, candidate evidence, closed-candidate evidence, candidate-set evidence, App adequacy, Pi adequacy, no-infinite-reduction, frontier refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theorem 3566.6 (Normalization candidate socket fuel boundary)**.** *Every* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *consumer that asks for bounded normalization receives only the displayed finite socket rows: the candidate term window M, a fuel row U, a bounded trace row T, a closedness-preservation row Q, and the structural rows H, C, P, N that transport and name that finite route. The trace row records that the fuel-indexed computation reaches the displayed bounded result within U steps and that each recorded step preserves the closedness row Q. The socket does not export a strong-normalization certificate, a no-infinite-reduction theorem, an erased candidate projection, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency from this bounded trace.*

Proof. Project the socket carrier of Definition 3566.1. The closed typed term window is available as M, while candidate, closed-candidate, and candidate-set rows remain the only rows that can support any strong-normalization export.

For bounded normalization, insert the fuel row U and bounded trace row T between the term window and the replay rows. The trace is finite because each step is indexed by the displayed fuel ledger rather than by an unbounded reduction argument.

Closedness preservation is carried separately by Q. Each trace edge may be read only together with the source and target closedness rows named by Q, so the consumer receives a closed finite computation rather than a global normalization theorem.

Finally, H, C, P, N transport, replay, package, and name exactly these displayed rows. Since no strong-normalization certificate is a coordinate of the bounded route, the socket boundary refuses any consumer that tries to read strong normalization from fuel alone. □

The bounded trace row U, T, Q is the local socket-side consumer of the MetaCIC normalization fuel boundary in chapter 5936. The socket fuel boundary reuses the MetaCIC fuel ledger as bounded trace evidence while refusing to turn fuel alone into strong normalization or no-infinite-reduction.

Theorem 3566.7 (Normalization candidate socket fuel-erasure refusal)**.** *Every* NormalizationCandidateSocket$^{\uparrow}$ *no-infinite-reduction read or closed strong-normalization read that crosses the socket fuel boundary must preserve the candidate rows K, D, E and the candidate-set fuel route before reading the no-infinite-reduction row I or frontier refusal row F. Erasing K, D, E from such a read turns the socket into an unconditional normalization endpoint over the closed typed term window M and fuel row U, but the carrier has no coordinate for that endpoint. The erased route is therefore refused at F rather than exported as evidence-free normalization.*

Proof. Project the carrier rows and use the fuel boundary of Definition 3566.6. The fuel row U and trace row T expose only bounded computation data, while the candidate rows K, D, E remain the visible evidence rows for strong-normalization and no-infinite-reduction reads.

Now apply the candidate-set fuel route of Definition 3566.8. A read that reaches candidate-set evidence must pass through E, the App and Pi adequacy rows, the bounded trace, the closedness-preservation row, and the structural rows before any public normalization-facing consequence is named.

Use the fuel-boundary candidate gate, Definition 3566.9. If K, D, E are erased, the fuel boundary cannot be lowered into a strong-normalization or no-infinite-reduction export; the only admissible output is the frontier refusal row F.

Finally specialize the candidate-set readback theorem, Definition 3566.10. It places the no-infinite-reduction row I downstream of M, E, A, B and the structural route. Thus reading I or F after deleting K, D, E would assert an endpoint that the carrier does not store, so the socket refuses the erased route. □

Theorem 3566.8 (Normalization candidate socket candidate-set fuel route)**.** *If an accepted* NormalizationCandidate *packet exposes the candidate-set row E and bounded fuel row U, then every bounded normalization read factors through candidate evidence, the closedness-preservation trace, App and Pi adequacy rows, the bounded trace, and the structural rows H, C, P, N. The route uses the candidate-set readback row E, the App adequacy row A, the Pi adequacy row B, the bounded trace row T, the closedness-preservation row Q, and the fuel row U; it does not export global strong normalization or completed closed consistency.*

Proof. Project the socket rows from Definition 3566.1. The candidate-set row E supplies the candidate evidence available to the bounded read, while the adequacy rows A and B keep application and Pi cases attached to that evidence.

Use Definition 3566.6. The bounded fuel row U and trace row T display the finite computation, and the closedness-preservation row Q accompanies each recorded step.

The transport and replay rows preserve the order of the read. Thus H, C, P, N can move and name only the route that has already passed through candidate evidence, adequacy rows, bounded fuel, bounded trace, and closedness preservation.

Since neither the candidate-set route nor the bounded-fuel boundary contains a coordinate for global strong normalization or completed closed consistency, those conclusions are not exported by the packet. □

Theorem 3566.9 (Normalization candidate socket fuel-boundary candidate gate)**.** *A fuel-indexed normalization read of an accepted* NormalizationCandidateSocket$^{\uparrow}$ *packet may lower or inspect the finite fuel boundary only while at least one of the candidate rows K, D, E remains visible. If K, D, E are erased, the read is forced to the frontier refusal row F and cannot export no-infinite-reduction, evidence-erased strong normalization, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency.*

Proof. Project the carrier of Definition 3566.1. The strong-normalization and no-infinite-reduction exports are mediated by the candidate rows K, D, E, while the fuel row is only route data for bounded inspection.

Apply the boundary theorem Definition 3566.2. It places normalization-facing reads downstream of visible candidate evidence rather than downstream of the closed term window alone.

Use candidate-erasure refusal, Definition 3566.3. When K, D, E are removed, the packet has no candidate evidence to support a no-infinite-reduction read, so the frontier refusal row F is the only admissible boundary.

Thus fuel inspection can refine a displayed bounded trace but cannot replace reducibility-candidate evidence. The excluded strong-normalization, confluence, quotient, evaluator, and consistency conclusions require coordinates absent from the fuel boundary. □

Theorem 3566.10 (Normalization candidate socket candidate-set readback)**.** *If an accepted* NormalizationCandidat *packet exposes the candidate-set row E, then closed typed strong-normalization and no-infinite-reduction reads factor through the finite route*

$$M, E, A, B, I, H, C, P, N.$$

Bounded fuel rows may refine the displayed trace, but they cannot replace E as the candidate-set readback row. The packet therefore refuses global normalization, erased candidate projection, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, and completed consistency.

Proof. Project the carrier of Definition 3566.1. The closed typed term window M is available to the socket, but Definition 3566.2 places strong-normalization and no-infinite-reduction exports downstream of candidate evidence.

Now specialize that boundary to the candidate-set row E. The application adequacy row A and Pi adequacy row B can refine the route through function and dependent-function cases, while I records the no-infinite-reduction read downstream of the candidate-mediated strong-normalization projection.

Use Definition 3566.6 for bounded fuel traces. A fuel row may display a finite computation and preserve closedness along that trace, but it supplies no candidate-set membership, no candidate soundness, and no beta-closure data. It therefore cannot replace E.

Finally H, C, P, N transport, replay, source, and name the candidate-set route. Since neither the base carrier nor the bounded-fuel extension contains rows for global normalization, erased candidate projection, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed consistency, those reads remain refused. □

The $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ dependency route reads the candidate rows K, D, E, App and Pi adequacy rows A, B, and frontier refusal row F beside the MetaCIC candidate normalization witness of chapter 6577. The socket therefore records witness-facing dependency as a horizontal route through displayed candidate evidence, not as a theorem-free shortcut from a closed term window to global normalization.

Theorem 3566.11 (Normalization candidate socket MetaCIC candidate dependency route)**.** *The* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *packet consumes candidate-mediated strong-normalization evidence and normalization-frontier rows through chapter 892 and chapter 765. Its accepted route therefore reads candidate, closed-candidate, candidate-set, App adequacy, Pi adequacy, no-infinite-reduction, and frontier-refusal rows before any kernel-facing consumer may use the socket. The socket is not a kernel-only packet and cannot export strong normalization or confluence without the displayed MetaCIC candidate dependency edge.*

Proof. Project the carrier of Definition 3566.1. The candidate rows K, D, E, adequacy rows A, B, no-infinite-reduction row I, and frontier refusal row F are all visible in the same finite socket.

Use the boundary theorem Definition 3566.2 and the diamond route Definition 3566.4. They keep normalization-facing reads downstream of the candidate evidence rows and attach the socket to the MetaCIC critical-path consumer.

Finally read the normalization frontier and critical path chapters as the candidate-mediated parents. The accepted socket route therefore depends on those MetaCIC rows rather than floating as a closed-term or kernel-only surface. □

The $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ packet reads the subject-reduction discharge surface through chapter 765 and the normalization-frontier sibling of chapter 892. A candidate-normalization consumer must therefore expose the critical-path subject-reduction budget, the displayed normalization frontier rows, and the socket-local candidate evidence before treating the socket as a closed proof. The route is a forward dependency edge for MetaCIC normalization discharge, not an independent strong-normalization theorem or a replacement for the subject-reduction proof surface. The $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ route is consumed by chapter 892 and chapter 6577 only after the candidate evidence rows, endpoint obstruction row, and socket rows remain visible in the same finite packet. The frontier read therefore passes through displayed candidate evidence rather than treating the socket as a theorem-free normalization endpoint.

Theorem 3566.12 (NormalizationCandidateSocket frontier cross-reference)**.** *Every* MetaCICNormalizationFrontier *consumer of a* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *packet must first pass through the candidate evidence rows, endpoint obstruction rows, socket rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before any normalization endpoint is read. The route reaches the frontier consumer of chapter 892 and the candidate witness surface of chapter 6577 only after those rows remain visible in the same finite packet.*

Proof. Project the accepted socket packet. Its public coordinates already contain the candidate evidence rows, endpoint obstruction rows, socket rows, transport, replay, provenance, and local naming.

The frontier route then consumes those displayed rows through the sibling dependency named in chapter 892. The witness route of chapter 6577 is available only as part of the same displayed candidate evidence surface.

Since no carrier coordinate stores an already-read endpoint or an external normalization result, any endpoint-facing read must traverse the listed rows before it reaches the frontier consumer. □

Theorem 3566.13 (NormalizationCandidateSocket frontier dependency)**.** *Every endpoint-facing* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ *read must expose candidate evidence rows, frontier refusal rows,* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* $\mathsf{MetaCICCriticalPath}^{\uparrow}$*, and candidate-normalization witness rows before it exports a normalization endpoint. The conclusion is conditional on the displayed socket packet and claims no global strong normalization, subject reduction, confluence, evaluator equality, or kernel consistency.*

Proof. Start with the frontier cross-reference of Definition 3566.12. It already routes a frontier consumer through candidate evidence, endpoint obstruction, socket, transport, replay, provenance, and local naming rows before any normalization endpoint is read.

Use the socket boundary theorem from the parent chapter. The endpoint-facing surface of $\mathsf{NormalizationCandidateSocket}^{\uparrow}$ is therefore not available until the finite packet has displayed the candidate evidence and refusal rows that keep the endpoint conditional.

The $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ row supplies the frontier side of that refusal, while the $\mathsf{MetaCICCriticalPath}^{\uparrow}$ row records the critical-path dependency that must remain visible to endpoint consumers. The candidate-normalization witness rows are read as part of the same finite packet, not as an external evaluator equality or kernel theorem.

Thus an endpoint-facing read can export only the conditional endpoint licensed by those displayed rows. It cannot turn the socket into global strong normalization, subject reduction, confluence, evaluator equality, or kernel consistency. □

Chapter 3567

A Concrete Naming Certificate for MetaCICSnCandidateInterface$^{\uparrow}$

The MetaCICSnCandidateInterface$^{\uparrow}$ packet realizes the candidate-mediated strong-normalization frontier of chapter 9386 as finite MetaCIC NameCert data. It sits beside the normalization frontier of chapter 892, the closure trace of chapter 795, the normalization certificate router of chapter 1108, and the closed-term substitution boundary of chapter 527. The packet names candidate evidence, closed-candidate routing, bounded-normal endpoint data, and subject-reduction frontier retention without claiming evidence-free closed-term normalization.

Definition 3567.1 (MetaCIC SN candidate interface carrier)**.** *A* MetaCICSnCandidateInterface$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, K, L, B, E, F, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term window in scope for the normalization read.*
2. *K is the candidate evidence row, allowing candidate, closed-candidate, or candidate-set evidence to be displayed explicitly.*
3. *L is the closed-candidate routing row that binds the evidence in K to the closed-term boundary consumed by downstream readers.*
4. *B is the bounded normalizer evidence row, recording the finite endpoint data available at the inspected fuel or budget.*
5. *E is the endpoint readback row that exposes the bounded normal form only after T, K, L, B have been displayed.*
6. *F is the subject-reduction frontier retention row, keeping the required subject-reduction discharge boundary visible instead of erasing it into an unconditional theorem.*
7. *H stores componentwise* hsame *transport for closed typed terms, candidate evidence, closed-candidate routing, bounded endpoint data, frontier retention, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay for candidate-mediated normalization requests.*

9. *P is the* Pkg *provenance over* $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICClosureTrace}^{\uparrow}$, $\mathsf{MetaCICNormalizationCertificateRouter}^{\uparrow}$, $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSnCandidateInterface}^{\uparrow}}$ *row.*

The classifier accepts only packets whose strong-normalization-facing read traverses $T, K, L, B, E, F, H, C, P, N$. It has no coordinate for unconditional closed-term normalization, evidence-free strong normalization, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or completed closed consistency.

Lean4 ✓ `BEDC.Derived.MetaCICSnCandidateInterfaceUp.MetaCICSnCandidateInterfaceTasteGate single carrier alignment`

Theorem 3567.2 (MetaCIC SN candidate interface NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$ *carrier $S = (T, K, L, B, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICSnCandidateInterface}^{\uparrow}}$ *obligations are exactly carrier admission, closed typed term scoping, candidate evidence admission, closed-candidate routing, bounded normalizer endpoint readback, subject-reduction frontier retention, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 3567.1. Carrier admission exposes exactly the closed term window, candidate evidence, closed-candidate route, bounded endpoint data, frontier retention, and structural rows.

Read the candidate side first. The rows T, K, L ensure that a closed typed term is paired with explicit candidate evidence and that the evidence is routed through the closed-term boundary before any endpoint readback is consumed.

The bounded endpoint row is then inspected through B and E. This read records only finite normalizer evidence at the displayed budget, not a global normalization theorem.

Finally, F, H, C, P, N keep the subject-reduction frontier, transport, replay, provenance, and local name visible. Since the carrier lacks evidence-free normalization, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, and completed consistency rows, the listed obligations exhaust the packet. □

Theorem 3567.3 (MetaCIC SN candidate interface frontier refusal)**.** *Any closed-term strong-normalization consumer of an accepted* $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$ *packet is refused unless the route exposes candidate evidence, bounded normalizer evidence, subject-reduction frontier retention, transport, replay, provenance, and local naming rows. The packet cannot be read as arbitrary closed-term normalization or as a completed MetaCIC consistency theorem.*

Proof. Start from the closed typed term window T. The carrier makes T visible only together with the candidate evidence row K and closed-candidate routing row L.

Inspect the endpoint data. Rows B and E provide bounded normalizer evidence and endpoint readback at the displayed budget, so a consumer cannot skip directly from a closed term to a strong-normalization conclusion.

Now read the frontier row F. It retains the subject-reduction boundary as part of the packet rather than discharging it as an unconditional theorem.

The structural rows H, C, P, N preserve and name the same candidate-mediated route. Therefore any consumer missing one of these rows is refused, and the packet cannot export evidence-free closed-term normalization or completed consistency. □

Falsifiable prediction: If a MetaCIC strong-normalization consumer exports a closed-term SN row without candidate evidence, bounded normalizer evidence, subject-reduction frontier retention, transport, replay, provenance, and local naming rows, then the packet is refuted.

Independence witness: metacicnormalizationfrontier, metacicclosuretrace, metacicnormalizationcertificaterouter, closedtermsubstitutionboundary: $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries candidate evidence, closed-candidate routing, bounded-normal endpoint data, and subject-reduction frontier retention.

The Lean TasteGate site for $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$ provides explicit Nontrivial MetaCICSnCandidateInter and FieldFaithful $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$ instances in `TasteGate.lean`. These instances preserve candidate evidence, closed-candidate routing, bounded endpoint readback, subject-reduction frontier retention, transport, replay, provenance, and local naming as distinguishable fields.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSnCandidateInterface}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$ packet is generated from a closed typed MetaCIC term window, candidate evidence, closed-candidate routing, bounded normalizer endpoint data, subject-reduction frontier retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSnCandidateInterface}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3567.1, Definition 3567.2, and Definition 3567.3 seed the finite candidate-mediated strong-normalization interface for MetaCIC readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSnCandidateInterface}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MetaCICSnCandidateInterfaceUp.MetaCICSnCandidateInterfaceTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close arbitrary closed-term normalization, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, completed closed consistency, full MetaCIC strong normalization, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate evidence routing, bounded endpoint readback, subject-reduction frontier retention, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICSnCandidateInterfaceUp.

$\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ reads its finite family-modulus packet as a consumer of chapter 388, chapter 369, and chapter 413, while the routed child files below keep the compact-net, equicontinuity, and completion handoffs separate.

Chapter 3568

A Concrete Naming Certificate for $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ packet records the finite-modulus subsequence route for an equicontinuous family on a compact metric source. It consumes the uniform-continuity witness pattern of chapter 3444, the compact source surface of chapter 129, the displayed map rows of chapter 130, the window schedules of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the dyadic tolerance arithmetic of chapter 291. The chapter names a finite extraction certificate; it does not assert general open-cover compactness, selected subsequence choice, host function-space compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Concretely, $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ consumes the equicontinuity-family rows of chapter 4076 and the compact metric finite-net rows of chapter 129 before exporting a finite modulus packet.

It also consumes the compact finite-net and uniform-modulus route of chapter 7330 together with the equicontinuity obligation surface of chapter 4076 before exposing the Arzela–Ascoli finite-modulus carrier.

The same finite-modulus route is consumed by the downstream selector lattice of chapter 4076, chapter 388, and chapter 914. Before selector rows are exported, the route also consumes the finite ProbeBundle realization route of chapter 3957, which supplies compact metric coverage, continuous pointwise moduli, RatUp lower-bound folds, and UniformModulusUp handoff rows for $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$. It also reads the finite compactness certificate of chapter 3586, whose compact-metric, finite-net-equicontinuity, compact-uniform-continuity-modulus, and finite-epsilon-net rows are available before the selector row is exported. The downstream equicontinuity and compact-uniform-continuity chapters consume the shared finite-modulus row M only through this displayed lattice, so their dependency on $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ is a row-level handoff rather than a hub-level citation. Those siblings may read the packet only after the compact metric, continuous-map, finite-window, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows are displayed. In row form, the selector lattice receives exactly $K, F, M, W, R, E, H, C, P, N$: K supplies the compact finite-net source, F the inspected continuous-map family, M the shared finite modulus, W the windows, R the rational readback, E the terminal real seal, and H, C, P, N the transport, replay, provenance, and local naming rows.

The finite-modulus extraction route also consumes the compact-uniform-continuity surface of chapter 388 and the uniform modulus ledger of chapter 369 before exporting any Arzela–Ascoli selection row. Compact finite nets provide the domain-side finite cover, while $\mathsf{UniformModulus}^{\uparrow}$ supplies the image-side modulus ledger that keeps the extracted windows tied to one displayed

tolerance schedule.

Before any selector-facing row is exported, the same finite-modulus extraction also consumes compact oscillation and compact uniform modulus rows, for example through chapter 2299. The dependency is row-level: compact finite-net data, oscillation or modulus ledgers, $\mathsf{UniformModulus}^{\uparrow}$ handoff, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows are exposed before selection data, without selected subsequence choice or host function-space compactness.

Definition 3568.1 (Arzela–Ascoli finite-modulus carrier)**.** *An* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, F, M, W, R, E, H, C, P, N)$$

with the following rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source certificate, read only through finite net and dyadic-radius data;*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family surface, inspected by finite* $\mathsf{StreamName}^{\uparrow}$ *windows rather than by a host function-space object;*
3. *M is the finite common modulus ledger, routed through* $\mathsf{HeineCantor}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows;*
4. *W is the finite net-window extraction surface for the chosen inspected depths;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the extracted finite values;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed pointwise limit windows;*
7. *H records componentwise* hsame *transport of K, F, M, W, R, E;*
8. *C records displayed* Cont *replay of the same finite extraction route;*
9. *P is the* Pkg *provenance over* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{HeineCantor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a choice-selected subsequence, function-space compactness, quotient equality of real names, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.ArzelaAscoliFiniteModulusUp.ArzelaAscoliFiniteModulusCarrier`
Lean4 ✓ `BEDC.Derived.ArzelaAscoliFiniteModulusUp.ArzelaAscoliFiniteModulusTasteGate single carrier alignment`

Theorem 3568.2 (Arzela–Ascoli finite-modulus NameCert obligations)**.** *For the carrier of Definition 3568.1, the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-metric source admission through K, continuous-map family admission through F, finite common modulus admission through M, finite net-window extraction through W, regular rational readback through R, pointwise* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ArzelaAscoliFiniteModulusUp.ArzelaAscoliFiniteModulusNamecertObligations`

Proof. Project the carrier. The compact source row K, continuous-map row F, and finite common modulus row M are visible before any limit seal is read.

Read the extraction rows next. The finite windows W are selected from displayed net data and inspected depths, while R reads those windows as regular rational schedules through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$.

Finally the seal row E and the structural rows H, C, P, N transport, replay, source, and name exactly that finite route. Since no other coordinate appears in the carrier, no open-cover compactness, selected subsequence choice, host function-space compactness, quotient real equality, or ambient completeness obligation is introduced. □

Theorem 3568.3 (Arzela–Ascoli equicontinuous finite-net extraction)**.** *Let $A = (K, F, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *carrier. Every equicontinuous extraction row factors through the compact metric finite-net data in K, the common finite modulus in M, and the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows in W before the regular rational readback R is consumed. Thus the extraction is a dyadic finite-net construction over* $\mathsf{DyadicRatCore}^{\uparrow}$ *and not a host compactness or function-space compactness principle.*

Proof. Use the compact source row K to obtain only the displayed finite-net and radius data. The row does not expose an arbitrary open-cover compactness theorem.

Apply the finite common modulus row M. It routes the inspected family values through the same Heine–Cantor-style modulus ledger at every selected depth.

The row W then records the finite net windows, and R reads them as $\mathsf{RegSeqRat}^{\uparrow}$ schedules. Transport and replay by H and C preserve the same dyadic route, so no selected subsequence or host function-space compactness object is available. □

Theorem 3568.4 (Arzela–Ascoli subsequence nonescape)**.** *Every subsequence or limit-facing consumer of an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *carrier must pass through*

$$K, F, M, W, R, E, H, C, P, N.$$

The consumer receives finite compact-source nets, continuous-map inspection rows, a shared modulus ledger, finite extraction windows, regular rational readback, and a $\mathsf{Real}^{\uparrow}$ *seal. It receives no selected subsequence choice, no host function-space compactness theorem, no quotient equality of real names, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with Definition 3568.3. It places the compact-source nets, common modulus, finite windows, and regular rational readback before the limit seal.

Then read the seal row E. It is downstream of K, F, M, W, R and therefore names only the displayed pointwise limit windows.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier inventory in Definition 3568.1 has no field for the excluded host principles, those principles cannot escape through the subsequence consumer. □

Theorem 3568.5 (Arzela–Ascoli finite-modulus forward lattice)**.** *Every downstream read of an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet by chapter 4076, chapter 388, or chapter 914 factors through the displayed rows*

$$K, F, M, W, R, E, H, C, P, N.$$

The consuming selector receives compact metric finite-net data, continuous-map inspection data, a finite common modulus ledger, finite windows, regular rational readback, the terminal $\mathsf{Real}^{\uparrow}$ *seal, and dyadic tolerance arithmetic before it can export any finite selector row. It receives no selected subsequence choice, host function-space compactness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 3568.1. The compact metric row K, continuous-map family row F, finite common modulus row M, and window row W are visible before any selector-facing consumer can read a limit row.

Apply Definition 3568.3. It places the finite-net and modulus route ahead of the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R and keeps the dyadic tolerance arithmetic in the displayed dependency surface.

Before the selector row is exported, read chapter 3586. Its compact-metric, finite-net-equicontinuity, compact-uniform-continuity-modulus, and finite-epsilon-net rows provide the finite compactness certificate that feeds the same selector route.

Finally apply Definition 3568.4. The real seal E and structural rows H, C, P, N preserve the same finite route for the equicontinuity, compact-uniform-continuity, and compact-net-modulus selector siblings. Since no excluded host principle is a carrier coordinate, no downstream selector can consume one through this packet. □

Theorem 3568.6 (Arzela–Ascoli Heine–Cantor compactness route)**.** *Every selector-facing finite-modulus read of an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *carrier*

$$A = (K, F, M, W, R, E, H, C, P, N)$$

first consumes the compact uniform modulus route supplied by $\mathsf{HeineCantor}^{\uparrow}$*, the finite-net source data of* $\mathsf{CompactMetric}^{\uparrow}$*, the pointwise rows of* $\mathsf{ContinuousMap}^{\uparrow}$*, the tolerance ledger of* $\mathsf{UniformModulus}^{\uparrow}$*, the finite windows of* $\mathsf{StreamName}^{\uparrow}$*, the regular readback of* $\mathsf{RegSeqRat}^{\uparrow}$*, the tolerance arithmetic of* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Only after these rows are visible may the selector export a finite-modulus handoff to chapter 4076, chapter 388, or chapter 914.*

Proof. Project the carrier. The displayed rows $K, F, M, W, R, E, H, C, P, N$ expose the compact source, inspected continuous-map family, finite modulus ledger, finite windows, rational readback, terminal real seal, transport, replay, provenance, and local naming.

Apply Definition 3568.5. It places the selector-facing read behind the compact metric, continuous-map, finite-modulus, window, readback, real-seal, and dyadic tolerance rows.

Now read Definition 3568.9. The compact-uniform finite-selector route forces the same consumer to pass through the $\mathsf{HeineCantor}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ sibling rows before it reaches the compact-uniform-continuity surface.

Finally apply Definition 3568.4. Since the packet has no selected subsequence choice, host function-space compactness, quotient real equality, or ambient completeness coordinate, the Heine–Cantor compactness route remains a finite row-level dependency for every selector-facing export. □

Theorem 3568.7 (Arzela–Ascoli compact-open dependency)**.** *Every finite-modulus extraction read that compares a family of maps in an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet must first pass through the* $\mathsf{CompactOpenMetric}^{\uparrow}$ *finite source-net, graph-sampling, target-distance, and sup-distance rows of chapter 1903 before exporting the* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *selector row. In the notation of Definition 3568.1, the dependency is read through*

$$K, F, M, W, R, E, H, C, P, N.$$

Proof. Project the accepted carrier. The compact source row K supplies the finite source-net surface, while the continuous-map family row F supplies the maps whose graph samples are compared.

Read the modulus and window rows M, W. They restrict the comparison to displayed finite source windows and keep the sampled values tied to one tolerance schedule.

Now apply the compact-open metric route of chapter 1903. Its target-distance and finite sup-distance rows are consumed before the regular rational readback R and terminal seal E are available to the selector.

Finally H, C, P, N transport, replay, source, and name the same route. Thus the Arzela–Ascoli finite-modulus selector receives a compact-open finite sup-distance dependency, not an unrecorded host function-space comparison. □

Theorem 3568.8 (Arzela–Ascoli finite modulus compactmetric link)**.** *Every selector-facing read through an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet consumes the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source,* $\mathsf{ContinuousMap}^{\uparrow}$ *family rows,* $\mathsf{Equicontinuity}^{\uparrow}$ *family-modulus rows,* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, and* $\mathsf{Real}^{\uparrow}$ *seal before exporting selector data. In the notation of Definition 3568.1, this read is carried by the finite rows*

$$K, F, M, W, R, E, H, C, P, N.$$

Proof. Begin with the compactmetric sibling readback in Definition 3568.3. It places the compact metric finite-net source K and the common finite modulus M before the regular rational readback.

Apply Definition 3568.5. The selector-facing lattice then reads the continuous-map family rows, equicontinuity family-modulus rows, finite windows, dyadic tolerance arithmetic, and terminal $\mathsf{Real}^{\uparrow}$ seal in the same displayed route.

Use Definition 3568.7 for the compact-open comparison. It keeps graph-sampling and finite sup-distance data downstream of the compact metric and continuous-map rows.

Finally apply Definition 3568.4. The seal and structural rows E, H, C, P, N prevent selector data from escaping the finite row surface, so no selected subsequence choice, host function-space compactness, quotient real equality, or ambient completeness is exported. □

Theorem 3568.9 (Arzela–Ascoli compact-uniform finite-selector route)**.** *Any* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *finite-selector consumer of an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet must first read*

$$K, F, M, W, R, E, H, C, P, N$$

together with the compact metric, continuous map, Heine–Cantor, $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *sibling rows. The route then lands in chapter 388 only through the finite selector surface also consumed by chapter 914.*

Proof. Project the carrier of Definition 3568.1. The rows $K, F, M, W, R, E, H, C, P, N$ expose the compact metric source, continuous-map family, finite common modulus, finite windows, regular rational readback, Real seal, transport, replay, provenance, and local naming.

Apply Definition 3568.5. It already forces every downstream finite-selector read to pass through the compact metric, continuous-map, Heine–Cantor, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before any selector-facing handoff is available.

Therefore the compact-uniform-continuity consumer reaches chapter 388 by the same finite route that feeds chapter 914, with no selected subsequence choice, host function-space compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle inserted. □

Falsifiable prediction: Every consumer of an $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ packet must read the compact metric finite nets, continuous-map family windows, finite common modulus, regular rational readback, and $\mathsf{Real}^{\uparrow}$ seal before consuming the extracted limit row.

Independence witness: compactmetric, continuousmap, heine-cantor, streamname, regseqrat, real, dyadicratcore: $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ is not bijective to any listed sibling because it

jointly carries compact-source nets, a continuous-map family surface, a finite common modulus ledger, finite extraction windows, regular rational readback, Real sealing, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}}$.

Constructive story: An $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ packet is generated from compact metric finite nets, continuous-map family windows, a finite common modulus ledger, finite extraction windows, regular rational readback, a RealUp seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3568.1, Definition 3568.2, Definition 3568.3, and Definition 3568.4 bind the finite-modulus extraction surface for one displayed equicontinuous family.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, selected subsequence choice, host function-space compactness, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Scoped closure requires the finite-net extraction rows, Real seal row, and NameCert dependency surface to be formalized for BEDC.Derived.ArzelaAscoliFiniteModulusUp.

Lemma 3568.10 (Arzela–Ascoli compact-metric forward lattice)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet consumes the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net carrier of chapter 129 and the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *modulus route before a finite selector row can be read. The dependency remains the displayed finite lattice through compact metric nets, compact-uniform-continuity moduli, inspected stream windows, regular rational readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal; it does not expose open-cover compactness, selected subsequence choice, host function-space compactness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3568.11 (Arzela–Ascoli compact metric forward route)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet consumes the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows of chapter 129 and the* $\mathsf{Equicontinuity}^{\uparrow}$ *pointwise modulus rows of chapter 4076 before exporting its finite subfamily modulus route. In the carrier of chapter 3568, the compact metric source row is read before the equicontinuity family row, the shared finite modulus row, the finite window ledger, the regular rational readback, and the terminal real seal.*

Lean4 ✓ `BEDC.Derived.Arzela ascoli finite modulusUp.ArzelaAscoliFiniteModulusCompactmetricForwardRoute`

Proof. Project the accepted $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ carrier through the local NameCert chapter chapter 3568. The compact metric coordinate supplies only finite-net centers, radius rows, and source coverage windows.

Read the equicontinuity coordinate next. Its pointwise modulus rows are attached to the displayed family and to the compact metric source windows, so the shared finite modulus cannot be exported before those two dependency surfaces are visible.

The finite subfamily modulus route then reads the window ledger, regular rational readback, real seal, transport, replay, provenance, and local naming rows. Since neither dependency chapter exports a selected subsequence or host function-space compactness row, the Arzela–Ascoli packet remains a finite forward route from $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{Equicontinuity}^{\uparrow}$ into the local selector surface. □

Theorem 3568.12 (Arzela–Ascoli compact metric forward reference)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *extraction first reads the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row* K *of chapter 129 before any selector output, finite window, regular rational readback, or terminal* $\mathsf{Real}^{\uparrow}$ *seal is public. The route then passes through the continuous-map row* F*, finite modulus row* M*, window row* W*, readback row*

R, seal row E, and structural rows H, C, P, N; it exports no open-cover compactness theorem, selected subsequence choice, host function-space compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3568.1. The compact source row K is the only coordinate that names compact metric data, and it is read as finite-net and dyadic-radius information.

Apply the finite-net extraction theorem Definition 3568.3. It places K before the shared modulus row M, the inspected windows W, and the regular rational readback R.

Finally use the nonescape theorem Definition 3568.4. The terminal seal E and the structural rows H, C, P, N preserve the same finite route, so no selector-facing consumer can bypass the $\mathsf{CompactMetric}^{\uparrow}$ source row or replace it by an excluded host compactness principle. □

Theorem 3568.13 (Arzela–Ascoli finite modulus compact-metric sibling readback)**.** *Any finite-modulus selector read through an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet must first consume the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows of chapter 129 and the* $\mathsf{ContinuousMap}^{\uparrow}$ *family rows before the selector row can be exported. The route passes through the compact-uniform-continuity finite-modulus handoff of chapter 7330; it therefore exposes finite covers, continuity witnesses, and the shared modulus ledger before a downstream consumer may read the* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *selector.*

Proof. Read the compact-metric sibling first. The finite-net rows named by chapter 129 provide the bounded finite cover surface on which a modulus selector can be evaluated.

Next read the $\mathsf{ContinuousMap}^{\uparrow}$ family rows. These rows keep the maps in the family visible as continuous data rather than as an external collection of functions.

Finally pass through chapter 7330. Its finite-modulus handoff is the point where compactness and continuity are combined, so the $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ selector row can be exported only after those sibling rows have been consumed. □

Theorem 3568.14 (Arzela–Ascoli compact-equicontinuity finite-modulus dependency)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *selector route consumes three sibling surfaces before the Arzela–Ascoli readback is public: the compact finite-net source of chapter 129, the shared family-modulus discipline of chapter 4076, and the compact-uniform finite-modulus handoff of chapter 7330. In carrier rows, the compact metric dependency supplies K, equicontinuity supplies the family-level constraint read by F and M, and compact-uniform continuity supplies the finite modulus handoff consumed before W, R, E, H, C, P, N are exported.*

Proof. Start with the compact metric sibling. Its finite-net source gives the only compact-domain row available to the selector route, so the readback cannot begin from an unrecorded host compactness theorem.

Next consume the equicontinuity sibling. The shared family-modulus rows constrain the continuous-map family before the finite-modulus row M can be read as a common selector budget.

Finally use the compact-uniform finite-modulus handoff. It combines compact finite nets with the displayed continuity rows before the stream windows, regular rational readback, and terminal real seal are exposed. Therefore the Arzela–Ascoli readback is a consumer of those three sibling surfaces, not a kernel-only packet detached from the dependency lattice. □

Theorem 3568.15 (Arzela–Ascoli compact-metric sibling route)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *selector row consumes the compact-metric finite-net source of chapter 129, the equicontinuity family rows, the compact-uniform-continuity finite-modulus handoff, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$

seal, the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and the local* $\mathsf{NameCert}$ *rows before the selector is public. In displayed carrier order the route is*

$$K,\ F,\ U,\ R,\ E,\ Q,\ H,\ C,\ P,\ N,$$

where K is the compact-metric finite-net source, F is the family-level equicontinuity surface, U is the compact-uniform finite-modulus handoff, R is regular-rational readback, E is the terminal Real seal, Q is the dyadic tolerance ledger, and H, C, P, N are componentwise transport, replay, provenance, and local naming.

Proof. Read the displayed row order. The compact-metric source K is first because the selector cannot choose a finite modulus over an unnamed compact domain; its substantive sibling source is chapter 129.

Next consume the equicontinuity family row F and the compact-uniform handoff U. These rows expose the family constraint and the finite-modulus transfer before any rational or Real-facing readback occurs.

Finally read R, E, Q, H, C, P, N in the stated order. The regular-rational row, Real seal, dyadic tolerance ledger, transport, replay, provenance, and local naming rows together make the selector public without adding an external compactness theorem, hidden choice of subsequence, or host-level equality. □

Theorem 3568.16 (Arzela–Ascoli compact-image bounded dependency route)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *finite-selector read that exports selector-facing modulus data must first consume the compact source nets of chapter 129, the displayed map rows of chapter 130, the finite tolerance ledger of chapter 369, and the bounded image radius route of chapter 3924. In carrier notation, the read stays inside*

$$K, F, M, W, R, E, H, C, P, N.$$

Thus the selector-facing finite modulus is exported only after compact source nets, uniform continuity data, bounded image radius data, regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ *seal have all been displayed.*

Proof. Project the accepted carrier of Definition 3568.1. The compact source row K, continuous-map row F, finite modulus row M, window row W, regular readback row R, terminal seal row E, and structural rows H, C, P, N are the only rows available to a selector-facing consumer.

Apply the forward lattice theorem Definition 3568.5. It places compact metric finite-net data, continuous-map inspection, finite common modulus data, finite windows, dyadic tolerance arithmetic, regular rational readback, and the $\mathsf{Real}^{\uparrow}$ seal before any downstream selector row is public.

Read the compact-image boundedness sibling next. The total-bounded image certificate of chapter 3924 supplies the bounded radius route consumed after the compact source nets, continuous-map rows, and uniform modulus ledger have been displayed.

Finally use subsequence nonescape from Definition 3568.4. Since the carrier has no coordinate for open-cover compactness, selected subsequence choice, host function-space compactness, quotient real equality, or ambient completeness, the selector-facing finite modulus cannot bypass the compact-image boundedness data while remaining inside the accepted packet. □

The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ packet consumes the finite Cauchy modulus surface of chapter 1486 together with the equicontinuity schedule rows already routed through the compact finite-net lattice. A compactness consumer therefore reads the Cauchy-modulus threshold, the

equicontinuity schedule, and the compact finite-net rows before it may inspect the Arzela–Ascoli finite-modulus packet. The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ selector-facing route also consumes the $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ packet of chapter 5549. This child route records the finite compact-net, pointwise modulus, rational lower-bound fold, and $\mathsf{UniformModulus}^{\uparrow}$ handoff rows as a dependency before any finite extraction data is public.

Theorem 3568.17 (Arzela–Ascoli compact-uniform-continuity ledger route)**.** *Every accepted* ArzelaAscoliFiniteMo *selector read that exports finite-modulus data must first consume the* $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ *rows through finite compact-net data, pointwise modulus rows, rational lower-bound folds, and the terminal* $\mathsf{UniformModulus}^{\uparrow}$ *handoff. In the notation of Definition 3568.1, the read remains inside*

$$K, F, M, W, R, E, H, C, P, N.$$

It therefore exports no open-cover compactness theorem, selected subcover, selected subsequence, host function-space compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3568.1. The compact source row K, continuous-map family row F, finite modulus row M, finite windows W, regular readback R, terminal seal E, and structural rows H, C, P, N are the only rows available to a selector-facing consumer.

Apply Definition 3568.5. It places compact finite-net data, inspected pointwise rows, finite tolerance ledgers, dyadic arithmetic, regular rational readback, and the $\mathsf{Real}^{\uparrow}$ seal before any selector row is exported.

Read the $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ route through Definition 5549.3. Its lower-bound fold and $\mathsf{UniformModulus}^{\uparrow}$ handoff supply the compact-uniform-continuity dependency consumed by the finite modulus row M.

Finally apply Definition 3568.4. Since the carrier contains no field for open-cover compactness, selected subcovers, selected subsequences, quotient real equality, countable choice, or ambient completeness, the selector-facing export cannot bypass the compact-uniform-continuity ledger. □

The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ finite modulus is consumed by compact-uniform-continuity and equicontinuity-family routes: chapter 388 uses the compact window budget as the continuity handoff, while chapter 413 reads the same finite family modulus before exporting an equicontinuity surface. The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ hub consumes the compact-uniform-continuity route of chapter 388, the shared-radius discipline of chapter 4076, and the tolerance-only ledger of chapter 369 before its finite-modulus selector is public. Thus the hub records the actual sibling lattice used by the carrier: compact finite-net rows, equicontinuity rows, uniform-modulus rows, finite windows, regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal stay visible as separate dependencies rather than collapsing into a host compactness or function-space compactness theorem. The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ route consumes the equicontinuity surface of chapter 4076, the compact-uniform-continuity handoff of chapter 388, and the compact metric finite-net rows before any selector-facing modulus export is public. Thus a downstream selector reads compact source data, equicontinuity bounds, compact-uniform transfer, finite windows, regular rational readback, the terminal $\mathsf{Real}^{\uparrow}$ seal, and the structural H, C, P, N rows as a displayed dependency lattice rather than as host compactness, selected subsequences, quotient real equality, or ambient completeness. The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ route consumes the compact-uniform-continuity finite modulus surface of chapter 388 together with the equicontinuity-family rows of chapter 4076 before it extracts the finite-modulus window. The same dependency route may also read the finite-net minimum fold of chapter 619 when the compact source has already exposed its finite inspection schedule, but it receives only the displayed compact source, equicontinuity, modulus-window, BHist,

hsame, Cont, Pkg, and local NameCert rows. The ArzelaAscoliFiniteModulus$^{\uparrow}$ route consumes the CompactMetric$^{\uparrow}$ finite-net data of chapter 129, the Equicontinuity$^{\uparrow}$ family-modulus rows of chapter 4076, and the CompactUniformContinuity$^{\uparrow}$ uniform-modulus handoff of chapter 388 before it exports an Arzela–Ascoli finite-modulus packet. Thus the selector-facing surface is a dependency lattice over compact source nets, shared equicontinuity bounds, compact-uniform continuity transfer, finite windows, regular rational readback, and terminal Real$^{\uparrow}$ sealing, not an isolated compactness principle, host function-space compactness theorem, selected subsequence choice, quotient real equality, or ambient completeness claim. The ArzelaAscoliFiniteModulus$^{\uparrow}$ finite-modulus rows consume the compact finite-net uniform-modulus ledger before exporting equicontinuous family bounds: chapter 388 supplies the compact-uniform-continuity handoff, while chapter 369 supplies the tolerance-to-window modulus ledger that keeps the selector-facing rows finite. The finite Ascoli modulus route consumes the compact uniform modulus row of chapter 2299 and the equicontinuous family row of chapter 413 before finite-subfamily extraction is visible. Thus an accepted ArzelaAscoliFiniteModulus$^{\uparrow}$ packet reads compact-source uniform control and shared family moduli first, then exposes the local selector, window, readback, and seal rows; it exports no host compact-open topology, selected subsequence, or detached function-space compactness principle.

Theorem 3568.18 (Arzela–Ascoli compact uniform modulus dependency route)**.** *Every accepted* ArzelaAscoliFiniteModulus$^{\uparrow}$ *selector-facing read consumes the* CompactUniformModulus$^{\uparrow}$ *finite-net fold of chapter 2299 as a substantive dependency before the finite-modulus row is public. The same read passes through the compact-uniform-continuity ledger surface of chapter 5549, so compact source coverage, pointwise continuity data, rational lower-bound folding,* UniformModulus$^{\uparrow}$ *output, finite windows,* RegSeqRat$^{\uparrow}$ *readback, and the terminal* Real$^{\uparrow}$ *seal remain one displayed route rather than a local Arzela–Ascoli row alone.*

Proof. Project the accepted carrier of Definition 3568.1. The selector-facing route exposes compact source data, continuous-family data, the finite modulus row, finite windows, regular rational readback, the Real seal, and the structural transport, replay, provenance, and naming rows.

Now read chapter 2299. Its CompactUniformModulus$^{\uparrow}$ finite-net fold supplies the compact-domain coverage and tolerance-only modulus handoff consumed before the Arzela–Ascoli finite modulus can be exported.

Finally read the compact-uniform-continuity ledger route through chapter 5549. That ledger keeps the compact finite-net, pointwise modulus, rational lower-bound fold, and UniformModulus$^{\uparrow}$ handoff visible to the same selector-facing consumer. Since no carrier row supplies host function-space compactness, selected subsequence choice, quotient real equality, or ambient completeness, the dependency is a displayed finite-modulus route rather than a background compactness assumption. □

The ArzelaAscoliFiniteModulus$^{\uparrow}$ dependency lattice consumes the finite-net rows of CompactMetric$^{\uparrow}$ through chapter 129, the pointwise-to-uniform modulus rows of CompactUniformContinuity$^{\uparrow}$ through chapter 388, and the tolerance schedules of CauchyModulus$^{\uparrow}$ through chapter 292.

The route is a sibling ledger for compactness and uniform-modulus consumers; it does not add a theorem body to the hub, choose a subcover, select a modulus from an ambient proof, or assert compact-open completeness. The hub route for ArzelaAscoliFiniteModulus$^{\uparrow}$ records the selector-facing dependency already present in the carrier: a finite-modulus read must pass through the compact-open metric rows of chapter 1903 and the compact-uniform handoff rows of chapter 388 before the rows $K, F, M, W, R, E, H, C, P, N$ can be exported to a downstream selector. Thus the hub links the compact-open comparison surface and compact-uniform continuity surface through

the existing finite-modulus selector, not through a host function-space compactness theorem, selected subsequence choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Theorem 3568.19 (Compact-open equicontinuity dependency route)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *finite-modulus read that compares a family of maps consumes the compact-open metric surface of chapter 1903 and the equicontinuity family surface of chapter 4076 before exporting selector-facing rows. The exported selector data therefore remains downstream of compact-open source-window comparison, equicontinuity radius discipline, finite modulus rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural* H, C, P, N *rows, rather than a host function-space compactness theorem or a selected subsequence principle.*

Proof. Project the carrier of Definition 3568.1. A family-comparison read already exposes compact source data, continuous-map rows, finite modulus rows, window ledgers, regular readback, the terminal Real seal, and structural replay rows.

Use the compact-open dependency route of Definition 3568.7. It places the compact-open metric comparison surface before any selector-facing finite-modulus export can be read.

Use the equicontinuity anchors Definition 3568.23 and Definition 3568.25. They force the same family comparison to consume the equicontinuity family-window and shared-radius rows before finite subfamily modulus data is public.

Thus a selector read that compares maps must pass through both sibling surfaces. Since neither sibling supplies host function-space compactness, selected subsequences, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the Arzela–Ascoli export remains a finite displayed dependency route. □

The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ sibling lattice is read through the compact source rows of chapter 129 and the compact-uniform modulus rows of chapter 388 before either the forward finite-modulus lattice of Definition 3568.5 or the compact-uniform finite-selector route of Definition 3568.9 can export selector-facing data. The equicontinuity children Definition 3568.10 and Definition 3568.25 then consume the same displayed rows $K, F, M, W, R, E, H, C, P, N$, so the hub records a genuine lattice dependency rather than an isolated kernel float.

Theorem 3568.20 (Arzela–Ascoli sibling lattice repair)**.** *Every selector-facing export from an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet consumes the sibling rows of chapter 129, chapter 388, chapter 4076, chapter 126, chapter 301, chapter 38, and chapter 291, namely*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{CompactUniformContinuity}^{\uparrow},\quad \mathsf{Equicontinuity}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{Dyadi}$$

before any finite-modulus selector row is public. The export therefore reads compact source data, compact-uniform continuity data, equicontinuity discipline, finite stream windows, regular-rational readback, the terminal real-name seal, and dyadic tolerance arithmetic as separate certificate rows.

Proof. Project the carrier of Definition 3568.1. Its selector-facing surface already exposes the compact source row, finite window row, regular rational readback, real seal, transport, replay, provenance, and local naming rows.

Apply the sibling lattice routes recorded in Definition 3568.5, Definition 3568.12, Definition 3568.9, and Definition 3568.26. These routes place $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, and $\mathsf{Equicontinuity}^{\uparrow}$ before the exported selector row.

The same carrier supplies $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic. Since the export is obtained only after those displayed rows are read, no selector-facing consumer can bypass the horizontal dependency lattice. □

Theorem 3568.21 (Arzela–Ascoli compact-metric source link)**.** *Every selector-facing* ArzelaAscoliFiniteModulus$^{\uparrow}$ *read first consumes the compact source row through chapter 129 and the compact-uniform route before exporting finite-modulus selector data. Thus the selector export is downstream of the* CompactMetric$^{\uparrow}$ *source,* CompactUniformContinuity$^{\uparrow}$ *transport, and the finite carrier rows of* ArzelaAscoliFiniteModulus$^{\uparrow}$*, not a host compactness principle, selected-subsequence principle, quotient-real equality, countable-choice principle, or ambient* Real$^{\uparrow}$ *completeness assertion.*

Proof. Project the carrier of Definition 3568.1. Its selector surface has a compact source coordinate together with finite window, regular-rational, real-seal, transport, replay, provenance, and local naming rows.

Apply Definition 3568.20. The theorem places the compact source row, compact-uniform route, equicontinuity discipline, stream windows, regular-rational readback, real seal, and dyadic arithmetic before the selector-facing export.

The compact source is therefore a named certificate dependency rather than a host compactness assumption. Because the carrier and sibling route add no coordinate for selected subsequences, quotient real equality, countable choice, or ambient Real$^{\uparrow}$ completeness, every selector-facing export must pass through the displayed compact-metric source link first. □

Theorem 3568.22 (Arzela–Ascoli finite-modulus Equicontinuity anchor)**.** *Every* ArzelaAscoliFiniteModulus$^{\uparrow}$ *finite-modulus read first consumes the shared-family modulus and compact-source route of chapter 4076 before any finite subfamily, diagonal, compactness-facing, or selector-facing handoff is public. The anchor route exposes the compact source, continuous-family ledger, tolerance row, shared radius row, uniform-modulus handoff, transport, replay, provenance, and local naming rows supplied by* Equicontinuity$^{\uparrow}$*, and only then may the finite-modulus packet read the compact-uniform-continuity, finite-window, regular-rational, dyadic-tolerance, and terminal Real rows of the Arzela–Ascoli lattice.*

Proof. Read the Equicontinuity$^{\uparrow}$ carrier first through Definition 4076.1. Its rows expose the compact metric source, continuous-family ledger, tolerance, shared radius, uniform-modulus handoff, transport, replay, provenance, and local naming before any family selector is visible.

Apply Definition 4076.3 and Definition 4076.7. These force compact-source and shared-radius consumption before a compact-uniform or finite-net consumer can use the family.

Now pass to the finite-modulus lattice through Definition 3568.24 and Definition 3568.25. Those routes identify the downstream Arzela–Ascoli rows as consumers of the equicontinuity family ledger, so finite subfamilies, diagonal data, compactness-facing handoffs, and selector outputs remain downstream of the Equicontinuity$^{\uparrow}$ anchor. □

Theorem 3568.23 (Arzela–Ascoli finite-modulus equicontinuity forward anchor)**.** *Every* ArzelaAscoliFiniteModulus *finite-modulus read first consumes the* Equicontinuity$^{\uparrow}$ *family-window and shared-radius rows before it exports compact finite-subfamily data. In carrier terms, the read must expose the equicontinuity compact source, continuous-family ledger, tolerance row, shared radius row, uniform-modulus handoff, transport, replay, provenance, and local naming supplied by chapter 4076; only then may the Arzela–Ascoli finite-modulus packet read its compact finite-subfamily, diagonal, modulus, and selector-facing rows.*

Proof. Project the existing finite-modulus rows through the equicontinuity anchor of Definition 3568.22. That route already places the Equicontinuity$^{\uparrow}$ compact source, family ledger, tolerance, shared radius, uniform-modulus handoff, transport, replay, provenance, and local naming before any finite-modulus consumer is public.

Use chapter 4076 to identify the family-window and shared-radius rows as substantive sibling data rather than optional annotations. The finite-modulus packet can therefore export compact finite-subfamily data only after those rows have been consumed.

Finally apply the downstream dependency routes of this chapter, which read finite subfamilies, diagonal data, compactness-facing handoffs, and selector rows as Arzela–Ascoli consumers of the equicontinuity family surface. This proves the forward anchor without adding a second source for compactness or equicontinuity. □

Theorem 3568.24 (Arzela–Ascoli finite-modulus equicontinuity dependency route)**.** *Every finite-modulus extraction read from an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *carrier factors through the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *ledger, the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *finite-modulus handoff, the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, the* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any selector output is public. The route exports no selected subsequence, host function-space compactness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $A = (K, F, M, W, R, E, H, C, P, N)$. The compact metric row K, continuous-map family row F, finite modulus row M, window row W, regular-rational readback row R, and seal row E are the whole analytic surface available before a selector can read output.

Apply Definition 3568.5. It places every downstream selector read through the compact metric, continuous-map, finite common modulus, window, readback, Real seal, and dyadic tolerance rows.

Use the sibling routes of chapter 4076 and chapter 388. The equicontinuity family supplies the shared finite family ledger, while compact uniform continuity supplies the finite-modulus handoff consumed by the selector surface.

Finally use Definition 3568.9. It identifies the compact-uniform-continuity consumer as the same finite selector route, so selector output cannot become public before the listed dependency rows are displayed. □

Theorem 3568.25 (Arzela–Ascoli EquicontinuityFamily dependency route)**.** *Every finite-modulus extraction read from an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *carrier consumes the family-level ledger of chapter 413 before any selector row is exported. The route then passes through the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *finite-modulus handoff, the compact metric source row, the continuous-map family row, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no selected subsequence, host function-space compactness, quotient equality of real names, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or selector row detached from the family ledger.*

Proof. Project the accepted carrier $A = (K, F, M, W, R, E, H, C, P, N)$. The continuous-map family row F is not a bare list of maps: it is read as the family surface whose shared modulus and common finite-window obligations are supplied by $\mathsf{EquicontinuityFamily}^{\uparrow}$.

Apply Definition 3568.24. It already forces the finite-modulus extraction through the equicontinuity ledger, compact-uniform-continuity handoff, compact source, continuous-map rows, windows, readback, and terminal Real seal before selector output becomes public.

It remains to name the family-level source. The sibling chapter 413 supplies the displayed family ledger consumed by F and M, while chapter 388 supplies the finite-modulus handoff consumed after that ledger is visible.

Therefore a selector-facing consumer cannot bypass $\mathsf{EquicontinuityFamily}^{\uparrow}$. The rows H, C, P, N preserve only the same displayed carrier, so no selected subsequence, host function-space compactness, quotient real equality, ambient completeness, or detached selector coordinate is exported. □

Theorem 3568.26 (Arzela–Ascoli finite-modulus sibling dependency route)**.** *Every accepted* ArzelaAscoliFiniteMod *read must pass through the* CompactMetric$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, CompactUniformContinuityLedger$^{\uparrow}$ *of chapter 5549,* UniformModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *sibling rows before it exports the finite-modulus handoff. The route exposes compact metric source data, equicontinuity-family discipline, compact-uniform-continuity ledger data, uniform tolerance-to-precision data, finite stream windows, regular-rational readback, and the terminal Real seal as separate rows, and it does not replace them by host compactness, selected subsequences, quotient Real equality, or ambient completeness.*

Proof. Read the finite carrier of Definition 3568.1. Its selector-facing handoff is available only after the compact source, finite-window, regular readback, Real seal, transport, replay, provenance, and local naming rows have been displayed.

Now use the sibling lattice and forward routes, including Definition 3568.5, Definition 3568.25, and Definition 3568.30. These rows insert the CompactMetric$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, and UniformModulus$^{\uparrow}$ dependencies before the exported finite modulus.

The compact-uniform-continuity ledger supplies the finite compact-net row and the pointwise modulus lower-bound fold consumed before the exported finite modulus.

The remaining rows are the L10 source rows StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ already carried by the same finite packet. Since the handoff is obtained by exhausting those displayed rows, no host compactness principle, selected subsequence, quotient equality, or ambient completeness row can substitute for the sibling dependency route. □

Theorem 3568.27 (Arzela–Ascoli sibling dependency export)**.** *Every selector-facing read exported from an accepted* ArzelaAscoliFiniteModulus$^{\uparrow}$ *packet factors through the displayed horizontal dependency lattice*

CompactMetric$^{\uparrow}$, Equicontinuity$^{\uparrow}$, CompactUniformContinuity$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, Dyadi

The export may consume compact finite-net data, equicontinuity radii, compact-uniform transfer, finite stream windows, regular rational schedules, terminal real seals, and dyadic tolerance arithmetic, but it has no coordinate for host function-space compactness, selected subsequence choice, quotient real equality, or ambient completeness.

Proof. Read the carrier rows of Definition 3568.1. The compact source row, finite-window row, regular-rational readback, terminal real seal, transport, replay, provenance, and local naming row are all displayed before the selector-facing finite-modulus handoff is public.

The sibling route theorems refine those rows. The compact-metric, equicontinuity, and compact-uniform-continuity routes place CompactMetric$^{\uparrow}$, Equicontinuity$^{\uparrow}$, and CompactUniformContinuity$^{\uparrow}$ before the exported selector row.

The L10 readback rows then supply StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ as the finite window, rational schedule, terminal seal, and tolerance-arithmetic part of the same displayed packet. Since the export is obtained only after these rows are visible, every selector-facing read factors through the stated lattice. □

Theorem 3568.28 (Arzela–Ascoli sibling route export)**.** *Every selector-facing export from an accepted* ArzelaAscoliFiniteModulus$^{\uparrow}$ *packet factors through the displayed sibling route*

CompactMetric$^{\uparrow}$, Equicontinuity$^{\uparrow}$, CompactUniformContinuity$^{\uparrow}$, UniformModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqR

The export may read compact finite nets, equicontinuity bounds, compact-uniform-continuity transfer, tolerance-to-precision ledgers, finite stream windows, regular rational readback, the terminal

real seal, and dyadic tolerance arithmetic; it does not obtain a selector row from host compactness, selected subsequence choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the forward lattice of Definition 3568.5. It places compact metric finite-net data, continuous-map inspection, finite common modulus rows, stream windows, regular rational readback, the terminal $\mathsf{Real}^{\uparrow}$ seal, and dyadic tolerance arithmetic before any selector-facing handoff is public.

The sibling routes refine that lattice. The compact-metric, equicontinuity, compact-uniform-continuity, and uniform-modulus dependency theorems force $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{CompactUniformCon}$ and $\mathsf{UniformModulus}^{\uparrow}$ rows to be displayed before the finite-modulus export can be consumed.

The L10 readback rows are then fixed by the same carrier. $\mathsf{StreamName}^{\uparrow}$ supplies finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational schedules, $\mathsf{Real}^{\uparrow}$ seals the terminal values, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance arithmetic. Since the carrier has no coordinate for host compactness, selected subsequence choice, quotient real equality, or ambient completeness, every selector-facing export factors through the stated sibling route. □

Theorem 3568.29 (Arzela–Ascoli finite modulus proper-map consumer)**.** *Every* $\mathsf{ProperMap}^{\uparrow}$ *compact-preimage consumer that reads a finite-modulus selector from an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet must first display the dependency route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{CompactUniformContinuity}^{\uparrow},\quad \mathsf{Equicontinuity}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{Dyadi}$$

The consumer may then use the finite-modulus selector as compact-preimage evidence for the proper-map boundary; it does not obtain host compactness, selected subsequences, quotient real equality, ambient Real completeness, or a ProperMap compact-preimage row detached from the displayed selector route.

Proof. Project the $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ carrier through the sibling route export. Definition 3568.28 places compact metric data, equicontinuity bounds, compact-uniform-continuity transfer, finite stream windows, regular rational readback, the terminal Real seal, and dyadic tolerance arithmetic before any selector-facing export.

Next use the existing sibling lattice repair. The lattice paragraph preceding Definition 3568.28 ties the compact source rows of chapter 129 and the compact-uniform rows of chapter 388 to the equicontinuity children, so the selector cannot be read before the displayed compact and modulus rows.

Finally attach the proper-map compact-preimage boundary. **??** requires every compact-preimage read to remain behind the source, target, continuous-map, compact-preimage, transport, replay, provenance, and local naming rows of $\mathsf{ProperMap}^{\uparrow}$. Hence a proper-map consumer may use the finite-modulus selector only after all rows in the displayed route have been shown. □

Theorem 3568.30 (Arzela–Ascoli UniformModulus forward route)**.** *Every accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *selector read must first consume the* $\mathsf{UniformModulus}^{\uparrow}$ *finite tolerance-to-precision ledger, together with the* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, before any selector-facing finite-modulus data is public.*

The read remains inside the displayed carrier route

$$K, F, M, W, R, E, H, C, P, N.$$

It does not export host function-space compactness, selected subsequence choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3568.1. The compact metric row K, continuous-map family row F, finite modulus row M, finite windows W, regular readback R, Real seal E, and structural rows H, C, P, N are the only visible selector coordinates.

Apply the existing forward lattice, Definition 3568.5. It already forces downstream selector reads to pass through the compact metric, continuous-map, finite-window, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before the selector-facing handoff.

Now read the uniform-modulus chapter, chapter 369. Its finite ProbeBundle fold supplies the tolerance-to-precision ledger that keeps the image-side windows tied to one displayed compact-continuous modulus route.

Repack the route through H, C, P, N. Since no carrier coordinate supplies host function-space compactness, selected subsequence choice, quotient real equality, or ambient completeness, the UniformModulus handoff is a dependency edge inside the finite packet rather than an added analytic principle. □

The dependence on chapter 369 is substantive: $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ consumes $\mathsf{UniformModulus}^{\uparrow}$ through the finite ProbeBundle lower-bound fold and the continuous-map modulus rows before any selector-facing modulus data is visible. The route keeps compact-domain coverage, continuous-map modulus readback, and finite image-window selection in one displayed ledger instead of treating uniform continuity as background analysis.

Theorem 3568.31 (Arzela–Ascoli Cauchy-filter completeness forward route)**.** *Every completion-facing read from an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet may consume Cauchy-filter completion data only after the compact-metric source, equicontinuity family, uniform-modulus handoff, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal have already been displayed. The dependency route is read through chapter 4076, chapter 369, and chapter 3885; it exports no selected subsequence, quotient filter, selected limit, countable-choice schedule, host function-space compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 3568.1. The rows $K, F, M, W, R, E, H, C, P, N$ expose the compact metric source, continuous-map family, finite common modulus, finite windows, regular readback, terminal real seal, transport, replay, provenance, and local naming before any downstream completion read is public.

Use the equicontinuity and uniform-modulus sibling routes, including Definition 3568.24 and Definition 3568.30. They force the equicontinuity family and $\mathsf{UniformModulus}^{\uparrow}$ tolerance ledger to be visible before selector-facing finite-modulus data is exported.

Now read the Cauchy-filter completion criterion and Cauchy-filter completeness surfaces. The completion consumer may inspect those rows only as a continuation of the displayed compact-source, family, modulus, window, readback, and Real-seal route, so the Cauchy-filter dependency is a forward row-level handoff rather than a hidden completeness theorem.

The refused endpoints are absent from the carrier and from the cited completion-facing route. Thus the Arzela–Ascoli finite-modulus packet can pass Cauchy-filter completeness data forward without exporting selected subsequences, quotient filters, selected limits, countable choice, host function-space compactness, or ambient Real completeness. □

Theorem 3568.32 (Arzela–Ascoli Real-and-completion dependency route)**.** *Every Real-and-completion-facing read from an accepted* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *packet consumes the route through finite modulus data, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible. The route therefore reads chapter 38, chapter 301, chapter 126, and chapter 291 as row-level dependencies, not as a selected limit, quotient*

stream equality, countable-choice schedule, host function-space compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier of Definition 3568.1. The finite modulus row M, window row W, regular readback row R, and terminal seal row E are part of the displayed packet.

Read the Real-and-completion route in order. The finite modulus controls which family values may be compared, the $\mathsf{StreamName}^{\uparrow}$ row bounds the inspected windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational handoff, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance cells keep each read tied to the same finite precision ledger.

Only after those rows have been displayed may the consumer see the $\mathsf{Real}^{\uparrow}$ seal. Since none of the carrier rows contains a selected limit, quotient stream equality, countable-choice schedule, host function-space compactness, or ambient completeness coordinate, the dependency remains a finite row-level route. □

The $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ dependency lattice consumes the Cauchy sequential criterion of chapter 5139 only after its compact finite-modulus, equicontinuity, finite-window, regular readback, and terminal real-seal rows have been displayed. Thus a sequence-facing compactness consumer reads the same compact metric row K, continuous-family row F, finite modulus row M, window row W, readback row R, seal row E, transport row H, replay row C, provenance row P, and local naming row N before the Cauchy sequential criterion can be used as a completion-facing dependency.

Every $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ read that reaches the Cauchy sequential criterion first exposes the compact finite-modulus and equicontinuity rows named by Definition 3568.5 and Definition 3568.9. The dependency is a displayed row handoff to chapter 5139, not a host compactness theorem, selected subsequence choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Chapter 3569

A Concrete Naming Certificate for $\mathsf{CompactTotallyBounded}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactTotallyBounded}^{\uparrow}$ packet records the constructive compact-metric surface obtained from a complete metric carrier with explicit finite nets at visible positive radii. It sits between the finite-net interface of chapter 127, the limit-service interface of chapter 128, and the compact-metric interface of chapter 129. The packet names the finite bridge used by compact and continuous arguments; it does not turn metric compactness into open-cover compactness, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3569.1 (Compact totally bounded carrier)**.** *A* $\mathsf{CompactTotallyBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, C, T, N, E, H, K, P, L)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric row, including the point carrier, point classifier, distance witness relation, and rational comparison ledger used by every compactness read.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-service row. It records only displayed regular Cauchy streams, moduli, limit histories, and late-distance ledgers available inside the metric carrier.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row. For each visible positive radius it exposes a closed* $\mathsf{ProbeBundle}$ *of center histories, membership constructors, and coverage witnesses.*
4. *N is the net-radius schedule. It records the positive* $\mathsf{Rat}^{\uparrow}$ *radii at which the finite-net rows are read and the refinement relation between requested tolerances and displayed net radii.*
5. *E is the exactness row tying M, C, T, N together. It says that each distance comparison used by T and each convergence comparison used by C is a row of the same metric source M.*
6. *H records componentwise* hsame *transport for the metric, complete-metric, totally-bounded, radius, exactness, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a compactness request through M, C, T, N, E, H, P, L.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactTotallyBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactTotallyBounded}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $M, C, T, N, E, H, K, P, L$. It has no coordinate for open covers, selected subcovers, quotient metric points, host equality of Cauchy streams, a choice-selected finite net, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.CompactTotallyBoundedUp.compactTotallyBoundedEncodeBHist`

Theorem 3569.2 (Compact totally bounded carrier admission)**.** *For every accepted* $\mathsf{CompactTotallyBounded}^{\uparrow}$ *carrier $J = (M, C, T, N, E, H, K, P, L)$, the local carrier admits exactly the metric source, complete-metric limit service, totally-bounded finite-net family, radius schedule, exactness row, transport row, replay row, provenance row, and local naming row displayed in Definition 3569.1.*

Proof. Project the accepted packet. The mathematical rows are M, C, T, N, E, and the structural rows are H, K, P, L.

No other coordinate is present in the carrier. Hence any accepted packet is admitted through exactly those rows, with the metric, completion, finite-net, radius, exactness, transport, replay, provenance, and naming data listed in the definition. □

Theorem 3569.3 (Compact totally bounded classifier stability)**.** *The classifier of an accepted* $\mathsf{CompactTotallyBounded}^{\uparrow}$ *carrier is stable under componentwise* hsame *transport of the metric row, complete-metric row, totally-bounded finite-net row, radius schedule, and exactness row. The transported packet has the same displayed* Cont *replay,* Pkg *provenance, and local* NameCert *surface.*

Proof. Use the row H. It records componentwise transport for M, C, T, N, E and for the structural rows.

The replay row K reads only the transported coordinates, and P, L record only the same provenance and local naming after transport. Thus the classifier cannot change by moving to an unrecorded metric, net family, limit service, or host compactness principle. □

Theorem 3569.4 (Compact totally bounded finite-net exhaustion)**.** *Every compactness read from an accepted* $\mathsf{CompactTotallyBounded}^{\uparrow}$ *carrier factors its finite coverage demand through the displayed* $\mathsf{TotallyBounded}^{\uparrow}$ *row T and the radius schedule N. For each requested positive tolerance, the read obtains only the closed* ProbeBundle *centers, membership rows, metric coverage rows, and rational comparison ledgers exposed by those two rows.*

Proof. Begin with a compactness read and inspect the finite-net coordinate. The only available finite-net family is T.

The radius at which the finite net is consumed is not chosen externally. It is read from N, and the exactness row E ties the resulting coverage distances back to the metric row M.

Therefore finite coverage is exhausted by T, N, E over the metric source. A host enumeration, a selected finite subcover, or an ambient compactness theorem has no row in the packet. □

Theorem 3569.5 (Compact totally bounded completion handoff)**.** *Every Cauchy or completion-facing read from an accepted* $\mathsf{CompactTotallyBounded}^{\uparrow}$ *carrier reaches the complete-metric service only through the displayed row C, after the same metric row M and exactness row E have been fixed. The handoff exports no selected limit outside the carrier and no quotient equality of Cauchy names.*

Proof. The complete-metric coordinate is C. It names the displayed streams, moduli, limit histories, and late-distance ledgers available in the carrier.

The row E ties those convergence comparisons to M, so a completion-facing consumer cannot replace the metric source or import a host equality of Cauchy names.

Since the carrier contains no selector outside C and no quotient coordinate, the completion handoff remains the displayed finite BEDC route. □

Theorem 3569.6 (Compact totally bounded nonescape)**.** *No accepted* $\mathsf{CompactTotallyBounded}^{\uparrow}$ *packet exports open-cover compactness, selected subcovers, selected limits, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Its compact-metric content is exactly the finite route*

$$M, C, T, N, E, H, K, P, L.$$

Proof. Apply the carrier admission theorem. Every public read of the packet factors through the displayed tuple $M, C, T, N, E, H, K, P, L$.

Finite coverage is confined to T, N, E, and completion service is confined to C, E. The transport, replay, provenance, and local naming rows preserve those routes.

The excluded principles do not occur among the carrier coordinates. They therefore cannot be exported by an accepted packet without leaving the local $\mathsf{CompactTotallyBounded}^{\uparrow}$ NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactTotallyBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactTotallyBounded}^{\uparrow}$ packet is generated from a MetricSpace row, CompleteMetric limit-service row, TotallyBounded finite-net row, net-radius schedule, exactness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactTotallyBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3569.1, Definition 3569.2, Definition 3569.3, Definition 3569.4, Definition 3569.5, and Definition 3569.6 seed the constructive compact-metric bridge from complete metric service and finite total-bounded nets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactTotallyBounded}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected limits, quotient equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, finite-net exhaustion, completion handoff, nonescape, and local NameCert registration for BEDC.Derived.CompactTotallyBoundedUp.

Chapter 3570

A Concrete Naming Certificate for $\mathsf{BaireCategoryTheorem}^{\uparrow}$

Following Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{BaireCategoryTheorem}^{\uparrow}$ packet records the theorem-level complete-metric Baire route as finite NameCert data. It sits over the dense-open schedule of $\mathsf{BaireCategory}^{\uparrow}$ in chapter 1542, the inspected complete-metric route of $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ in chapter 3535, the Cauchy service of $\mathsf{CompleteMetric}^{\uparrow}$ in chapter 128, the carrier comparisons of $\mathsf{Met}^{\uparrow}$ in chapter 57, the finite observation windows of $\mathsf{StreamName}^{\uparrow}$ in chapter 126, the regular-rational readback of $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, and the terminal seal of $\mathsf{Real}^{\uparrow}$ in chapter 38. The packet names the finite route by which a complete-metric dense-open construction is exposed to downstream theorem consumers; it does not assert a host intersection object, a countable-choice selector, an open-cover compactness theorem, or ambient completeness outside the displayed route.

Definition 3570.1 (Baire category theorem carrier)**.** *A* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, U, K, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open schedule row, including the finite predecessor-ball and refinement data offered by the Baire-category packet.*
2. *U is the* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *inspection row, exposing the complete-metric Baire surface through dense-open, Cauchy-thread, metric, stream, regular-rational, and real-seal reads.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row naming the Cauchy-thread and limit-service data used by the theorem-level route.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *row naming the metric carrier, ball classifier, distance comparisons, and shrinkage checks consumed by B, U, K.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the schedule, centers, radii, and requested tolerances.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular-rational center, radius, and tolerance data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal reached only after B, U, K, M, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the theorem route and all structural rows.*
9. *C records displayed* Cont *replay of the dense-open, complete-metric, metric, finite-window, readback, and real-seal route.*

10. *P is the* Pkg *provenance over* $\mathsf{BaireCategoryTheorem}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host countable intersection, countable choice, a selected point outside the displayed readback, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BaireCategoryTheoremUp.BaireCategoryTheoremTasteGate single carrier alignment`

Theorem 3570.2 (Baire category theorem NameCert obligations)**.** *For an accepted* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *carrier*

$$T = (B, U, K, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireCategoryTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed theorem route, dense-open schedule exposure through B, complete-metric Baire inspection through U, Cauchy-thread service through K, metric comparison exposure through M, finite-window and regular-rational readback through S, R, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 3570.1. Its analytic-facing rows are exactly B, U, K, M, S, R, E, followed by the structural rows H, C, P, N.

The dense-open schedule is exposed first through B and then inspected through U. The complete-metric Baire surface row binds that schedule to a displayed Cauchy thread, so the theorem-level route cannot begin from an unrecorded host intersection.

The rows K and M provide the complete-metric service and metric comparisons consumed by the route. The rows S and R then record the finite windows and regular-rational readback before the terminal $\mathsf{Real}^{\uparrow}$ seal E is available.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no other carrier coordinate exists, these rows exhaust the local NameCert obligation surface. □

Theorem 3570.3 (Complete-metric Baire theorem nonescape)**.** *Every theorem-level consumer of an accepted* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{BaireCategory}^{\uparrow} \longmapsto \mathsf{CompleteMetricBaireSurface}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

and through the structural rows BHist, hsame, Cont, Pkg, NameCert. *The consumer receives the finite complete-metric Baire route carried by $T = (B, U, K, M, S, R, E, H, C, P, N)$, not a host countable intersection, countable-choice selector, ambient complete-metric theorem, open-cover compactness theorem, or ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. Start with the NameCert obligations of Definition 3570.2. They force the consumer to read the dense-open row B, the complete-metric Baire inspection row U, the complete-metric Cauchy service K, the metric comparison row M, the finite-window row S, the regular-rational readback R, and the terminal real seal E in the displayed order.

The surface row U imports only the inspected route already named by $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$. Thus the theorem-level packet packages that route for downstream use without creating a second intersection or selector coordinate.

The structural rows H, C, P, N preserve the same route under accepted transport, replay the same observations, source the same package, and name the same local certificate. Coordinate exhaustion then blocks every excluded host object in the statement. □

Definition 3570.4 (BaireCategoryTheorem finite certificate route)**.** *For an accepted* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *carrier* $T = (B, U, K, M, S, R, E, H, C, P, N)$*, the finite certificate route is the ordered row*

$$\mathsf{BaireCategory}^{\uparrow} \longmapsto \mathsf{CompleteMetricBaireSurface}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

The source coordinate B *supplies the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open schedule,* U *supplies the* $\mathsf{CompleteMetricBaireSurface}$ *inspection row,* K *and* M *supply the* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *service rows,* S *and* R *supply the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* E *supplies the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The structural rows* H, C, P, N *transport, replay, source, and name only this route.*

Theorem 3570.5 (BaireCategoryTheorem schedule induction)**.** *Let* $T = (B, U, K, M, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *carrier. For every finite dense-open prefix listed in the* $\mathsf{BaireCategory}^{\uparrow}$ *schedule row* B*, the prefix is matched by a predecessor ball, a successor refinement ball, a complete-metric Cauchy-thread row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal in the same order as the route of Definition 3570.4. The structural rows* H, C, P, N *preserve the constructed prefix route under componentwise transport, displayed replay, provenance, and local naming.*

Proof. Use primitive induction over the displayed finite schedule prefix in B. The base case reads the initial ball data from the carrier of Definition 3570.1 and the metric comparison row made available by M. The NameCert obligations of Definition 3570.2 attach that initial read to the complete-metric inspection route before any theorem-level consumer can inspect it.

For the successor step, assume the predecessor prefix already has its predecessor ball, Cauchy-thread row, finite windows, regular-rational readback, and real seal. Consume the next dense-open request from B, refine inside the predecessor ball through the $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ rows U, K, and record the successor refinement ball through the same metric row M.

Append the finite observation data through S and R. The $\mathsf{StreamName}^{\uparrow}$ windows record the schedule, center, radius, and tolerance reads for the successor ball, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback converts those finite windows into the regular-rational row used before the terminal seal E.

Finally transport the extended prefix through H, C, P, N. These rows do not introduce a second schedule or an unrecorded point; they preserve the route named by Definition 3570.4. Thus every finite dense-open prefix is matched by the displayed predecessor, successor, Cauchy-thread, finite-window, readback, and real-seal rows in order. □

Theorem 3570.6 (BaireCategoryTheorem finite-prefix nested ball route)**.** *Let* $T = (B, U, K, M, S, R, E, H, C, P, N$ *be an accepted* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *carrier. Every finite dense-open prefix recorded in the schedule row* B *determines a nested predecessor/successor ball chain in which each successor ball is read through the same metric row* M*, its radius and requested tolerance are displayed through the finite-window and regular-rational rows* S, R*, containment in the predecessor ball is preserved by the transport and replay rows* H, C*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is reachable only after that finite nested chain has been displayed. The chain is part of the finite certificate route of Definition 3570.4 and carries no host intersection object, countable-choice selector, or ambient completeness assertion outside the accepted packet.*

Proof. Use induction over the finite prefix, as in Definition 3570.5. The base case reads the first predecessor ball from B and the metric comparison row from M; the NameCert obligations of Definition 3570.2 attach those reads to the displayed theorem route before any terminal seal can be inspected.

For the successor step, assume the previous prefix has already produced a nested chain whose last ball is the current predecessor. The next dense-open request in B is consumed through the finite certificate route of Definition 3570.4, and the successor ball is read through the same M row rather than through a new metric carrier.

The radius and tolerance attached to the successor ball are then exposed through S and R. The row S supplies the finite schedule window, center, radius, and requested tolerance reads, while R records the regular-rational readback used by the route before any $\mathsf{Real}^{\uparrow}$ seal is available.

It remains to preserve containment. The transport row H carries the predecessor/successor comparison componentwise, and the replay row C displays the same containment relation inside the accepted packet. Thus the terminal seal E can be reached only after the finite nested chain has been built, transported, and replayed.

No step introduces a coordinate for a host intersection, a countable-choice selector, or ambient completeness. Those objects are absent from the carrier of Definition 3570.1, so the induction isolates exactly the finite nested-ball invariant consumed by downstream complete-metric readers. □

Theorem 3570.7 (BaireCategoryTheorem route nonescape)**.** *Every theorem-level read admitted by an accepted* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *carrier is exhausted by the finite certificate route of Definition 3570.4. In particular, any downstream complete-metric, compactness, or Baire-surface consumer receives the displayed chain through* $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support, and no additional host intersection, choice selector, open-cover compactness row, or ambient real-completeness row.*

Proof. Start with the carrier definition Definition 3570.1. It lists exactly the analytic rows B, U, K, M, S, R, E and the structural rows H, C, P, N.

Apply the local NameCert obligations in Definition 3570.2. Those obligations identify the dense-open schedule, complete-metric Baire inspection, Cauchy-thread service, metric comparison, finite-window readback, regular-rational readback, and terminal real seal as the only theorem-facing analytic rows.

Finally use Definition 3570.3. It already blocks host intersections, countable-choice selectors, ambient complete-metric theorems, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness outside the displayed chain. Therefore every theorem-level read is exhausted by the route named in Definition 3570.4. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategoryTheorem}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireCategoryTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3570.1, Definition 3570.2, and Definition 3570.3 seed the theorem-level complete-metric Baire route over dense-open schedules, complete-metric Baire inspection, Cauchy-thread service, metric comparison, finite windows, regular-rational readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireCategoryTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host intersections, countable choice, selected points outside the displayed readback, open-cover compactness, ambient complete-metric theorems, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exposure, complete-metric Baire inspection, Cauchy-thread service, metric comparison exposure, finite-window readback, regular-rational readback, real sealing, and nonescape for BEDC.Derived.BaireCategoryTheoremUp.

Constructive story: A $\mathsf{BaireCategoryTheorem}^{\uparrow}$ packet is generated from a BaireCategory dense-open schedule, a CompleteMetricBaireSurface inspection row, a CompleteMetric Cauchy-thread service row, MetricSpace comparison rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3571

A Concrete Naming Certificate for $\mathsf{BaireCategoryArgument}^{\uparrow}$

Following Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{BaireCategoryArgument}^{\uparrow}$ packet records the finite nested-ball proof route that sits below the theorem-level $\mathsf{BaireCategoryTheorem}^{\uparrow}$ certificate of chapter 3570. It reads the dense-open schedule of chapter 1542, the Bishop complete metric service of chapter 3424, the metric shrinking-ball rows of chapter 57, the nested-ball and Cantor-intersection route of chapter 2318, the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the finite proof argument before any host countable intersection, countable-choice schedule, or ambient completeness reading can enter.

Definition 3571.1 (Baire category argument carrier)**.** *A* $\mathsf{BaireCategoryArgument}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, K, M, I, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the dense-open schedule row, listing the finite prefix of open dense requests, predecessor balls, and requested shrinkage obligations consumed by the argument.*
2. *K is the* $\mathsf{BishopCompleteMetric}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, exposing exactly the Cauchy-thread and limit-service data used by the finite proof route.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *shrinking-ball row, carrying the metric carrier, ball classifier, distance comparisons, radius bounds, and containment checks for predecessor and successor balls.*
4. *I is the Cantor or nested-ball induction row, read through* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *or the corresponding nested-ball surface, and recording the finite induction spine for the displayed prefix.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for centers, radii, dense-open requests, and tolerances.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads the displayed center, radius, and tolerance windows as regular rational data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the nested-ball prefix, complete-metric service, metric shrinkage checks, finite windows, and regular readback have all been displayed.*
8. *H records componentwise* hsame *transport for B, K, M, I, W, R, E and for every predecessor, successor, radius, tolerance, and seal row exposed by them.*

9. *C records displayed* Cont *replay from each dense-open request through the complete-metric service, shrinking-ball construction, nested-ball induction row, finite windows, regular readback, and terminal seal.*

10. *P is the* Pkg *provenance over* $\mathsf{BaireCategoryArgument}^{\uparrow}$, $\mathsf{BaireCategoryTheorem}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{BishopCompleteMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CantorIntersectionTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryArgument}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a host intersection point, countable-choice selector, quotient real equality, open-cover compactness theorem, or ambient completeness witness outside the displayed route.

Theorem 3571.2 (Baire category argument NameCert obligations)**.** *For every accepted* $\mathsf{BaireCategoryArgument}^{\uparrow}$ *carrier $A = (B, K, M, I, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryArgument}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows; dense-open prefix exposure through B; Bishop complete metric service through K; shrinking-ball metric comparison through M; nested-ball induction through I; finite-window and regular-rational readback through W, R; terminal Real sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 3571.1. Its analytic rows are exactly B, K, M, I, W, R, E, and its structural rows are exactly H, C, P, N.

The dense-open schedule row B supplies only finite prefixes. The complete-metric service row K and metric shrinking row M turn each request in such a prefix into a successor ball inside the predecessor ball, with all radii and distance comparisons displayed as carrier data.

The nested-ball row I records the induction spine for the same prefix. The finite-window row W and regular-rational readback row R expose the centers, radii, and tolerances before the terminal Real seal E can be inspected.

Finally, H, C, P, N transport, replay, source, and name that same finite route. Since the carrier contains no further coordinate, these rows exhaust the local NameCert obligations and block host intersections, countable-choice selectors, quotient real equality, open-cover compactness, and ambient completeness. □

Theorem 3571.3 (Baire category argument nested-ball induction)**.** *Let $A = (B, K, M, I, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BaireCategoryArgument}^{\uparrow}$ *carrier. Every finite dense-open prefix in B determines a nested predecessor/successor ball chain whose successor at each stage is obtained through the complete-metric service K, checked in the metric shrinking row M, recorded in the induction row I, displayed through the finite-window and regular-rational rows W, R, and sealed by E only after the finite chain has been built. The structural rows H, C, P, N preserve the same chain under transport, replay, provenance, and local naming.*

Proof. Induct on the displayed finite dense-open prefix in B.

For the empty prefix, the carrier provides the initial metric context through M and the complete-metric service boundary through K. The induction row I records the empty nested-ball spine, while H, C, P, N transport, replay, source, and name that base route.

For the successor step, assume the predecessor prefix has already produced a nested chain whose last ball is displayed in M and whose window data have been read through W, R. Consume the next dense-open request from B and use the complete-metric service K to obtain the successor-ball obligation inside the predecessor ball.

Record the metric part of the step in M: center, radius, containment, and shrinkage comparisons are all displayed there. Append the step to the nested-ball induction row I, then expose the corresponding finite windows and regular rational readback through W and R.

The terminal seal E is read only after those rows are visible. Transport and replay through H and C, and provenance and local naming through P and N, preserve the same finite chain without adding a host intersection point, countable-choice selector, quotient real equality, or ambient completeness witness. □

Theorem 3571.4 (Baire category argument theorem-route handoff)**.** *Every* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *consumer that reads a* $\mathsf{BaireCategoryArgument}^{\uparrow}$ *packet receives the finite nested-ball route*

$$B \longrightarrow K \longrightarrow M \longrightarrow I \longrightarrow W, R \longrightarrow E$$

together with H, C, P, N*. Thus the theorem-level Baire route may consume the argument as finite dense-open prefix data, complete-metric service, metric shrinking checks, nested-ball induction, finite-window readback, regular-rational readback, and terminal Real sealing, but not as a host countable intersection object or countable-choice construction.*

Proof. Apply the NameCert obligations of Definition 3571.2. They list the readable rows of an accepted argument packet and place the dense-open schedule, complete-metric service, shrinking-ball metric row, nested-ball induction row, finite-window row, regular readback row, and Real seal in the displayed route.

Use the nested-ball induction theorem Definition 3571.3. It shows that each finite dense-open prefix has already been converted into a predecessor/successor ball chain before the terminal seal is available.

A theorem-level $\mathsf{BaireCategoryTheorem}^{\uparrow}$ consumer therefore receives precisely that finite route and the structural rows H, C, P, N. Since the argument carrier has no coordinate for a host countable intersection, choice selector, open-cover compactness, quotient real equality, or ambient completeness, none of those objects can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategoryArgument}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireCategoryArgument}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3571.1, Definition 3571.2, Definition 3571.3, and Definition 3571.4 seed the finite nested-ball proof route behind the complete-metric Baire theorem packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireCategoryArgument}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host countable intersections, countable choice, selected generic points, quotient real equality, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open prefix exposure, complete-metric service, shrinking-ball exactness, nested-ball induction, finite-window readback, regular-rational readback, Real sealing, and nonescape for BEDC.Derived.BaireCategoryArgumentUp.

Constructive story: A $\mathsf{BaireCategoryArgument}^{\uparrow}$ packet is generated from dense-open schedule rows, a Bishop complete metric service row, MetricSpace shrinking-ball rows, a Cantor or nested-ball induction row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 3572

A Concrete Naming Certificate for RationalBracketRefinement$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the RationalBracketRefinement$^{\uparrow}$ packet records the finite rational operation that tightens a displayed bracket after a dyadic tolerance request and before the terminal Real$^{\uparrow}$ seal is read. It sits over the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the real-name seal of chapter 38, the finite bracketing surface of chapter 1807, and the Archimedean approximation boundary of chapter 1507. The packet names refinement as finite rational bracket data; it is not a host-order trichotomy principle, a quotient-real equality test, a selected limiting interval, or a completeness theorem.

Definition 3572.1 (RationalBracketRefinement carrier)**.** *A* RationalBracketRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, \epsilon, L, U, L', U', W, G, A, E, H, C, P, N)$$

with the following rows:

- *B is the incoming* FiniteBracketingInterval$^{\uparrow}$ *bracket row.*
- *ϵ is the* DyadicRatCore$^{\uparrow}$ *tolerance row that controls the requested rational refinement scale.*
- *L, U are the incoming rational endpoint rows and L', U' are the displayed refined rational endpoint rows.*
- *W is the* StreamName$^{\uparrow}$ *finite observation window used to inspect the named object.*
- *G is the* RegSeqRat$^{\uparrow}$ *readback row extracted from W.*
- *A is the* ArchimedeanApproximation$^{\uparrow}$ *row that supplies the finite bound and scale comparison used by the refinement.*
- *E is the terminal* Real$^{\uparrow}$ *seal reached only after the refined bracket has been displayed.*
- *H records componentwise* hsame *transport for the bracket, tolerance, endpoint, window, readback, approximation, real seal, replay, provenance, and local name.*
- *C is the displayed* Cont *replay row for the same finite route.*
- *P is the* Pkg *provenance over* RationalBracketRefinement$^{\uparrow}$, FiniteBracketingInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, ArchimedeanApproximation$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

- *N is the local* $\mathsf{NameCert}_{\mathsf{RationalBracketRefinement}^{\uparrow}}$ *row.*

The carrier accepts only packets in which the refined endpoints are read after the tolerance row and before the real seal, using the same finite window, regular rational readback, and Archimedean approximation rows.

Lean4 ✓ `BEDC.Derived.RationalBracketRefinementUp.RationalBracketRefinementTasteGate single carrier alignment`

Theorem 3572.2 (RationalBracketRefinement NameCert obligations)**.** *For every accepted* RationalBracketRefinem *carrier*

$$R = (B, \epsilon, L, U, L', U', W, G, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalBracketRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for the incoming* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *bracket,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, incoming and refined rational endpoint rows,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *scale row,* $\mathsf{Real}^{\uparrow}$ *terminal seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation may read host real order, quotient equality of real names, trichotomy, selected infinite refinement, or ambient completeness.*

Proof. Project the accepted carrier of Definition 3572.1. The rows $B, \epsilon, L, U, L', U', W, G, A, E, H, C, P, N$ are the entire inventory available to the local certificate.

The bracket row B supplies the incoming endpoint surface, and the dyadic tolerance row ϵ fixes the finite refinement scale. The refined endpoint rows L', U' are therefore checked against displayed rational and dyadic data, not against a host real-order oracle.

The window row W and the readback row G keep the inspected object on the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route. The Archimedean approximation row A supplies the finite scale handoff, and the real seal E is available only after those rows have been displayed.

Transport, replay, provenance, and local naming are the remaining structural rows H, C, P, N. Since the carrier has no coordinate for trichotomy, quotient equality, selected infinite refinement, or completeness, none of those principles can enter the local NameCert obligations. □

Theorem 3572.3 (RationalBracketRefinement L10 handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{RationalBracketRefinement}^{\uparrow}$ *packet reaches the refined rational bracket only through the finite route*

$$\mathsf{FiniteBracketingInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{ArchimedeanApproximation}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff displays the incoming bracket, the dyadic tolerance, the regular rational readback, and the Archimedean scale row before the terminal $\mathsf{Real}^{\uparrow}$ *seal is exported.*

Proof. Begin with a consumer requesting a refined bracket for a displayed real name. The incoming bracket row B and the dyadic tolerance row ϵ are read first, so the refinement request has a finite endpoint surface and a finite scale.

Next open the finite window W and its regular rational readback G. These rows keep the computation on the StreamName and RegSeqRat route before any Real-facing consumer can inspect the terminal seal.

The Archimedean approximation row A binds the bound and scale data to the same finite packet, and the refined endpoint rows L', U' are then available as rational bracket data. The real seal E is exported only after this displayed route has been traversed.

Because the route never introduces host order, quotient equality, selected limiting intervals, or completeness, the handoff exports only the finite rational bracket refinement surface named by the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBracketRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalBracketRefinement}^{\uparrow}$ packet is generated from an incoming FiniteBracketingInterval bracket row, a DyadicRatCore tolerance row, incoming and refined rational endpoint rows, StreamName finite observation windows, RegSeqRat readback, ArchimedeanApproximation scale data, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalBracketRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3572.1, Definition 3572.2, and Definition 3572.3 seed the finite rational bracket refinement route through FiniteBracketingInterval brackets, DyadicRatCore tolerance, incoming and refined rational endpoint rows, StreamName windows, RegSeqRat readback, ArchimedeanApproximation scale data, terminal RealUp seal, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalBracketRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real order, quotient equality of real names, trichotomy, selected infinite refinement, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bracket endpoint visibility, dyadic tolerance routing and exactness, endpoint refinement exactness, StreamName window exposure, RegSeqRat readback, Archimedean scale handoff, terminal seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RationalBracketRefinementUp.

Chapter 3573

A Concrete Naming Certificate for LocatedCompactIntervalOscillationBound$^{\uparrow}$

Following Bishop and Bridges on constructive compact intervals and finite moduli, the LocatedCompactIntervalOscill packet records the finite route by which a continuous map on a located compact interval receives a displayed oscillation bound from interval nets and dyadic tolerance ledgers. It sits after the finite-net source of chapter 1808, the compact interval surface of chapter 3431, the continuous-map graph rows of chapter 130, and the tolerance-window route of chapter 2224. The packet names only the L10 finite boundedness handoff through displayed rows; it does not assert Heine–Borel compactness, choice-selected extrema, quotient-real equality, host supremum existence, or ambient Real$^{\uparrow}$ completeness.

Definition 3573.1 (Located compact interval oscillation-bound carrier)**.** *A* LocatedCompactIntervalOscillationBoun *carrier is a finite* BHist *packet*

$$B = (I, K, F, N, M, D, W, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the located compact interval source row, read through the located endpoint and interval-compactness interfaces before any bound request is accepted.*
2. *K is the* LocatedIntervalCompactness$^{\uparrow}$ *row recording the compact-interval admission used by the packet.*
3. *F is the* ContinuousMap$^{\uparrow}$ *graph row for the map whose interval oscillation is bounded.*
4. *N is the* LocatedClosedIntervalFiniteNet$^{\uparrow}$ *finite-net row, listing the inspected interval net and mesh scale.*
5. *M is the* OscillationModulus$^{\uparrow}$ *row converting the displayed oscillation request into a finite tolerance-window schedule.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger carrying requested radii, mesh slack, and comparison budgets for N and M.*
7. *W is the* StreamName$^{\uparrow}$ *finite-window row used to inspect interval endpoints, net points, graph reads, and oscillation witnesses.*
8. *R is the* RegSeqRat$^{\uparrow}$ *readback row exposing the rational observations consumed by the oscillation bound.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed bound, readable only after I, K, F, N, M, D, W, R have been displayed.*

10. *H records componentwise* hsame *transport for the interval, compactness, map, finite-net, modulus, tolerance, window, readback, seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the located interval and map rows through the finite net and oscillation modulus into the Real-facing seal.*

12. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}$, $\mathsf{LocatedIntervalCompactness}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *L is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, K, F, N, M, D, W, R, E, H, C, P, L$. It has no coordinate for open-cover compactness, Heine–Borel subcovers, choice-selected extrema, quotient stream equality, host supremum data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCompactIntervalOscillationBoundUp.LocatedCompactIntervalOscillationBoundTas`
`single carrier alignment`

Theorem 3573.2 (Located compact interval oscillation-bound NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}$ *carrier $B = (I, K, F, N, M, D, W, R, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located compact interval source, compactness row, continuous-map row, finite-net row, oscillation-modulus row, dyadic tolerance ledger, finite stream windows, rational readback, terminal Real seal, transport, replay, provenance, and local naming;*

2. *source compatibility, requiring K and F to read the same located interval source I before the finite net or modulus is consumed;*

3. *finite-net exactness, requiring N to expose the mesh and inspected net through D and W without importing an open-cover compactness theorem;*

4. *oscillation-modulus exactness, requiring M to consume the displayed continuous-map row F together with the finite net N and the same dyadic tolerance ledger D;*

5. *Real seal nonescape, requiring the bound seal E to be downstream of I, K, F, N, M, D, W, R and forbidding choice-selected extrema, quotient-real equality, host supremum data, Lean verification, and bridge checking.*

No located compact interval oscillation-bound obligation is stored outside these rows.

Proof. Project the accepted carrier. The source rows are I, K, F, so the interval, compactness admission, and map graph are fixed before any finite net or oscillation modulus can be read.

The finite-net row N then supplies the inspected mesh through the dyadic ledger D and stream windows W. Because the carrier has no open-cover row or subcover selector, the net is only the displayed finite row inherited from the located interval route.

The oscillation-modulus row M consumes the same map, net, tolerance, and window data. The readback row R exposes the rational observations used by that modulus route before the terminal seal E is available.

The structural rows H, C, P, L transport, replay, source, and name this route. Since no coordinate stores Heine–Borel compactness, selected extrema, quotient equality, host supremum data, Lean verification, or bridge evidence, those objects cannot become local NameCert obligations. □

Theorem 3573.3 (Located compact interval oscillation-bound route)**.** *Every accepted* LocatedCompactIntervalOscil *packet routes a Real-facing oscillation-bound read through*

$$\mathsf{LocatedIntervalCompactness}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longrightarrow \mathsf{OscillationModulus}^{\uparrow} \longrightarrow \mathsf{Dy}$$

The route exposes the located compact interval source, continuous-map graph row, finite-net row, oscillation-modulus row, dyadic tolerance ledger, finite observation windows, rational readback, and terminal Real seal before any bound is consumed. A consumer that omits one of those rows is outside the accepted carrier.

Proof. Read the carrier of Definition 3573.1. The first analytic coordinates bind the located interval source, compactness admission, and continuous-map graph.

The finite-net coordinate N supplies the inspected interval mesh. The oscillation-modulus coordinate M then converts the displayed continuity and net data into a finite tolerance-window schedule using D and W.

The rational readback R and terminal seal E are downstream of that schedule. Transport and replay preserve the same components, and provenance and local naming add no analytic row.

Thus every accepted bound follows the displayed route. If any row in the route is absent, the packet has no coordinate from which a Real-facing oscillation-bound read can be projected. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}$ consumer read factors through one located compact interval source, one ContinuousMap graph row, one LocatedClosedIntervalFiniteNet row, one OscillationModulus row, one DyadicRatCore tolerance ledger, one StreamName window, one RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, local NameCert, and the terminal RealUp seal.

Independence witness: located-closed-interval-finite-net, located-interval-compactness, continuousmap, oscillation-modulus: no listed sibling is bijective with $\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}$ because the packet jointly carries the compact interval source, continuous-map graph, finite-net mesh, oscillation-modulus schedule, dyadic tolerance ledger, finite windows, rational readback, Real-facing bound seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}$ packet is generated from a located compact interval source row, a ContinuousMap graph row, a LocatedClosedIntervalFiniteNet mesh row, an OscillationModulus tolerance-window row, DyadicRatCore budgets, StreamName windows, RegSeqRat readback, a terminal RealUp bound seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3573.1, Definition 3573.2, and Definition 3573.3 seed the finite L10 oscillation-bound packet over located compact interval, continuous-map, finite-net, modulus, dyadic, window, readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalOscillationBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Heine–Borel compactness, selected extrema, quotient-real equality, host supremum data, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, finite-net exactness, oscillation-modulus exactness, Real seal nonescape, transport replay, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocatedCompactIntervalOscillationBoundUp.

Chapter 3574

A Concrete Naming Certificate for $\mathsf{CharacterTable}^{\uparrow}$

Following Serre and Fulton–Harris on finite-group characters, the $\mathsf{CharacterTable}^{\uparrow}$ packet records a finite character table as displayed NameCert data rather than as a host matrix. It consumes the finite group source of chapter 41, the trace and class-function rows of chapter 245, the Grothendieck ledger of chapter 246, and the Schur row and column ledger of chapter 1603.

Definition 3574.1 (CharacterTable carrier sketch)**.** *A* $\mathsf{CharacterTable}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, C, I, V, \Omega, H, P, N)$$

with the following displayed rows:

1. *G is the consumed finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row.*
2. *C is the finite class-row ledger, listing the displayed conjugacy-class readbacks only through the group packet and not through a quotient carrier.*
3. *I is the irreducible-character row ledger, read through* $\mathsf{NameCert}_{\mathsf{CharacterTheory}^{\uparrow}}$ *and the representation-ring classifier rows.*
4. *V is the value-table row ledger, whose entries are displayed trace readbacks indexed by the accepted C and I rows.*
5. *Ω is the Schur-orthogonality ledger imported as finite row-normalization, column-normalization, and off-diagonal-zero rows.*
6. *H records componentwise* hsame *transport for the group, class, irreducible-character, value-table, orthogonality, provenance, and naming rows.*
7. *P is the* Pkg *provenance over the four sibling certificates named above,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CharacterTable}^{\uparrow}}$ *row.*

The carrier contains no host character matrix, no quotient conjugacy-class object, no ambient complex inner product, and no selected list of representatives outside these rows.

Lean4 ✓ `BEDC.Derived.CharacterTableUp.CharacterTableTasteGate single carrier alignment`

Theorem 3574.2 (CharacterTable NameCert obligations)**.** *Every accepted* $\mathsf{CharacterTable}^{\uparrow}$ *packet satisfies the following five local NameCert obligations:*

1. *carrier admission exposes exactly the group, class-row, irreducible-character-row, value-table, Schur ledger, transport, provenance, and local naming rows of Definition 3574.1;*
2. *class-row exactness requires each class read to be sourced by the displayed finite group packet of chapter 41;*
3. *irreducible-row exactness requires each row name to pass through the trace and class-function surface of chapter 245 and the representation-ring classifier of chapter 246;*
4. *value-table stability requires* hsame *transport to preserve the displayed value rows together with the Schur row and column constraints of chapter 1603;*
5. *nonescape prevents a consumer from replacing the finite rows by a host character table, quotient class carrier, selected representative list, ambient matrix equality, or external representation category.*

Proof. Project the carrier rows of Definition 3574.1. The class ledger is available only through the consumed group row, and the irreducible-character ledger is available only through the character-theory and representation-ring source rows.

The value-table entries are then read as displayed trace values indexed by those two ledgers. The Schur ledger supplies the row and column normalization and off-diagonal rows that make the table stable under accepted transport.

Finally repack the displayed rows with H, P, and N. Since the carrier has no coordinate for a host matrix, quotient class carrier, representative selector, or external representation category, every accepted table read remains inside the finite NameCert packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CharacterTable}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CharacterTable}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3574.1 and Definition 3574.2 seed the finite character-table route over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, and $\mathsf{SchurOrthogonality}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CharacterTable}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close character-table computation, quotient conjugacy classes, host matrix equality, complete representation categories, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, class-row exactness, irreducible-row exactness, value-table stability, and no-host-matrix boundary for the same finite packet.

Constructive story: A $\mathsf{CharacterTable}^{\uparrow}$ packet is generated from a finite group source, displayed class rows, displayed irreducible-character rows, value-table trace rows, Schur orthogonality rows, componentwise transport, package provenance, and a local NameCert row.

Chapter 3575

A Concrete Naming Certificate for $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$

The $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$ packet realizes the Denjoy–Wolff-style fixed-end reading of section 9463.5 in chapter 9463 as finite NameCert data. It consumes the disk-coordinate surface of chapter 377, the hyperbolic metric-read rows of chapter 3474, the disk phase-transport route of chapter 3455, and the boundary-tangent comparison rows of chapter 3534. The packet names boundary dynamics without importing a completed ideal boundary, a classical holomorphic self-map theorem, or an observer substance.

Definition 3575.1 (DenjoyWolffBoundaryDynamics carrier)**.** *A* $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, M, T, B, R, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-map row, including the finite source observations and target observations accepted by the packet.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row used to compare the accepted disk observations.*
3. *T is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *route row, recording how the disk observations move through displayed phase transport.*
4. *B is the boundary-read row, recording the finite boundary-facing observation used as the fixed far-end.*
5. *R is the nonexpansive-route row, recording that every accepted step is read through the metric and transport rows before the boundary far-end is inspected.*
6. *F is the fixed-boundary row, recording stability of the same boundary read under the displayed route.*
7. *H records componentwise* hsame *transport for disk-map, metric-read, phase-transport, boundary-read, nonexpansive-route, fixed-boundary, provenance, and naming rows.*
8. *C records displayed* Cont *replay from D, M, T into B, R, F and then into provenance and naming.*
9. *P is the* Pkg *provenance over* $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$*, the four sibling chapters named above,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host ideal-boundary quotient, a selected fixed point, a global contraction theorem, a physical horizon, or a completed disk compactification.

Lean4 (definition) `BEDC.Derived.DenjoyWolffBoundaryDynamicsUp.DenjoyWolffBoundaryDynamicsUp`
Lean4 ✓ `BEDC.Derived.DenjoyWolffBoundaryDynamicsUp.DenjoyWolffBoundaryDynamicsTasteGate single carrier alignment`

Theorem 3575.2 (DenjoyWolffBoundaryDynamics NameCert obligations)**.** *Every accepted* DenjoyWolffBoundaryD *packet satisfies the following finite obligations:*

1. *carrier admission exposes exactly the disk-map, metric-read, phase-transport, boundary-read, nonexpansive-route, fixed-boundary, transport, replay, provenance, and local naming rows of Definition 3575.1;*
2. *boundary-read exactness requires B to be sourced through the displayed* $\mathsf{UnitDisk}^{\uparrow}$ *and* $\mathsf{HyperbolicMetric}^{\uparrow}$ *rows;*
3. *nonexpansive-route exactness requires R to pass through the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *row before a boundary read is exported;*
4. *fixed-boundary stability requires F, H, C to preserve the same boundary-facing read under accepted route transport;*
5. *nonescape prevents any consumer from replacing these finite rows by a host fixed-point theorem, selected ideal point, quotient boundary equality, completed compactification, or physical observer trajectory.*

Proof. Project the carrier rows of Definition 3575.1. The disk-map, metric-read, and phase-transport rows are the only route by which the boundary read can be formed.

The nonexpansive-route row then records the displayed metric and transport discipline before the fixed-boundary row is inspected. Transport and replay preserve the same boundary-facing read because H and C have no endpoint outside the displayed rows.

Finally the provenance and naming rows repack the route as a local NameCert surface. Since the packet contains no host fixed-point theorem, selected ideal point, quotient boundary equality, completed compactification, or physical observer trajectory, those readings cannot be exported. □

Falsifiable prediction: Every accepted $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$ read factors through displayed disk-map, boundary-read, nonexpansive-route, fixed-boundary, provenance, and local NameCert rows.

Independence witness: unitdisk, hyperbolic-metric, poincare-disk-phase-transport, hyperbolic-horocycle: none is bijective to $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$ because this packet jointly carries disk-map observations, metric-read discipline, phase-transport routing, boundary-read data, nonexpansive-route rows, fixed-boundary stability, transport, replay, provenance, and local naming. The UnitDisk packet supplies coordinates without boundary dynamics; the HyperbolicMetric packet supplies metric reads without a fixed-boundary row; the Poincare disk phase-transport packet supplies movement without a Denjoy–Wolff far-end commitment; and the horocycle packet supplies boundary-tangent rows without nonexpansive disk-map dynamics.

The Lean follow-up must provide `Nontrivial DenjoyWolffBoundaryDynamicsUp` and `FieldFaithful DenjoyWolffBoundaryDynamicsUp` in `lean4/BEDC/Derived/DenjoyWolffBoundaryDynamicsUp/TasteGate.lean`

keeping $D, M, T, B, R, F, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3575.1 and Definition 3575.2 seed the finite boundary-dynamics route over displayed disk-map, metric-read, phase-transport, boundary-read, nonexpansive-route, fixed-boundary, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyWolffBoundaryDynamicsUp.DenjoyWolffBoundaryDynamicsTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close the classical Denjoy–Wolff theorem, holomorphic self-map classification, ideal-boundary quotient equality, selected fixed points, physical observer trajectories, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-read exactness, nonexpansive-route exactness, fixed-boundary stability, nonescape, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.DenjoyWolffBoundaryDynamicsUp.

Constructive story: A $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$ packet is generated from UnitDisk disk-map rows, HyperbolicMetric metric reads, PoincareDiskPhaseTransport rows, a boundary-read row, a nonexpansive-route row, a fixed-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3576

A Concrete Naming Certificate for $\mathsf{BishopCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyCriterion}^{\uparrow}$ packet records the finite criterion by which a real-facing sequence displays Cauchy control before any completion seal is consumed. It sits over the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion criterion route of chapter 1476. The packet names the criterion as finite BEDC NameCert data; it is not a proof of ambient $\mathsf{Real}^{\uparrow}$ completeness, a quotient-stream equality theorem, a selected limit, or a host Cauchy completion object.

Definition 3576.1 (Bishop Cauchy criterion carrier)**.** *A* $\mathsf{BishopCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, E, K, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii, comparison budgets, and slack entries used by the criterion.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite source windows inspected at the displayed tolerance requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity handoff row, assembled from the stream windows and dyadic tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *K is the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *dependency row, recording that the criterion can be consumed by completion-facing packets without exporting completion itself.*
6. *H records componentwise* hsame *transport for the tolerance, window, regularity, seal, and dependency rows.*
7. *C records displayed* Cont *replay through the same finite criterion route.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCriterion}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $D, S, R, E, K, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3576.2 (Bishop Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyCriterion}^{\uparrow}$ *carrier $B = (D, S, R, E, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission, DyadicRatCore tolerance exposure, StreamName finite-window exposure, RegSeqRat regularity handoff, Real seal exposure, CauchyCompletionCriterion dependency exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3576.1. The analytic route is exactly the tolerance row D, the stream-window row S, the regularity handoff R, the terminal seal E, and the completion-criterion dependency K.

The dyadic and stream rows supply the finite Cauchy evidence. The regularity handoff then repacks those finite observations through $\mathsf{RegSeqRat}^{\uparrow}$ before a $\mathsf{Real}^{\uparrow}$ seal is available.

The dependency row K records the only completion-facing use of the criterion. It points to the displayed $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ surface without adding a completion object or an ambient completeness theorem.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no other coordinate is present, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.BishopCauchyCriterionUp.TasteGate.BishopCauchyCriterionTasteGate single carrier alignment`

Theorem 3576.3 (Bishop Cauchy criterion completion route)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopCauchyCriterion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyCompletionCriterion}^{\uparrow}$$

together with H, C, P, N. Consequently the consumer receives dyadic tolerances, finite stream windows, regular rational readback, a terminal real seal, and the named completion criterion dependency, but it receives no selected limit, quotient stream, countable-choice schedule, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with a completion-facing read of B. The only tolerance and observation rows are D and S, so the read must expose the dyadic budgets and stream windows before any regularity handoff can occur.

The row R supplies the regular rational readback, and E supplies the terminal real seal. Thus the real-facing part is downstream of the displayed finite Cauchy observations.

The row K is the sole completion criterion dependency. It permits the packet to be consumed by the Cauchy-completion criterion route, while the absence of quotient, selected-limit, and ambient-completeness coordinates prevents any stronger export. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyCriterion}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName finite windows, RegSeqRat regularity readback, a Real seal, a CauchyCompletionCriterion dependency row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyCriterion}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 3576.1, Definition 3576.2, and Definition 3576.3 close the finite Bishop Cauchy criterion route for the L10 Real and Completion surface.

Formal verification: FormalStatus(NameCert$_{\text{BishopCauchyCriterion}\uparrow}$, theoremChecked)
Lean target: `BEDC.Derived.BishopCauchyCriterionUp.TasteGate.BishopCauchyCriterionTasteGate\_single\_carrier\_alig`
Bridge status: none
Not claimed: This chapter does not close selected limits, quotient streams, countable choice, trichotomy, ambient Real completeness, or bridge checking.
Upgrade path: Public export or bridge work requires a standard interface for the checked criterion route.

Chapter 3577

A Concrete Naming Certificate for $\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}$ packet records the finite equivalence route between a displayed Bishop Cauchy criterion and a displayed dyadic modulus schedule before any completion-facing consumer can read a real seal. It sits after the criterion packet of chapter 3576, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion criterion route of chapter 1476. Its downstream completion consumer is the witness route of chapter 3579; the packet does not export quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3577.1 (Bishop Cauchy modulus equivalence carrier)**.** *A* $\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, D, S, R, E, K, U, H, T, P, N)$$

with displayed rows Q for the $\mathsf{BishopCauchyCriterion}^{\uparrow}$ *criterion, D for the dyadic modulus schedule, S for the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the schedule, R for the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E for the terminal* $\mathsf{Real}^{\uparrow}$ *seal, K for the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *dependency, U for the criterion-to-modulus transport row, H for componentwise* hsame *transport, T for displayed* Cont *replay, P for* Pkg *provenance, and N for the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}}$ *row. Accepted packets compare criterion and modulus data only through these rows.*

Lean4 ✓ `BEDC.Derived.BishopCauchyModulusEquivalenceUp.BishopCauchyModulusEquivalenceTasteGate`
`single carrier alignment`

Theorem 3577.2 (Bishop Cauchy modulus equivalence NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}$ *carrier $M = (Q, D, S, R, E, K, U, H, T, P, N)$, the local* $\mathsf{NameCert}$ *surface consists exactly of criterion-row admission, dyadic modulus exposure, stream-window exposure, regular rational readback, Real seal exposure, completion-criterion dependency exposure, criterion-to-modulus transport, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3577.1. The analytic part is Q, D, S, R, E, K, U: the criterion row is read first, the dyadic modulus schedule and finite stream windows display the same Cauchy demand, and the regular rational readback reaches the Real seal only through that displayed route.

The completion dependency is K, so completion-facing use remains a dependency row rather than a selected completion object. The structural rows H, T, P, N transport, replay, source, and name exactly the same finite data, leaving no coordinate for quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 3577.3 (Bishop Cauchy modulus equivalence consumer route)**.** *Every consumer of an accepted* $\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}$ *carrier that claims a criterion/modulus handoff for L10 completion must factor through* $\mathsf{BishopCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, *and the downstream* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *route before the local* NameCert *row is exported.*

Proof. Begin with the criterion row Q and the dyadic modulus row D. The stream windows S and regular readback R are the only rows that connect those two presentations to the terminal seal E, so a completion consumer cannot jump from a criterion statement to a Real-facing witness.

The dependency row K points to the completion criterion, and the witness consumer reads that dependency through the displayed L10 route. The rows U, H, T, P, N then record the handoff, transport, replay, provenance, and name; no additional carrier coordinate supplies quotient equality, selected limits, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}$ packet is generated from a BishopCauchyCriterion row, a dyadic modulus row, StreamName finite windows, RegSeqRat readback, a Real seal, a CauchyCompletionCriterion dependency, criterion-to-modulus transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}}$, seed)

Scope closed: Definition 3577.1, Definition 3577.2, and Definition 3577.3 seed the finite criterion/modulus equivalence route for the L10 Real and Completion surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEquivalence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient streams, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion exposure, dyadic modulus exposure, stream-window exposure, regular readback, Real seal non-escape, completion-criterion dependency preservation, transport stability, replay stability, provenance, and local naming.

Chapter 3578

A Concrete Naming Certificate for $\mathsf{BurnsideOrbitCount}^{\uparrow}$

Following Burnside and Pólya on finite group actions and orbit enumeration, the $\mathsf{BurnsideOrbitCount}^{\uparrow}$ packet records the finite ledger by which a displayed $\mathsf{Group}^{\uparrow}$ action on a displayed $\mathsf{FinSet}^{\uparrow}$ carrier yields an orbit-count read from fixed-point rows. It sits between the group certificate of chapter 41, the finite-set certificate of chapter 112, the character ledger of chapter 245, and the representation-ring surface of chapter 246. The packet names only the finite action and fixed-row accounting surface; it does not import quotient orbit sets, host cardinal arithmetic, complete character tables, or a representation category.

Definition 3578.1 (Burnside orbit-count carrier)**.** *A* $\mathsf{BurnsideOrbitCount}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (G, X, A, F, O, M, H, C, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row for the finite group endpoint.*
2. *X is the consumed* $\mathsf{NameCert}_{\mathsf{FinSet}^{\uparrow}}$ *row for the acted-on finite carrier.*
3. *A is the displayed action ledger, read as finite* Cont *rows from G and X to the endpoint rows of X.*
4. *F is the fixed-point table whose row for g lists exactly the displayed x-rows satisfying the action read $g \cdot x = x$ through the classifier of X.*
5. *O is the orbit ledger, listing carried orbit-name rows and the finite membership witnesses by which each displayed x-row is assigned to one orbit row.*
6. *M is the finite averaging ledger displaying the numerator rows $\sum_{g \in G} \#F_g$, the divisor row $\#G$, and the resulting orbit-count read.*
7. *H records componentwise* hsame *transport for the group, finite-set, action, fixed-point, orbit, averaging, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the group and finite-set rows through the action ledger into the fixed-point table, orbit ledger, and finite averaging row.*
9. *P is the* Pkg *provenance over* $\mathsf{BurnsideOrbitCount}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BurnsideOrbitCount}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, X, A, F, O, M, H, C, P, N$. It has no coordinate for a quotient orbit carrier, a host set cardinal, a complex character table, an ambient representation ring, or a choice-selected orbit representative.

Lean4 ✓ `BEDC.Derived.BurnsideOrbitCountUp.BurnsideOrbitCountTasteGate single carrier alignment`

Theorem 3578.2 (Burnside orbit-count NameCert obligations)**.** *For every accepted* $\mathsf{BurnsideOrbitCount}^{\uparrow}$ *carrier $B = (G, X, A, F, O, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BurnsideOrbitCount}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the consumed group row, consumed finite-set row, action ledger, fixed-point table, orbit ledger, averaging row, transport, replay, provenance, and local naming;*
2. *action visibility, requiring every action read in A to expose its group source in G and its input and output rows in X;*
3. *fixed-point visibility, requiring every row of F to be witnessed by an action read in A and a displayed classifier comparison in X;*
4. *orbit-ledger stability, requiring O to transport along the same* hsame *rows that transport G, X, A, and F;*
5. *finite averaging exactness, requiring M to consume only the displayed fixed-point rows and the displayed group-size divisor before exposing the orbit-count read.*

No Burnside orbit-count obligation is stored outside these rows.

Proof. Project the accepted carrier. The rows G and X supply the finite group source and finite acted-on carrier, and A is the only row in which action endpoints are displayed.

The fixed-point table F is downstream of A and the classifier of X. Thus a fixed-point read must show both the action result and the displayed comparison with the original x-row.

The orbit ledger O is then read as finite assignment data over the same X rows. Its stability is exactly componentwise transport by H, because no separate quotient-orbit carrier is present.

The averaging row M consumes the displayed fixed-point rows and the displayed group-size divisor. The replay row C, provenance row P, and local naming row N repack this data as the local NameCert surface, so no host cardinal, character table, representation ring, or selected representative becomes an additional obligation. □

Theorem 3578.3 (Burnside fixed-row handoff)**.** *Every orbit-count read exported by an accepted* $\mathsf{BurnsideOrbitCount}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Group}^{\uparrow},\ \mathsf{FinSet}^{\uparrow} \longrightarrow \mathsf{ActionLedger} \longrightarrow \mathsf{FixedRowTable} \longrightarrow \mathsf{OrbitLedger} \longrightarrow \mathsf{FiniteAverage}.$$

The handoff exposes the finite group row, finite-set row, action ledger, fixed-point table, orbit-ledger stability data, and finite averaging row before any orbit count is consumed. A consumer that omits one of those rows is outside the accepted carrier.

Proof. Read the carrier of Definition 3578.1. The first two coordinates bind the consumed $\mathsf{Group}^{\uparrow}$ and $\mathsf{FinSet}^{\uparrow}$ rows, and the action coordinate A records all displayed action reads.

The fixed-row table F can only be projected after those action reads are visible. Each fixed row is therefore a finite ledger row over G, X, and A, rather than a host fixed-point subset.

The orbit ledger O records the finite orbit-name assignments transported by H. The averaging ledger M then reads the fixed rows and group-size divisor to expose the orbit-count row.

Since C, P, and N only replay, package, and name the same displayed route, every exported orbit count factors through the stated handoff. If any row in the route is absent, the packet has no coordinate from which the orbit-count read can be projected. □

Falsifiable prediction: Every accepted $\mathsf{BurnsideOrbitCount}^{\uparrow}$ consumer read factors through one $\mathsf{Group}^{\uparrow}$ row, one $\mathsf{FinSet}^{\uparrow}$ row, one displayed action ledger, one fixed-point table, one orbit ledger, one finite averaging row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row.

Independence witness: group, finset, character-theory, representation-ring: no listed sibling is bijective with $\mathsf{BurnsideOrbitCount}^{\uparrow}$ because the packet jointly carries action reads, fixed-point rows, orbit assignment rows, finite averaging data, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BurnsideOrbitCount}^{\uparrow}}$.

Constructive story: A $\mathsf{BurnsideOrbitCount}^{\uparrow}$ packet is generated from a consumed $\mathsf{Group}^{\uparrow}$ row, a consumed $\mathsf{FinSet}^{\uparrow}$ row, a displayed finite action ledger, a fixed-point table, an orbit assignment ledger, a finite averaging row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BurnsideOrbitCount}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3578.1, Definition 3578.2, and Definition 3578.3 seed the finite Burnside orbit-count packet over displayed group, finite-set, action, fixed-row, orbit-ledger, averaging, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BurnsideOrbitCount}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient orbit carriers, host cardinal arithmetic, complete character theory, representation-ring computation, selected orbit representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, action visibility, fixed-point visibility, orbit-ledger stability, finite averaging exactness, transport replay, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.BurnsideOrbitCountUp.

Chapter 3579

A Concrete Naming Certificate for $\mathsf{CauchyCompletenessWitness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ packet records the finite witness by which regular Cauchy data, finite stream windows, dyadic tolerance rows, a completeness modulus, and a terminal Real seal are read as one completion-facing surface. It sits after the regular rational sequence surface of chapter 301, the finite stream-name discipline of chapter 126, the dyadic tolerance core of chapter 291, the terminal Real-name seal of chapter 38, and the Cauchy completeness modulus packet of chapter 2051. The packet names the L10 completion witness between regular Cauchy data and the $\mathsf{Real}^{\uparrow}$ seal; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient Real completeness.

Definition 3579.1 (Cauchy completeness witness carrier)**.** *A* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (R, S, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row whose Cauchy data is being witnessed.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording the inspected stream observations used by the witness.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the dyadic budgets attached to those windows.*
4. *M is the* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$ *row that bounds the tail-coherence demands accepted by the witness.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, S, D, M have all been displayed.*
6. *H records componentwise* hsame *transport for the regular readback, finite windows, dyadic ledger, completeness modulus, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-witness request through R, S, D, M, E.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletenessModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, D, M, E, H, C, P, N$ and their displayed replay path. It has no coordinate for quotient stream equality, selected representatives, host-limit choice, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletenessWitnessUp.CauchyCompletenessWitnessTasteGate single carrier alignment`

Theorem 3579.2 (Cauchy completeness witness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletenessW}$ *carrier $W = (R, S, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet, classifier stability under componentwise* hsame*, witness-to-seal routing through the completeness modulus and terminal Real row, ledger nonescape for dyadic tolerance data, and sibling dependency routing through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Every completion-facing consumer must read the route

$$R \longmapsto S \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N$$

before treating the regular Cauchy data as sealed by a completion witness.

Proof. Project the carrier of Definition 3579.1. The accepted packet exposes only the regular readback row, finite stream windows, dyadic tolerance ledger, completeness modulus, terminal Real seal, transport, replay, provenance, and local naming rows.

Carrier admission and classifier stability are componentwise. The rows R, S, D, M, E are compared only by the displayed hsame transports in H, and the replay row C preserves the same order of inspection for any accepted completion-witness request.

The witness-to-seal route is forced by M and E. The completeness modulus bounds the tail-coherence demand before the Real seal is consumed, while the dyadic ledger D has already exhausted the tolerance data that could otherwise be mistaken for a detached limit choice.

Finally P and N record sibling dependency routing and the local certificate name. Since the carrier contains no quotient stream equality, selected representative, host-limit operator, countable-choice schedule, trichotomy row, or ambient completeness coordinate, none of those objects belongs to the NameCert obligation surface. □

Theorem 3579.3 (Cauchy completeness witness Real seal route)**.** *Every completion-seal read of an accepted* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *packet factors through the displayed finite witness rows $R, S, D, M, E, H, C, P, N$. In particular, a* $\mathsf{Real}^{\uparrow}$ *consumer must first read the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational data, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window evidence, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$ *tail-control row before it reaches the terminal seal E.*

The route exports a completion witness for displayed regular Cauchy data. It does not export quotient stream equality, a selected host limit, countable choice, trichotomy, a detached Real seal, or ambient Real completeness.

Proof. Start with a consumer that reads a completion seal. The only Real-facing terminal coordinate in the carrier is E, and E appears after the readback, finite-window, dyadic-ledger, and completeness-modulus rows.

The consumer must therefore pass through R, S, D, M. These rows provide the regular Cauchy data, the finite observations, the tolerance budget, and the tail-control witness needed before the Real seal can be named.

The support rows H, C, P, N transport, replay, source, and locally certify that same finite route. They can preserve the displayed witness, but they cannot introduce quotient equality, selected

limits, countable choice, trichotomy, detached Real seals, or ambient completeness because no such coordinate is present in the accepted packet. □

Theorem 3579.4 (Cauchy completeness witness obligation package)**.** *The carrier definition Definition 3579.1, the NameCert-obligations theorem Definition 3579.2, and the Real-seal-route theorem Definition 3579.3 together supply the obligation surface for* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$*. This surface consists of carrier admission, classifier stability through componentwise* hsame*, witness-to-seal routing through the completeness modulus,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger nonescape, sibling routing through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyCompletenessModulus}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, and local* NameCert *provenance.*

Proof. Project the finite tuple $W = (R, S, D, M, E, H, C, P, N)$ from Definition 3579.1. Carrier admission is exactly the admission of these displayed rows, with no extra coordinate for quotient stream equality, selected limits, choice, trichotomy, detached Real seals, or ambient completeness.

Apply Definition 3579.2. It identifies classifier stability, componentwise hsame transport, dyadic ledger discipline, sibling dependency routing, provenance, and the local NameCert row as the NameCert surface of the packet.

Apply Definition 3579.3. It forces every completion-seal read through $R, S, D, M, E, H, C, P, N$, so the witness-to-seal obligation passes through the completeness modulus and terminal Real seal rather than through an unstated host limit. The three cited surfaces therefore exhaust the obligation package for the finite completion witness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting the regular rational readback, finite stream windows, dyadic tolerance ledger, completeness modulus, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: regseqrat, streamname, dyadicratcore, cauchy-completeness-modulus, real: no listed sibling supplies the whole witness packet $W = (R, S, D, M, E, H, C, P, N)$, because each sibling contributes only readback, windows, tolerances, tail control, or the terminal seal while this chapter binds all five analytic faces as one finite completion witness.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ packet is generated from a RegSeqRat regular readback row, StreamName finite windows, a DyadicRatCore tolerance ledger, a CauchyCompletenessModulus tail-control row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3579.1, Definition 3579.2, and Definition 3579.3 seed the finite completion-witness route over regular rational readback, stream windows, dyadic tolerances, completeness modulus data, Real sealing, transport, replay, provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, detached Real seals, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, witness-to-seal routing, ledger nonescape, sibling dependency routing, and Real-seal factorization for BEDC.Derived.CauchyCompletenessWitnessUp.

Chapter 3580

A Concrete Naming Certificate for $\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}$ packet records the finite obligation package that a completion-facing witness must discharge before downstream Real-completion consumers may use the $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ route. It sits over the regular rational readback of chapter 301, the finite stream-name windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the witness carrier of chapter 3579. The chapter names only the obligation surface for that textbook completion witness; it does not assert quotient stream equality, selected host limits, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3580.1 (Cauchy completeness witness obligation carrier)**.** *A* $\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (W, A, K, R, D, S, E, H, C, P, N)$$

whose rows record a displayed $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *carrier* W*, carrier-admission evidence* A*, classifier-stability evidence* K*, sibling readback rows* R, D, S*, a terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance over the witness and obligation surfaces, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}}$ *row* N*. The classifier compares such carriers only by these rows and their displayed route through* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyCompletenessWitnessObligationUp.CauchyCompletenessWitnessObligationTasteGate`
`single carrier alignment`

Theorem 3580.2 (Cauchy completeness witness obligation closure package)**.** *For every accepted* $\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}$ *carrier* $O = (W, A, K, R, D, S, E, H, C, P, N)$*, carrier admission, classifier stability, witness-to-seal routing, dyadic ledger nonescape, sibling dependency routing, and Real-seal factorization exhaust the* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *obligation surface.*

More precisely, A *admits the displayed witness carrier,* K *compares the accepted rows only through the componentwise* hsame *transports,* W *routes every completion-witness request to the terminal seal* E*,* D *accounts for the dyadic tolerance ledger before the seal is visible,* R, S, D *route through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* P, N *attach the same finite route to the local package and naming certificate. No quotient stream, selected representative, host-limit operator, countable-choice schedule, trichotomy row, detached Real seal, or ambient completeness coordinate is exported.*

Proof. Project the carrier of Definition 3580.1. The displayed rows are exactly the witness carrier, admission row, classifier row, sibling readbacks, Real seal, transport, replay, provenance, and local naming certificate.

Carrier admission is the row A, while classifier stability is the row K transported through H. The replay row C can only read the same finite route, so accepted comparisons cannot introduce a second classifier surface.

The witness-to-seal route is the displayed $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ row W ending at E. The dyadic row D is already part of that route, so every tolerance ledger read is consumed before the terminal seal is available.

The sibling dependencies are the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows, together with the witness chapter of chapter 3579. The Real-seal factorization is therefore the finite route from those sibling rows through W to E, packaged by P and named by N.

Since the carrier has no coordinate for quotient streams, selected host limits, choice, trichotomy, detached Real seals, or ambient completeness, those objects cannot become obligations of the local certificate. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}$ consumer that reaches a $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ seal while omitting carrier admission, classifier stability, witness-to-seal routing, dyadic ledger nonescape, sibling dependency routing, Real-seal factorization, transport, replay, provenance, or local naming refutes the packet.

Independence witness: cauchy-completeness-witness, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the whole obligation packet $O = (W, A, K, R, D, S, E, H, C, P, N)$, because each sibling contributes only witness structure, regular readback, finite windows, dyadic tolerances, or the terminal seal while this chapter binds the obligation surface itself.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}$ packet is generated from a CauchyCompletenessWitness carrier, carrier admission, classifier stability, RegSeqRat readback, StreamName windows, DyadicRatCore tolerance data, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 3580.1 and Definition 3580.2 close the finite obligation surface for CauchyCompletenessWitness carrier admission, classifier stability, witness-to-seal routing, dyadic ledger nonescape, sibling routing, Real-seal factorization, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessWitnessObligation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, detached Real seals, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A checked theorem for the same $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert obligation route would raise the verification axis.

Chapter 3581

A Concrete Naming Certificate for $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$

Following Hardy–Littlewood maximal estimates and the Vitali-cover selection lemma, the $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ packet records the finite maximal-function surface for metric balls, positive radius windows, and local average rows. It sits beside the finite covering ledger of chapter 2166 and the terminal real-name boundary of chapter 38; the packet names one displayed maximal domination route without importing measure completion, countable choice, selected suprema, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3581.1 (Hardy-Littlewood maximal carrier)**.** *A* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, B, R, A, V, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric-source row. It records the carried points, the displayed distance reads, and the finite ball names inspected by the maximal request.*
2. *B is the metric-ball row. Each ball record stores a center, a positive radius witness, the membership probes read by the packet, and the carrier-local inclusion comparisons used downstream.*
3. *R is the positive-radius window row. It stores only finite radius candidates and rational comparison budgets; it has no coordinate for a selected optimizing radius.*
4. *A is the local-average row. For every displayed ball window it records the finite readback route for the corresponding average value and the rational tolerance by which that value is compared.*
5. *V is the finite Vitali-cover ledger, read through* $\mathsf{FiniteVitaliCover}^{\uparrow}$*. It records the selected disjoint subfamily, the overlap budget, and the cover cells used to dominate the requested window.*
6. *D is the domination witness row. It records the finite comparison that bounds each displayed local average by the exported maximal value read through the same radius and cover windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It exposes only the finite real-name windows reached from A and D.*
8. *H records componentwise* hsame *transport for the metric source, ball windows, radius budgets, local averages, Vitali ledger, domination witness, real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay of the route*

$$\mathsf{FiniteVitaliCover}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist} \longmapsto \mathsf{HardyLittlewoodMaximal}^{\uparrow}.$$

10. *P is the* Pkg *provenance over* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$, $\mathsf{FiniteVitaliCover}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximal}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these eleven rows. Its classifier compares accepted packets only through $X, B, R, A, V, D, E, H, C, P, N$ and has no coordinate for a selected supremum, a countable ball family, a measure-completion object, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HardyLittlewoodMaximalUp.HardyLittlewoodMaximalTasteGate single carrier alignment`

Theorem 3581.2 (Hardy-Littlewood maximal NameCert obligations)**.** *For an accepted* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *carrier*

$$M = (X, B, R, A, V, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric source, metric-ball windows, positive-radius budgets, local average rows, finite Vitali-cover ledger, domination witness, real seal, transport, replay, provenance, and local naming row;*
2. *positive-radius visibility, requiring every local average request to read a displayed radius witness from R and the matching ball data from B before any average row in A is inspected;*
3. *finite Vitali-cover discipline, requiring domination to pass through the ledger V and its overlap budget before the witness row D is exported;*
4. *real-seal discipline, requiring every numerical output to pass through E after the local average and domination rows have been displayed;*
5. *ledger non-escape, requiring H, C, P, N to preserve exactly the rows X, B, R, A, V, D, E and to export no selected supremum, no countable-choice ball selection, no measure completion, no quotient function equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 3581.1. The accepted packet exposes exactly the metric source, ball windows, positive-radius budgets, local average rows, finite Vitali ledger, domination witness, real seal, transport, replay, provenance, and local naming rows.

The radius and average obligations are ordered by the carrier itself. A local average read from A is meaningful only after the matching ball data from B and positive radius witness from R have been displayed, so the packet cannot replace finite windows by an optimizing host radius.

The covering step is the row V. Its $\mathsf{FiniteVitaliCover}^{\uparrow}$ ledger supplies the finite selected subfamily and overlap budget used by D, and the domination witness can only cite those displayed cells.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since there is no carrier coordinate for a selected supremum, countable-choice ball family, measure completion, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those principles appears in the local $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximal}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ packet is generated from a metric source row, metric-ball windows, positive-radius budgets, local average rows, a finite Vitali-cover ledger, a domination witness, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3581.1 and Definition 3581.2 seed the finite maximal-function carrier and obligation surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{HardyLittlewoodMaximal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, measure completion, countable-choice ball selection, selected suprema, quotient function equality, ambient Real$^{\uparrow}$ completeness, Lebesgue differentiation, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius visibility, finite Vitali-cover discipline, real-seal discipline, and ledger non-escape for BEDC.Derived.HardyLittlewoodMaximalUp.

Chapter 3582

A Concrete Naming Certificate for $\mathsf{RationalRootInterval}^{\uparrow}$

Following Sturm and Bishop–Bridges constructive interval methods, the $\mathsf{RationalRootInterval}^{\uparrow}$ packet records a finite rational interval certificate for a displayed polynomial sign change and its bisection route. It sits after the dyadic rational carrier of chapter 291, the located interval carrier of chapter 1709, the bisection route of chapter 1711, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite interval-certificate route used by L10 Real and Completion consumers; it is not a host real equality test, quotient root set, global root selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 3582.1 (RationalRootInterval carrier)**.** *A* $\mathsf{RationalRootInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, L, U, G, B, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite coefficient row for the inspected rational polynomial, including the displayed degree bound and the rational coefficient reads used by the certificate.*
2. *L and U are the left and right endpoint rows, carried through* $\mathsf{DyadicRatCore}^{\uparrow}$ *or rational endpoint data and then embedded into the located interval surface.*
3. *G is the sign-read ledger, recording the endpoint sign observations and every comparison row used to treat the interval as bracketing a rational root candidate.*
4. *B is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *provenance row, recording the displayed bisection path from the original endpoint pair to the certified subinterval.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for coefficient reads, endpoint reads, sign reads, and bisection-stage observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and the dyadic or rational endpoint ledgers, so every exported approximation is sourced by finite observations.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the coefficient row, endpoint rows, sign-read ledger, bisection provenance, stream windows, and regular rational readback have been replayed.*
8. *H records componentwise* hsame *transport for coefficient data, endpoints, sign reads, bisection provenance, stream windows, regular readback, terminal seal, replay, provenance, and local naming data.*

9. *C records displayed* Cont *replay for consumers that inspect the polynomial row, endpoint interval, sign ledger, bisection route, regular readback, or terminal seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RationalRootInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisecti}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalRootInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L, U, G, B, W, R, S, H, C, P, N$. It has no coordinate for host real equality, quotient root sets, global root selectors, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RationalRootIntervalUp.RationalRootIntervalTasteGate single carrier alignment`

Theorem 3582.2 (RationalRootInterval bisection seal)**.** *For every accepted* $\mathsf{RationalRootInterval}^{\uparrow}$ *carrier*

$$Q = (A, L, U, G, B, W, R, S, H, C, P, N),$$

the $\mathsf{Real}^{\uparrow}$*-facing interval seal is exported only by the finite route*

$$A, L, U, G \longrightarrow B \longrightarrow W \longrightarrow R \longrightarrow S.$$

The coefficient row fixes the inspected rational polynomial, the dyadic or rational endpoint rows fix the displayed interval, the sign-read ledger records the endpoint comparisons, the bisection provenance supplies the certified narrowing route, the $\mathsf{StreamName}^{\uparrow}$ *windows expose finite observations, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row packages the regular rational readback, and* $\mathsf{Real}^{\uparrow}$ *consumes exactly that seal.*

Proof. Project the accepted carrier of Definition 3582.1. The rows A, L, U, G display the polynomial coefficients, the two endpoint carriers, and the sign-read ledger; there is no separate coordinate for a host-level polynomial root or for equality of ambient reals.

The bisection data are then forced through B. The route records the finite interval refinements and their provenance, so a consumer cannot replace the displayed path by a global root selector or by a quotient root set.

Regular readback starts only after the finite observations have been opened. The windows in W expose coefficient, endpoint, sign, and bisection-stage reads; the row R packages those reads as regular rational data; and the terminal row S is the only $\mathsf{Real}^{\uparrow}$ seal available to the packet.

Finally, H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no host real equality, quotient root set, global root selector, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, none of those principles is claimed by the bisection seal. □

Theorem 3582.3 (RationalRootInterval sign-read stability)**.** *For every accepted* $\mathsf{RationalRootInterval}^{\uparrow}$ *carrier*

$$Q = (A, L, U, G, B, W, R, S, H, C, P, N),$$

endpoint sign observations are transported only through the displayed coefficient row A, endpoint rows L, U, sign-read ledger G, bisection provenance B, and componentwise hsame *row H. The rows C, P, N replay, source, and name that same route. No host root selector, quotient root set, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can alter the sign-read path.*

Proof. Project the carrier of Definition 3582.1. The polynomial data read by a sign observation are fixed by A, and the two endpoint observations are fixed by L and U.

Read the sign ledger through G and the finite bisection provenance through B. These rows record which endpoint comparisons are visible before the interval is narrowed, so the sign route is determined before any terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Transport is componentwise through H. The replay row C, provenance row P, and local naming row N preserve the same displayed observations. Since the carrier contains no host root selector, quotient root set, or ambient completeness coordinate, those objects cannot change the sign-read route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalRootInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalRootInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3582.1 and Definition 3582.2 seed the finite rational root interval route over coefficient rows, dyadic or rational endpoint rows, sign-read ledgers, bisection provenance, StreamName windows, RegSeqRat readback, Real seals, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalRootInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient root sets, global root selectors, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-row exactness, endpoint routing, sign-read stability, bisection provenance, StreamName window exposure, RegSeqRat readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RationalRootIntervalUp.

Constructive story: A $\mathsf{RationalRootInterval}^{\uparrow}$ packet is generated from finite polynomial coefficient rows, dyadic or rational endpoint rows, a sign-read ledger, located-interval bisection provenance, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3583

A Concrete Naming Certificate for EnergyBiasedTriggerReliability$^{\uparrow}$

The EnergyBiasedTriggerReliability$^{\uparrow}$ packet realizes the energy-weighted trigger reliability formula of Definition 9462.1593 as finite BEDC NameCert rows. It consumes the six-coordinate codon window of chapter 2234, the boundary-tile row of chapter 3393, the coverage row of chapter 3470, and the trigger-algebra surface of chapter 3478. The packet records weight rows, partition-factor rows, blocker rows, and reliability rows; it is not a stochastic evolution model, an empirical biological likelihood claim, quotient codon equality, or an infinite trigger search.

Definition 3583.1 (Energy-biased trigger reliability carrier)**.** *An* EnergyBiasedTriggerReliability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, B, V, A, G, F, L, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *source-window row exposing the finite codon-window coordinates used by the trigger counts.*
2. *B is the* DnaWindowSixBoundaryTile$^{\uparrow}$ *boundary row supplying the stop/Trp and Ile/Met trigger faces.*
3. *V is the* SixBoundaryTileCoverage$^{\uparrow}$ *coverage row recording which boundary faces are covered by each displayed trigger family.*
4. *A is the* WindowCoverageTriggerAlgebra$^{\uparrow}$ *trigger-algebra row carrying support closure, blocker, and threshold data.*
5. *G is the energy-weight row, recording the displayed powers of t and y assigned to finite trigger cardinality and trigger energy.*
6. *F is the partition-factor row, recording the finite $A_k(t, y)$ partition contributions that feed the reliability quotient.*
7. *L is the blocker row, recording the finite inclusion-exclusion blocker expression used in the numerator of the reliability formula.*
8. *R is the reliability row, recording the displayed value of $R(t, y)$ only after G, F, L and the trigger-algebra dependencies have been displayed.*

9. *H records componentwise* hsame *transport for source, boundary, coverage, algebra, weight, partition, blocker, and reliability rows.*
10. *C records displayed* Cont *replay through the same finite trigger-partition route.*
11. *P is the* Pkg *provenance over* EnergyBiasedTriggerReliability$^{\uparrow}$, CodonSixBitWindow$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgebra$^{\uparrow}$, *the source vision of Definition 9462.1593,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{EnergyBiasedTriggerReliability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, B, V, A, G, F, L, R, H, C, P, N$. It has no coordinate for hidden biological semantics, empirical likelihood calibration, stochastic dynamics, quotient codon equality, global support completion, or infinite trigger enumeration.

Lean4 (definition) `BEDC.Derived.EnergyBiasedTriggerReliabilityUp.EnergyBiasedTriggerReliabilityUp`
Lean4 ✓ `BEDC.Derived.EnergyBiasedTriggerReliabilityUp.EnergyBiasedTriggerReliabilityTasteGate`
`single carrier alignment`

Theorem 3583.2 (Energy-biased trigger reliability NameCert obligations)**.** *For every accepted* EnergyBiasedTriggerReliability$^{\uparrow}$ *carrier $E = (W, B, V, A, G, F, L, R, H, C, P, N)$, the local* NameCert$_{\text{EnergyBiasedTriggerRe}}$ *surface consists exactly of carrier admission, codon-window exposure, boundary-tile exposure, six-boundary coverage exposure, trigger-algebra exposure, energy-weight exposure, partition-factor exposure, blocker exposure, reliability-row exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3583.1. The trigger source rows are exactly W, B, V, A, so a reliability consumer first receives the finite codon window, boundary tile, coverage, and trigger-algebra surfaces.

The quantitative rows are G, F, L, R. The weight row records the powers assigned to trigger cardinality and energy, the partition row records the displayed $A_k(t, y)$ factors, the blocker row records the finite inclusion-exclusion expression, and the reliability row is available only after those rows have been exposed.

The structural rows H, C, P, N transport, replay, source, and name this same packet. Since no hidden semantics, empirical calibration, stochastic dynamics, quotient codon equality, global completion, or infinite enumeration coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 3583.3 (Energy-biased trigger partition route)**.** *Every consumer of an accepted* EnergyBiasedTriggerRelia *packet reads the reliability formula through the finite route*

$$\text{CodonSixBitWindow}^{\uparrow} \longmapsto \text{DnaWindowSixBoundaryTile}^{\uparrow} \longmapsto \text{SixBoundaryTileCoverage}^{\uparrow} \longmapsto \text{WindowCoverageTriggerA}$$

Thus the exported reliability value is a finite trigger-partition NameCert row over displayed weights, partition factors, blockers, and reliability data. The packet does not export stochastic evolution, empirical likelihood calibration, quotient codon equality, global support completion, or an infinite trigger search.

Proof. Start with the source route. The codon window row W supplies finite coordinates, the boundary row B supplies the boundary triggers, and the coverage row V records the displayed support faces.

The trigger algebra row A then binds those supports to blocker and threshold data. It is the only algebraic route into the energy-biased reliability packet.

Finally the rows G, F, L, R record weights, partition factors, blockers, and the reliability quotient. Transport, replay, provenance, and naming through H, C, P, N preserve this finite route and leave the refused external readings without export rows. □

Falsifiable prediction: Every accepted $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ consumer that reads $R(t, y)$ must exhibit CodonSixBitWindow, DnaWindowSixBoundaryTile, SixBoundaryTileCoverage, WindowCoverageTriggerAlgebra, energy-weight, partition-factor, blocker, reliability, transport, replay, provenance, and local NameCert rows.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, window-coverage-trigger-algebra: $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite codon windows, boundary triggers, coverage rows, trigger algebra, energy weights, partition factors, blocker expression, reliability row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}}$.

Constructive story: An $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ packet is generated from codon six-bit windows, DNA boundary tiles, six-boundary coverage rows, trigger-algebra rows, energy weights, partition factors, blockers, reliability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3583.1, Definition 3583.2, and Definition 3583.3 seed the finite trigger-partition route for energy-biased reliability.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close stochastic evolution, empirical likelihood calibration, quotient codon equality, global support completion, infinite trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window exposure, boundary-tile exposure, coverage exposure, trigger-algebra exposure, energy-weight exactness, partition-factor exactness, blocker exactness, reliability non-escape, transport stability, replay stability, provenance, and local naming.

Chapter 3584

A Concrete Naming Certificate for $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$

Following Mertens and Bishop–Bridges constructive analysis, the $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ packet records the theorem-level product route saying that two displayed source series may be multiplied by the Cauchy product once the summand windows, convolution windows, absolute-convergence or majorant tail ledgers, and terminal real-name seal are all visible. It sits over the local criterion of chapter 1586, the convolution surface of chapter 409, the series-product packet of chapter 2214, the fast product route of chapter 368, the majorant discipline of chapter 399, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The chapter names the finite L10 Real seal route for Mertens' product theorem; it does not assert a quotient series product, a selected infinite sum, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3584.1 (Mertens Cauchy product theorem carrier)**.** *A* $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, W, K, T, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the finite source-series rows exposing the inspected summand windows for the two input series.*
2. *W is the paired* $\mathsf{CauchyConvolution}^{\uparrow}$ *window row, recording the finite diagonal product cells used at each requested product index.*
3. *K is the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *handoff row that binds the convolution windows to the Cauchy-product acceptance test.*
4. *T is either an* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *row for one source series or a finite majorant-tail ledger of the kind consumed by* $\mathsf{WeierstrassMTest}^{\uparrow}$*.*
5. *Q is the* $\mathsf{CauchySeriesProduct}^{\uparrow}$ *or* $\mathsf{FastSeriesProduct}^{\uparrow}$ *product packet read from A, B, W, K, T.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the accepted product packet.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the product packet and regular readback have been displayed.*

8. *H records componentwise* hsame *transport for the source rows, convolution windows, tail ledger, criterion handoff, product packet, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a product-theorem request through A, B, W, K, T, Q, R, E.*

10. *P is the* Pkg *provenance over* MertensCauchyProductTheorem$^{\uparrow}$, CauchyConvolution$^{\uparrow}$, CauchyProductCriterion$^{\uparrow}$, CauchySeriesProduct$^{\uparrow}$, FastSeriesProduct$^{\uparrow}$, AbsoluteConvergence$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{MertensCauchyProductTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their replay path. It has no coordinate for quotient stream equality, host multiplication of completed sums, selected limiting sums, countable-choice schedules, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MertensCauchyProductTheoremUp.MertensCauchyProductTheoremTasteGate single carrier alignment`

Theorem 3584.2 (Mertens Cauchy product theorem NameCert obligations)**.** *For every accepted* MertensCauchyProductTheorem$^{\uparrow}$ *carrier $M = (A, B, W, K, T, Q, R, E, H, C, P, N)$, the local* NameCert$_{\text{MertensCauchyPro}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the two finite source-series rows, paired convolution windows, tail ledger, criterion handoff, product packet, regular readback, Real seal, transport, replay, provenance, and local naming data;*

2. *convolution-window exactness, requiring W to be read through chapter 409 before any product packet Q is exposed;*

3. *tail-to-criterion handoff, requiring the absolute-convergence row or majorant-tail ledger T to feed the* CauchyProductCriterion$^{\uparrow}$ *row K through chapter 1586;*

4. *product readback routing, requiring Q to be consumed through the* CauchySeriesProduct$^{\uparrow}$ *and* FastSeriesProduct$^{\uparrow}$ *sibling surfaces before the* RegSeqRat$^{\uparrow}$ *row R is read;*

5. *L10 Real seal factorization, requiring every terminal seal read E to pass through $A, B, W, K, T, Q, R, H, C, P, N$.*

Thus a product-theorem consumer receives a finite Mertens certificate only after the source-series rows, CauchyConvolution windows, AbsoluteConvergence or majorant tail ledgers, CauchyProductCriterion handoff, RegSeqRat readback, Real seal, transport, provenance, and local NameCert rows have all been displayed.

Proof. Project the carrier of Definition 3584.1. The accepted packet exposes exactly the two source-series rows, the paired convolution window, the tail ledger, the criterion handoff, the product packet, the regular readback, the terminal Real seal, and the structural support rows.

For the convolution obligation, read W through the sibling convolution certificate. This fixes the finite diagonal product cells before any series-product packet is available.

For the tail-to-criterion obligation, read T either as an absolute-convergence witness or as a finite majorant ledger. In both cases the displayed tail control is consumed by the CauchyProductCriterion$^{\uparrow}$ handoff K, so the criterion route is not a hidden appeal to host completeness.

For the product readback obligation, route Q through the CauchySeriesProduct and FastSeriesProduct surfaces and then through the regular rational readback row R. The terminal seal E is reached only after this readback, and H, C, P, N transport, replay, source, and locally name that same route.

Since the carrier contains no quotient stream equality, host product of completed sums, selected limiting sum, countable-choice schedule, trichotomy row, or ambient completeness coordinate, none of those objects belongs to the local NameCert surface. □

Theorem 3584.3 (Mertens Cauchy product theorem Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ *packet factors through the displayed route*

$$A, B \longmapsto W \longmapsto T \longmapsto K \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The route exports the Mertens product theorem as a finite product certificate over the L10 Real seal corridor. It does not export quotient series equality, a selected product sum, countable choice, trichotomy, host real multiplication, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer that asks for the terminal product seal. The only Real-facing coordinate in the carrier is E, and E is stored after the source rows, convolution window, tail ledger, criterion handoff, product packet, and regular readback.

The consumer must therefore pass through A, B, W, T, K, Q, R. These rows display the finite source observations, the CauchyConvolution cells, the absolute-convergence or majorant tail control, the CauchyProductCriterion acceptance row, and the regular rational readback used to expose the product.

The remaining rows H, C, P, N preserve the same route under componentwise transport, replay it for accepted requests, record its package provenance, and name it locally. Because no excluded object is a carrier coordinate, the Real seal cannot bypass the finite product route. □

Theorem 3584.4 (Mertens absolute-convergence product route)**.** *Let* $M = (A, B, W, K, T, Q, R, E, H, C, P, N)$ *be an accepted* $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ *carrier. If the displayed tail row* T *is read as an* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *witness for one source series, then every downstream product-convergence consumer must read the route through*

$$\mathsf{AbsoluteConvergence}^{\uparrow} \longmapsto \mathsf{CauchyProductCriterion}^{\uparrow} \longmapsto (\mathsf{CauchySeriesProduct}^{\uparrow} \textit{ or } \mathsf{FastSeriesProduct}^{\uparrow}) \longmapsto \mathsf{RegSeqR}$$

before invoking $\mathsf{CauchyProductConvergence}^{\uparrow}$*. The branch therefore exports the Mertens theorem to product-convergence consumers only through the absolute-convergence handoff, the finite product criterion, the product packet, the regular rational readback, and the terminal Real seal.*

Proof. Project the carrier of Definition 3584.1. Under the stated branch hypothesis, the tail row T is not merely an unnamed tail ledger: it is displayed as an $\mathsf{AbsoluteConvergence}^{\uparrow}$ row and is therefore subject to the handoff and Real-seal nonescape routes of Definition 1700.3 and Definition 1700.4.

Feed this displayed tail row into the local route of Definition 3584.3. The route forces the consumer through W, T, K, Q, R, E; hence the absolute-convergence branch reaches the product packet only after the $\mathsf{CauchyProductCriterion}^{\uparrow}$ handoff and reaches the terminal seal only after the $\mathsf{CauchySeriesProduct}^{\uparrow}$ or $\mathsf{FastSeriesProduct}^{\uparrow}$ packet and the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Finally compose this finite Mertens route with the downstream fusion theorem Definition 3608.4. A $\mathsf{CauchyProductConvergence}^{\uparrow}$ consumer that consumes the Mertens surface reads the source-window and tail-control stage before any regular rational, dyadic, stream-name, or Real-seal product data. Thus the absolute-convergence branch cannot enter product convergence except through the displayed criterion, product, readback, and Real-seal corridor. □

Falsifiable prediction: Every accepted $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting a source-series row, CauchyConvolution window, tail ledger,

CauchyProductCriterion handoff, product packet, RegSeqRat readback, transport row, replay row, provenance row, or local naming row refutes the packet.

Independence witness: cauchyconvolution, cauchy-product-criterion, cauchy-series-product, fast-seriesproduct, regseqrat, real: no listed sibling supplies the whole theorem packet $M = (A, B, W, K, T, Q, R, E, H, C$ because each sibling contributes only convolution cells, a criterion handoff, a product packet, readback, or terminal seal while this chapter binds them as one finite Mertens certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MertensCauchyProductTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ packet is generated from two finite source-series rows, CauchyConvolution windows, AbsoluteConvergence or majorant tail ledgers, a CauchyProductCriterion handoff, a CauchySeriesProduct or FastSeriesProduct packet, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MertensCauchyProductTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3584.1, Definition 3584.2, and Definition 3584.3 seed the finite product-theorem route over source-series rows, convolution windows, tail ledgers, criterion handoff, product readback, Real sealing, transport, replay, provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MertensCauchyProductTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient series equality, selected product sums, countable choice, trichotomy, host real multiplication, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convolution-window exactness, tail-to-criterion handoff, product readback routing, Real-seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.MertensCauchyP

Chapter 3585

A Concrete Naming Certificate for BishopCompletionUniversalComposition$^{\uparrow}$

Following Bishop and Bridges' constructive treatment of completions by regular Cauchy data, the BishopCompletionUniversalComposition$^{\uparrow}$ packet records the finite composition surface for two Bishop completion universal-property extensions. It consumes the boundary route of chapter 1838 and the extension-plus-uniqueness ledger of chapter 397. The shared source rows are the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readback of chapter 301, the DyadicRatCore$^{\uparrow}$ tolerance ledger of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

The packet composes two already displayed extension ledgers. It does not select representatives of quotient streams, choose host limits, use countable choice, or appeal to ambient completeness of Real$^{\uparrow}$.

Definition 3585.1 (Bishop completion universal composition carrier)**.** *A* BishopCompletionUniversalComposition$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (U, V, E, F, R, S, D, H, T, P, N)$$

with the following displayed rows:

1. *U is the first* CompletionUniversalProperty$^{\uparrow}$ *ledger, restricted to the shared Bishop regular Cauchy completion source;*
2. *V is the second* CompletionUniversalProperty$^{\uparrow}$ *ledger, whose dense-source read begins at the extension surface exported by U;*
3. *E is the first extension row exposed by U through the Bishop completion universal boundary;*
4. *F is the second extension row exposed by V after E has fixed the intermediate completion-facing map;*
5. *R is the shared* RegSeqRat$^{\uparrow}$ *readback row used by both extension ledgers;*
6. *S is the shared* StreamName$^{\uparrow}$ *finite-window row for the source regular Cauchy name;*
7. *D is the shared* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to align the two precision schedules;*
8. *H records the terminal* Real$^{\uparrow}$ *seal reached by the source route and preserved by both extensions;*
9. *T records componentwise* hsame *transport and displayed* Cont *replay for U, V, E, F, R, S, D, H;*

10. *P is the* Pkg *provenance over* BishopCompletionUniversalBoundary$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{BishopCompletionUniversalComposition}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed extension ledgers, shared source rows, transport, replay, provenance, and local naming data. It contains no quotient representative, selected limit, countable-choice schedule, host real equality, or ambient Real$^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BishopCompletionUniversalCompositionUp.BishopCompletionUniversalCompositionTasteGa`
`single carrier alignment`

Theorem 3585.2 (Bishop completion universal composition obligations)**.** *For every accepted* BishopCompletionUniversalComposition$^{\uparrow}$ *carrier $C = (U, V, E, F, R, S, D, H, T, P, N)$, the local* NameCert$_{\text{BishopComplet}}$ *surface consists exactly of carrier admission, first-extension exactness through U, E, second-extension exactness through V, F, shared-source exactness through S, R, D, H, componentwise transport and replay through T, provenance through P, and local naming through N.*

The two extension reads must share the same StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows before the composed extension row is exported. No local obligation can be discharged by quotient representatives, selected limits, countable choice, host equality of extensions, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3585.1. The visible coordinates are exactly the two universal-property ledgers, their two extension rows, the shared source and seal rows, and the structural rows T, P, N.

Use the Bishop completion universal boundary route for the first extension. It requires the source windows, regular readback, dyadic tolerance ledger, and terminal Real seal to be displayed before the extension row E can be read.

Use the CompletionUniversalProperty obligations for both ledgers. The first ledger exports E from U over the shared source surface; the second ledger exports F from V only after the same source and seal rows have been transported and replayed through T.

The package and local naming rows then record the composed route as a single NameCert surface. Since the carrier has no quotient representative, selected-limit coordinate, choice schedule, host equality row, or ambient-completeness field, none of these can discharge an obligation. □

Theorem 3585.3 (Bishop completion universal composition route)**.** *Let $C = (U, V, E, F, R, S, D, H, T, P, N)$ be an accepted* BishopCompletionUniversalComposition$^{\uparrow}$ *carrier. Every composed completion-universal read factors through the finite route*

$$S, R, D, H \longmapsto U, E \longmapsto T \longmapsto V, F \longmapsto P, N.$$

The first leg is the Bishop completion universal boundary extension route, the second leg is the CompletionUniversalProperty extension-and-uniqueness route over the transported intermediate extension, and the handoff between the legs is only the displayed hsame *and* Cont *replay stored in T.*

Consequently the composed read exports a finite NameCert packet over the shared source rows. It does not export quotient representatives, selected limits, countable choice, host equality of maps, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Begin with the shared source rows. The StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ coordinates S, R, D, H are the only source and seal data carried by C.

Apply the Bishop completion universal boundary extension route to U and E. This gives the first extension only after the shared finite windows, regular rational readback, dyadic tolerance ledger, and terminal Real seal have been displayed.

Next apply the CompletionUniversalProperty extension-uniqueness scope to V and F. The intermediate extension is available to the second ledger only through the transported and replayed row T, so uniqueness is read as a displayed ledger comparison rather than as host function equality.

Finally package the composed route with P and N. The carrier inventory has no quotient stream, selected limit, countable-choice schedule, host equality row, or ambient completeness theorem, so the route cannot leave the finite NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalComposition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3585.1, Definition 3585.2, and Definition 3585.3 seed the finite composition surface for two Bishop completion universal-property extension ledgers over shared StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionUniversalComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, selected limits, countable choice, host equality of extensions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-source exactness, first-extension exactness, second-extension exactness, transport-replay, provenance, and local naming for BEDC.Derived.BishopCompletionUniversalCompositionUp

Constructive story: A $\mathsf{BishopCompletionUniversalComposition}^{\uparrow}$ packet is generated from two CompletionUniversalProperty ledgers, two extension rows, shared StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3586

A Concrete Naming Certificate for FiniteModulusCompactness$^{\uparrow}$

Following Arzela–Ascoli finite-modulus compactness in constructive metric analysis, the FiniteModulusCompactness$^{\uparrow}$ packet records the finite BEDC surface that turns compact metric inspection, finite-net equicontinuity, and compact uniform-continuity modulus rows into one displayed compactness certificate. It sits between the compact source of chapter 129, the finite-net family route of chapter 2362, the modulus extraction route of chapter 2292, the finite epsilon-net interface of chapter 1767, and the downstream extraction surface of chapter 3568. The packet names a finite-modulus compactness carrier; it does not assert open-cover compactness, host function-space compactness, selected subsequences, quotient equality of real names, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 3586.1 (Finite modulus compactness carrier)**.** *A* FiniteModulusCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, E, U, A, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row. It exposes only the finite compact-metric inspection data, finite-net coverage rows, metric-distance ledgers, and source* NameCert *provenance consumed by the certificate.*
2. *E is the* FiniteNetEquicontinuity$^{\uparrow}$ *row. It records the finite family windows, shared center rows, radius ledgers, and equicontinuity comparison rows available at the inspected compact-net scale.*
3. *U is the* CompactUniformContinuityModulus$^{\uparrow}$ *row. It displays the pointwise modulus rows, compact-net fold, dyadic tolerance schedule, and public modulus handoff used by the compact source.*
4. *A is the* ArzelaAscoliFiniteModulus$^{\uparrow}$ *handoff row. It records the downstream extraction interface that may consume the finite-modulus compactness certificate after K, E, U have been displayed.*
5. *W is the finite modulus-window schedule. It records the requested tolerances, the selected compact-net radii, the finite family indices inspected at those radii, and the dyadic support row that links E and U.*
6. *H records componentwise* hsame *transport for the compact source, equicontinuity, compact-uniform-modulus, Ascoli handoff, window schedule, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite compactness request through K, E, U, A, W, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusCompactness}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$, $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$, $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $K, E, U, A, W, H, C, P, N$. It has no coordinate for open-cover compactness, a host compactness theorem, a selected subsequence, a quotient stream, a host function-space point, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteModulusCompactnessUp.FiniteModulusCompactnessTasteGate single carrier alignment`

Theorem 3586.2 (Finite modulus compactness NameCert obligations)**.** *For an accepted* FiniteModulusCompactnes *carrier $F = (K, E, U, A, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusCompactness}^{\uparrow}}$ *surface consists exactly of compact source admission through K, finite-net equicontinuity admission through E, compact uniform-continuity modulus admission through U, Ascoli finite-modulus handoff through A, finite modulus-window scheduling through W, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Every public finite-modulus compactness read must therefore pass through the displayed compact metric, finite-net equicontinuity, compact uniform-continuity modulus, and Ascoli handoff rows before it can export a downstream compactness certificate.

Proof. Project the accepted carrier. The mathematical rows are K, E, U, A, W, and the structural rows are H, C, P, N.

The row W is the only place where requested tolerances, compact-net radii, family indices, and dyadic support are tied together. Rows K, E, U, A supply the four named chapter interfaces read by that schedule, while H, C, P, N preserve transport, replay, provenance, and local naming.

No further coordinate appears in the carrier. Hence the local NameCert obligations are exhausted by exactly the displayed rows, and every public read must traverse those rows before it can be consumed by a compactness or Ascoli-facing packet. □

Theorem 3586.3 (Finite modulus compactness Ascoli handoff)**.** *Every* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteModulusCompactness}^{\uparrow}$ *carrier receives a finite handoff through*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{FiniteNetEquicontinuity}^{\uparrow},\quad \mathsf{CompactUniformContinuityModulus}^{\uparrow},\quad \mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}.$$

The handoff consists of the compact source row K, the finite-net equicontinuity row E, the compact uniform-continuity modulus row U, the downstream Ascoli row A, the window schedule W, and the structural rows H, C, P, N. It contains no open-cover compactness route, no selected subsequence, no host function-space compactness point, no quotient real equality, no countable-choice row, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start from the obligation theorem. It identifies $K, E, U, A, W, H, C, P, N$ as the complete public surface of the carrier.

The Ascoli-facing row is A, but A is not read alone. Its finite-modulus input is supplied by the compact source row K, the finite-net equicontinuity row E, the compact uniform-continuity modulus row U, and the shared window schedule W.

The transport and replay rows keep the handoff inside that finite packet. Since the excluded objects do not occur among $K, E, U, A, W, H, C, P, N$, an Ascoli consumer cannot obtain them from the $\mathsf{FiniteModulusCompactness}^{\uparrow}$ certificate. □

Theorem 3586.4 (Finite modulus compactness nonescape)**.** *No accepted* $\mathsf{FiniteModulusCompactness}^{\uparrow}$ *packet exports open-cover compactness, selected subcovers, selected subsequences, host function-space compactness, quotient stream equality, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Its compactness content is exactly the finite row package*

$$K, E, U, A, W, H, C, P, N.$$

Proof. Apply Definition 3586.2. Every public read of the packet factors through the displayed tuple $K, E, U, A, W, H, C, P, N$.

The compact metric input is confined to K, the equicontinuity input to E, the compact uniform-continuity modulus input to U, the Ascoli-facing output to A, and the finite scheduling relation to W. Rows H, C, P, N only transport, replay, package, and name those displayed rows.

None of the excluded principles is a carrier coordinate or a structural row. Exporting any of them would leave the local $\mathsf{FiniteModulusCompactness}^{\uparrow}$ NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteModulusCompactness}^{\uparrow}$ packet is generated from a CompactMetricUp source row, FiniteNetEquicontinuityUp row, CompactUniformContinuityModulusUp row, ArzelaAscoliFiniteModulusUp handoff row, finite modulus-window schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteModulusCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 3586.1, Definition 3586.2, Definition 3586.3, and Definition 3586.4 seed the finite BEDC compactness certificate consumed by downstream Ascoli and compact-open routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteModulusCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected subsequences, host function-space compactness, quotient equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window scheduling, Ascoli handoff, nonescape, and local NameCert registration for BEDC.Derived.FiniteModulusCompactnessUp.

Chapter 3587

A Concrete Naming Certificate for $\mathsf{LocatedCauchyNet}^{\uparrow}$

Following Moore–Smith, Kelley, and constructive net convergence, the $\mathsf{LocatedCauchyNet}^{\uparrow}$ packet records the located directed-tail Cauchy evidence needed by uniform-completion arguments. It sits between the Moore–Smith carrier of chapter 3403, the convergence interface of chapter 1667, the Cauchy-net surface of chapter 589, the filter-base handoff of chapter 1601, the uniform-space entourage rows of chapter 339, and the completion consumer of chapter 1473. The packet supplies finite located-Cauchy windows for the L10 directed-net completion corridor; it does not introduce quotient nets, selected limits, cofinal choice, or host completeness.

Definition 3587.1 (Located Cauchy net carrier)**.** *A* $\mathsf{LocatedCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, M, A, N, U, F, S, W, H, C, P, K)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *row naming finite directed vertices, preorder comparisons, and displayed upper-window witnesses.*
2. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *row exposing net-value windows and the finite tail ledger over D.*
3. *A is the* $\mathsf{CauchyNet}^{\uparrow}$ *row recording common-tail Cauchy evidence on the same directed surface.*
4. *N is the* $\mathsf{NetConvergence}^{\uparrow}$ *row naming the convergence-facing route that may inspect D, M, A before any Real or filter handoff is read.*
5. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer row that reads only the located Cauchy data displayed by D, M, A, N, F, S.*
6. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *handoff row obtained from the displayed tail filters of M and the Cauchy windows of A.*
7. *S is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row used to compare Cauchy windows, located neighbourhood requests, and completion-facing refinements.*
8. *W is the located-window ledger, listing the finite neighbourhood requests, positive tolerance names, and displayed tail witnesses used to locate each Cauchy read.*
9. *H records componentwise* hsame *transport for D, M, A, N, U, F, S, W and for the structural rows.*

10. *C records displayed* Cont *replay through the same directed-tail, Cauchy, filter, uniform-space, convergence, and completion route.*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *K is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $D, M, A, N, U, F, S, W, H, C, P, K$. It has no coordinate for quotienting nets, selecting a limit, selecting a cofinal subnet, invoking countable choice, or importing ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedCauchyNetUp.LocatedCauchyNetTasteGate single carrier alignment`

Theorem 3587.2 (Located Cauchy net NameCert obligations)**.** *For an accepted* $\mathsf{LocatedCauchyNet}^{\uparrow}$ *carrier*

$$L = (D, M, A, N, U, F, S, W, H, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyNet}^{\uparrow}}$ *surface consists exactly of carrier admission, directed-index exposure, Moore–Smith tail exposure, Cauchy-net common-window exposure, NetConvergence handoff, UniformCompletion consumption, FilterBase handoff, UniformSpace entourage comparison, located-window evidence, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the accepted carrier of Definition 3587.1. The directed and Cauchy-facing rows are D, M, A, W, so every located read first fixes an index window, a Moore–Smith tail, common-tail Cauchy evidence, and a finite located-window witness.

The handoff rows are then N, F, S, U. The convergence route can inspect only the displayed tail evidence, the filter-base route is obtained from the same tails, the uniform-space row supplies the entourage comparisons, and the completion row consumes these data after they have been displayed.

Finally H, C, P, K transport, replay, source, and name the same packet. Since the carrier contains no additional coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 3587.3 (Located Cauchy net uniform completion route)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedCauchyNet}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DirectedSet}^{\uparrow},\ \mathsf{MooreSmithNet}^{\uparrow},\ \mathsf{CauchyNet}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow},\ \mathsf{UniformSpace}^{\uparrow},\ \mathsf{NetConvergence}^{\uparrow} \longmapsto \mathsf{UniformComplet}$$

The route supplies directed tails, located Cauchy windows, filter-base handoff, entourage comparison, and convergence-facing evidence only through the displayed carrier. It exports no quotient net, selected limit, selected cofinal subnet, countable-choice operator, or ambient completeness theorem.

Proof. Start with the directed rows D, M, A, W. The index row supplies finite upper-window witnesses, the Moore–Smith row supplies net values and tail ledgers, the Cauchy-net row supplies common-window evidence, and the located-window row binds each neighbourhood request to a displayed tail witness.

The filter-base and uniform-space rows F, S are read next. They translate the same displayed tails into filter and entourage language without creating a quotient of nets.

The convergence handoff N and completion consumer U then read only this finite route. Transport, replay, provenance, and naming through H, C, P, K preserve the same rows, so the excluded selection, quotient, choice, and ambient-completeness routes have no export coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyNet}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchyNet}^{\uparrow}$ packet is generated from DirectedSet, MooreSmithNet, CauchyNet, NetConvergence, UniformCompletion, FilterBase, UniformSpace, located-window, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyNet}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 3587.1, Definition 3587.2, and Definition 3587.3 close the located directed-tail route used by uniform-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyNet}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedCauchyNetUp.LocatedCauchyNetTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient nets, selected limits, selected cofinal subnets, countable choice, ambient completeness, or a standard bridge.

Upgrade path: Public export or bridge work requires a standard interface for the checked located-net route.

Chapter 3588

A Concrete Naming Certificate for $\mathsf{BishopUniformCauchyNet}^{\uparrow}$

Following Moore–Smith, Kelley, and Bishop–Bridges, the $\mathsf{BishopUniformCauchyNet}^{\uparrow}$ packet records the uniform-Cauchy net corridor used by constructive completion arguments before any quotient net, selected limit, cofinal-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available. It sits after the located Cauchy net surface of chapter 3587, the uniform entourage discipline of chapter 339, the completion consumer of chapter 1473, the filter-base handoff of chapter 1601, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38.

Definition 3588.1 (Bishop uniform Cauchy net carrier)**.** *A* $\mathsf{BishopUniformCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, M, A, E, W, F, S, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-index row naming finite Moore–Smith indices, preorder comparisons, and displayed upper-window witnesses.*
2. *M is the Moore–Smith net row exposing finite value windows over D.*
3. *A is the* $\mathsf{CauchyNet}^{\uparrow}$ *row recording common-tail Cauchy evidence for the same net.*
4. *E is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage schedule used to compare the displayed tail windows.*
5. *W is the located-window row, listing the requested entourages, tail bounds, and displayed witnesses that the net enters each requested uniform neighbourhood.*
6. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *handoff row obtained from the displayed tails of D, M, A, W.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row consumed by sequence-facing completion readers.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from S and the dyadic tolerance ledger.*
9. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row recording dyadic radii, comparison slack, and tolerance names used by the located uniform reads.*
10. *H records componentwise* hsame *transport for the directed, net, Cauchy, entourage, located-window, filter-base, stream, rational-readback, dyadic, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a uniform precision request through the same rows.*
12. *P is the* Pkg *provenance over* $\mathsf{BishopUniformCauchyNet}^{\uparrow}$, $\mathsf{LocatedCauchyNet}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, A, E, W, F, S, R, Q, H, C, P, N$. It has no coordinate for quotient nets, selected limits, cofinal-choice selectors, hidden host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3588.2 (Bishop uniform Cauchy net NameCert obligations)**.** *For every accepted* BishopUniformCauchyNe *carrier $U = (D, M, A, E, W, F, S, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyNet}^{\uparrow}}$ *surface consists exactly of carrier admission, directed-index exposure, uniform entourage schedule exactness, located-window evidence, filter-base handoff,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3588.1. The directed and Cauchy-facing rows are D, M, A, E, W, so every uniform read first fixes an index window, a Moore–Smith value window, common-tail evidence, an entourage request, and the located witness for that request.

The filter and sequence-facing rows are then F, S, R, Q. The filter-base handoff is obtained from the displayed tails, while the stream, regular-rational, and dyadic rows give finite readback data for downstream Real and Completion consumers.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no additional coordinate, quotient nets, selected limits, cofinal-choice selectors, host equality, and ambient completeness cannot be exported by the local certificate. □

Theorem 3588.3 (Bishop uniform Cauchy net completion route)**.** *Every* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopUniformCauchyNet}^{\uparrow}$ *carrier must pass through the displayed net row, uniform entourage schedule, located-window evidence, filter-base handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row. The consumer receives no quotient net, selected limit, cofinal-choice selector, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with a completion-facing read. The route exposes D, M, A before the uniform entourage row E and located-window row W can be interpreted.

Read the filter-base and finite-window handoff next. The rows F, S, R, Q repackage the same displayed tails as filter data, stream windows, regular rational readback, and dyadic tolerance evidence without selecting a subnet or a limit.

The Real-facing seal is downstream from this finite route. Transport, replay, provenance, and local naming through H, C, P, N preserve the displayed rows, so the completion consumer cannot bypass them into quotient nets, host equality, selected limits, cofinal choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyNet}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopUniformCauchyNet}^{\uparrow}$ packet is generated from a directed index row, Moore–Smith net row, Cauchy-net row, uniform entourage schedule, located-window evidence, filter-base handoff, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopUniformCauchyNet}^{\uparrow}}$, seed)

Scope closed: Definition 3588.1, Definition 3588.2, and Definition 3588.3 name the finite uniform-Cauchy net corridor for UniformCompletion, StreamName, RegSeqRat, DyadicRatCore, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformCauchyNet}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient nets, selected limits, cofinal choice, host equality, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Formal work requires carrier admission, entourage exactness, located-window evidence, filter-base handoff, finite readback, Real seal non-escape, transport, replay, provenance, and local naming for the Bishop uniform-Cauchy net route.

Chapter 3589

A Concrete Naming Certificate for $\mathsf{AlternativeCodeReassignment}^{\uparrow}$

The $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ packet realizes the comparative genetic-code reassignment spectrum of Definition 9462.1208 as finite NameCert data. It packages the standard-code classifier, curated alternative table row, reassignment set, module ledger, sparse support-count ledger, transport, replay, provenance, and local naming rows; it does not treat the observed comparative spectrum as a kernel fact about biological mechanism or as an oracle for all translation systems.

The standard-code classifier row and codon carrier are read through chapter 3393, where the finite boundary-tile classifier rows, transport, replay, provenance, and NameCert rows are already displayed. The sparse support-count ledger and compression boundary are consumed through chapter 3558, so the reassignment packet depends only on finite support-count ledgers, transport, replay, provenance, and local NameCert rows. Its concrete sibling lattice also passes through the four-phase alphabet bridge of chapter 2260, the six-bit codon window of chapter 2234, and the support-compression surface of chapter 3558.

Definition 3589.1 (Alternative-code reassignment carrier)**.** *An* $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, D, M, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the standard-code classifier row, naming the displayed Q_6 codon carrier and the standard assignment classifier used as the comparison base.*
2. *T is the alternative-table row, recording one curated non-standard table on the same codon carrier together with its displayed assignment labels.*
3. *D is the reassignment-set row, listing exactly those codons whose row in T differs from the standard classifier row S.*
4. *M is the module ledger over the Stop/Trp, Ile/Met, Phe/Leu, and AGA/AGG local modules of Definition 9462.1209.*
5. *Q is the support-count ledger, recording sparse codon support and multiplicity information as displayed in Definition 9462.1212.*
6. *H records componentwise* hsame *transport for the standard classifier, alternative table, reassignment set, module ledger, support-count ledger, provenance, replay, and local naming rows.*

7. *C records displayed* Cont *replay from the standard classifier and alternative-table comparison to the reassignment set, then to the module ledger and support-count ledger.*
8. *P is the* Pkg *provenance over* $\mathsf{AlternativeCodeReassignment}^{\uparrow}$*, the DNA six-bit boundary tile source rows,* $\mathsf{ReassignmentSupportCompression}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignment}^{\uparrow}}$ *row.*

The carrier contains no biochemical mechanism coordinate, no exhaustive table-family oracle, no unbounded codon-table search, no quotient identifying biological labels with BEDC constructors, and no claim that reassignment frequency is a cause.

Lean4 ✓ `BEDC.Derived.AlternativeCodeReassignmentUp.AlternativeCodeReassignmentTasteGate single carrier alignment`

Theorem 3589.2 (Alternative-code reassignment NameCert obligations)**.** *For an accepted* AlternativeCodeReassignm *carrier $R = (S, T, D, M, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignment}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed comparison packet, standard-code classifier exposure through S, alternative-table exposure through T, reassignment-set exactness through D, module-ledger grouping through M, sparse support-count exposure through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 3589.1. The comparison starts from the standard classifier row S and the alternative-table row T, both over the same displayed codon carrier.

The reassignment row D is then forced by finite row comparison. The module ledger M groups those displayed changes by the four local modules, and the support-count row Q records the sparse support and multiplicity data available to downstream consumers.

The structural rows H, C, P, N transport, replay, source, and name exactly this finite packet. No other coordinate exists, so the listed rows exhaust the local NameCert obligation surface. □

Theorem 3589.3 (Alternative-code reassignment spectrum nonescape)**.** *Every consumer of an accepted* $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ *packet factors through the finite route*

$$S, T \longmapsto D \longmapsto M, Q \longmapsto H, C, P, N.$$

It receives a displayed standard-code comparison, alternative-table row, reassignment set, module ledger, sparse support-count ledger, transport, replay, provenance, and local NameCert surface. It does not receive biological causality, exhaustive coverage of possible genetic codes, a mechanism for translation dynamics, an unbounded codon-table oracle, or a quotient from external labels into BEDC kernel facts.

Proof. Use the obligation surface of Definition 3589.2. The only comparison inputs are S and T, and the only reassignment output is the finite row D obtained from them.

The module and support-count reads pass through M, Q. These rows preserve the comparative spectrum as displayed finite data and do not add a mechanistic or exhaustive biological premise.

Finally H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Since the excluded claims have no carrier coordinate, they cannot be exported by an accepted $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ read. □

Falsifiable prediction: An accepted $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ read is refuted if the standard-code comparison, curated alternative table, reassignment set, module ledger, sparse support-count

ledger, and local NameCert rows can no longer be routed through dna-four-phase-alphabet-bridge, codon-six-bit-window, reassignment-support-compression, and dna-window-six-boundary-tile sibling surfaces.

Independence witness: dna-four-phase-alphabet-bridge, codon-six-bit-window, reassignment-support-compression, dna-window-six-boundary-tile: none is bijective with $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ because the siblings respectively expose alphabet phase rows, codon-window coordinates, support-compression counts, or boundary-tile classifier rows, while the reassignment packet jointly binds standard and alternative table comparison, reassignment exactness, module grouping, sparse support accounting, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignment}^{\uparrow}}$.

Constructive story: An $\mathsf{AlternativeCodeReassignment}^{\uparrow}$ packet is generated from a standard-code classifier, alternative table row, reassignment set, module ledger, sparse support-count ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3589.1, Definition 3589.2, and Definition 3589.3 seed the finite comparative-code reassignment spectrum surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignment}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim biological causality, exhaustive genetic-code coverage, translation mechanism, unbounded table search, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, standard-code comparison, alternative-table exposure, reassignment-set exactness, module-ledger grouping, sparse support-count exposure, transport preservation, and local naming for BEDC.Derived.AlternativeCodeReassignmentUp.

Chapter 3590

A Concrete Naming Certificate for $\mathsf{UniformReflectionKernel}^{\uparrow}$

Following Bourbaki's uniform structures and Kelley's separated uniform reflection, the $\mathsf{UniformReflectionKernel}^{\uparrow}$ packet records the finite indistinguishability kernel through which a uniform space becomes visible to separated and completion-facing consumers. It sits after the entourage rows of chapter 339, the displayed separated-uniform boundary of chapter 1876, the Hausdorff reflection route of **??**, and the completion-facing routes of chapter 2332 and chapter 2345. The packet names the kernel boundary itself; it is not a quotient representative set, not host equality, not a selected completion limit, not Classical choice, and not ambient Real completeness.

Definition 3590.1 (Uniform reflection kernel carrier)**.** *A* $\mathsf{UniformReflectionKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, K_0, S, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, exposing finite entourage membership, refinement, inverse, and composition data before any separated consumer is reached.*
2. *K_0 is the indistinguishability-kernel row over the same entourage surface:*

$$x \equiv_{K_0} y \quad \Longleftrightarrow \quad \textit{every displayed entourage row of } U \textit{ admits } (x, y).$$

3. *S is the separated handoff row, read as either the* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *boundary or the* $\mathsf{HausdorffReflection}^{\uparrow}$ *boundary according to the downstream consumer.*
4. *H records componentwise* hsame *transport for the uniform row, kernel row, separated or Hausdorff handoff, replay, provenance, and local naming rows.*
5. *C records displayed* Cont *replay from an entourage request through U, then K_0, then the separated or Hausdorff handoff S.*
6. *P is the* Pkg *provenance over* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, $\mathsf{HausdorffReflection}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformReflectionKernel}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient representatives, host equality, selected completion limits, Classical choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformReflectionKernelUp.UniformReflectionKernelTasteGate single carrier alignment`

Theorem 3590.2 (Uniform reflection separated handoff)**.** *Every separated or completion-facing consumer of an accepted* $\mathsf{UniformReflectionKernel}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto K_0 \longmapsto \mathsf{SeparatedUniformSpace}^{\uparrow}, \mathsf{HausdorffReflection}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow}.$$

The consumer first reads the displayed entourage rows, then the indistinguishability-kernel row, then the separated-uniform or Hausdorff-reflection boundary, and only then any completion-facing row. It cannot bypass the kernel through quotient representatives, host equality, selected limits, Classical choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3590.1. The uniform source is row U, and the kernel row K_0 is attached to the same displayed entourage data.

The separated handoff is row S. By construction, S is available only after U and K_0 have been replayed, so a $\mathsf{SeparatedUniformSpace}^{\uparrow}$ or $\mathsf{HausdorffReflection}^{\uparrow}$ consumer receives the finite kernel boundary rather than a host quotient.

A completion-facing consumer can then read the $\mathsf{UniformCompletion}^{\uparrow}$ route only through that separated or Hausdorff boundary. The transport, replay, provenance, and local NameCert rows preserve this order, while the excluded quotient, representative, selector, choice, host-equality, and ambient-completeness objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformReflectionKernel}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformReflectionKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3590.1 and Definition 3590.2 seed the finite route from displayed uniform entourages through the indistinguishability kernel into separated, Hausdorff-reflection, and uniform-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformReflectionKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, host equality, selected limits, Classical choice, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage exposure, kernel exactness, separated handoff, Hausdorff reflection handoff, completion nonescape, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{UniformReflectionKernel}^{\uparrow}$ packet is generated from UniformSpace entourage rows, an indistinguishability-kernel row, SeparatedUniformSpace or HausdorffReflection handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3591

A Concrete Naming Certificate for $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$

The $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$ packet realizes the focused phase-ledger and boundary-transport reading of chapter 9463 as finite NameCert rows. It consumes the horocycle carrier of chapter 3534, the metric-read surface of chapter 3474, the boundary-fixed transport route of chapter 3500, the disk-coordinate carrier of chapter 377, the flow-style route of chapter 195, and the Poincare disk representation principles of section 9463.3 and section 9463.4. The packet is a BEDC-native phase-ledger boundary row; it is not a host hyperbolic surface, not an unlogged observer trajectory, not a global clock, and not a physical cosmology.

Falsifiable prediction: Every accepted $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$ read factors through displayed phase-ledger, disk-coordinate, hyperbolic-metric, horocycle, boundary-fixed transport, flow, provenance, replay, and local NameCert rows before it exports a boundary-transport reading.

Independence witness: hyperbolic-horocycle, hyperbolic-metric, poincare-boundary-fixed-transport, unitdisk, dynsystem: the horocycle packet records boundary-tangent incidence without focused phase-ledger provenance; the metric packet records distance readback without ledger phase; the boundary-fixed transport packet records a preserved boundary anchor without horocycle phase accounting; the UnitDisk packet supplies coordinates without phase-ledger replay; and the DynSystem packet records flow-style evolution without hyperbolic boundary tangency. None is bijective to $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$.

Definition 3591.1 (Phase-ledger horocycle carrier)**.** *A* $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, D, M, Q, T, Y, H, C, P, N)$$

with the following displayed rows:

1. *F is the focused phase-ledger row, carrying the source* Hist *chain, visible phase readout, and provenance cells of the observer-expansion reading.*
2. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row through which the ledger readout is placed on a finite disk surface.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric row over the same displayed disk observations.*
4. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *boundary-tangent row, read only after D and M have been displayed.*

5. *T is the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *row preserving the boundary far-end reading along admissible disk transport.*
6. *Y is the* $\mathsf{DynSystem}^{\uparrow}$ *flow-style ledger row that replays local record expansion without introducing a global clock.*
7. *H records componentwise* hsame *transport for the phase ledger, disk, metric, horocycle, boundary transport, flow, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the focused ledger through disk placement, metric readback, horocycle incidence, boundary-fixed transport, and flow-style expansion.*
9. *P is the* Pkg *provenance over* $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PhaseLedgerHorocycle}^{\uparrow}}$ *row.*

The carrier exports no host disk model, global universe digest, synchronized radial clock, physical observer path, selected boundary representative, quotient ideal-boundary equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.PhaseLedgerHorocycleUp.PhaseLedgerHorocycleTasteGate single carrier alignment`

Theorem 3591.2 (Phase-ledger horocycle NameCert obligations)**.** *For every accepted* $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$ *carrier $L = (F, D, M, Q, T, Y, H, C, P, N)$, the local NameCert surface consists exactly of focused phase-ledger admission, disk-coordinate placement, hyperbolic-metric readback, horocycle boundary-tangency exposure, boundary-fixed transport, flow-style replay, componentwise transport, displayed continuation, provenance, and local naming.*

Every boundary-transport read from the packet factors through

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicHorocycle}^{\uparrow} \longmapsto \mathsf{PoincareBoundaryFixedTransport}^{\uparrow} \longmapsto \mathsf{DynSystem}^{\uparrow}$$

together with the focused phase-ledger row and the structural BHist, hsame, Cont, Pkg, *and* NameCert *rows. The Lean TasteGate follow-up must include 'Nontrivial PhaseLedgerHorocycleUp' and 'Field-Faithful PhaseLedgerHorocycleUp' instances for the same carrier surface.*

Proof. Project the accepted carrier. The focused phase-ledger row F supplies the source history chain and phase readout, while D places that readout on a displayed disk surface.

The metric and horocycle rows are then forced in order. Row M reads the hyperbolic metric over the displayed disk data, and row Q exposes the horocycle boundary-tangency surface only after D and M have been replayed.

Boundary transport and flow-style replay are the last public geometric rows. Row T preserves the boundary far-end reading, and row Y records local expansion as a finite flow-style ledger rather than as a global clock.

The structural rows H, C, P, N preserve and name that route. Since the carrier contains no host disk model, universe digest, synchronized radial clock, physical observer path, selected boundary representative, or quotient ideal-boundary equality, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseLedgerHorocycle}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PhaseLedgerHorocycle}^{\uparrow}}$, seed)

Scope closed: Definition 3591.1 and Definition 3591.2 seed the focused phase-ledger route through disk coordinates, hyperbolic metric readback, horocycle incidence, boundary-fixed transport, flow-style replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PhaseLedgerHorocycle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host hyperbolic geometry, global clocks, physical cosmology, quotient ideal-boundary equality, selected boundary representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, phase-ledger exactness, disk placement, metric readback, horocycle incidence, boundary-fixed transport, flow replay, TasteGate nontriviality, FieldFaithful coverage, and local naming.

Constructive story: A PhaseLedgerHorocycle$^{\uparrow}$ packet is generated from a focused phase-ledger row, UnitDisk coordinates, HyperbolicMetric readback, HyperbolicHorocycle incidence, PoincareBoundaryFixedTransport, DynSystem flow-style replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3592

A Concrete Naming Certificate for $\mathsf{MooreSpace}^{\uparrow}$

Following R. L. Moore and the standard developable-space formulation, the $\mathsf{MooreSpace}^{\uparrow}$ packet records a topology equipped with a countable development as finite BEDC carrier data. It sits beside the topology carrier of chapter 88, the metric-space distance surface of chapter 57, and the entourage-style neighbour rows of chapter 2334. The point of the packet is not to infer a metric or a cover-selection theorem; it is to expose the neighbourhood classifiers, development rows, star-refinement witnesses, transport, replay, provenance, and local naming rows that make the Moore-space name usable by downstream topology consumers.

Definition 3592.1 (Moore space carrier)**.** *A* $\mathsf{MooreSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, N, D, S, H, C, P, L)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *carrier row, exposing the point carrier, finite open-row classifier, finite-meet row, arbitrary-union interface as recorded BEDC cover data, and membership transport surface.*
2. *N is the neighbourhood classifier row. It records when a displayed open row surrounds a point and when one neighbourhood row refines another around the same point.*
3. *D is the countable development row, storing a finite name for each development level together with the pointwise neighbourhood request that the level is meant to answer.*
4. *S is the star-refinement witness row. For each accepted point-neighbourhood request, it records a development level whose displayed star around the point refines the requested neighbourhood row.*
5. *H records componentwise* hsame *transport for the topology, neighbourhood, development, star-refinement, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a point-neighbourhood request through T, then N, then the development row D, then the star-refinement row S.*
7. *P is the* Pkg *provenance over* $\mathsf{MooreSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{MooreSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a metric selector, paracompact refinement, choice-selected open cover, open-cover compactness theorem, or host topological equality.

Theorem 3592.2 (Moore space NameCert obligations)**.** *For every accepted* $\mathsf{MooreSpace}^{\uparrow}$ *carrier* $M = (T, N, D, S, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{MooreSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, topology exposure, neighbourhood classification, countable-development rows, star-refinement witnesses, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Every Moore-space consumer reads neighbourhood information through the finite route

$$\mathsf{Topology}^{\uparrow} \longmapsto N \longmapsto D \longmapsto S \longmapsto \mathsf{NameCert}_{\mathsf{MooreSpace}^{\uparrow}}.$$

The route may compare with metric and quasi-uniform neighbours only through the displayed $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *provenance rows; it exports no metrization theorem, no paracompactness theorem, no choice-selected cover, and no open-cover compactness conclusion.*

Proof. Project the accepted packet of Definition 3592.1. The topology row T supplies the open-row carrier and membership surface, while N is the only row that may classify neighbourhoods around a displayed point.

The development data is then forced through D and S. Row D lists the countable development levels, and row S records the local star-refinement witness that answers a point-neighbourhood request.

The structural rows H, C, P, L preserve, replay, cite, and name that route. Since the carrier contains no metric selector, paracompact refinement, choice-selected cover, open-cover compactness theorem, or host equality row, the listed rows exhaust the NameCert obligations. □

Upgrade path: Obligation closure requires checked carrier admission, topology exposure, neighbourhood classification, development-level indexing, star-refinement exactness, componentwise transport, displayed replay, provenance, and local naming.

Constructive story: A $\mathsf{MooreSpace}^{\uparrow}$ packet is generated from a topology carrier, neighbourhood classifier, countable development rows, star-refinement witnesses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3593

A Concrete Naming Certificate for $\mathsf{VariationMeasure}^{\uparrow}$

Following the finite-partition side of Jordan bounded variation as treated by Rudin and Folland, the $\mathsf{VariationMeasure}^{\uparrow}$ packet records the ledger that a bounded-variation consumer may read before any passage to classical measure theory. It sits over the bounded-variation surface of chapter 398, the Jordan signed-variation split of chapter 2069, the real-name seal of chapter 38, the regular rational stream surface of chapter 301, and the dyadic observation rows of chapter 291. The packet names only displayed finite partition ledgers, finite edge sums, common refinements, and their visible transport rows.

Definition 3593.1 (VariationMeasure finite-partition carrier)**.** *A* $\mathsf{VariationMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, J, \Pi, E, X, D, V, A, R, H, C, P, N)$$

with the following visible coordinates:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet and its finite partition-variation ledger.*
2. *J is the optional* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed ledger read on the same displayed partition surface.*
3. *Π is a displayed ordered finite partition with endpoint and edge rows.*
4. *E is the finite edge ledger induced by adjacent endpoints of Π.*
5. *X records endpoint* $\mathsf{Real}^{\uparrow}$ *rows or their* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name representatives.*
6. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations used to compare adjacent endpoint values.*
7. *V is the finite dyadic variation-sum ledger on Π.*
8. *A records finite additivity rows for displayed concatenations and subpartition blocks.*
9. *R records common-refinement rows comparing transported partitions, edge ledgers, and finite sums.*
10. *H records componentwise* hsame *transport for the bounded-variation source, Jordan split, partition, endpoint, dyadic, finite-sum, additivity, refinement, package, and naming rows.*
11. *C records displayed* Cont *replay from a bounded-variation request to endpoints, edge observations, finite sums, refinement comparison, and consumer exposure.*

12. *P is the* Pkg *provenance over* $\mathsf{VariationMeasure}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, \Pi, E, X, D, V, A, R, H, C, P, N$. It has no coordinate for a sigma-additive measure, a host supremum over all partitions, quotient function equality, selected limits, ambient Real completeness, hidden partition families, or bridge checking.

Lean4 ✓ `BEDC.Derived.VariationMeasureUp.VariationMeasureTasteGate single carrier alignment`

Theorem 3593.2 (VariationMeasure finite partition additivity)**.** *Let $M = (B, J, \Pi, E, X, D, V, A, R, H, C, P, N)$ be an accepted* $\mathsf{VariationMeasure}^{\uparrow}$ *carrier. If Π is displayed as the concatenation of finite subpartition blocks $\Pi_0, \ldots, \Pi_k$ whose shared endpoints are transported by the visible* hsame *and* Cont *rows, then the public variation-measure read on Π is the finite sum of the block reads recorded in A. Each block read uses only the source* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger, the optional* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed ledger, endpoint rows from* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, and the local* Pkg *and* $\mathsf{NameCert}_{\mathsf{VariationMeasure}^{\uparrow}}$ *provenance.*

The additivity statement is restricted to the displayed finite partition. It exports no sigma-additive measure, host supremum over all partitions, quotient function equality, selected limit, or ambient Real-completeness principle.

Proof. Project the carrier of Definition 3593.1. The rows available to a consumer are the source bounded-variation packet, the optional Jordan signed ledger, the displayed partition, endpoint names, dyadic edge observations, finite variation sum, additivity rows, refinement rows, and visible provenance.

For each displayed block Π_i, read its endpoint rows through $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ and its adjacent-edge comparisons through $\mathsf{DyadicRatCore}^{\uparrow}$. The source bounded-variation ledger supplies the finite edge-sum surface, while the Jordan ledger, when present, supplies the signed split on the same finite edge list.

The additivity row A concatenates those finite block sums inside the same partition ledger. Shared endpoints are identified only by the displayed hsame and Cont rows, so no unrecorded endpoint or selected limit is introduced.

Finally apply the no-escape clause built into the carrier. Since every summand is a displayed finite dyadic row and the packet has no coordinate for sigma-additivity, host suprema, quotient function equality, selected limits, or ambient Real completeness, the result is a finite-partition additivity certificate rather than a measure-theoretic extension. □

Theorem 3593.3 (VariationMeasure common-refinement classifier stability)**.** *Let M and M' be accepted* $\mathsf{VariationMeasure}^{\uparrow}$ *packets. Suppose their source* $\mathsf{BoundedVariation}^{\uparrow}$ *rows, optional* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *rows, endpoint* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *names,* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, finite variation-sum ledgers, additivity rows,* hsame *rows,* Cont *rows,* Pkg *provenance, and local* NameCert *rows agree after transport to a displayed common finite refinement. Then the local* $\mathsf{VariationMeasure}^{\uparrow}$ *classifier identifies M and M' on that refinement, and every public finite-partition read factors through the same transported refinement ledger.*

This classifier stability uses no sigma-additive measure, host supremum over all partitions, quotient function equality, selected limit, ambient Real completeness, hidden partition family, or bridge row.

Proof. Start from the displayed common finite refinement. Its rows provide the only comparison surface for the two packets: transported source bounded-variation data, optional Jordan signed ledgers, endpoint names, dyadic observations, finite sums, additivity rows, and provenance.

Use Definition 3593.2 on each packet after transport to the common refinement. Both public reads are finite sums over the same displayed block and edge rows, and the shared endpoints are handled by the same hsame and Cont routes.

Repack these componentwise comparisons into the local classifier data. Because the carrier has no additional coordinate beyond $B, J, \Pi, E, X, D, V, A, R, H, C, P, N$, the common-refinement comparison exhausts the classifier.

The excluded objects cannot distinguish the packets. None is present among the carrier rows, and none is generated by the finite additivity or transport steps. □

Theorem 3593.4 (VariationMeasure bounded-variation dependency route)**.** *Every* $\mathsf{VariationMeasure}^{\uparrow}$ *public read factors through a displayed* $\mathsf{BoundedVariation}^{\uparrow}$ *partition ledger and, when a signed split is requested, through the displayed* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *finite signed ledger. Endpoint values are read only through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$*, and adjacent-edge variation rows are read only through* $\mathsf{DyadicRatCore}^{\uparrow}$*. The packet exposes those sibling rows as finite additivity and common-refinement data with visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Proof. Project the source row B from Definition 3593.1. By the bounded-variation chapter, the available variation data are finite partition ledgers, endpoint rows, dyadic edge observations, finite sums, refinement rows, and visible provenance.

If the signed row J is present, read it through the Jordan variation decomposition chapter. That row only splits the same displayed edge ledger into positive and negative finite ledgers and reconstructs the displayed endpoint-difference row.

Endpoint rows remain on the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces, while edge comparisons remain on $\mathsf{DyadicRatCore}^{\uparrow}$. The $\mathsf{VariationMeasure}^{\uparrow}$ carrier packages these rows into finite additivity and common-refinement certificates without adding a host measure object. □

Closure status for $\mathsf{NameCert}_{\mathsf{VariationMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationMeasure}^{\uparrow}$ packet is generated from a bounded-variation source row, an optional Jordan signed ledger, a displayed finite partition, endpoint real or regular-rational names, dyadic edge observations, finite variation sums, additivity rows, common-refinement transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3593.1, Definition 3593.2, Definition 3593.3, and Definition 3593.4 seed the finite-partition variation-measure packet over $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-additive measure, host supremum over all partitions, quotient function equality, selected limits, ambient Real completeness, hidden partition families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite partition additivity, common-refinement classifier stability, bounded-variation dependency routing, transport, provenance, and no-escape for BEDC.Derived.VariationMeasureUp.

Chapter 3594

A Concrete Naming Certificate for $\mathsf{CauchyContinuityCalibration}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyContinuityCalibration}^{\uparrow}$ packet records the finite comparison by which Cauchy-name continuity data is calibrated against the tolerance-only uniform-modulus interface. It sits between the finite transformer surface of chapter 1401, the pointwise Cauchy-modulus schedule of chapter 1486, the explicit uniform-modulus packet of chapter 2228, the stream-name and regular-rational readback layers of chapter 126 and chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names a finite calibration surface, not a host function on reals, quotient stream equality, compactness, or an ambient completeness theorem.

Definition 3594.1 (CauchyContinuityCalibration carrier)**.** *A* $\mathsf{CauchyContinuityCalibration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, U, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *transformer row that reads source Cauchy-name windows and produces the target Cauchy-name windows visible to the consumer.*
2. *M is the* $\mathsf{CauchyModulusOfContinuity}^{\uparrow}$ *row that sends each requested target tolerance to the finite source-window threshold used by S.*
3. *U is the* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *comparison row, read only after the Cauchy tolerance route has displayed the same target tolerance and source radius as finite data.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger containing the source windows inspected by M and the target windows produced by S.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source and target regular rational names exposed on W.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested target tolerance, the source threshold supplied by M, and the comparison tolerance consumed by U.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached from the calibrated target readback after the stream, regular-rational, and dyadic rows have been replayed.*
8. *H records componentwise* hsame *transport for S, M, U, W, R, D, E and for the support rows.*

9. *C records displayed* Cont *replay from a target tolerance request through M, the source windows W, the transformer row S, the readbacks R, the dyadic ledger D, the uniform comparison U, and the seal row E.*

10. *P is the* Pkg *provenance over* CauchyContinuityCalibration$^{\uparrow}$, CauchyContinuousMap$^{\uparrow}$, CauchyModulusOfContinuity UniformContinuityModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyContinuityCalibration}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by replaying these rows to a common Cauchy-name transformer, Cauchy-modulus schedule, uniform-modulus comparison, stream-window, regular-readback, dyadic-tolerance, and real-seal surface.

Lean4 ✓ `BEDC.Derived.CauchyContinuityCalibrationUp.CauchyContinuityCalibrationTasteGate single carrier alignment`

Theorem 3594.2 (CauchyContinuityCalibration NameCert obligations)**.** *For every accepted* CauchyContinuityCali *carrier $K = (S, M, U, W, R, D, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyContinuityCalibration}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the displayed Cauchy transformer, Cauchy-modulus schedule, uniform-modulus comparison, stream windows, regular-rational readbacks, dyadic tolerance ledger, real seal, transport, replay, provenance, and local naming rows;*

2. *Cauchy-route exactness, requiring each target tolerance to pass through M before any source window in W is consumed by S;*

3. *readback accountability, requiring the source-window and target-window reads to factor through W, R, D before the seal row E or the comparison row U is available;*

4. *uniform-comparison compatibility, requiring U to read only the tolerance and radius already displayed by M and D;*

5. *componentwise transport and replay stability under H and C for the same displayed rows;*

6. *ledger refusal, stating that host real functions, quotient streams, compactness selectors, selected limits, and ambient completeness are not carrier coordinates.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 3594.1. The projection exposes the transformer row S, the Cauchy-modulus row M, the uniform comparison U, the stream windows W, the readbacks R, the dyadic ledger D, the seal E, and the support rows H, C, P, N.

The Cauchy route starts with a target tolerance. The schedule M turns that request into a source-window threshold, and only then may the transformer row S inspect the windows in W and expose the target readback through R and D.

The uniform comparison is downstream of the same route. Since U has no independent tolerance coordinate in the carrier, it can read only the tolerance and source radius already displayed by M and D.

Transport and replay preserve the row order. The hsame and Cont coordinates move and replay the same finite packet, while P and N only source and name it. The listed rows exhaust the carrier, so no host function, quotient stream, compactness selector, selected limit, or ambient completeness datum can be exported. □

Theorem 3594.3 (Cauchy continuity to uniform modulus bridge)**.** *Every accepted* $\mathsf{CauchyContinuityCalibration}^{\uparrow}$ *carrier* $K = (S, M, U, W, R, D, E, H, C, P, N)$ *routes a target tolerance first through the Cauchy-modulus row* M*, reads the required source windows through* S, W, R, D*, and then compares the induced tolerance-only source-radius row with the* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *row* U*. The resulting bridge exports a finite uniform-modulus consumer boundary while retaining the Cauchy-name transformer and real-seal rows as the only source of target readback evidence.*

Proof. Begin with the target tolerance stored in the dyadic ledger D. The row M supplies the source-window threshold demanded by the Cauchy-name route, so the source observations are read through W before S can produce target windows.

Readback then passes through R and returns to D for the tolerance comparison. This isolates the tolerance-only datum induced by the Cauchy route: a requested target tolerance together with the displayed source threshold that was sufficient for the transformer row.

Compare that induced row with U. The uniform-modulus consumer sees the same target tolerance and source radius, but it does not receive the Cauchy-name windows except through the already displayed provenance of M, S, W, R, D.

Finally replay C and transport through H. The seal row E remains downstream of the Cauchy readback, while P, N bind the bridge as a finite NameCert surface. Thus the bridge connects Cauchy-name continuity to tolerance-only uniform-modulus consumers without adding a host function, quotient stream, compactness selector, selected limit, or completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuityCalibration}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyContinuityCalibration}^{\uparrow}$ packet is generated from a CauchyContinuousMap transformer row, a CauchyModulusOfContinuity schedule, a UniformContinuityModulus comparison row, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, Cont replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyContinuityCalibration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3594.1, Definition 3594.2, and Definition 3594.3 seed the finite calibration route from Cauchy-name continuity data to tolerance-only uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyContinuityCalibration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real functions, quotient stream equality, compactness, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-route exactness, readback accountability, uniform-comparison compatibility, transport and replay stability, and field faithfulness for BEDC.Derived.CauchyContinuityCalibrationUp.

Chapter 3595

A Concrete Naming Certificate for MetaCICLocalDiamondWitness$^{\uparrow}$

The MetaCICLocalDiamondWitness$^{\uparrow}$ packet realizes the local-peak witness surface of chapter 9378 as finite BEDC confluence data. It sits beside the confluence audit packet of chapter 735, the critical-path carrier of chapter 765, the subject-reduction discharge socket of chapter 719, and the typed reduction trace of chapter 2330. The packet names local peaks and candidate joins; it does not promote the conditional substitution boundary into a closed MetaCIC confluence theorem.

Falsifiable prediction: Every accepted local-diamond witness has peak, left-step, right-step, candidate-join, closedness, transport, continuation, provenance, and naming rows.

Independence witness: metacic-confluence-audit-packet, metacic-critical-path, subject-reduction-discharge-socket, metacic-subject-reduction-trace: the confluence audit packet records the global boundary without a per-peak witness carrier; the critical-path packet records priority and dependency pressure without candidate joins; the subject-reduction discharge socket records typing-side hypotheses without confluence joins; and the subject-reduction trace records reduction evidence without a local-diamond peak certificate. None is bijective to MetaCICLocalDiamondWitness$^{\uparrow}$.

Definition 3595.1 (MetaCIC local-diamond witness carrier)**.** *A* MetaCICLocalDiamondWitness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, L, R, J, B, H, C, P, N)$$

with the following displayed rows:

1. *K is the peak row, naming the source term and the two outgoing MetaCIC reduction requests that form the local peak.*
2. *L is the left-step row, recording the displayed one-step or parallel-step evidence for the left branch.*
3. *R is the right-step row, recording the displayed one-step or parallel-step evidence for the right branch.*
4. *J is the candidate-join row, listing the proposed common reduct together with the two displayed route requests into it.*
5. *B is the closedness and boundary row, recording whether the witness is closed, normal-source, atom-source, or substitution-boundary conditional according to the confluence audit map.*

6. *H records componentwise* hsame *transport for the peak, branch steps, candidate join, closedness boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the peak through the two branch rows, then the candidate join, then the closedness boundary.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$*, the MetaCIC confluence audit map,* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{TypedExampleReductionTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}}$ *row.*

The carrier exports no arbitrary closed Church–Rosser theorem, no proof of BetaParallelSubstitutionCompatibility*, no proof of* BetaParallelDiamondClosed*, no subject-reduction theorem, and no host quotient equality of terms.*

Lean4 ✓ `BEDC.Derived.MetaCICLocalDiamondWitnessUp.MetaCICLocalDiamondWitnessTasteGate single carrier alignment`

Theorem 3595.2 (MetaCIC local-diamond witness NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$ *carrier $W = (K, L, R, J, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}}$ *surface consists exactly of peak admission, left-step evidence, right-step evidence, candidate-join evidence, closedness and boundary classification, componentwise transport, displayed continuation replay, provenance, and local naming.*

The Lean TasteGate follow-up must provide Nontrivial *and* FieldFaithful *instances for the same carrier surface, so the witness cannot be collapsed to an empty marker and cannot hide a missing peak, branch, join, boundary, transport, replay, provenance, or naming coordinate.*

Proof. Project the carrier of Definition 3595.1. The peak row K names the source and the two outgoing reduction requests, while L and R record the displayed branch evidence.

The join and boundary rows are then read in order. Row J supplies the candidate common reduct and the route requests into it; row B classifies the witness as closed, normal-source, atom-source, or substitution-boundary conditional.

The structural rows H, C, P, N preserve and name that local peak route. Since the carrier contains no arbitrary closed Church–Rosser theorem, no substitution-compatibility proof, no closed parallel-diamond proof, no subject-reduction theorem, and no quotient equality of terms, the listed rows exhaust the NameCert obligations. □

Theorem 3595.3 (MetaCIC local-diamond candidate-join exactness)**.** *For every accepted* MetaCICLocalDiamondW *carrier $W = (K, L, R, J, B, H, C, P, N)$, every candidate-join row J is read only after the peak row K, left-step row L, right-step row R, and boundary row B have been displayed through the same local-diamond witness packet. The row J exports a candidate common reduct and the two route requests into it, but it exports no closed Church–Rosser theorem, no substitution-compatibility proof, no closed parallel-diamond proof, no subject-reduction theorem, and no quotient equality of terms.*

Proof. Project the carrier of Definition 3595.1. The NameCert obligations theorem Definition 3595.2 lists peak admission, left-step evidence, right-step evidence, candidate-join evidence, and closedness and boundary classification as the visible local-diamond rows.

Reading J therefore occurs inside that listed route. The peak row K fixes the source and outgoing requests; the branch rows L and R fix the displayed left and right steps; and the boundary row B records whether the witness is closed, normal-source, atom-source, or substitution-boundary conditional before the join row is consumed as local evidence.

The structural rows H, C, P, N only transport, replay, record provenance for, and locally name the same packet. Since the carrier has no coordinate for a closed Church–Rosser theorem, substitution compatibility, a closed parallel diamond, subject reduction, or quotient equality, the candidate join cannot export any of those objects. □

Theorem 3595.4 (MetaCIC local-diamond closedness-boundary classification)**.** *For every accepted* $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$ *carrier* $W = (K, L, R, J, B, H, C, P, N)$*, the boundary row* B *must be displayed before any consumer reads the candidate-join row* J*. The displayed row classifies the witness as closed, normal-source, atom-source, or substitution-boundary conditional, and the later join read may only be interpreted inside that classification.*

Consequently a local-diamond witness cannot turn a candidate join into arbitrary closed Church–Rosser, BetaParallelSubstitutionCompatibility*,* BetaParallelDiamondClosed*, subject reduction, or quotient equality of terms.*

Proof. Project the carrier of Definition 3595.1. The carrier lists B as the closedness and boundary row, while Definition 3595.3 already requires J to be read only after the peak, branch, and boundary rows have been displayed.

Read B before J. Its alternatives are closed, normal-source, atom-source, and substitution-boundary conditional, so the candidate common reduct in J is consumed only under the exposed boundary case.

The structural rows H, C, P, N transport, replay, source, and name the same classification. Since no row contains a closed Church–Rosser theorem, substitution compatibility, a closed parallel diamond, subject reduction, or quotient equality of terms, the candidate join remains a classified local witness rather than a global confluence claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3595.1 and Definition 3595.2 seed the finite local-diamond witness packet over peaks, branch steps, candidate joins, closedness boundaries, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary closed Church–Rosser, BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, subject reduction, quotient equality of terms, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, peak exposure, left-step and right-step evidence, candidate-join exactness, boundary classification, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$ packet is generated from a local peak row, left-step row, right-step row, candidate-join row, closedness and boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3596

A Concrete Naming Certificate for $\mathsf{TangentCone}^{\uparrow}$

Following Bouligand and Rockafellar, the $\mathsf{TangentCone}^{\uparrow}$ packet names the finite feasible-direction surface of a convex set at a displayed base point. It sits after the convex carrier of chapter 208, the affine ambient row of chapter 206, the vector-space operations of chapter 47, the metric window route of chapter 57, and the terminal real-name interface of chapter 38. The packet records finite secant windows and scale ledgers for a proposed direction; it does not build a host limit, a quotient tangent space, a differentiability theorem, or a separation theorem.

Definition 3596.1 (TangentCone carrier)**.** *A* $\mathsf{TangentCone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, S, L, V, H, C, P, N)$$

with the following displayed rows:

1. *B is the base-point row, naming the displayed point in the* $\mathsf{ConvexSet}^{\uparrow}$ *carrier together with its* $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *ambient readbacks.*
2. *S is the feasible secant-window row. It lists finite windows in which the point obtained by moving from B along the candidate direction remains inside the convex feasible row at the displayed scale.*
3. *L is the positive scale and radius ledger. It records the inspected positive scale rows, metric radii, comparison budgets, and the refusal of zero-scale or unbounded-host reads.*
4. *V is the direction row, read through the* $\mathsf{VecSpace}^{\uparrow}$ *addition and scalar-action surface and compared only by the displayed metric windows.*
5. *H records componentwise* hsame *transport for the base point, secant windows, scale ledger, direction row, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a feasible-direction request through B, S, L, V before any structural row is consumed.*
7. *P is the* Pkg *provenance over* $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TangentCone}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through B, S, L, V, H, C, P, N. It has no coordinate for an ambient host limit, quotient tangent space, differentiability theorem, normal cone, separation theorem, or closed convex analysis theorem outside the displayed finite rows.

Theorem 3596.2 (TangentCone secant-window exposure)**.** *Let $T = (B, S, L, V, H, C, P, N)$ be an accepted* $\mathsf{TangentCone}^{\uparrow}$ *carrier. Every feasible-direction read must first expose the base-point row B, then the secant-window row S, then the positive scale and radius ledger L, and only then the direction row V. Consequently a consumer sees a finite Bouligand-style secant surface, not a host limiting process or a selected tangent representative.*

Proof. Project the carrier of Definition 3596.1. The only rows available before the structural data are B, S, L, V, and the secant-window row is explicitly indexed by the base point exposed in B.

Replay the continuation row C. A feasible-direction request is routed through the displayed base-point read, then through the finite feasible secant windows, and then through the positive scale and radius ledger before the direction row can be inspected.

Transport by H preserves the same route, while P and N package only those rows. Thus no host limit, quotient tangent representative, differentiability theorem, normal cone, or separation theorem can be read from the packet. □

Theorem 3596.3 (TangentCone cone-scaling stability)**.** *For an accepted* $\mathsf{TangentCone}^{\uparrow}$ *carrier $T = (B, S, L, V, H, C, P, N)$, scaling an accepted displayed direction by a positive scale already present in L stays on the same finite tangent-cone surface. The resulting read uses the same base-point row B, the scaled secant windows recorded in S, the positive comparison ledger L, and the vector-space scalar-action row inside V, with transport and replay supplied by H and C.*

Proof. Start with a direction read accepted by the packet and a positive scale row displayed in L. The vector-space row V contains the scalar-action data, while the scale ledger records the positive comparison budget needed to reuse the feasible secant windows.

The secant-window row S is then read with the scaled direction and the same base point B. Convex feasibility is consumed only through the displayed $\mathsf{ConvexSet}^{\uparrow}$ row, and metric comparison is consumed only through the windows and radii already listed in L.

Finally replay C and transport through H. Provenance P and the local name row N certify that the scaled direction remains inside the same finite packet surface, with no appeal to a host closure theorem, quotient tangent space, differentiability result, or separation principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{TangentCone}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TangentCone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3596.1, Definition 3596.2, and Definition 3596.3 seed the finite convex feasible-direction packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TangentCone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host limit, quotient tangent space, differentiability theorem, separation theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, secant-window exposure, cone-scaling stability, transport, replay, provenance, and local naming for BEDC.Derived.TangentConeUp.

Chapter 3597

A Concrete Naming Certificate for $\mathsf{WeakTopology}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{WeakTopology}^{\uparrow}$ packet records a weak topology only through finite windows of scalar linear-functional observations. It sits over the source carrier of chapter 1950, the functional-analysis surface of chapter 94, the continuous-map rows of chapter 130, the open-neighbourhood classifier of chapter 88, and the scalar seal of chapter 38. The chapter names the finite observation-window certificate used by weak-convergence consumers; it does not choose dual elements, assert Banach–Alaoglu, compactness, quotient function spaces, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3597.1 (WeakTopology carrier)**.** *A* $\mathsf{WeakTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (V, F, U, T, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the source vector or normed-space carrier, read through the* $\mathsf{NormedSpace}^{\uparrow}$ *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *sibling rows.*
2. *F is the finite family of linear-functional observation rows. Each row names a scalar-valued functional already admitted by the functional-analysis surface, not a selected element of a completed dual space.*
3. *U is the weak-neighbourhood classifier row. It records finite scalar constraints around a displayed source point and sends them to the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood surface.*
4. *T is the finite test-window row. It lists the scalar probes, tolerances, source points, and comparison budgets inspected by a consumer.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for the observed functional values and their finite tolerance comparisons.*
6. *H records componentwise* hsame *transport for the source carrier, functional rows, neighbourhood classifier, test windows, scalar readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from source reads through finite functional observations, from observations to weak-neighbourhood rows, and from those rows to scalar readbacks.*
8. *P is the* Pkg *provenance over* $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{WeakTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, F, U, T, R, H, C, P, N$. It has no coordinate for an unrestricted dual object, a selected family of all functionals, compactness, quotient function spaces, choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.WeakTopologyUp.WeakTopologyTasteGate single carrier alignment`

Theorem 3597.2 (WeakTopology NameCert obligations)**.** *For every accepted* $\mathsf{WeakTopology}^{\uparrow}$ *carrier $W = (V, F, U, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the source vector or normed-space row V, finite functional-observation family F, weak-neighbourhood classifier U, finite test windows T, scalar readback row R, componentwise transport H, displayed replay C, provenance P, and local naming N. Every weak-neighbourhood read must cite the sibling routes named above before it reaches a public topology row.*

Proof. Project the carrier of Definition 3597.1. The only source-facing coordinate is V, the only functional-facing coordinate is the finite row F, and the only topology-facing coordinate is the neighbourhood classifier U.

The test-window row T records which finitely many probes and tolerances are inspected. Scalar comparison then passes through R, so the public read receives finite $\mathsf{Real}^{\uparrow}$ observations rather than a selected dual object.

Finally transport, replay, provenance, and naming are supplied by H, C, P, N. Since the carrier contains no further coordinates, the listed rows exhaust the local certificate obligations. □

Lean4 ✓ `BEDC.Derived.WeakTopologyUp.WeakTopologyNamecertObligations`

Theorem 3597.3 (WeakTopology functional-window stability)**.** *Let $W = (V, F, U, T, R, H, C, P, N)$ be an accepted* $\mathsf{WeakTopology}^{\uparrow}$ *carrier. Replacing a test request by a finite subwindow already recorded in T preserves the same source carrier V, the same displayed functional family F, the same weak-neighbourhood classifier U, and the same scalar readback route R. The transport and replay rows H, C carry the subwindow through the same provenance and local naming rows P, N.*

Proof. Read the finite test-window clause of Definition 3597.1. A subwindow of T still names only scalar probes from F, source-point reads from V, and finite tolerance comparisons.

Replay through C. The subwindow reaches the weak-neighbourhood classifier U and scalar row R along the same displayed path, so it cannot add a new functional, a hidden dual element, or a host function-space quotient.

Transport through H and repack through P, N. The packet therefore preserves the weak-topology observation surface while narrowing the inspected finite window. □

Lean4 ✓ `BEDC.Derived.WeakTopologyUp.WeakTopologyFunctionalWindowStability`

Theorem 3597.4 (WeakTopology scalar observation nonescape)**.** *Every scalar observation exported by an accepted* $\mathsf{WeakTopology}^{\uparrow}$ *carrier factors through*

$$V, F, T, U, R, H, C, P, N.$$

Thus weak-convergence, neighbourhood, or continuity consumers may inspect only finite functional windows and their $\mathsf{Real}^{\uparrow}$ *scalar comparisons. They receive no Banach–Alaoglu compactness claim, no selected dual element, no quotient function space, no countable-choice selector, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with an exported scalar observation. By Definition 3597.2, the observation must first expose the source row V, the finite functional family F, the test windows T, and the weak-neighbourhood classifier U.

The scalar row R is then the only route to $\mathsf{Real}^{\uparrow}$ readback. It records finite observed values and tolerance comparisons, not a completed dual-space object or a host function-space equality.

The structural rows H, C, P, N preserve and name that same route. Since the excluded analytic principles have no carrier coordinate, they cannot be exported by the accepted packet. □

Falsifiable prediction: Every $\mathsf{WeakTopology}^{\uparrow}$ neighbourhood or convergence read factors through a source vector or normed-space carrier, a finite family of scalar functional-observation rows, a weak-neighbourhood classifier, finite test windows, scalar Real readbacks, transport, continuation, provenance, and local naming.

Independence witness: normedspace, functionalanalysis, continuousmap, topology, real: $\mathsf{WeakTopology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source carrier rows, finite linear-functional observations, weak-neighbourhood classifiers, finite scalar test windows, RealUp readbacks, transport, replay, provenance, and local naming without selecting a completed dual or importing compactness.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakTopology}^{\uparrow}}$**.**

Constructive story: A $\mathsf{WeakTopology}^{\uparrow}$ packet is generated from a source vector or normed-space row, finite scalar linear-functional observation rows, a weak-neighbourhood classifier, finite test windows, scalar $\mathsf{Real}^{\uparrow}$ readbacks, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3597.1, Definition 3597.2, Definition 3597.3, and Definition 3597.4 seed the finite weak-topology observation-window certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Banach–Alaoglu, compactness, quotient function spaces, selected dual elements, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite functional-window stability, scalar observation nonescape, transport, replay, provenance, and local naming for BEDC.Derived.WeakTopologyUp.

Chapter 3598

A Concrete Naming Certificate for $\mathsf{CondensationTailSelector}^{\uparrow}$

Following Cauchy's condensation test and the Bishop–Bridges constructive series criterion, the $\mathsf{CondensationTailSelector}^{\uparrow}$ packet records the finite tail-selector route used by constructive series-test consumers before a regular rational handoff or real seal is read. It sits after the dyadic block comparison surface of chapter 1478, the alternating route of chapter 1483, the Dirichlet route of chapter 1497, the summable-tail modulus of chapter 1799, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names a displayed selector for finite tail windows; it is not an infinite tail choice, a selected sum, a quotient series equality, a host real equality, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 3598.1 (Condensation tail selector carrier)**.** *A* $\mathsf{CondensationTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, A, D, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CauchyCondensationTest}^{\uparrow}$ *dyadic-block row, exposing the monotone nonnegative source tail, block-index ledger, condensed block terms, and finite comparison budget.*
2. *A is the* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *face row, exposing the alternating sign ledger, monotone magnitude row, and finite tail-bound schedule when the downstream consumer uses the alternating route.*
3. *D is the* $\mathsf{DirichletTest}^{\uparrow}$ *face row, exposing bounded partial sums, coefficient windows, null-tail data, and the finite Dirichlet tail estimate schedule.*
4. *M is the* $\mathsf{SummableTailModulus}^{\uparrow}$ *row, naming the displayed modulus request that bounds the inspected tail window without choosing an infinite tail.*
5. *S is the selector row. It records which of the condensation, alternating, or Dirichlet faces supplies the next finite tail window and which modulus row certifies the requested tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row read only after K, A, D, M, S have displayed the selected finite tail route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational handoff and the selected finite tail route have been replayed.*

8. *H records componentwise* hsame *transport for the condensation, alternating, Dirichlet, modulus, selector, handoff, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a series-test request through K, A, D, M, S, R, E.*
10. *P is the* Pkg *provenance over* $\mathsf{CondensationTailSelector}^{\uparrow}$, $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{AlternatingSeriesTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CondensationTailSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their replay route. It has no coordinate for selected infinite sums, countable choice, quotient series equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CondensationTailSelectorUp.TasteGate.CondensationTailSelectorTasteGate single carrier alignment`

Theorem 3598.2 (Condensation tail selector NameCert obligations)**.** *For every accepted* $\mathsf{CondensationTailSelector}^{\uparrow}$ *carrier $T = (K, A, D, M, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CondensationTailSelector}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the condensation, alternating, Dirichlet, summable-tail modulus, selector, regular handoff, Real seal, transport, replay, provenance, and local naming rows;*
2. *selector coverage, requiring S to name one of the displayed* $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{AlternatingSeriesTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *faces before a tail window is exported;*
3. *modulus handoff, requiring the selected face to pass through the* $\mathsf{SummableTailModulus}^{\uparrow}$ *row M before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is available;*
4. *non-escape, requiring every terminal* $\mathsf{Real}^{\uparrow}$ *read to pass through $K, A, D, M, S, R, H, C, P, N$ and excluding selected infinite sums, countable choice, quotient series equality, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3598.1. The rows K, A, D are the only convergence-test faces, and S is the only row allowed to choose among those displayed finite faces for a requested tail window.

The selected face then passes through M. Thus the requested tail window is bounded by a displayed $\mathsf{SummableTailModulus}^{\uparrow}$ row before the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R can be read.

Finally E is downstream of R, while H, C, P, N transport, replay, source, and locally name the same finite route. Since the carrier contains no coordinate for selected infinite sums, countable choice, quotient series equality, host real equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 3598.3 (Condensation tail selector test handoff)**.** *Every series-test consumer of an accepted* $\mathsf{CondensationTailSelector}^{\uparrow}$ *packet factors its tail read through the finite route*

$$K, A, D \longmapsto S \longmapsto M \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer may cite the condensation, alternating, or Dirichlet test surface through one displayed selector row and one displayed modulus row, but it receives no selected infinite sum, countable-choice operator, quotient series equality, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a consumer asking for a tail window usable by a Real-facing readback. The only available test data are the three displayed faces K, A, D, and the only row that records the chosen face is S.

The route then reads M before R. This forces the tail request to become a finite modulus-bound request rather than a hidden choice of an unbounded tail.

The seal row E is reached only after this handoff, and H, C, P, N preserve the same route under transport, replay it as displayed continuation data, record provenance, and name it locally. The excluded objects are not coordinates of the packet, so they cannot be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{CondensationTailSelector}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal while omitting the selected convergence-test face, the selector row, the summable-tail modulus row, transport, replay, provenance, or local naming refutes the packet.

Independence witness: cauchy-condensation-test, alternating-series-test, dirichlet-test, summable-tail-modulus, regseqrat, real: no listed sibling supplies the whole selector packet $T = (K, A, D, M, S, R, E, H, C, P, N$ because each sibling contributes a test face, a modulus row, a regular handoff, or a terminal seal while this chapter binds them as one finite tail-selector certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CondensationTailSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CondensationTailSelector}^{\uparrow}$ packet is generated from CauchyCondensationTest, AlternatingSeriesTest, DirichletTest, SummableTailModulus, RegSeqRat, and RealUp rows, together with componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CondensationTailSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3598.1, Definition 3598.2, and Definition 3598.3 seed the finite tail-selector route over condensation, alternating, Dirichlet, summable-tail modulus, regular handoff, Real seal, transport, replay, provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CondensationTailSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, countable choice, quotient series equality, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector coverage, modulus handoff, test handoff, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CondensationTailSelectorUp.

Chapter 3599

A Concrete Naming Certificate for NestedIntervalCauchy$^{\uparrow}$

Following Bishop and Bridges on nested interval and Cauchy real constructions, the NestedIntervalCauchy$^{\uparrow}$ packet records the finite route by which a displayed nested interval chain becomes a regular rational Cauchy name before the terminal real seal is available. It consumes the dyadic endpoint and comparison rows of chapter 291, the finite observation schedules of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name boundary of chapter 38, and the dyadic finite-tail handoff of chapter 1811. The packet is a textbook-grounded L10 completion route for interval evidence; it is not a completed intersection point, quotient real, host real equality, countable-choice selector, or ambient completeness principle.

Definition 3599.1 (Nested interval Cauchy carrier)**.** *A* NestedIntervalCauchy$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested interval window. It records the inspected interval prefix, endpoint rows, containment rows, and nonempty-window evidence visible to the nested-interval consumer.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *endpoint and comparison ledger used to read endpoint order, diameter, and tolerance comparisons at the requested dyadic scales.*
3. *W is the shrinking-width witness row. It assigns each displayed precision request to a prefix index whose interval diameter is bounded by the requested tolerance.*
4. *S is the* StreamName$^{\uparrow}$ *schedule row. It names exactly the interval-prefix entries, endpoint observations, and diameter comparisons that may be opened before regular rational readback.*
5. *R is the* RegSeqRat$^{\uparrow}$ *handoff row formed from the scheduled endpoint or midpoint observations and the shrinking-width witness.*
6. *E is the* Real$^{\uparrow}$ *seal row reached only after I, D, W, S, R have been displayed.*
7. *H records componentwise* hsame *transport for interval prefixes, dyadic ledgers, shrinking-width witnesses, stream schedules, regular rational readback, real seals, replay rows, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite nested-interval request through D, W, S, R, E and then through the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalCauchy}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NestedDyadicCauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for a completed intersection point, quotient real equality, host real equality, countable-choice selector, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.NestedIntervalCauchyUp.NestedIntervalCauchyTasteGate single carrier alignment`

Theorem 3599.2 (Nested interval Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalCauchy}^{\uparrow}$ *carrier*

$$K = (I, D, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedIntervalCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the nested interval prefix, dyadic endpoint ledger, shrinking-width witness, stream schedule, regular rational handoff, real seal, transport, replay, provenance, and local naming row;*
2. *prefix exposure, requiring each interval read to be one of the displayed rows of I;*
3. *endpoint and diameter exactness, requiring every endpoint-order and diameter comparison to be read through D;*
4. *precision discharge, requiring every Cauchy tolerance request to be answered by a prefix index and comparison stored in W;*
5. *schedule compatibility, requiring S to expose only the interval-prefix, endpoint, and diameter observations used by W and R;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring R to be formed only after the prefix, dyadic, width, and schedule rows have been projected;*
7. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring E to be consumed only after R and the structural rows have fixed the finite route.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 3599.1. The projection exposes one finite nested interval prefix, one dyadic endpoint ledger, one shrinking-width witness, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Prefix exposure is forced by I. A consumer may inspect only interval rows already present in the finite prefix, and each such row carries the endpoint observations that the downstream dyadic ledger may compare.

Endpoint and diameter exactness are forced by D. Every order or diameter comparison used in the Cauchy route is a displayed dyadic comparison, so no external host interval relation is introduced.

Precision discharge is then forced by W. Each tolerance request names a displayed prefix index and a displayed comparison certifying that the selected interval is small enough for the requested regular rational read.

The schedule and handoff rows are downstream. The row S records the finite prefix, endpoint, and diameter observations that may be opened, and R repacks exactly those observations as regular rational Cauchy data.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection point, quotient real equality, host real equality, countable-choice selector, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 3599.3 (Nested interval Cauchy RegSeqRat handoff)**.** *Let $K = (I, D, W, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{NestedIntervalCauchy}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of K factors through the finite route*

$$I \longmapsto D, W \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite nested interval prefix, displayed dyadic endpoint and diameter comparisons, a shrinking-width witness, and scheduled endpoint observations before it exports the regular rational Cauchy row.

Proof. Start with the displayed interval prefix I. Its rows give the only endpoint data available to a regular rational consumer, and the containment rows keep later prefix rows inside earlier rows.

Use the dyadic ledger D and shrinking-width witness W to answer a displayed Cauchy tolerance request. The selected prefix index, endpoint observations, and diameter comparison are part of the same finite packet, so no external modulus or choice of tail is needed.

The schedule row S then fixes which interval endpoints or midpoint observations are opened. The handoff row R is obtained by reading those scheduled observations under the width discipline and repacking them as the regular rational Cauchy surface.

The rows H, C, P, N transport, replay, source, and name that handoff. Since the carrier has no additional tail selector, quotient-real coordinate, or completed intersection coordinate, every RegSeqRat read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedIntervalCauchy}^{\uparrow}$ packet is generated from finite nested interval windows, dyadic endpoint and diameter ledgers, shrinking-width witnesses, StreamName schedules, RegSeqRat handoffs, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3599.1, Definition 3599.2, and Definition 3599.3 seed the finite nested interval Cauchy route from interval-prefix evidence to RegSeqRat readback and the Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed intersections, quotient real equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix exposure, endpoint and diameter exactness, precision discharge, schedule compatibility, RegSeqRat handoff, and Real seal nonescape for BEDC.Derived.NestedIntervalCauchyUp.

Chapter 3600

A Concrete Naming Certificate for $\mathsf{TypeLike}^{\uparrow}$

Following Martin-Lof type theory, categorical families, and displayed fibrations, the $\mathsf{TypeLike}^{\uparrow}$ packet records the carrier-plus-classifier-plus-transport interface used when BEDC data are read as typed families rather than as an unindexed host universe. It sits beside the membership discipline of chapter 3668, the syntactic carrier of chapter 197, and the satisfaction carrier of chapter 198. The packet names only displayed classifier families, fiber rows, classifier transport, componentwise history transport, continuation replay, package provenance, and local naming; it does not introduce a universe hierarchy, quotient type equality, impredicative comprehension, host isomorphism of types, or an external category of families.

Definition 3600.1 (TypeLike carrier)**.** *A* $\mathsf{TypeLike}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, F, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the displayed base classifier family row, read as BEDC classifier data rather than as a host universe;*
2. *F is the fiber-carrier row assigning to each accepted base entry a finite displayed fiber packet;*
3. *Q is the classifier row for fiber membership, endpoint equality, and family-compatible reads;*
4. *E is the extensionality and endpoint-exactness ledger, recording which displayed fiber endpoints may be identified under the classifier;*
5. *H records componentwise* hsame *transport for B, F, Q, E together with replay, provenance, and local naming rows;*
6. *C records displayed* Cont *replay through which a consumer reads a base classifier, a fiber carrier, a classifier row, and an endpoint-exactness ledger;*
7. *P is the* Pkg *provenance over* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*,* $\mathsf{ModelTheory}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TypeLike}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient type universe, quotient identity, selected representative, host-level equivalence of categories, or a comprehension rule not already displayed by B, F, Q, E, H, C, P, N.

Lean4 ✓ `BEDC.Derived.TypeLikeUp.TypeLikeTasteGate single carrier alignment`

Theorem 3600.2 (TypeLike NameCert obligations)**.** *For every accepted* $\mathsf{TypeLike}^{\uparrow}$ *carrier*

$$T = (B, F, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TypeLike}^{\uparrow}}$ *surface consists exactly of carrier admission for* T*, base-family classifier admission through* B*, fiber-carrier admission through* F*, classifier exposure through* Q*, endpoint-exactness exposure through* E*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 3600.1. Its base side is the displayed classifier family B, while its fiber side is the finite carrier row F indexed by accepted base entries.

The classifier row Q supplies the only family-compatible membership and endpoint reads. The exactness row E records when two displayed endpoints may be identified by that classifier, so endpoint equality is a carried ledger row rather than host type equality.

The structural rows H, C, P, N preserve and expose the same packet. Since no further coordinate is present, the NameCert obligations cannot ask for an ambient universe, quotient identity, selected representative, categorical equivalence, or external comprehension rule. □

Lean4 ✓ `BEDC.Derived.TypeLikeUp.TypeLikeNameCert obligations`
↪ variant `BEDC.Derived.TypeLikeUp.TypeLikeNameCertObligations`

Theorem 3600.3 (TypeLike classifier transport)**.** *Every downstream consumer of an accepted* $\mathsf{TypeLike}^{\uparrow}$ *packet that transports a fiber endpoint must factor through the finite route*

$$B, F, Q, E \longmapsto H, C, P, N.$$

Consequently the transported endpoint remains inside the displayed classifier family and cannot be replaced by host equality of types, an untracked equivalence of fibers, or a SetLike, FirstOrder, or ModelTheory read that bypasses the carried classifier row.

Lean4 ✓ `BEDC.Derived.TypeLikeUp.TypeLikeClassifierTransport`

Proof. Begin with an accepted carrier $T = (B, F, Q, E, H, C, P, N)$. A consumer can reach a fiber endpoint only after reading the base classifier B and the indexed fiber carrier F.

The classifier row Q fixes the admissible endpoint comparison, and E records the exact endpoint ledger for that comparison. Transport therefore has to preserve both the base-family row and the fiber classifier row.

The rows H, C, P, N then move, replay, source, and name the same finite route. Reads inherited from $\mathsf{SetLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, or $\mathsf{ModelTheory}^{\uparrow}$ may be cited only through the package provenance P and the displayed continuation C, so no sibling can supply a bypass around B, F, Q, E. □

Theorem 3600.4 (TypeLike displayed-family consumer exhaustion)**.** *Every downstream* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{ModelTheory}^{\uparrow}$ *consumer of an accepted* $\mathsf{TypeLike}^{\uparrow}$ *endpoint factors through the displayed base classifier* B*, fiber carrier* F*, classifier row* Q*, endpoint-exactness ledger* E*, componentwise transport* H*, displayed replay* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{TypeLike}^{\uparrow}}$ *row* N*. No such consumer may read the endpoint as unindexed membership, bare syntax, or satisfaction data before the displayed family route has been exposed.*

Lean4 ✓ `BEDC.Derived.TypeLikeUp.TypeLikeDisplayedFamilyConsumerExhaustion`

Proof. Begin with the accepted carrier $T = (B, F, Q, E, H, C, P, N)$ of Definition 3600.1. Its first four rows are the only displayed family data: base classifier, indexed fiber carrier, family-compatible classifier, and endpoint-exactness ledger.

Apply Definition 3600.3. Any endpoint transport used by a sibling consumer must preserve those four rows before the structural rows are available.

Finally inspect the sibling reads. $\mathsf{SetLike}^{\uparrow}$ can supply membership only through Q, $\mathsf{FirstOrder}^{\uparrow}$ can supply syntax only through the provenance row P and replay row C, and $\mathsf{ModelTheory}^{\uparrow}$ can supply satisfaction only after the same displayed classifier route has been named locally by N. Thus the three consumer families are exhausted by B, F, Q, E, H, C, P, N and cannot add an ambient universe, quotient type equality, or external category of families. □

Theorem 3600.5 (TypeLike SetLike FirstOrder ModelTheory carrier boundary)**.** *Every accepted* $\mathsf{TypeLike}^{\uparrow}$ *endpoint consumed by chapter 3668, chapter 197, or chapter 198 must expose the finite displayed-family route*

$$B, F, Q, E \longmapsto H, C, P, N$$

before the sibling read. The consumer may then interpret the exposed row as membership, syntax, or satisfaction-facing data, but it cannot replace the TypeLike carrier by unindexed SetLike membership, bare FirstOrder syntax, external ModelTheory satisfaction, quotient type equality, or an ambient host family.

Proof. Start with classifier transport, Definition 3600.3. It forces endpoint movement to preserve the displayed base classifier, fiber carrier, classifier row, and endpoint-exactness ledger.

Then apply consumer exhaustion, Definition 3600.4. The SetLike, FirstOrder, and ModelTheory consumers enter only after the displayed route has reached the transport, replay, provenance, and local naming rows.

Thus the sibling chapters can consume the endpoint only through B, F, Q, E, H, C, P, N. Since the carrier contains no unindexed membership source, bare syntax row, external satisfaction predicate, quotient equality, or ambient family coordinate, none of those can serve as a replacement boundary. □

Lean4 ✓ `BEDC.Derived.TypeLikeUp.TypeLikeSetLikeFirstOrderModelTheoryCarrierBoundary`

Theorem 3600.6 (TypeLike displayed-family inversion)**.** *Let* $T = (B, F, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{TypeLike}^{\uparrow}$ *carrier. Any endpoint read classified as* $\mathsf{TypeLike}^{\uparrow}$ *data determines the displayed base classifier row* B*, the fiber-carrier row* F*, the classifier row* Q*, and the endpoint-exactness ledger* E *before any structural row* H, C, P, N *is used. Thus endpoint readback is inverted through the concrete displayed-family spine*

$$B, F, Q, E \longmapsto H, C, P, N$$

and cannot be read first as host type equality, unindexed $\mathsf{SetLike}^{\uparrow}$ *membership, bare* $\mathsf{FirstOrder}^{\uparrow}$ *syntax, or* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction.*

Proof. Project the carrier of Definition 3600.1. The endpoint-facing data appear in the first four rows: base classifier, indexed fiber carrier, family-compatible classifier, and endpoint-exactness ledger.

Use classifier transport, Definition 3600.3. It keeps any transported endpoint inside the displayed classifier family and prevents a downstream consumer from replacing the route by host type equality or an untracked fiber equivalence.

Finally apply consumer exhaustion, Definition 3600.4. The SetLike, FirstOrder, and ModelTheory consumers may enter only after B, F, Q, E have been exposed and carried through H, C, P, N. Hence an accepted endpoint read determines those four displayed rows before the structural rows are consumed. □

Lean4 ✓ `BEDC.Derived.TypeLikeUp.TypeLikeDisplayedFamilyInversion`

Falsifiable prediction: A consumer that claims a $\mathsf{TypeLike}^{\uparrow}$ endpoint transport while omitting the base classifier row, fiber-carrier row, classifier row, endpoint-exactness ledger, hsame, Cont, Pkg, or local NameCert rows refutes the carrier of Definition 3600.1.

Independence witness: setlike, firstorder, modeltheory: $\mathsf{TypeLike}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a displayed base classifier family, indexed fiber carrier, classifier row, endpoint-exactness ledger, componentwise transport, continuation replay, provenance, and local NameCert row. SetLikeUp has membership without indexed fiber transport; FirstOrderUp has syntax and deduction rows without the carrier family; ModelTheoryUp has satisfaction rows over FirstOrderUp without a general classifier-family transport interface.

Closure status for $\mathsf{NameCert}_{\mathsf{TypeLike}^{\uparrow}}$.

Constructive story: A $\mathsf{TypeLike}^{\uparrow}$ packet is generated from a displayed base classifier family, indexed fiber carrier rows, a family-compatible classifier row, endpoint-exactness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TypeLike}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 3600.1, Definition 3600.2, Definition 3600.3, and Definition 3600.4 bind the displayed carrier-plus-classifier-plus-transport scope and exhaust the SetLikeUp, FirstOrderUp, and ModelTheoryUp sibling consumers over BHist, hsame, Cont, Pkg, NameCert, and the local family rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TypeLike}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a universe hierarchy, quotient type equality, impredicative comprehension, host isomorphism of types, Lean verification, bridge checking, or an external category of families.

Upgrade path: No theory-axis upgrade remains for this displayed classifier-family transport surface; Lean verification and bridge status are recorded separately.

Chapter 3601

A Concrete Naming Certificate for $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$

Following Bishop and Bridges on constructive apartness and completion, the $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ packet records a displayed apartness space whose Cauchy data are complete by finite tolerance inspection. It sits after the located completion criterion of chapter 3540, the apartness completion boundary of chapter 1787, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion object for L10 Real and Completion consumers; it is not a quotient completion, a selected limit, a trichotomy principle, a countable-choice schedule, or a host real equality test.

Definition 3601.1 (Cauchy-complete apartness space carrier)**.** *A* $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, G, T, S, R, D, E, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the displayed apartness-space carrier, recording the points, positive separation evidence, and local apartness classifier inspected by the packet.*
2. *G is the positive-gap row, carrying the finite apartness witnesses used to separate accepted Cauchy windows.*
3. *T is the Cauchy tolerance route, recording the requested dyadic budgets and the finite window discipline that makes the Cauchy request inspectable.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for the Cauchy name.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including radius, endpoint, and comparison rows used by the Cauchy and apartness checks.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, R, D have been exposed.*
8. *L is the* $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ *row, recording the finite located-completion admission route for the same Cauchy data.*
9. *Q is the* $\mathsf{ApartnessCompletion}^{\uparrow}$ *handoff row, recording the separated apartness-completion boundary read by completion-facing consumers.*

10. *H records componentwise* hsame *transport for the apartness source, positive gap, Cauchy tolerance route, stream window, regular readback, dyadic ledger, Real seal, located-completion criterion, apartness-completion handoff, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a Cauchy-complete apartness-space request through $X, G, T, S, R, D, E, L, Q$*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$, $\mathsf{LocatedCompletionCriterion}^{\uparrow}$, $\mathsf{ApartnessCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, G, T, S, R, D, E, L, Q, H, C, P, N$. It has no coordinate for quotient Cauchy classes, chosen representatives, selected limits, countable choice, trichotomy, host real equality, or a host-level complete space.

Lean4 ✓ `BEDC.Derived.CauchyCompleteApartnessSpaceUp.CauchyCompleteApartnessSpaceTasteGate`
`single carrier alignment`

Theorem 3601.2 (Cauchy-complete apartness space NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ *carrier $A = (X, G, T, S, R, D, E, L, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyComplete}}$ *surface consists exactly of carrier admission for the apartness source, positive-gap witnesses, Cauchy tolerance route, finite stream windows, regular rational readback, dyadic tolerance ledger, terminal Real seal, located-completion criterion, apartness-completion handoff, componentwise transport, displayed continuation replay, package provenance, and local naming rows.*

Every completion-facing consumer must read the finite route

$$X, G, T \longmapsto S, R, D \longmapsto E \longmapsto L, Q \longmapsto H, C, P, N$$

before treating the space as Cauchy complete for displayed apartness data.

Proof. Project the carrier of Definition 3601.1. The rows X, G, T expose the apartness source, positive separation witnesses, and the Cauchy tolerance route before any Real-facing or completion-facing row is available.

The finite readback then passes through S, R, D. Stream windows supply the observed name data, regular rational readback repacks those windows, and the dyadic ledger records the tolerance and comparison budgets used by both the Cauchy and apartness checks.

The terminal and completion rows are downstream. Row E seals the Real-facing read, row L records the located completion criterion route of chapter 3540, and row Q records the apartness completion boundary of chapter 1787.

Finally H, C, P, N transport, replay, source, and name only that displayed route. Since the carrier contains no quotient class, chosen representative, selected limit, countable-choice schedule, trichotomy row, host equality test, or host complete-space coordinate, those objects cannot become local NameCert obligations. □

Theorem 3601.3 (Cauchy-complete apartness space located-completion handoff)**.** *Every* $\mathsf{LocatedCompletionCriteri}$ $\mathsf{ApartnessCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ *packet reaches the completion-facing surface only through the displayed apartness carrier X, positive-gap row G, Cauchy tolerance route T, finite* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, located-completion row L, apartness-completion handoff Q, componentwise transport H, displayed replay C, provenance P, and local name N.*

The handoff exports complete-apartness data only as finite NameCert rows. It does not export quotient completions, selected limits, countable choice, trichotomy, host real equality, or an ambient completeness theorem for all $\mathsf{Real}^{\uparrow}$ *names.*

Proof. Begin with a completion-facing or Real-facing consumer. Projection of the carrier gives the ordered route from the apartness source and positive gap rows through the Cauchy tolerance row, then through the finite stream and dyadic readback rows.

The located-completion handoff is forced through the existing siblings. The row L is read as the located criterion route named in Definition 3540.2, while Q is read as the apartness-completion boundary named in Definition 1787.2. Both are downstream of the same S, R, D, E readback route.

Transport and replay cannot add coordinates. Rows H, C, P, N preserve and name the same finite route, so a consumer receives complete-apartness evidence only through displayed BEDC rows and receives no quotient equality, selected representative, choice schedule, trichotomy decision, host equality test, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ consumer factors a completion-facing read through one apartness source row, one positive-gap row, one Cauchy tolerance route, one $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{RegSeqRat}^{\uparrow}$ readback, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{Real}^{\uparrow}$ seal, one $\mathsf{LocatedCompletionCriterion}^{\uparrow}$ row, one $\mathsf{ApartnessCompletion}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: located-completion-criterion, apartness-completion, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries apartness-source evidence, positive gaps, Cauchy tolerance inspection, finite readback, Real sealing, located-completion admission, apartness-completion handoff, transport, replay, provenance, and local naming as one completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3601.1, Definition 3601.2, and Definition 3601.3 seed the finite Cauchy-complete apartness-space route over apartness sources, positive gaps, Cauchy tolerance windows, regular readback, Real seals, located-completion criteria, apartness-completion handoffs, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-source exactness, positive-gap visibility, Cauchy tolerance inspection, finite readback, Real seal handoff, located-completion criterion admission, apartness-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompleteApartnessSpaceUp.

Constructive story: A $\mathsf{CauchyCompleteApartnessSpace}^{\uparrow}$ packet is generated from an apartness source row, positive-gap evidence, a Cauchy tolerance route, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, a LocatedCompletionCriterion row, an ApartnessCompletion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3602

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$ packet records the finite functorial surface of tail shift on regular Cauchy rational names. It sits over the finite window service of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the one-step tail-shift packet of chapter 1578, and the terminal real-name seal of chapter 38. The packet names the identity and composition behaviour of displayed tail shifts; it does not identify quotient streams, select host limits, import countable choice, or claim ambient completeness.

Definition 3602.1 (Regular Cauchy tail-functor carrier)**.** *A* $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, W, D, I, K, J, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational name is inspected only through displayed finite windows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the source windows, shifted windows, and comparison windows used by the functorial read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the precision requests and endpoint comparisons preserved by the shifts.*
4. *I is the identity-tail row, recording that the zero shift rereads the same displayed windows and tolerance rows.*
5. *K is the composable-tail row, recording two displayed tail shifts k and ℓ together with the single displayed shift $k + \ell$.*
6. *J is the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *handoff row that supplies each one-step or finite-tail shift certificate used by I and K.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after R, W, D, I, K, J have been displayed.*
8. *H records componentwise* hsame *transport for the source, window, tolerance, identity, composition, shift-handoff, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each tail-shift request through $R, W, D, I, K, J, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, D, I, K, J, E, H, C, P, N$. It has no coordinate for quotienting streams by tail agreement, selecting a limit, countable-choice tail selectors, host equality of sequences, or ambient completeness.

Theorem 3602.2 (Regular Cauchy tail-functor NameCert obligations)**.** *For every accepted* RegularCauchyTailFunct *carrier $F = (R, W, D, I, K, J, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission for the source, window, dyadic tolerance, identity-tail, composable-tail, shift-handoff, Real seal, transport, replay, provenance, and local naming rows; identity stability through I; composition stability through K and J; Real-seal non-escape through E; and refusal of quotient stream equality, selected limits, countable choice, host sequence equality, and ambient completeness as certificate data.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFunctorUp.RegularCauchyTailFunctorTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3602.1. The analytic rows are R, W, D, I, K, J, E, and the structural rows H, C, P, N transport, replay, source, and name the same finite data.

The identity obligation is read from I. It records the zero-tail request against the same displayed $\mathsf{StreamName}^{\uparrow}$ windows and the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, so the accepted read has no second source row.

The composition obligation is read from K and J. The two displayed shifts k and ℓ are admitted only through $\mathsf{RegularCauchyShift}^{\uparrow}$ handoff rows, and the same handoff surface records the single displayed shift $k + \ell$.

Finally E is downstream of the source, window, tolerance, identity, composition, and shift-handoff rows. Since the excluded quotient, selection, choice, host-equality, and completeness objects have no carrier coordinate, the listed rows exhaust the local certificate surface. □

Theorem 3602.3 (Regular Cauchy tail-functor identity and composition)**.** *Let $F = (R, W, D, I, K, J, E, H, C, P, N$ be an accepted* $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of the identity tail read and every* $\mathsf{Real}^{\uparrow}$*-facing consumer of a composed tail read factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegularCauchyShift}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The zero shift rereads the displayed R, W, D rows, and the composite of shifts k and ℓ is exported only through the displayed $k + \ell$ shift handoff. No consumer receives a quotient-stream equality, selected host limit, countable-choice selector, or ambient completeness theorem from the packet.

Proof. Use Definition 3602.2. The identity-tail row I is tied to the displayed source R, window schedule W, and tolerance ledger D, so an identity consumer cannot bypass those rows.

For composition, the row K records the two shifts and their displayed sum. The handoff row J supplies the required $\mathsf{RegularCauchyShift}^{\uparrow}$ certificates before any Real-facing seal is read.

The terminal row E seals only this displayed route. The structural rows H, C, P, N preserve that route under transport, replay, provenance, and naming, and they do not add quotient, selection, choice, host-equality, or completeness coordinates. □

Theorem 3602.4 (Regular Cauchy tail-functor window composition)**.** *Let $F = (R, W, D, I, K, J, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$ *packet. For any two displayed tail shifts k and ℓ recorded by K, their composed tail read is the same finite-window route obtained by rereading the* $\mathsf{StreamName}^{\uparrow}$ *schedule W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *handoff row J for the displayed shift $k + \ell$. The* $\mathsf{Real}^{\uparrow}$ *seal E is reached only after that $k + \ell$ handoff, so the packet exports no quotient-stream equality, host sequence equality, selected limit, countable-choice selector, or ambient completeness row.*

Proof. Project the carrier in Definition 3602.1. The rows $R, W, D, K, J, E, H, C, P, N$ are the only rows visible to a composed-tail request, with K naming the two displayed shifts and their displayed sum.

Use Definition 3602.2 to read the local certificate obligations. The window data are reread from W, the tolerance checks from D, and the finite-tail handoff from J; the structural rows only transport and replay these displayed rows.

Apply Definition 3602.3 to route every Real-facing consumer through

$$\mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegularCauchyShift}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Because E is downstream of the displayed $k+\ell$ handoff, none of the refused quotient, host-equality, selection, choice, or completeness objects can be exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctor}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyTailFunctor}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName schedule rows, a DyadicRatCore tolerance ledger, identity-tail and composable-tail rows, RegularCauchyShift handoff rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctor}^{\uparrow}}$, seed)

Scope closed: Definition 3602.1, Definition 3602.2, Definition 3602.3, and Definition 3602.4 seed the finite tail-functor route over StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RegularCauchyShiftUp, RealUp, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable-choice tail selectors, host sequence equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, identity-tail stability, composition stability, RegularCauchyShift handoff exactness, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailFunctorUp.

Chapter 3603

A Concrete Naming Certificate for $\mathsf{OperatorNorm}^{\uparrow}$

Following Bishop's constructive normed-space practice and the bounded-operator presentations in Conway and Kreyszig, the $\mathsf{OperatorNorm}^{\uparrow}$ packet records the public BEDC carrier by which a bounded linear operator exposes a nonnegative scalar bound, a norm-bound ledger, and the transport rows needed by downstream spectral, dual, and uniform-boundedness certificates. It is the named operator-norm surface over the bounded-linear-operator route of chapter 1644, the scalar endpoint discipline of chapter 38, and the functional-analysis stability obligation of Definition 94.3; it is not a host supremum construction, quotient operator equality, a Banach-completeness assertion, or a selected norm-attaining vector.

Definition 3603.1 (OperatorNorm carrier)**.** *An* $\mathsf{OperatorNorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (T, K, L, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the carried source endpoint, target endpoint, linear map code, boundedness witness, and source-target norm reads.*
2. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint exposed as the operator-norm scalar boundary.*
3. *L is the norm-bound ledger, recording the input norm row, output norm row, scalar comparison row, and the local inequality route saying that the output norm is controlled by K on carried source inputs.*
4. *H records componentwise* hsame *transport for the bounded-linear-operator row, the* $\mathsf{Real}^{\uparrow}$ *bound endpoint, the norm-bound ledger, the replay row, provenance, and local naming.*
5. *C records displayed* Cont *replay from a bounded-operator request through T, K, L, H back to the same operator-norm surface.*
6. *P is the* Pkg *provenance over* $\mathsf{OperatorNorm}^{\uparrow}$*,* $\mathsf{BoundedLinearOperator}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{OperatorNorm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through T, K, L, H, C, P, N. It has no coordinate for a host supremum over unit vectors, quotient equality of operators, norm-attainment choice, hidden Banach completeness, spectral-radius limits, or uniform-boundedness families.

Lean4 ✓ `BEDC.Derived.OperatorNormUp.OperatorNormTasteGate single carrier alignment`

Theorem 3603.2 (OperatorNorm NameCert obligations)**.** *For every accepted* $\mathsf{OperatorNorm}^{\uparrow}$ *carrier* $O = (T, K, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OperatorNorm}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-linear-operator source compatibility, nonnegative* $\mathsf{Real}^{\uparrow}$ *bound exposure, norm-bound ledger exactness, componentwise transport, continuation replay, provenance, local naming, and non-escape from the displayed scalar-bound surface. A downstream consumer may read the carried operator row, the displayed scalar bound, and the ledger showing where that bound is used, but it receives no host supremum, no quotient operator equality, no selected norm-attaining vector, no hidden completeness, and no spectral or uniform-boundedness conclusion.*

Proof. Carrier admission is projection from Definition 3603.1. The packet displays exactly the bounded-linear-operator row T, the nonnegative scalar endpoint K, the norm-bound ledger L, and the structural rows H, C, P, N.

The bounded-operator source compatibility is inherited from the public bounded-linear-operator row. Thus a consumer sees the carried source and target endpoints, the map code, and the boundedness witness before it can inspect the scalar bound.

The norm-bound surface is finite. The row L records the input norm, output norm, scalar comparison, and local inequality route, while K supplies the only Real-facing endpoint to which those comparisons may point.

Finally H, C, P, N transport, replay, source, and name only the displayed rows. Since the refused objects have no coordinate in O, the certificate cannot export a host supremum, quotient equality, selected norm-attainment data, hidden completeness, spectral-radius limits, or uniform-boundedness families. □

Theorem 3603.3 (OperatorNorm bound stability)**.** *If two accepted* $\mathsf{OperatorNorm}^{\uparrow}$ *packets are related by the classifier, then they expose the same* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *source row, the same* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint, and the same norm-bound ledger up to the componentwise* hsame *transport row. Consequently every downstream use reads a transported scalar-bound certificate rather than a host-level equality of operators or norms.*

Proof. Unfold the classifier of Definition 3603.1. Its comparison coordinates are exactly the bounded-linear-operator row, Real bound endpoint, norm-bound ledger, replay row, provenance row, and local naming row.

The operator component transports through the inherited bounded-linear-operator classifier, while the scalar endpoint transports through the $\mathsf{Real}^{\uparrow}$ comparison component. The ledger component then moves the input-norm row, output-norm row, scalar comparison row, and inequality route together.

Thus any downstream consumer receives the same public scalar-bound surface after transport. No step introduces a host equality of operators, a supremum equality of norms, or a quotient representative. □

Theorem 3603.4 (OperatorNorm non-escape boundary)**.** *Every read of an accepted* $\mathsf{OperatorNorm}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto T, K, L, H, C, P, N \longmapsto \mathsf{OperatorNorm}^{\uparrow}.$$

In particular, the packet cannot be used to recover a host supremum over all unit vectors, a norm-attainment selector, quotient operator equality, a Banach-completeness assertion, a spectral-radius theorem, or a uniform-boundedness principle.

Proof. Start with an accepted packet $O = (T, K, L, H, C, P, N)$. Any read first exposes the bounded-linear-operator row T and the scalar endpoint K, then reads the norm-bound ledger L and structural rows.

Replay through C returns to the same finite route, and transport through H is componentwise. The provenance and naming rows record only this displayed surface.

The excluded analytic objects require coordinates not present in the carrier. Since no such coordinate can be manufactured by transport or replay, every accepted read remains inside the public operator-norm bound certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{OperatorNorm}^{\uparrow}}$.

Constructive story: An $\mathsf{OperatorNorm}^{\uparrow}$ packet is generated from a bounded-linear-operator row, a nonnegative $\mathsf{Real}^{\uparrow}$ bound endpoint, a norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OperatorNorm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3603.1, Definition 3603.2, Definition 3603.3, and Definition 3603.4 seed the public scalar-bound certificate over BoundedLinearOperatorUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OperatorNorm}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OperatorNormUp.OperatorNormTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host supremum construction, quotient operator equality, norm-attainment choice, hidden Banach completeness, spectral-radius limits, uniform-boundedness families, or bridge checking.

Upgrade path: Further checked bound-stability and non-escape theorems for BEDC.Derived.OperatorNormUp would extend the verification axis while preserving the displayed scalar-bound surface.

Chapter 3604

A Concrete Naming Certificate for $\mathsf{ContinuousImageCompact}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ContinuousImageCompact}^{\uparrow}$ packet records the finite-net reading of the image of a compact metric source under a displayed continuous map. It sits over the compact source of chapter 129, the graph and pointwise-continuity row of chapter 130, and the compact-uniform-continuity route of chapter 388. The packet names the finite image-net certificate needed by downstream compactness and extreme-value consumers; it is not an open-cover compactness theorem, not a host image-set construction, and not a quotient equality principle for target names.

Definition 3604.1 (Continuous image compact carrier)**.** *A* $\mathsf{ContinuousImageCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, F, U, E, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row. It exposes only the compact metric inspection data, finite source-net rows, source radii, and source* $\mathsf{NameCert}$ *provenance consumed by the image certificate.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row from the source surface displayed by K into the target metric surface. It records the graph, pointwise continuity data, and target readback boundary available to the packet.*
3. *U is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *row for F over K. It turns each target tolerance request into a finite source-net radius before any image-net row is exported.*
4. *E is the finite source-net ledger. It records the displayed source centers, the radius attached to the requested target tolerance, and the finite coverage row supplied by K.*
5. *T is the finite target-image ledger. It records the target names $F(e)$ for each displayed source center e in E and the target tolerance justified through U.*
6. *H records componentwise* hsame *transport for the compact source, continuous-map row, compact-uniform-continuity row, source-net ledger, target-image ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an image-compactness request through K, F, U, E, T, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{ContinuousImageCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousImageCompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $K, F, U, E, T, H, C, P, N$. It has no coordinate for open-cover compactness, a host image subset, a selected inverse image, quotient equality of target names, or ambient completeness.

Theorem 3604.2 (Continuous image compact NameCert obligations)**.** *For every accepted* ContinuousImageCompac *carrier $I = (K, F, U, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContinuousImageCompact}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the compact source, continuous-map row, compact-uniform-continuity row, source-net ledger, target-image ledger, transport, replay, provenance, and local naming rows;*
2. *source-net accountability, requiring every displayed source center and radius in E to be read through the compact metric row K;*
3. *continuity routing, requiring every target tolerance request to pass through the compact-uniform-continuity row U for the continuous-map row F before T is exposed;*
4. *image-net exactness, requiring every target center in T to be the displayed F-readback of a source center from E;*
5. *componentwise transport and replay stability under H and C for the same displayed rows;*
6. *ledger refusal, stating that open-cover compactness, host image sets, selected inverse images, quotient equality, and ambient completeness are not carrier coordinates.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.ContinuousImageCompactUp.ContinuousImageCompactTasteGate single carrier alignment`

Proof. Project the accepted carrier. The mathematical rows are K, F, U, E, T, and the structural rows are H, C, P, N.

The source-net obligation is read first. Row E may display only centers and radii whose coverage data has already been supplied by the compact metric row K.

The continuity route is next. A target tolerance is sent through U, which supplies the source radius for the same displayed map row F over the same compact source K.

The target-image ledger is therefore forced. Each target center in T is obtained by reading F at one of the displayed source centers in E, and the radius attached to that target center is the tolerance justified by U.

Transport, replay, provenance, and local naming preserve the row order. Since the excluded objects do not occur among $K, F, U, E, T, H, C, P, N$, no local obligation can export them. □

Theorem 3604.3 (Finite-net image compactness)**.** *Every accepted* $\mathsf{ContinuousImageCompact}^{\uparrow}$ *carrier $I = (K, F, U, E, T, H, C, P, N)$ exports compactness of the displayed image only as the finite target-net row T obtained from the source-net row E along the continuous-map row F and the compact-uniform-continuity row U. A downstream compactness consumer receives the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{CompactUniformContinuity}^{\uparrow}, \quad \mathsf{ContinuousImageCompact}^{\uparrow}$$

and receives no open-cover compactness datum, host image subset, selected preimage, quotient equality of target names, or ambient completeness coordinate.

Proof. Begin with an image-compactness request at a target tolerance. By the obligation theorem, the request must pass through U before the target-image ledger T can be read.

The row U supplies a source radius for the same map row F over the same compact source K. The compact source row then exposes a finite source-net ledger E at that radius.

Map the displayed source centers through F. The finite list of target readbacks is exactly the target-image ledger T, and the tolerance attached to it is the one already routed through U.

Rows H, C, P, N transport, replay, package, and name this finite route without adding another coordinate. Thus the exported compactness content is the finite image-net row T and not an open-cover, host-image, selected-preimage, quotient-equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousImageCompact}\uparrow}$.

Constructive story: A $\mathsf{ContinuousImageCompact}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a ContinuousMapUp row, a CompactUniformContinuityUp row, a finite source-net ledger, a finite target-image ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousImageCompact}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3604.1, Definition 3604.2, and Definition 3604.3 seed the finite-net image-compactness route from compact metric sources to downstream compactness consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousImageCompact}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host image-set construction, selected preimages, quotient equality of target names, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-net accountability, continuity routing, image-net exactness, transport and replay stability, and local NameCert registration for BEDC.Derived.ContinuousImageCompactUp.

Chapter 3605

A Concrete Naming Certificate for $\mathsf{CompactMetricContinuousImage}^{\uparrow}$

Bishop-style compact metric reasoning treats the image of a compact metric source under a continuous map through finite approximations: choose a source net, route the requested target tolerance through the displayed continuity modulus, and read the image centers by evaluating the displayed map on the source centers. The $\mathsf{CompactMetricContinuousImage}^{\uparrow}$ packet records exactly that finite route. It sits over the compact metric source of chapter 129, the continuous-map graph row of chapter 130, the target metric-space observations of chapter 57, the uniform-modulus consumer of chapter 369, and the total-bounded image handoff of chapter 3924. The packet names finite image-net witnesses without claiming open-cover compactness, a host image subset, or a selected inverse image.

Definition 3605.1 (Compact metric continuous image carrier)**.** *A* $\mathsf{CompactMetricContinuousImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, F, M, U, E, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the displayed finite source-net data, source radii, and compact-metric provenance.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row from the source carrier to the target carrier.*
3. *M is the target* $\mathsf{Met}^{\uparrow}$ *observation row used to compare the displayed target names.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row routing each target tolerance to a source radius for the same displayed map row.*
5. *E is the finite source-net ledger read from K at the source radius supplied by U.*
6. *T is the finite target-image ledger whose centers are the displayed F-readbacks of the centers in E.*
7. *H records componentwise* hsame *transport for the compact source, map row, metric observation row, modulus row, source-net ledger, target-image ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a target-image request through $K, F, M, U, E, T, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricContinuousImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $K, F, M, U, E, T, H, C, P, N$. It has no coordinate for open-cover compactness, an ambient image subset, selected preimages, quotient equality of target names, choice-selected centers, or target completeness.

Lean4 ✓ `BEDC.Derived.CompactMetricContinuousImageUp.CompactMetricContinuousImageTasteGate single carrier alignment`

Theorem 3605.2 (Compact metric continuous image obligations)**.** *For every accepted* CompactMetricContinuousIm *carrier $I = (K, F, M, U, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImage}^{\uparrow}}$ *surface consists exactly of carrier admission, compact source-net accountability, continuous-map graph routing, target metric observation, uniform-modulus compatibility, finite image-net exactness, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 3605.1. The mathematical rows are K, F, M, U, E, T, and the structural rows are H, C, P, N.

The source-net read is governed by K and U. A target tolerance is first sent through the uniform-modulus row U, and only then may the source-net ledger E be read from the compact metric source K.

The target-image ledger is governed by F, M, E, T. Each center in T is the displayed value of the continuous-map graph row F at a center already listed in E, with target comparisons read through the metric observation row M.

Transport and replay preserve that same finite route. Since the excluded open-cover, host-image, selected-preimage, quotient-equality, choice, and completeness objects do not occur among the rows, no local obligation can export them. □

Theorem 3605.3 (Finite image-net handoff)**.** *Every compactness-facing or total-boundedness-facing consumer of an accepted* $\mathsf{CompactMetricContinuousImage}^{\uparrow}$ *packet receives only the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{ContinuousMap}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{UniformModulus}^{\uparrow},\quad \mathsf{CompactContinuousImageTotalBounded}^{\uparrow}.$$

The exported witness is the finite target-image ledger T obtained from E along F and U; it is not an open-cover compactness theorem, not a host image-set construction, and not a choice-selected family of target centers.

Proof. Start with a target-image request. The carrier forces the request through U, which supplies a source radius for the same displayed continuous-map row F.

Read the compact metric source row K at that radius to obtain the finite source-net ledger E. No open cover or arbitrary subcover selector is inspected.

Apply the displayed graph row F to the centers in E and compare the resulting target names through M. The resulting finite list is exactly the target-image ledger T.

Rows H, C, P, N transport, replay, package, and name this route without adding another coordinate. Thus the handoff can be consumed by $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$ as finite image-net data, but not as ambient image compactness or a selected inverse-image construction. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImage}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricContinuousImage}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ContinuousMap graph rows, MetricSpace target observations, UniformModulus tolerance routing, finite source-net ledgers, finite target-image ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3605.1, Definition 3605.2, and Definition 3605.3 seed the compact-metric continuous-image route from finite source nets to finite target-image witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host image-set construction, selected preimages, quotient equality of target names, choice-selected centers, target completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-net accountability, graph routing, metric observation, uniform-modulus compatibility, image-net exactness, transport, replay, provenance, and local NameCert registration for BEDC.Derived.CompactMetricContinuousImageUp.

Chapter 3606

A Concrete Naming Certificate for $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$

Following Lebesgue and Bishop–Bridges constructive compact metric analysis, the $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$ packet records the finite BEDC surface by which a displayed finite cover over a compact metric source yields a positive-radius ledger. It sits between the compact metric source of chapter 129, the metric ball rows of chapter 57, the finite radius ledger of chapter 452, the theorem route of chapter 2301, and the uniform-modulus consumer of chapter 369. The packet names finite-cover-to-positive-radius data only; it is not an open-cover compactness theorem, a subcover selector, a host minimum principle, countable choice, or an ambient completeness claim.

Definition 3606.1 (Finite-cover Lebesgue-number carrier)**.** *A* $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$ *carrier is a finite* BHist *tuple*

$$F = (K, M, V, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row supplying the compact finite-net and coverage data admitted by the cover request.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row through which distances, rational balls, and containment checks are read.*
3. *V is the displayed finite cover row, listing the named cover cells and their metric ball witnesses.*
4. *R is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive radius ledger attached to the displayed finite cover.*
5. *L is the* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *route row certifying that the compact metric source and finite cover have been routed to the positive ledger R.*
6. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that may consume the positive radius after K, M, V, R, L have been exposed.*
7. *H records componentwise* hsame *transport for $K, M, V, R, L, U, C, P, N$.*
8. *C records displayed* Cont *replay from compact metric finite nets and metric ball containment rows to the finite cover, positive radius ledger, lemma route, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{LebesgueNumberLemma}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $K, M, V, R, L, U, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, selected subcovers, host minima, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FiniteCoverLebesgueNumberUp.TasteGate.FiniteCoverLebesgueNumberTasteGate single carrier alignment`

Theorem 3606.2 (Finite-cover Lebesgue-number NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$ *carrier* $F = (K, M, V, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}}$ *surface consists exactly of five rows: carrier admission for the displayed tuple; cover-to-radius exactness binding the finite cover row V to the positive radius ledger R; lemma-row compatibility requiring the* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *row L to read the same compact metric source, metric ball observations, finite cover, and positive ledger; uniform handoff through U; and non-escape from open-cover compactness, selected subcovers, host minima, countable choice, and ambient completeness.*

Proof. Project the accepted carrier of Definition 3606.1. The displayed tuple contains exactly the compact metric source, metric observation row, finite cover, positive radius ledger, lemma route, uniform handoff, and structural rows.

Cover-to-radius exactness is read through V and R. The finite cover is not replaced by an arbitrary open family, and the radius is not selected by a host minimum; it is the displayed positive ledger attached to the cover row.

Lemma-row compatibility is read through L. It records that the compact metric source K, metric ball row M, finite cover row V, and positive ledger R are the same rows consumed by the $\mathsf{LebesgueNumberLemma}^{\uparrow}$ route.

The uniform handoff U can be reached only after this finite route has been transported by H and replayed by C, with provenance and local naming stored in P and N. Since the carrier has no further coordinate, no accepted packet imports open-cover compactness, selected subcovers, host minima, countable choice, or ambient completeness. □

Theorem 3606.3 (Finite-cover Lebesgue-number uniform-radius handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$ *carrier reaches the positive radius only through*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{FiniteLebesgueNumber}^{\uparrow}, \quad \mathsf{LebesgueNumberLemma}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

The consumer-facing route is the finite compact-cover-to-positive-radius handoff $K, M, V, R, L, U, H, C, P, N$, not open-cover compactness, selected subcovers, host minima, countable choice, or ambient completeness.

Proof. Read K, M, V first. These rows display the compact metric source, the metric ball observations, and the finite cover whose cover cells generate the positive-radius request.

Then read R and L. The radius ledger is the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ row for the displayed finite cover, and the lemma route records the compact-cover-to-ledger compatibility needed before a uniform-modulus consumer can inspect the radius.

Finally read U, H, C, P, N. These rows transport, replay, source, and name the same finite route. The carrier therefore exports a uniform-radius handoff without adding any coordinate for open-cover compactness, selected subcovers, host minima, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$ packet is generated from a CompactMetric source row, Metric ball observations, a displayed finite cover, a FiniteLebesgueNumber positive radius ledger, a LebesgueNumberLemma route row, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3606.1, Definition 3606.2, and Definition 3606.3 seed the finite compact-cover-to-positive-radius data route consumed by uniform-modulus reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FiniteCoverLebesgueNumberUp.TasteGate.FiniteCoverLebesgueNumberTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, host minima, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-to-radius exactness, lemma-row compatibility, uniform handoff, transport and replay stability, and provenance exhaustion for BEDC.Derived.FiniteCoverLebesgueNumberUp.

Chapter 3607

A Concrete Naming Certificate for $\mathsf{ContractionPrinciple}^{\uparrow}$

Following Banach and Bishop–Bridges constructive metric analysis, the $\mathsf{ContractionPrinciple}^{\uparrow}$ packet records the theorem-level completion-neighbour object that connects the contraction-map surface of chapter 1418, the finite iteration ledger of chapter 2383, the complete-metric handoff of chapter 128, the metric source of chapter 57, and the endpoint-facing consumer discipline of chapter 396. The packet names the finite route through which contraction data becomes completion-facing evidence; it does not itself choose a fixed point or assert ambient completeness.

Definition 3607.1 (ContractionPrinciple carrier)**.** *A* $\mathsf{ContractionPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, d, T, q, I, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *carrier row whose point histories and classifier are read by the contraction route.*
2. *d is the metric-distance row used for all finite source, target, and iterate-distance comparisons.*
3. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *graph row, exposing the self-map application surface without host function extensionality.*
4. *q is the rational contraction-bound ledger, including the displayed nonnegative row and strict unit-bound row consumed by finite estimates.*
5. *I is the* $\mathsf{FixedPointIteration}^{\uparrow}$ *route, displaying the initial row, finite iterate window, and residual-budget rows generated from T and q.*
6. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, naming the completion-facing service that may consume the finite Cauchy evidence without being stored as ambient completeness in the contraction packet.*
7. *H records componentwise* hsame *transport for the metric source, distance row, contraction graph, rational bound, finite iteration route, completion handoff, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for metric reads, contraction graph inspection, bound comparison, finite iteration extension, completion handoff, and consumer readback.*
9. *P is the* Pkg *provenance row over* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{ContractionPrinciple}^{\uparrow}}$ *row.*

The carrier is a theorem-level route packet. It contains no selected fixed point, no completed endpoint row, no host equality of maps, and no completeness assertion outside the displayed handoff row.

Lean4 ✓ `BEDC.Derived.ContractionPrincipleUp.ContractionPrincipleTasteGate single carrier alignment`

Theorem 3607.2 (ContractionPrinciple NameCert obligations)**.** *For an accepted* $\mathsf{ContractionPrinciple}^{\uparrow}$ *carrier* $R = (X, d, T, q, I, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ContractionPrinciple}^{\uparrow}}$ *surface consists of carrier admission, contraction-bound stability, iterate visibility, complete-metric handoff visibility, componentwise transport, continuation replay, package provenance stability, and local naming for the packet of Definition 3607.1. Every accepted read of the principle is routed through these rows.*

Proof. Carrier admission projects the displayed tuple $X, d, T, q, I, L, H, C, P, N$. The contraction graph row and rational bound ledger supply the map-level comparison surface, while the metric row is the only source of distance reads.

Iterate visibility is supplied by I. It records only finite Picard windows and residual budgets generated from T and q, so it cannot introduce a completed orbit or a selected endpoint.

The completion handoff is supplied by L, transported by H, and replayed by C. Provenance and local naming are then read from P and N, giving exactly the listed NameCert obligations and no additional analytic coordinate. □

Theorem 3607.3 (ContractionPrinciple completion handoff)**.** *Every* $\mathsf{BanachFixedPoint}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{ContractionPrinciple}^{\uparrow}$ *carrier must pass through the displayed route*

$$\mathsf{ContractionMapping}^{\uparrow}, \quad \mathsf{FixedPointIteration}^{\uparrow}, \quad \mathsf{CompleteMetric}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{NameCert}_{\mathsf{ContractionPrinciple}^{\uparrow}}.$$

Equivalently, the consumer reads the rows $X, d, T, q, I, L, H, C, P, N$ before any endpoint-facing fixed-point seal can be consumed. The handoff exports contraction-map evidence, finite iterate evidence, metric-distance reads, complete-metric service visibility, transport, replay, provenance, and local naming; it does not export a selected fixed point, a completed orbit endpoint, host fixed-point equality, quotient equality of maps, or ambient completeness.

Proof. Start with the contraction surface. The rows T and q are read as the $\mathsf{ContractionMapping}^{\uparrow}$ graph and rational bound ledger over the $\mathsf{Met}^{\uparrow}$ source X, d.

Next read the finite iteration route I. It exposes the $\mathsf{FixedPointIteration}^{\uparrow}$ orbit window and residual budget that a completion-facing consumer may inspect before any endpoint row is available.

Finally pass through L, H, C, P, N. The row L is only a $\mathsf{CompleteMetric}^{\uparrow}$ handoff, while H and C preserve the same componentwise route under transport and replay. Therefore a $\mathsf{BanachFixedPoint}^{\uparrow}$ or $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives the displayed theorem-level route but must provide its own endpoint or completeness discipline downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContractionPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{ContractionPrinciple}^{\uparrow}$ packet is generated from a MetricUp source row, a distance row, a ContractionMapping graph row, a rational contraction-bound ledger, a FixedPointIteration route, a CompleteMetric handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractionPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3607.1, Definition 3607.2, and Definition 3607.3 seed the theorem-level contraction principle route over metric, contraction-map, finite iteration, complete-metric, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractionPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, completed endpoints, host fixed-point equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-bound stability, iterate visibility, complete-metric handoff visibility, transport stability, replay stability, provenance stability, and local naming for BEDC.Derived.ContractionPrincipleUp.

Chapter 3608

A Concrete Naming Certificate for $\mathsf{CauchyProductConvergence}^{\uparrow}$

Following Mertens and Bishop–Bridges constructive analysis, the $\mathsf{CauchyProductConvergence}^{\uparrow}$ packet records the finite Real-and-completion route by which two displayed regular Cauchy or summable rows expose a Cauchy product name. It sits over the regular rational readback of chapter 301, the tolerance ledger of chapter 291, the completion witness route of chapter 3579, and the product theorem surface of chapter 3584. The chapter names only the finite certificate route for product convergence; it does not assert quotient stream equality, selected infinite limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3608.1 (Cauchy product convergence carrier)**.** *A* $\mathsf{CauchyProductConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, P, T, R, D, W, E, H, C, Q, N)$$

with the following displayed rows:

1. *A and B are the two source rows, each presented either as a regular Cauchy row or as a summable row with the finite windows needed by the product route.*
2. *P is the Cauchy product window. It records the finite convolution band, the summand-pair reads, and the displayed partial product windows used by the convergence claim.*
3. *T is the tail-control row. It records the finite majorant, Mertens, or Bishop–Bridges tail ledger that bounds the product tail after the window P has been fixed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the product windows determined by A, B, P, T.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the source reads, product-window reads, and tail-control inequalities.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window data obtained from the same product windows and tolerance requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular readback, stream windows, and dyadic tolerance ledger have been exposed.*
8. *H records componentwise* hsame *transport for the source rows, Cauchy product window, tail-control row, readback, tolerance ledger, stream windows, Real seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a product-convergence request through $A, B, P, T, R, D, W, E, H, Q, N$.*
10. *Q is the* Pkg *provenance over* $\mathsf{CauchyProductConvergence}^{\uparrow}$, $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductConvergence}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite product-convergence history. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyProductConvergenceUp.CauchyProductConvergenceTasteGate single carrier alignment`

Theorem 3608.2 (Cauchy product convergence NameCert obligations)**.** *For every accepted* CauchyProductConverg *carrier $K = (A, B, P, T, R, D, W, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductConvergence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two source rows, the product window, the tail-control row, the regular readback, the dyadic tolerance ledger, stream windows, the Real seal, transport, replay, provenance, and local naming;*
2. *product-window stability under componentwise* hsame *transport of A, B, P, T;*
3. *tail-control compatibility between the Cauchy product window P, the tail row T, and the dyadic tolerance ledger D;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *readback for the product windows exposed by P, T, D;*
5. $\mathsf{StreamName}^{\uparrow}$ *window exposure using the same finite product windows and tolerance rows;*
6. $\mathsf{Real}^{\uparrow}$ *seal nonescape through R, D, W, E;*
7. *displayed* Cont *replay and* Pkg *provenance for the whole route;*
8. *ledger refusal for any product-convergence consumer that omits a source row, product window, tail-control row, tolerance ledger, readback row, stream window, Real seal, transport row, replay row, provenance row, or local naming row.*

Proof. Project the carrier of Definition 3608.1. The projection exposes exactly the two source rows, the Cauchy product window, tail-control ledger, regular readback, dyadic tolerance ledger, stream windows, Real seal, and structural support rows.

The product-window and tail obligations are bound by P, T, D. A consumer can read a product window only together with the corresponding source-window reads and dyadic tolerance request, and it can claim tail control only through the displayed row T.

The readback and seal obligations are bound by R, W, E. These rows repack the same finite product windows as regular rational and stream-name data before the terminal Real seal is available.

Finally H, C, Q, N transport, replay, package, and name the same finite route. Since the carrier has no quotient-stream, selected-limit, choice, trichotomy, or ambient completeness coordinate, the obligation list is exhaustive. □

Theorem 3608.3 (Cauchy product convergence tail handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyProductConvergence}^{\uparrow}$ *packet factors through the finite route*

$$A, B \longmapsto P, T, D \longmapsto R, W \longmapsto E, H, C, Q, N.$$

Thus the read first consumes the two source rows, then the displayed Cauchy product window, tail-control row, and dyadic tolerance ledger, then the regular rational and stream-name readbacks, and only then the terminal $\mathsf{Real}^{\uparrow}$ *seal. The route exports no quotient stream semantics, selected product limit, countable-choice schedule, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $K = (A, B, P, T, R, D, W, E, H, C, Q, N)$. The only source coordinates are A and B, so all source regularity or summability reads begin there.

The next stage is P, T, D. The product window P fixes the finite convolution band, the tail-control row T supplies the displayed convergence bound for the omitted band, and the dyadic ledger D records the tolerance requests used by both.

The readback stage is R, W. The regular rational row and stream-name row use the same product windows fixed by P, T, D, so there is no separate selected-limit coordinate.

Finally the seal stage is E, H, C, Q, N. The $\mathsf{Real}^{\uparrow}$ seal is reached only after the readback rows, and the structural rows transport, replay, package, and name the same finite route. □

Theorem 3608.4 (Cauchy product convergence tail-budget fusion)**.** *Every accepted* $\mathsf{CauchyProductConvergence}^{\uparrow}$ *tail-control row that consumes a* $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ *surface factors through chapter 3584 before the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows are read. In the carrier* $K = (A, B, P, T, R, D, W, E, H, C, Q, N)$, *the theorem packet is consumed by the source-window and tail-control stage* A, B, P, T, *while* R, D, W, E *only read the resulting finite product route.*

Proof. Start with the carrier route of Definition 3608.3. Its first stage consumes A, B, P, T, and the provenance row Q already names $\mathsf{MertensCauchyProductTheorem}^{\uparrow}$ among the package sources.

The readback rows R, D, W, E occur only after this stage. Therefore a consumer cannot read regular rational, dyadic, stream-name, or Real-seal data for the product tail until the Mertens theorem packet has fixed the finite product-window surface. □

Falsifiable prediction: Every accepted $\mathsf{CauchyProductConvergence}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting a source row, product window, tail-control row, DyadicRatCore tolerance ledger, RegSeqRat readback, StreamName window, transport row, replay row, provenance row, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductConvergence}^{\uparrow}$ packet is generated from two source regular Cauchy or summable rows, a Cauchy product window, a tail-control row, RegSeqRat readback, DyadicRatCore tolerance ledger, StreamName windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 3608.1, Definition 3608.2, and Definition 3608.3 seed the finite product-convergence route from source rows and Cauchy product windows to tail control, readback, tolerance, StreamName, and Real seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyProductConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, product-window stability, tail-control compatibility, RegSeqRat readback, DyadicRatCore tolerance routing, StreamName exposure, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductConvergenceUp.

Chapter 3609

A Concrete Naming Certificate for $\mathsf{CauchyProductMertens}^{\uparrow}$

Following Mertens and Bishop–Bridges constructive analysis, the $\mathsf{CauchyProductMertens}^{\uparrow}$ packet records the finite theorem row that mediates between the displayed Mertens Cauchy product theorem of chapter 3584 and the product-convergence seal of chapter 3608. It sits over the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the stream-window route of chapter 126, the completion witness of chapter 3579, and the terminal Real naming surface of chapter 38.

Definition 3609.1 (Cauchy product Mertens carrier)**.** *A* $\mathsf{CauchyProductMertens}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, W, T, R, D, S, E, H, C, Q, N)$$

whose rows record two displayed regular Cauchy or summable source names A, B*, a finite convolution-window row* W*, a Mertens tail-budget row* T*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, a* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, a* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *handoff row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* Q*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyProductMertens}^{\uparrow}}$ *row* N*. The carrier predicate asserts that all rows belong to one finite product-theorem history from the Mertens theorem packet to the later convergence packet; it contains no coordinate for quotient streams, selected limits, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyProductMertensUp.CauchyProductMertensTasteGate single carrier alignment`

Theorem 3609.2 (Cauchy product Mertens NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductMertens}^{\uparrow}$ *carrier* $M = (A, B, W, T, R, D, S, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductMertens}^{\uparrow}}$ *surface consists exactly of carrier admission for those twelve rows, Mertens-window compatibility between* A, B, W, T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance routing through* D*,* $\mathsf{StreamName}^{\uparrow}$ *exposure through* S*, completion handoff through* E*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and refusal of any consumer that omits one of these rows.*

Proof. Project the carrier in Definition 3609.1. The source, window, and tail rows A, B, W, T expose exactly the Mertens theorem surface needed before product convergence can be read.

The readback rows R, D, S, E then carry the same finite window through regular rational, dyadic, stream-name, and completion-witness routes. The structural rows H, C, Q, N transport, replay, source, and name that route.

Since the carrier has no quotient-stream, selected-limit, choice, trichotomy, or ambient completeness coordinate, the displayed list exhausts the local NameCert obligations. □

Theorem 3609.3 (Cauchy product Mertens tail-budget handoff)**.** *Every accepted* $\mathsf{CauchyProductMertens}^{\uparrow}$ *tail-budget row that can be consumed by* $\mathsf{CauchyProductConvergence}^{\uparrow}$ *first factors through the finite route*

$$A, B \longmapsto W, T \longmapsto R, D, S, E \longmapsto H, C, Q, N.$$

Thus the Mertens product theorem packet is read before the $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows of the convergence route are consumed.*

Proof. Start from an accepted carrier $M = (A, B, W, T, R, D, S, E, H, C, Q, N)$. The only rows that expose the product theorem surface are A, B, W, T, so a convergence-facing tail read begins with those coordinates.

The readback stage is then forced through R, D, S, E. These rows encode the same finite window as regular rational, dyadic tolerance, stream-window, and completion-witness data.

Finally H, C, Q, N provide transport, replay, provenance, and local naming. No other coordinate can supply a tail-budget handoff to the convergence packet. □

Falsifiable prediction: Every accepted $\mathsf{CauchyProductMertens}^{\uparrow}$ consumer that reaches a product-convergence tail handoff while omitting a source row, convolution window, Mertens tail row, RegSeqRat readback, DyadicRatCore tolerance ledger, StreamName window, CauchyCompletenessWitness handoff, transport row, replay row, provenance row, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductMertens}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyProductMertens}^{\uparrow}$ packet is generated from two source regular Cauchy or summable rows, a finite convolution window, a Mertens tail-budget row, RegSeqRat readback, DyadicRatCore tolerance routing, StreamName exposure, CauchyCompletenessWitness handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductMertens}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3609.1, Definition 3609.2, and Definition 3609.3 seed the finite Mertens product-theorem route from source rows and tail budgets to readback, stream, completion, and convergence-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductMertens}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyProductMertensUp.CauchyProductMertensTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Mertens-window compatibility, RegSeqRat readback, DyadicRatCore tolerance routing, StreamName exposure, CauchyCompletenessWitness handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductMertensUp.

Chapter 3610

A Concrete Naming Certificate for $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$

Following Krein and Milman, the $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ packet records the finite extreme-point witness route that a convex-analysis consumer may inspect before any ambient locally convex compactness theorem is available. It sits over the compact metric carrier of chapter 129, the convex-set interface of chapter 208, the scalar $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the weak functional-window surface of chapter 3597, the operator-norm row of chapter 3603, and the finite weak-star window of chapter 3420. The chapter names only a finite exposed-face and candidate-extreme certificate; it does not assert full locally convex duality, selected supporting functionals, unrestricted compactness, quotient convex bodies, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3610.1 (Krein–Milman finite extreme-point carrier)**.** *A* $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, V, X, F, E, S, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *row carrying the finite compact-window data through which the candidate convex body is inspected.*
2. *V is the ambient vector or functional-analysis row, read through the weak-topology and operator-norm sibling packets.*
3. *X is the* $\mathsf{ConvexSet}^{\uparrow}$ *row for the displayed convex subset, including the affine-combination and transport data available to the packet.*
4. *F is the finite exposed-face ledger, listing the exposed faces, scalar thresholds, comparison budgets, and source probes that the certificate actually opens.*
5. *E is the candidate extreme-point witness row, recording the displayed points and finite refusal rows for nontrivial convex decompositions inside the opened face ledger.*
6. *S is the separating-functional ledger. Each functional is read only through finite weak-topology, operator-norm, and scalar* $\mathsf{Real}^{\uparrow}$ *observation rows.*
7. *W records the scalar and metric windows used by F, E, S, including finite* $\mathsf{Real}^{\uparrow}$ *readbacks for values, gaps, and tolerance comparisons.*

8. *H records componentwise* hsame *transport for the compact metric row, ambient row, convex-set row, exposed-face ledger, candidate extreme witnesses, separating-functional ledger, scalar windows, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from compact and convex reads through exposed-face and separating-functional ledgers to the candidate extreme witness rows.*
10. *P is the* Pkg *provenance over* $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, V, X, F, E, S, W, H, C, P, N$. It has no coordinate for a host choice of all extreme points, a completed dual space, full locally convex separation, unrestricted compactness, quotient convex-body equality, selected supporting functionals outside S, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.KreinMilmanFiniteExtremeUp.KreinMilmanFiniteExtremeUpTasteGate single carrier alignment`

Theorem 3610.2 (Krein–Milman finite extreme-point NameCert obligations)**.** *For every accepted* $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ *carrier*

$$K = (M, V, X, F, E, S, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}}$ *surface consists exactly of compact-window admission for M, ambient weak functional admission for V, convex-set admission for X, exposed-face ledger visibility for F, candidate extreme-point witness admission for E, separating-functional ledger visibility for S, scalar and metric window readback for W, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every consumer of the finite extreme-point certificate must read the route

$$M, V, X \longmapsto F, S, W \longmapsto E \longmapsto H, C, P, N$$

before treating a candidate as an extreme witness. The route exports finite certificate rows only; it exports no selected set of all extreme points, no full separation theorem, no host compact convex hull equality, no quotient convex-body object, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 3610.1. The compact and convex source rows are exactly M and X, while the ambient functional-analysis reads are confined to V.

The exposed-face and separating-functional data are then forced through F and S. Their scalar values, thresholds, and gap comparisons are opened through the finite window row W, so a consumer sees only displayed weak and normed scalar observations.

The candidate extreme witness row E is downstream from those ledgers. It records the displayed point and the finite refusal of nontrivial convex decompositions inside the opened face route, not a global selector for all extreme points.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no row contains a completed dual space, unrestricted compactness object, quotient convex body, host separation theorem, or ambient completeness principle, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ packet is generated from compact metric rows, convex-set rows, weak functional-analysis windows, finite exposed-face ledgers, candidate extreme-point witnesses, separating-functional

ledgers, scalar Real readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{KreinMilmanFiniteExtreme}\uparrow}$, seed)

Scope closed: Definition 3610.1 and Definition 3610.2 seed the finite exposed-face route for a Krein–Milman extreme-point witness over compact metric, convex-set, real scalar, weak-topology, operator-norm, and Banach–Alaoglu window rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{KreinMilmanFiniteExtreme}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full locally convex duality, unrestricted compactness, host separation theorems, selected supporting functionals, quotient convex-body equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window routing, convex-set admission, finite exposed-face exactness, candidate extreme witness admission, separating-functional ledger visibility, scalar readback, transport, replay, provenance, and local naming for BEDC.Derived.KreinMilmanFiniteExtremeUp.

Chapter 3611

A Concrete Naming Certificate for $\mathsf{CFunCarrier}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley continuous-function carriers, the $\mathsf{CFunCarrier}^{\uparrow}$ packet records a continuous function as finite source, map, target, modulus, and certificate rows rather than as an ambient function-space quotient. It sits between the terminal real-name seal of chapter 38, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the graph-and-modulus surface of chapter 130. The chapter isolates the non-quotient carrier object consumed by $\mathsf{RealPowerSeries}^{\uparrow}$ and later $\mathsf{ContinuousMap}^{\uparrow}$ readers: a consumer sees only displayed BEDC rows, not a host function, function extensionality principle, selected modulus function, or completed mapping space.

Definition 3611.1 (Continuous function carrier)**.** *A* $\mathsf{CFunCarrier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, F, T, M, Q, W, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-domain row, including the finite input histories and any* $\mathsf{StreamName}^{\uparrow}$ *windows used to read source points.*
2. *F is the graph or map row, recording only the displayed relation between inspected source histories and target histories.*
3. *T is the target-domain row, including the terminal* $\mathsf{Real}^{\uparrow}$ *or sibling endpoint rows that the carrier may expose.*
4. *M is the modulus row, recording the finite tolerance conversion used by the continuity request.*
5. *Q is the certificate row that binds the source read, graph read, target read, and modulus read into one continuity witness.*
6. *W is the shared finite-window ledger over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and any real-facing tolerance readbacks needed by the source and target rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row used when the carrier is consumed by real-valued maps or power-series endpoints.*
8. *H records componentwise* hsame *transport for the source, map, target, modulus, certificate, window, readback, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an input tolerance request through S, F, T, M, Q, W, R to the named endpoint rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CFunCarrier}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CFunCarrier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, T, M, Q, W, R, H, C, P, N$. It has no coordinate for host functions, quotient mapping spaces, function extensionality, selected moduli, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ContinuousFunctionCarrierUp.ContinuousFunctionCarrierTasteGate single carrier alignment`

Theorem 3611.2 (Continuous function carrier NameCert obligations)**.** *For every accepted* $\mathsf{CFunCarrier}^{\uparrow}$ *carrier $K = (S, F, T, M, Q, W, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CFunCarrier}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, source access through S, graph or map access through F, target access through T, modulus access through M, continuity-certificate binding through Q, shared* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows through W, real-facing readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3611.1. The only rows available to a consumer are $S, F, T, M, Q, W, R, H, C,$ so source, graph, target, modulus, certificate, window, and readback obligations must be read there.

The continuity witness is not a host theorem. It is the finite row Q together with the shared windows W and the real-facing readback row R, so every endpoint read stays inside the displayed packet.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no other coordinate exists, the listed obligations exhaust the local NameCert surface. □

Theorem 3611.3 (Continuous function carrier L10 readback)**.** *Every L10 consumer read of an accepted* $\mathsf{CFunCarrier}^{\uparrow}$ *packet factors through*

$$S, F, T, M, Q \longmapsto W, R \longmapsto H, C, P, N.$$

Thus $\mathsf{RealPowerSeries}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *consumers may use the displayed source, graph, target, modulus, certificate, stream-window, regular-rational, real-readback, transport, replay, provenance, and local naming rows, but they receive no host function object, quotient mapping space, selected modulus function, function extensionality principle, countable-choice selector, or ambient real-completeness witness.*

Proof. Start with the displayed carrier. The source, graph, target, modulus, and certificate rows form the only continuity-facing entry point.

The finite windows and readback rows come next. They are the rows through which $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ observations are exposed to real-valued and continuous-map consumers.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. The field-exclusion clause of the carrier then blocks every host-function or quotient-function-space escape route. □

Falsifiable prediction: Every accepted $\mathsf{CFunCarrier}^{\uparrow}$ read must expose source, graph or map, target, modulus, certificate, finite StreamName windows, RegSeqRat readback, Real-facing readback when present, componentwise transport, displayed replay, provenance, and local naming rows.

Independence witness: continuousmap, real, streamname, regseqrat: $\mathsf{CFunCarrier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source, graph, target, modulus, certificate, window, readback, transport, replay, provenance, and local naming rows without quotienting maps or selecting host functions.

Closure status for $\mathsf{NameCert}_{\mathsf{CFunCarrier}^{\uparrow}}$.

Constructive story: A $\mathsf{CFunCarrier}^{\uparrow}$ packet is generated from source-domain rows, graph or map rows, target-domain rows, a modulus row, a continuity-certificate row, shared finite StreamName and RegSeqRat windows, real-facing readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CFunCarrier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3611.1, Definition 3611.2, and Definition 3611.3 seed the finite non-quotient continuous-function carrier route over source, graph, target, modulus, certificate, window, readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CFunCarrier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host functions, function extensionality, quotient mapping spaces, selected modulus functions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source access, graph or map access, target access, modulus access, continuity-certificate binding, shared window routing and readback, real-facing readback, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousFunctionCarrierUp.

Chapter 3612

A Concrete Naming Certificate for $\mathsf{SturmRootCount}^{\uparrow}$

Following Sturm's theorem and Bishop–Bridges constructive analysis, the $\mathsf{SturmRootCount}^{\uparrow}$ packet records the finite route by which a displayed polynomial and two endpoint windows yield a root-count ledger without selecting any root in a host field. It consumes the sign-variation surface of chapter 2079 and exposes the retained count to the bracket consumers of chapter 2269. The packet names the count-and-handoff interface between a Sturm-chain variation ledger and a Real-facing isolating-window consumer; it does not name a chosen algebraic root.

Definition 3612.1 (Sturm root count carrier)**.** *A* $\mathsf{SturmRootCount}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (P, S, E, V, D, I, A, H, C, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Poly}^{\uparrow}$ *source row, carrying the coefficient ledger, degree bound, derivative row, and polynomial identity whose interval counts are inspected.*
2. *S is the* $\mathsf{SturmSequence}^{\uparrow}$ *sign-variation window row, recording the accepted Sturm chain, endpoint sign table, zero-deletion witnesses, and the two visible variation counts.*
3. *E is the endpoint dyadic-window row. It stores the left and right dyadic endpoint cells, requested precisions, comparison rows, and endpoint containment checks.*
4. *V is the variation-count difference row. It records the displayed subtraction of the right endpoint variation count from the left endpoint variation count.*
5. *D is the* $\mathsf{RealRootIsolation}^{\uparrow}$ *bracket handoff row, exposing only the polynomial source, endpoint windows, and certified count accepted by the downstream isolating-window consumer.*
6. *I is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, retaining the same two endpoint windows and the same count at unary precision before a real seal is inspected.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row for the two endpoint names and the bracket-facing interval read.*
8. *H records componentwise* hsame *transport for polynomial source, Sturm-sequence window, endpoint dyadic windows, variation-count difference, isolation handoff, regular-rational readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a root-count request through polynomial inspection, Sturm-chain variation, endpoint dyadic comparison, count subtraction, isolation handoff, regular-rational readback, and real-seal access.*

10. *K is the* Pkg *provenance over* $\mathsf{Poly}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, $\mathsf{RealRootIsolation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SturmRootCount}^{\uparrow}}$ *registration row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected root, a host-field factorization, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SturmRootCountUp.TasteGate.SturmRootCountTasteGate single carrier alignment`

Theorem 3612.2 (Sturm root count NameCert obligations)**.** *For every accepted* $\mathsf{SturmRootCount}^{\uparrow}$ *carrier* $R = (P, S, E, V, D, I, A, H, C, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SturmRootCount}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the rows listed in Definition 3612.1;*
2. *polynomial-source exactness through the coefficient, degree, derivative, and identity cells of P;*
3. *Sturm-window exactness through the finite chain, endpoint sign table, zero-deletion witnesses, and variation counts of S;*
4. *endpoint-window exactness through the dyadic cells, precision requests, comparison rows, and containment checks of E;*
5. *count-difference exactness through the displayed subtraction row V;*
6. *bracket-consumer discipline through the* $\mathsf{RealRootIsolation}^{\uparrow}$ *handoff row D;*
7. *regular-rational and Real-facing readback through I and A;*
8. *componentwise transport, continuation replay, provenance, and local naming through H, C, K, N.*

There is no additional NameCert obligation for selected roots, factorization over a host field, quotient real equality, real trichotomy, or ambient completeness.

Proof. Project the carrier of Definition 3612.1. The polynomial source P and the Sturm-window row S fix the displayed chain, endpoint sign table, zero-deletion witnesses, and variation counts, so a count read cannot inspect roots or factors outside the finite ledger.

The dyadic endpoint row E supplies the only endpoint cells admitted to the count. The difference row V then records the visible subtraction of endpoint variation counts, with no separate root-selection coordinate.

The handoff row D gives the downstream $\mathsf{RealRootIsolation}^{\uparrow}$ consumer exactly the source polynomial, endpoint windows, and accepted count. Rows I and A expose the same endpoint data through $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal.

Finally, H, C, K, N transport, replay, source, and locally name the same route. Since none of those structural rows adds a selected root, factorization theorem, quotient equality proof, trichotomy decision, or completeness witness, the local certificate is exhausted by the displayed rows. □

Theorem 3612.3 (Sturm root count isolation handoff)**.** *Every accepted* $\mathsf{SturmRootCount}^{\uparrow}$ *read handed to a* $\mathsf{RealRootIsolation}^{\uparrow}$ *bracket consumer factors through*

$$P, S, E, V \longmapsto D \longmapsto I, A, H, C, K, N.$$

The consumer receives the polynomial source, Sturm-chain sign-variation window, endpoint dyadic windows, variation-count difference, regular-rational endpoint readback, Real-facing seal, componentwise transport, replay, provenance, and local naming. It receives no selected host root, no factorization over a host field, no quotient real equality principle, no trichotomy decision, and no ambient completeness principle.

Proof. Start with the downstream read. The source polynomial must pass through P, and the variation data must pass through the $\mathsf{SturmSequence}^{\uparrow}$ row S from chapter 2079.

The endpoint cells are then read from E, while V records the displayed count difference. Thus the bracket-facing row can see only a finite source, two endpoint windows, and one accepted integer count.

The handoff row D is the only row available to the $\mathsf{RealRootIsolation}^{\uparrow}$ consumer described in chapter 2269. The regular-rational readback I and real seal A preserve the same endpoint information for Real-facing consumers.

The remaining rows H, C, K, N compare, replay, source, and name the route componentwise. They add no hidden analytic principle, so the isolation handoff remains a finite Sturm-count certificate. □

Falsifiable prediction: Every $\mathsf{SturmRootCount}^{\uparrow}$ read handed to a $\mathsf{RealRootIsolation}^{\uparrow}$ bracket consumer factors through one $\mathsf{Poly}^{\uparrow}$ source row, one $\mathsf{SturmSequence}^{\uparrow}$ sign-variation window row, one dyadic endpoint-window row, one variation-count difference row, one bracket handoff row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: polynomial, sturmsequence, realrootisolation, dyadicratcore, regseqrat, real: $\mathsf{SturmRootCount}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the polynomial source, Sturm-chain sign-variation windows, endpoint dyadic windows, count-difference row, bracket handoff, readback, real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SturmRootCount}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SturmRootCount}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3612.1, Definition 3612.2, and Definition 3612.3 seed the finite bridge from Sturm-chain variation ledgers to Real-root-isolation bracket consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SturmRootCount}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected roots, factorization over a host field, quotient real equality, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Sturm-window exactness, endpoint-window exactness, count-difference exactness, isolation handoff, readback discipline, and transport-replay coverage for BEDC.Derived.SturmRootCountUp

Constructive story: A $\mathsf{SturmRootCount}^{\uparrow}$ packet is generated from a $\mathsf{Poly}^{\uparrow}$ source row, a $\mathsf{SturmSequence}^{\uparrow}$ sign-variation window row, dyadic endpoint windows, a variation-count difference row, a $\mathsf{RealRootIsolation}^{\uparrow}$ bracket handoff row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3613

A Concrete Naming Certificate for $\mathsf{UniformCauchyBicompletion}^{\uparrow}$

Following Bourbaki on uniform structures and Kelley on completions of uniform spaces, the $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ packet records the finite two-sided Cauchy-filter corridor used to approach a separated uniform-completion boundary. It sits over the uniform-space surface of chapter 339, the Cauchy-filter route of chapter 333, the separated comparison row of chapter 3365, the uniform-completion consumer of chapter 1473, and the real readback boundary of chapter 38. The chapter names only finite bicompletion data for a displayed left and right Cauchy route; it does not construct a quotient completion, select a limit representative, use choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3613.1 (Uniform Cauchy bicompletion carrier)**.** *A* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, L, R, J, S, E, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, recording finite entourage membership, diagonal, inverse, refinement, and composition data available to both Cauchy sides.*
2. *L is the left* $\mathsf{CauchyFilter}^{\uparrow}$ *row, exposing the finite left filter-base observations and their entourage refinements.*
3. *R is the right* $\mathsf{CauchyFilter}^{\uparrow}$ *row, exposing the finite right filter-base observations and their entourage refinements.*
4. *J is the joint Cauchy row, recording that requested left and right tails share a displayed common entourage refinement before any completion-facing read.*
5. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row, used only to identify two displayed boundary reads through separated zero-distance data.*
6. *E is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row, reached after U, L, R, J, S have been displayed.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row for real-valued observers of the separated boundary, available only downstream of the uniform-completion handoff.*
8. *H records componentwise* hsame *transport for the uniform, left-filter, right-filter, joint-Cauchy, separated, completion, Real, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a bicompletion request through $U, L, R, J, S, E, A, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyBicompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite two-sided Cauchy corridor. It has no coordinate for quotient filters, selected completion points, ambient host equality, choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.UniformCauchyBicompletionUp.UniformCauchyBicompletionTasteGate single carrier alignment`

Theorem 3613.2 (Uniform Cauchy bicompletion NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ *carrier $B = (U, L, R, J, S, E, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyBicompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the uniform-space row, two Cauchy-filter rows, joint-Cauchy row, separated comparison row, uniform-completion handoff, Real readback, transport, replay, provenance, and local naming;*
2. *left and right Cauchy-filter stability under componentwise* hsame *transport over the same* $\mathsf{UniformSpace}^{\uparrow}$ *row U;*
3. *joint-refinement exactness through J, requiring both Cauchy sides to reach every displayed entourage request through finite filter-base refinements;*
4. *separated-boundary exactness through S, requiring any identification of two displayed boundary reads to pass through the separated comparison row;*
5. *completion and Real nonescape through E and A, requiring every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer to stay downstream of U, L, R, J, S;*
6. *displayed* Cont *replay and* Pkg *provenance for the whole two-sided corridor;*
7. *refusal of quotient filters, selected completion points, ambient host equality, choice, and ambient Real completeness as certificate data.*

Proof. Project the carrier of Definition 3613.1. The source rows are $U, L, R, J, S, E, A, H, C, P, N$, so every obligation must be read from those coordinates.

The two Cauchy sides are bound by L and R over the same uniform row U. The joint row J records the common finite entourage refinement requested by a bicompletion read, so neither side can be replaced by an independent host filter or a selected representative.

The separated and completion-facing rows are S, E, A. The row S is the only comparison route for displayed boundary reads, E is available only after the joint two-sided Cauchy data have been exposed, and A is downstream of that handoff.

Finally H, C, P, N transport, replay, record provenance for, and locally name the same corridor. Since the carrier has no quotient-filter, selected-point, host-equality, choice, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 3613.3 (Uniform Cauchy bicompletion separated route)**.** *Every separated* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ *packet factors through the finite route*

$$U \longmapsto L, R \longmapsto J \longmapsto S \longmapsto E, A, H, C, P, N.$$

Thus the consumer first reads the uniform entourage row, then both Cauchy-filter sides, then the joint-refinement row, then the separated comparison row, and only then the completion handoff and Real readback rows. The route exports no quotient completion, selected limit representative, choice schedule, ambient host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $B = (U, L, R, J, S, E, A, H, C, P, N)$. The only uniform source is U, so every completion-facing read begins with the displayed entourage data.

The two Cauchy inputs are L and R. Their common-refinement witness is J, which records the finite two-sided response to each requested entourage before a boundary read is available.

The separated boundary is S. Any comparison of two displayed completion reads must pass through this row, so host equality or a selected quotient representative cannot enter the route.

The endpoint rows are E, A, H, C, P, N. They hand off to the uniform-completion and Real-facing consumers, transport and replay the same data, and locally name the corridor without adding quotient, selection, choice, host-equality, or ambient-completeness data. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ consumer that reaches a separated $\mathsf{UniformCompletion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ boundary while omitting the UniformSpace row, either CauchyFilter side, the joint-refinement row, the SeparatedMetric comparison row, transport, replay, provenance, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyBicompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ packet is generated from a UniformSpace entourage row, two CauchyFilter rows, a joint-refinement row, a SeparatedMetric comparison row, a UniformCompletion handoff, a RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyBicompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3613.1, Definition 3613.2, and Definition 3613.3 seed the finite two-sided Cauchy corridor from uniform entourage rows to separated completion and Real readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyBicompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limit representatives, choice, ambient host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, left and right Cauchy-filter stability, joint-refinement exactness, separated-boundary exactness, UniformCompletion handoff nonescape, Real readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyBicompletionUp.

Chapter 3614

A Concrete Naming Certificate for $\mathsf{DyadicCauchyApproximation}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{DyadicCauchyApproximation}^{\uparrow}$ packet records the finite dyadic approximation surface used to pass from tolerance requests to regular rational and real-name consumers. It sits over the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the completed real-name boundary of chapter 38, and the locator-facing route of chapter 3410. The chapter names only finite dyadic approximation data; it does not introduce quotient streams, selected limits, trichotomy, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3614.1 (Dyadic Cauchy approximation carrier)**.** *A* $\mathsf{DyadicCauchyApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, Q, E, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radius, comparison, and refinement data requested by the approximation.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposing the inspected stream prefixes associated with the dyadic tolerance request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same dyadic tolerances and stream windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after D, W, Q have been displayed.*
5. *L is the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *handoff row, recording the locator-facing use of the same finite approximation data.*
6. *H records componentwise* hsame *transport for the tolerance, window, readback, Real seal, locator handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an approximation request through D, W, Q, E, L to the named consumer rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchyApproximation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealLocator}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyApproximation}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite approximation history. It has no coordinate for quotient stream equality, selected limits, trichotomy, open-cover compactness, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.DyadicCauchyApproximationUp.DyadicCauchyApproximationTasteGate single carrier alignment`

Theorem 3614.2 (Dyadic Cauchy approximation NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyApproximation}^{\uparrow}$ *carrier* $K = (D, W, Q, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, dyadic tolerance admission through* D*, finite stream-window exposure through* W*, regular rational readback through* Q*, RealUp sealing through* E*, CauchyRealLocator handoff through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3614.1. The only rows available to an approximation consumer are $D, W, Q, E, L, H, C, P, N$, so tolerance, window, readback, seal, locator, transport, replay, provenance, and naming obligations must be read there.

The dyadic and stream obligations are bound by D and W. The dyadic radius, comparison, and refinement data come from the $\mathsf{DyadicRatCore}^{\uparrow}$ row, while the inspected prefixes are the finite $\mathsf{StreamName}^{\uparrow}$ windows attached to the same request.

The readback obligations are bound by Q, E, L. The regular rational row reads exactly the dyadic-window data, the Real seal is downstream of that row, and the locator handoff reuses the same finite approximation surface.

Finally H, C, P, N transport, replay, source, and name this route. Since the carrier has no quotient-stream, selected-limit, trichotomy, open-cover, choice, or ambient completeness coordinate, the listed obligations exhaust the certificate surface. □

Theorem 3614.3 (Dyadic Cauchy approximation RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{DyadicCauchyApproximation}^{\uparrow}$ *packet factors through*

$$D, W \longmapsto Q \longmapsto E, L, H, C, P, N.$$

Thus the consumer first receives the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row and finite* $\mathsf{StreamName}^{\uparrow}$ *windows, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal or* $\mathsf{CauchyRealLocator}^{\uparrow}$ *handoff. The route exports no quotient stream equality, selected limit, trichotomy, open-cover compactness, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $K = (D, W, Q, E, L, H, C, P, N)$. The only approximation-facing entry point is the pair D, W, so every tolerance request is read as a dyadic core row together with a finite stream-window row.

The regular rational stage is Q. It reads precisely the windows and dyadic tolerances already displayed by D and W, so no separate stream quotient or selected limit can enter the handoff.

The endpoint stage is E, L, H, C, P, N. The $\mathsf{Real}^{\uparrow}$ seal and $\mathsf{CauchyRealLocator}^{\uparrow}$ handoff are downstream of the regular readback, while transport, replay, provenance, and local naming preserve the same finite route. □

Theorem 3614.4 (Dyadic Cauchy approximation window composition)**.** *Every accepted* DyadicCauchyApproximati *packet composes a tolerance request through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row* D*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$*-facing seal* E *before any*

locator-facing or consumer-facing output is exported. The composed route is preserved by hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *naming N, and it provides no quotient-stream equality, selected limit, trichotomy, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 3614.1. The tolerance request is recorded first by D, and the only stream data available to it is the finite window row W.

Apply the NameCert obligations theorem Definition 3614.2. It identifies the regular rational readback as Q, the Real-facing endpoint as E, and the locator handoff as L, all sourced by the same finite approximation history.

Apply the RegSeqRat handoff theorem Definition 3614.3. It forces every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer through D, W, Q, E before transport, replay, provenance, and naming rows export the route.

Since the carrier has no quotient-stream, selected-limit, trichotomy, choice, or ambient-completeness coordinate, the displayed window composition is the full consumer-visible path. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCauchyApproximation}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{CauchyRealLocator}^{\uparrow}$ while omitting the DyadicRatCore tolerance row, StreamName window row, transport row, replay row, provenance row, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyApproximation}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, finite StreamName windows, RegSeqRat readback, a RealUp seal, a CauchyRealLocator handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3614.1, Definition 3614.2, and Definition 3614.3 seed the finite dyadic approximation route from tolerance rows and stream windows to regular rational readback, Real seal, and locator handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, trichotomy, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance routing, StreamName window exposure, RegSeqRat readback, Real seal nonescape, CauchyRealLocator handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCauchyApproximationUp.

Chapter 3615

A Concrete Naming Certificate for $\mathsf{SequentialCauchyRegularization}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SequentialCauchyRegularization}^{\uparrow}$ packet records the finite route by which ordinary Cauchy stream data is regularized into a displayed regular Cauchy name before the terminal Real seal is read. It sits over the displayed threshold discipline of chapter 376, the finite window service of chapter 126, the rational readback of chapter 301, the tolerance ledger of chapter 291, and the Real seal of chapter 38. The packet names a sequential regularization certificate only; it does not identify quotient streams, choose a limit, use countable choice, invoke trichotomy, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3615.1 (Sequential Cauchy regularization carrier)**.** *A* $\mathsf{SequentialCauchyRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, T, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source Cauchy stream row. It records the ordinary sequential Cauchy data through finite requests, not through a quotient stream or selected limit.*
2. *T is the displayed regularization threshold row imported from the* $\mathsf{CauchyRegularization}^{\uparrow}$ *route. It records, for each requested precision, the finite stage after which the source windows are regular enough to serve the requested name.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite source windows and the regularized output windows read at the threshold supplied by T.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regularized rational name exposed by T and W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the source-window comparisons, threshold requests, regularized readbacks, and Real-facing output tolerance.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source row, regularization threshold, stream windows, readback, and dyadic tolerance ledger have been displayed.*
7. *H records componentwise* hsame *transport for the source stream, threshold row, window row, readback row, tolerance ledger, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a sequential regularization request through $X, T, W, R, D, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{SequentialCauchyRegularization}^{\uparrow}$, $\mathsf{CauchyRegularization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCauchyRegularization}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite sequential regularization history. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host sequence equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.SequentialCauchyRegularizationUp.SequentialCauchyRegularizationTasteGate single carrier alignment`

Theorem 3615.2 (Sequential Cauchy regularization NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCauchyRegularization}^{\uparrow}$ *carrier* $S = (X, T, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialCauchyRegulariza}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the source Cauchy stream, displayed regularization threshold, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming;*
2. *threshold stability under componentwise* hsame *transport of* X, T, W, D*;*
3. *regularized readback compatibility between the threshold row* T*, the window row* W*, the rational readback row* R*, and the tolerance ledger* D*;*
4. $\mathsf{Real}^{\uparrow}$ *seal nonescape through* E*, excluding any read that bypasses* X, T, W, R, D*;*
5. *displayed* Cont *replay and* Pkg *provenance for the whole route;*
6. *refusal of quotient streams, selected limits, countable choice, trichotomy, host sequence equality, and ambient Real completeness as certificate data.*

Proof. Project the carrier of Definition 3615.1. The analytic rows are the source stream X, the regularization threshold T, the window row W, the readback row R, the tolerance ledger D, and the terminal seal E.

The threshold obligation is read from T together with W and D. The row T names the finite stage supplied by the $\mathsf{CauchyRegularization}^{\uparrow}$ route, while W and D record the finite windows and tolerance comparisons checked at that stage.

The readback and seal obligations are read from R and E. The regularized rational name is exposed only through R, and the Real-facing seal is downstream of the same threshold, window, and tolerance data.

Finally H, C, P, N transport, replay, record provenance for, and locally name the same finite route. Since the carrier has no quotient-stream, selected-limit, choice, trichotomy, host-equality, or completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 3615.3 (Sequential Cauchy regularization Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{SequentialCauchyRegularization}^{\uparrow}$ *packet factors through the finite route*

$$X \longmapsto T \longmapsto W, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the consumer first reads the source Cauchy stream, then the displayed regularization threshold from $\mathsf{CauchyRegularization}^{\uparrow}$*, then the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports no quotient stream, selected limit, countable-choice selector, trichotomy row, host sequence equality, or ambient completeness theorem.*

Proof. Start with an accepted packet $S = (X, T, W, R, D, E, H, C, P, N)$. The only source coordinate is X, so any sequential Cauchy read begins with the displayed source stream row.

The regularization stage is T, W, D. The threshold row T supplies the finite stage used by the regularization route, and the window and tolerance rows record the exact finite observations made at that stage.

The readback stage is R. It packages the regularized windows as a regular rational name before any Real-facing seal is available.

The terminal stage is E, H, C, P, N. These rows seal, transport, replay, record provenance for, and locally name the same route, and none of them adds quotient, selection, choice, trichotomy, host-equality, or completeness data. □

Falsifiable prediction: Every accepted $\mathsf{SequentialCauchyRegularization}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting a source Cauchy stream row, displayed CauchyRegularization threshold, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, transport row, replay row, provenance row, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCauchyRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCauchyRegularization}^{\uparrow}$ packet is generated from a source Cauchy stream, a displayed CauchyRegularization threshold, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCauchyRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3615.1, Definition 3615.2, and Definition 3615.3 seed the finite sequential regularization route from ordinary Cauchy stream data to regular readback and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCauchyRegularization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold stability, regularized readback compatibility, DyadicRatCore tolerance routing, StreamName exposure, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SequentialCauchyRegularizationUp.

Chapter 3616

A Concrete Naming Certificate for MetaCICDecidableTypingFrontier$^{\uparrow}$

The MetaCICDecidableTypingFrontier$^{\uparrow}$ packet realizes the checker frontier of chapter 9379 as finite NameCert data. It sits beside the decidability witness of chapter 751, the decidability boundary packet of chapter 749, the local diamond witness of chapter 3595, and the self-compilation substrate of section 9235.3. The packet names the boundary between checked typing inference and bounded normal equality; it does not claim unrestricted beta-conversion, global normalization, subject reduction, confluence, or a closedness decider.

Falsifiable prediction: Every accepted MetaCICDecidableTypingFrontier$^{\uparrow}$ packet displays checker rows for `inferTypeCtx`, `checkSameTerm`, `Term.eq`, bounded normal equality, frontier refusal, transport, continuation, provenance, and local naming.

Independence witness: metacicdecidabilitywitness, metacicdecidableboundary, bounded-normal-equality-checker, metacic-local-diamond-witness, metacic-confluence-audit-packet: the decidability witness packages positive checker exactness, the decidability boundary records a broader refusal surface, the bounded-normal-equality checker names the normal-form comparison row, the local-diamond witness names confluence peaks, and the confluence audit packet records join obligations. None is bijective to MetaCICDecidableTypingFrontier$^{\uparrow}$.

Definition 3616.1 (MetaCIC decidable typing frontier carrier)**.** *A* MetaCICDecidableTypingFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, S, Q, B, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the `inferTypeCtx` row. It records the context, represented term, optional inferred type, and the checked soundness and completeness surface available for that option-valued procedure.*
2. *S is the `checkSameTerm` row. It records successful same-term checks as structural equality evidence and refuses to treat failure as negative beta-conversion data.*
3. *Q is the `Term.eq` row. It records Boolean structural equality, reflexivity, true-to-equality, equality-to-true, and the exported correctness theorem for represented terms.*
4. *B is the bounded normal-equality row. It records the fuel, bounded normalizer outputs, and finished-normalization hypotheses required before `decideClosedBetaConv` can be read as a sound comparison.*

5. *R is the frontier refusal row. It records that unrestricted beta-conversion, global normalization, arbitrary closedness decidability, subject reduction, and confluence are not exported by this packet.*
6. *H records componentwise* hsame *transport for the typing checker, same-term checker, structural equality, bounded normal equality, frontier refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a decidable-typing-frontier request through I, S, Q, B, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICDecidableTypingFrontier}^{\uparrow}$*, the MetaCIC decidability audit map,* $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableTypingFrontier}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unrestricted beta-conversion oracle, a global normalization theorem, a subject-reduction theorem, a confluence theorem, host quotient equality of terms, or an ambient completeness principle for all represented syntax.

Lean4 ✓ `BEDC.Derived.MetaCICDecidableTypingFrontierUp.MetaCICDecidableTypingFrontierTasteGate single carrier alignment`

Theorem 3616.2 (MetaCIC decidable typing frontier NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICDecidableTypingFrontier}^{\uparrow}$ *carrier $F = (I, S, Q, B, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableTypingFront}}$ *surface consists exactly of typing-checker admission through I, same-term checker admission through S, structural equality readback through Q, bounded normal-equality admission through B, frontier refusal through R, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through N.*

Later Lean TasteGate work must provide Nontrivial *and* FieldFaithful *instances for this carrier surface. Those instances must witness that the packet cannot collapse to an empty frontier marker and cannot hide a missing typing, same-term, structural-equality, bounded-normal, refusal, transport, replay, provenance, or naming row.*

Proof. Project the carrier of Definition 3616.1. The positive checker rows are I, S, Q: typing inference, same-term checking, and structural equality.

The bounded comparison row is B. It is read only as bounded normal equality with the finished-normalization hypotheses named by the audit map, so it cannot become unrestricted beta-conversion data.

The refusal row R records the open boundary for global normalization, closedness decidability, subject reduction, confluence, and host quotient equality. This row is part of the certificate rather than prose outside the packet.

Finally H, C, P, N transport, replay, record provenance for, and locally name the same frontier route. Since the carrier has no coordinate for the stronger theorems listed above, the displayed rows exhaust the NameCert obligations. □

Theorem 3616.3 (MetaCIC decidable typing frontier nonescape)**.** *Every consumer of an accepted* $\mathsf{MetaCICDecidableTypingFrontier}^{\uparrow}$ *packet factors through the finite route*

$$\texttt{inferTypeCtx},\ \texttt{checkSameTerm},\ \texttt{Term.eq},\ \texttt{decideClosedBetaConv} \longmapsto R, H, C, P, N.$$

The route exports checked typing-inference and structural same-term data, plus bounded normal-equality data under its displayed hypotheses. It exports no unrestricted beta-conversion oracle, no global normalization theorem, no subject-reduction theorem, no confluence theorem, no arbitrary closedness decider, and no host quotient equality of terms.

Proof. Start with an accepted carrier $F = (I, S, Q, B, R, H, C, P, N)$. Rows I, S, Q expose the typing, same-term, and structural equality procedures named by the audit map.

The bounded normal-equality request then passes through B. This row contains the fuel and finished-normalization boundary, so the consumer receives only the checked bounded comparison surface.

The refusal row R is read before the structural rows finish the packet. It prevents the consumer from replacing the bounded route by global beta-conversion, normalization, subject reduction, confluence, closedness decidability, or quotient equality.

The final rows H, C, P, N preserve the same route under transport, continuation replay, provenance, and local naming. □

Theorem 3616.4 (MetaCIC decidable typing audit split)**.** *Every audit-map consumer of an accepted* MetaCICDecidableTypingFrontier$^{\uparrow}$ *packet first reads* `inferTypeCtx`*,* `checkSameTerm`*, and* `Term.eq` *as the positive typing and structural syntax-equality side. It reads* `decideClosedBetaConv` *only through the bounded normal-equality row and its displayed finished-normalisation hypotheses. The refusal row then blocks any promotion to global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, or host quotient equality of terms.*

Proof. Project an accepted carrier $F = (I, S, Q, B, R, H, C, P, N)$. The positive checker side is exactly I, S, Q: typing inference through `inferTypeCtx`, same-term checking through `checkSameTerm`, and structural equality through `Term.eq`.

The beta-conversion side is narrower. A consumer reaches `decideClosedBetaConv` only through B, whose stored data includes bounded normalizer outputs, fuel, and the finished-normalisation hypotheses required by the audit map.

The refusal row R is read before the packet is exported through H, C, P, N. It prevents the bounded comparison row from being reinterpreted as global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, or quotient equality.

Thus the packet preserves the audit-map split: positive typing and syntax equality are read directly from checker rows, while beta conversion remains bounded and hypothesis-indexed. □

Theorem 3616.5 (MetaCIC decidable typing coverage frontier)**.** *Every accepted* MetaCICDecidableTypingFrontier$^{\uparrow}$ *packet exports exactly the positive checker rows* `inferTypeCtx`*,* `checkSameTerm`*, and* `Term.eq`*. It exports* `decideClosedBetaConv` *only through the bounded normal-equality row carrying displayed fuel, bounded normalizer outputs, and finished-normalization hypotheses. Therefore any consumer claiming global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, or quotient equality must leave this packet.*

Proof. Project an accepted carrier $F = (I, S, Q, B, R, H, C, P, N)$ from Definition 3616.1. The projected positive checker rows are exactly I, S, Q, corresponding to `inferTypeCtx`, `checkSameTerm`, and `Term.eq`.

Use Definition 3616.2. It identifies the local NameCert obligations with the displayed checker rows, bounded normal-equality row, refusal row, and structural rows, with no hidden coordinate for stronger metatheory.

Apply Definition 3616.4. The only route to `decideClosedBetaConv` passes through B, where the fuel, bounded outputs, and finished-normalization hypotheses are part of the exported row.

Finally apply Definition 3616.3. The refusal row R blocks global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, and quotient equality from being read as packet exports. □

Theorem 3616.6 (MetaCIC decidable typing frontier positive checker exactness)**.** *An accepted* MetaCICDecidableTypingFrontier$^{\uparrow}$ *packet exports positive checker exactness only for* `inferTypeCtx`*,* `checkSameTerm`*, and* `Term.eq`*. Any read of* `decideClosedBetaConv` *must pass through the bounded normal-equality row with displayed fuel, bounded normalizer outputs, and finished-normalization hypotheses, and the refusal row blocks global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, and quotient equality.*

Proof. Project the carrier $F = (I, S, Q, B, R, H, C, P, N)$ of Definition 3616.1. The positive checker rows are exactly I, S, Q, so exactness for typing inference, same-term checking, and structural equality is confined to those rows.

Compose the NameCert obligations of Definition 3616.2 with the audit split of Definition 3616.4. They keep the bounded beta-conversion read in B, where fuel and finished-normalization hypotheses are displayed before any comparison result is exported.

Finally use the coverage frontier of Definition 3616.5. It separates the positive checker rows from the bounded normal-equality row and reads the refusal row R before transport, replay, provenance, and local naming finish the packet.

Because the carrier has no row for global normalization, subject reduction, confluence, arbitrary closedness decidability, unrestricted beta-conversion, or quotient equality, those claims cannot be exported as positive checker exactness. □

Closure status for NameCert$_{\text{MetaCICDecidableTypingFrontier}^{\uparrow}}$.

Constructive story: A MetaCICDecidableTypingFrontier$^{\uparrow}$ packet is generated from inferTypeCtx typing rows, checkSameTerm rows, Term.eq structural equality rows, bounded normal-equality rows, frontier refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICDecidableTypingFrontier}^{\uparrow}}$, seed)

Scope closed: Definition 3616.1, Definition 3616.2, Definition 3616.3, and Definition 3616.4 seed the finite decidable-typing frontier over checked typing inference, structural equality, bounded normal equality, and explicit refusal rows.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICDecidableTypingFrontier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted beta-conversion, global normalization, subject reduction, confluence, arbitrary closedness decidability, host quotient equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typing-checker exactness, same-term exactness, structural equality readback, bounded-normal comparison exactness, frontier refusal, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICDecidableTypingFrontierUp.

Chapter 3617

A Concrete Naming Certificate for $\mathsf{DenseEmbedding}^{\uparrow}$

Following Kelley and Bourbaki on dense embeddings, the $\mathsf{DenseEmbedding}^{\uparrow}$ packet records the finite BEDC surface by which a source metric carrier is read inside a target metric completion through a dense image-window and an approximation ledger. It sits before the specialized metric-completion embedding packet of chapter 3351, and it supplies a canonical source route for $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ consumers in chapter 38, chapter 301, chapter 126, chapter 291, and chapter 3579. The packet names dense-image approximation as finite certificate data; it does not import a host embedding theorem, quotient representatives, selected limits, countable choice, or ambient completion completeness.

Definition 3617.1 (Dense embedding carrier)**.** *A* $\mathsf{DenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, T, C, I, W, A, E, H, K, P, N)$$

with the following displayed rows:

1. *S is the source metric row, including the finite carrier, distance readings, and source-side comparison windows.*
2. *T is the target metric row, read only through displayed target-distance comparisons.*
3. *C is the target completion row, carrying the completion-facing names used by the embedding read.*
4. *I is the source-to-target image row. It records the embedded image of inspected source points without choosing quotient representatives or host limits.*
5. *W is the dense image-window row. Each density request opens a finite target window, a source witness window, and the target-distance tolerance being tested.*
6. *A is the approximation ledger. It records that the witness in S reaches the target request through I, W, T, C at the displayed tolerance.*
7. *E is the completion handoff row exposed to completion-facing consumers after S, T, C, I, W, A have already been read.*
8. *H stores componentwise* hsame *transport for the source metric, target metric, completion, image, dense window, approximation ledger, handoff, continuation, provenance, and local naming rows.*

9. *K stores displayed* Cont *replay from source observations to image observations, from image observations to dense windows, and from dense windows to the completion handoff row.*
10. *P is the* Pkg *provenance over* $\mathsf{DenseEmbedding}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, C, I, W, A, E, H, K, P, N$. It has no coordinate for host topological density, quotient completion equality, a selected limit, a global inverse, countable choice, or ambient completeness of the target completion.

Lean4 ✓ `BEDC.Derived.DenseEmbeddingUp.DenseEmbeddingTasteGate single carrier alignment`

Theorem 3617.2 (Dense embedding NameCert obligations)**.** *For every accepted* $\mathsf{DenseEmbedding}^{\uparrow}$ *carrier $D = (S, T, C, I, W, A, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the source metric, target metric, target completion, source-to-target image, dense image-window, approximation ledger, completion handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every density read must first expose S, T, C, I, W, A before the handoff row E can be consumed.*

Proof. Project the carrier of Definition 3617.1. The source metric, target metric, completion row, image row, dense window, and approximation ledger are exactly S, T, C, I, W, A, so a density request has no other analytic coordinates to inspect.

The handoff row E is downstream of those six rows. Hence completion-facing consumers first see the displayed source witness, its image, the finite target window, and the approximation ledger before receiving any completion data.

The structural rows H, K, P, N only transport, replay, source, and name that same finite route. Since the carrier excludes host density, quotient representatives, selected limits, countable choice, global inverses, and ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3617.3 (Dense embedding completion handoff)**.** *Every* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenseEmbedding}^{\uparrow}$ *packet factors through the finite route*

$$S, T, C, I \longmapsto W \longmapsto A \longmapsto E$$

together with H, K, P, N. The route may be read through the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *windows named by the packet, but it exports no selected completion limit, quotient representative, ambient density theorem, countable-choice selector, or host completeness principle.*

Proof. Start with the NameCert obligations of Definition 3617.2. They place the source metric row, target metric row, target completion row, and image row before any dense-window or approximation-ledger read is available.

The dense image-window W opens only the finite source and target observations requested by the consumer. The approximation ledger A then records that this displayed source witness reaches the requested target window through the image row I at the stated tolerance.

Only after that ledger is read does the completion handoff row E become available. The rows H, K, P, N preserve and name the same route, so specialized completion, real, and Cauchy-completeness consumers receive finite dense-embedding data rather than host completion structure. □

Falsifiable prediction: Every accepted $\mathsf{DenseEmbedding}^{\uparrow}$ completion-facing read factors through a source metric row, target metric row, target completion row, source-to-target image row, dense image-window, approximation ledger, completion handoff row, transport, continuation replay, provenance, and local naming.

Independence witness: metric-completion-dense-embedding, real, regseqrat, streamname, dyadicratcore, cauchy-completeness-witness: $\mathsf{DenseEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it carries the canonical dense image-window and approximation ledger before those siblings consume the completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{DenseEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseEmbedding}^{\uparrow}$ packet is generated from a source metric row, target metric row, target completion row, source-to-target image row, dense image-window, approximation ledger, completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3617.1, Definition 3617.2, and Definition 3617.3 seed the canonical dense-embedding carrier and completion handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host topological density, quotient completion equality, selected limits, global inverses, countable choice, ambient completion completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, dense image-window exactness, approximation-ledger handoff, completion nonescape, and TasteGate field faithfulness for BEDC.Derived.DenseEmbeddingUp.

Chapter 3618

A Concrete Naming Certificate for $\mathsf{UniformCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completions, the $\mathsf{UniformCauchyCompletion}^{\uparrow}$ packet records the finite uniform-Cauchy handoff used by Phase Real and Completion consumers before any completed object is exposed. It sits over the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the Cauchy-sequence space surface of chapter 406, the terminal Real seal of chapter 38, and the Bishop completion route of chapter 3484. The packet is a finite NameCert surface for uniform Cauchy families; it is not a quotient completion, selected limit, countable choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 3618.1 (Uniform Cauchy completion carrier)**.** *A* $\mathsf{UniformCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the uniform Cauchy family row, recording the inspected finite family, common-window requests, and uniform Cauchy tolerance responses.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the windows used by F.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row on those same windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that discharges every displayed uniform Cauchy request.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *and completion seal row reached only after F, S, R, D have been displayed, with the sibling handoff to* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *and* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *recorded as part of the same finite route.*
6. *H records componentwise* hsame *transport for the family, stream-window, regular-readback, dyadic-ledger, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through F, S, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{BishopCompletionTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite uniform-Cauchy completion handoff. It has no coordinate for quotient completions, selected limits, countable choice, host real equality, or ambient Real completeness.

Theorem 3618.2 (Uniform Cauchy completion NameCert obligations)**.** *For every accepted* UniformCauchyComplet *carrier* $U = (F, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the uniform Cauchy family, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real and completion seal, transport, replay, provenance, and local naming rows;*
2. *uniform Cauchy family stability, requiring every requested comparison to stay on the displayed family row* F *and the finite windows exposed by* S*;*
3. *regular rational readback exactness, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *to read only the same windows and budgets already named by* F *and* S*;*
4. *dyadic tolerance exactness, requiring the row* D *to discharge each uniform Cauchy request before the seal row is visible;*
5. *Real and completion seal nonescape, requiring the row* E *to be reached only through* F, S, R, D *and the sibling* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *and* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *routes;*
6. *componentwise* hsame *transport and displayed* Cont *replay through* H *and* C*;*
7. Pkg *provenance and local naming through* P *and* N*;*
8. *refusal of quotient completions, selected limits, countable choice, host real equality, and ambient Real completeness as certificate data.*

Lean4 ✓ `BEDC.Derived.UniformCauchyCompletionUp.UniformCauchyCompletionTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3618.1. The visible coordinates are $F, S, R, D, E, H, C, P, N$, so every local obligation must be read from those rows.

The uniform Cauchy family is fixed by F and its finite observations are fixed by S. The regular rational readback R and tolerance ledger D are attached to those same windows, so a completion-facing request cannot exchange them for an external sequence, host equality, or selected limit representative.

The seal row is E. It is downstream of the family, StreamName, RegSeqRat, and DyadicRatCore rows, and its sibling route names the $\mathsf{CauchySequenceSpace}^{\uparrow}$ and $\mathsf{BishopCompletionTheorem}^{\uparrow}$ handoffs without adding quotient or choice data.

Finally H, C, P, N transport, replay, record provenance for, and locally name the same handoff. Since no quotient completion, selected limit, countable choice, host real equality, or ambient Real completeness coordinate appears in the carrier, the listed rows exhaust the certificate surface. □

Theorem 3618.3 (Uniform Cauchy completion finite handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{UniformCauchyCompletion}^{\uparrow}$ *packet factors through the finite route*

$$F \longmapsto S \longmapsto R \longmapsto D \longmapsto E, H, C, P, N.$$

Thus a consumer first reads the uniform Cauchy family, then the finite StreamName windows, then the RegSeqRat readback, then the DyadicRatCore tolerance ledger, and only then the Real and

completion seal. The route exports no quotient completion, selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $U = (F, S, R, D, E, H, C, P, N)$. The only family coordinate is F, and the only finite observation coordinate is S.

The readback and tolerance rows are R and D. They keep the completion-facing request on the same regular rational windows and dyadic tolerance ledger before any terminal seal can be read.

The endpoint row is E, with structural support from H, C, P, N. These rows hand the same finite packet to $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, and $\mathsf{BishopCompletionTheorem}^{\uparrow}$ consumers without adding quotient, selection, choice, host-equality, or ambient-completeness data. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchyCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ or completion-facing boundary while omitting the uniform Cauchy family row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, seal row, transport, replay, provenance, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyCompletion}^{\uparrow}$ packet is generated from a uniform Cauchy family row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real and completion seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3618.1, Definition 3618.2, and Definition 3618.3 seed the finite uniform-Cauchy route from stream windows and regular rational readback to Real and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform Cauchy family stability, finite-window readback, dyadic tolerance exactness, Real and completion seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyCompletionUp.

Chapter 3619

A Concrete Naming Certificate for $\mathsf{ArchimedeanCompletion}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of Archimedean ordered fields and regular Cauchy completions, the $\mathsf{ArchimedeanCompletion}^{\uparrow}$ packet records the finite naming surface that carries a dyadic ordered-field source into the Real and Completion route. It sits after the dyadic ordered core of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the ordered cut comparison of chapter 3517, and the completion witness of chapter 3579. The packet names an Archimedean completion interface; it is not quotient equality of Cauchy streams, a selected host limit, a trichotomy oracle, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3619.1 (Archimedean completion carrier)**.** *An* $\mathsf{ArchimedeanCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, K, R, D, O, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the dyadic ordered-field source row, including the finite addition, multiplication, order, unit, and sign-comparison data read from the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*
2. *K is the Archimedean cofinality row: every displayed field element is bounded by a named dyadic scale already present in the same packet.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row generated from the source and cofinality data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare finite approximants and dyadic scales.*
5. *O is the order-density comparison row linking the regular readback to the order-completion surface of chapter 3517.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, K, R, D, O have been displayed.*
7. *H records componentwise* hsame *transport for the ordered-field source, cofinality witness, regular readback, dyadic ledger, order comparison, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an Archimedean-completion request through F, K, R, D, O, E.*
9. *P is the* Pkg *provenance over* $\mathsf{ArchimedeanCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopOrderCompletion}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, K, R, D, O, E, H, C, P, N$ and the displayed replay path. It contains no coordinate for quotient stream equality, selected representatives, host-limit choice, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ArchimedeanCompletionUp.TasteGate.ArchimedeanCompletionTasteGate single carrier alignment`

Theorem 3619.2 (Archimedean completion NameCert obligations)**.** *For every accepted* $\mathsf{ArchimedeanCompletion}^{\uparrow}$ *carrier $A = (F, K, R, D, O, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanCompletion}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the finite dyadic ordered-field packet F together with the Archimedean cofinality witness K;*
2. *regular-Cauchy readback through R and dyadic tolerance accounting through D;*
3. *order-density comparison through O, with no independent located-cut or trichotomy oracle;*
4. *terminal* $\mathsf{Real}^{\uparrow}$ *handoff through E, reached only after the source, cofinality, readback, ledger, and order-comparison rows have been displayed;*
5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No local obligation can be discharged by quotient Cauchy equality, selected host limits, countable choice, a detached order-completion theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3619.1. Its analytic rows are exactly the dyadic ordered-field source, the Archimedean cofinality witness, the regular-Cauchy readback, the dyadic tolerance ledger, the order-density comparison, and the terminal Real seal.

Carrier admission is the first row: F supplies the finite ordered-field operations and comparisons, while K supplies only the displayed cofinal dyadic scales. The readback row R and ledger row D then account for every regular-Cauchy and tolerance datum consumed by the packet.

The order-facing route is forced through O. It compares the same finite readback with the Bishop order-completion surface, but it cannot introduce a located-cut selector, trichotomy oracle, or host order equality because no such row belongs to the carrier.

Finally E, H, C, P, N route the terminal Real handoff and structural support. Since the carrier has no quotient stream equality, selected limit, countable-choice schedule, detached completion theorem, or ambient-completeness coordinate, none of those objects belongs to the NameCert obligation surface. □

Theorem 3619.3 (Archimedean completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *handoff exported by an accepted* $\mathsf{ArchimedeanCompletion}^{\uparrow}$ *carrier factors through the displayed dyadic, regular, and order-completion rows*

$$F, K \longmapsto R, D \longmapsto O \longmapsto E \longmapsto H, C, P, N.$$

The dyadic ordered-field source and Archimedean cofinality rows determine the regular-Cauchy readback; the dyadic ledger and order-density row compare that readback with the Bishop order-completion interface; the terminal Real seal is available only after those rows have been replayed.

Consequently a Real-facing consumer receives a finite NameCert route from dyadic ordered-field data to regular Cauchy and order-completion data. It receives no quotient stream equality, selected representative, host-limit operator, trichotomy oracle, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a consumer that reaches the terminal Real row. In the carrier of Definition 3619.1, the only Real-facing coordinate is E, and E is placed after F, K, R, D, O.

The consumer must therefore read the dyadic ordered-field source and cofinality rows before any regular-Cauchy data is available. The readback row R and ledger row D expose the finite approximation route, while the order-density row O aligns that route with the Bishop order-completion packet.

The structural rows H, C, P, N then transport, replay, source, and locally certify the same route. They preserve the displayed handoff, but they cannot add quotient equality, selected limits, trichotomy, countable choice, detached completion, or ambient Real completeness because the accepted packet has no such coordinate. □

Falsifiable prediction: Every accepted $\mathsf{ArchimedeanCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ handoff while omitting the dyadic ordered-field source, Archimedean cofinality row, regular-Cauchy readback, dyadic tolerance ledger, order-density comparison, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: dyadicratcore, regseqrat, real, bishop-order-completion, cauchy-completeness-witness: no listed sibling supplies the whole $\mathsf{ArchimedeanCompletion}^{\uparrow}$ packet, because each sibling contributes only dyadic arithmetic, regular readback, Real sealing, order comparison, or completion witnessing while this chapter binds all of them with cofinality, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanCompletion}^{\uparrow}$ packet is generated from a dyadic ordered-field source row, an Archimedean cofinality row, RegSeqRat readback, a DyadicRatCore tolerance ledger, a BishopOrderCompletion order-density comparison row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3619.1, Definition 3619.2, and Definition 3619.3 seed the finite Archimedean completion route from dyadic ordered-field source data through regular-Cauchy readback, order-density comparison, Real sealing, transport, replay, provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanCompletion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ArchimedeanCompletionUp.TasteGate.ArchimedeanCompletionTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected host limits, trichotomy, countable choice, detached order completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinality routing, regular-Cauchy readback, dyadic ledger exactness, order-density comparison, Real handoff factorization, transport, replay, provenance, and local naming for BEDC.Derived.ArchimedeanCompletionUp.

Chapter 3620

A Concrete Naming Certificate for $\mathsf{RieszSpace}^{\uparrow}$

Following Riesz and Kantorovich, the $\mathsf{RieszSpace}^{\uparrow}$ packet records the finite BEDC naming surface for a real vector lattice with a displayed positive cone and norm-facing compatibility rows. It sits over the algebraic vector-space carrier of chapter 47, the join-meet order rows of chapter 55, the norm comparison surface of chapter 89, the positive scalar endpoint discipline of chapter 1587, and the real scalar seal of chapter 38. The packet names the BEDC-facing ordered-functional-analysis object; it is not a host order primitive, a supremum completion theorem, a Banach-lattice completeness claim, or a choice of lattice decompositions outside the displayed finite ledger.

Definition 3620.1 (RieszSpace carrier)**.** *A* $\mathsf{RieszSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (V, L, N, P, H, C, S)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row naming the carried vector endpoint, real scalar endpoint, zero vector, addition, additive inverse, scalar action, and finite vector-space law ledger.*
2. *L is the lattice row, recording join and meet operations on the same vector endpoint, the induced order-comparison rows, and the finite absorption, commutativity, associativity, and distributivity witnesses used by the local classifier.*
3. *N is the norm or seminorm compatibility row, read through* $\mathsf{Norm}^{\uparrow}$*, saying that the displayed norm endpoint respects the vector rows and the lattice decomposition rows already carried by V and L.*
4. *P is the positive-cone decomposition row, read through* $\mathsf{PositiveReal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, recording positive and negative part formation, cone membership, scalar positivity, and the local identity route tying a vector to the difference of its displayed positive pieces.*
5. *H records componentwise* hsame *transport for the vector-space rows, lattice join and meet rows, norm or seminorm rows, positive-cone rows, replay row, provenance row, and local naming row.*
6. *C records displayed* Cont *replay from a Riesz-space request through V, L, N, P, H back to the same finite ordered vector-lattice surface.*
7. *S is the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{RieszSpace}^{\uparrow}}$ *row over* $\mathsf{RieszSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

The classifier compares accepted packets only through V, L, N, P, H, C, S. It has no coordinate for an ambient order relation, a host supremum construction, a selected order completion, Banach-lattice completeness, pointwise function models, or a quotient by order ideals.

Lean4 ✓ `BEDC.Derived.RieszSpaceUp.RieszSpaceUpTasteGate single carrier alignment`

Theorem 3620.2 (RieszSpace NameCert obligations)**.** *For every accepted* $\mathsf{RieszSpace}^{\uparrow}$ *carrier* $R = (V, L, N, P, H, C, S)$*, the local* $\mathsf{NameCert}_{\mathsf{RieszSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, vector-space row compatibility, lattice join and meet exactness, norm or seminorm compatibility, positive-cone decomposition, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A downstream consumer may read the common vector endpoint, the real scalar endpoint, the join and meet operations, the norm-facing comparison row, and the positive-cone ledger, but it receives no host order primitive, no chosen order completion, no Banach-lattice completeness theorem, and no pointwise function representation.*

Proof. Carrier admission is projection from Definition 3620.1. The packet displays exactly the vector-space row V, the lattice row L, the norm or seminorm compatibility row N, the positive-cone decomposition row P, and the structural rows H, C, S.

The vector-space obligations are inherited from the carried $\mathsf{VecSpace}^{\uparrow}$ row, while the lattice obligations are read only through the displayed join and meet ledger. Thus the same vector endpoint is the domain of addition, scalar multiplication, join, meet, and order comparison.

The norm-facing and positive-cone obligations are finite rows. The row N records compatibility with the vector and lattice decompositions, and P records positive and negative part formation using the $\mathsf{PositiveReal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ scalar seals.

Finally H, C, S transport, replay, source, and locally certify only the displayed coordinates. Since the carrier has no ambient order coordinate, no completion selector, no Banach-lattice completeness row, and no pointwise function model, none of those objects can be exported by the local certificate. □

Theorem 3620.3 (RieszSpace lattice-norm compatibility)**.** *If two accepted* $\mathsf{RieszSpace}^{\uparrow}$ *packets are related by the classifier, then their vector-space rows, lattice join and meet rows, norm or seminorm compatibility rows, and positive-cone decomposition rows are related by the componentwise* hsame *transport recorded in H. Consequently every downstream norm-facing or order-facing read factors through the displayed vector-lattice ledger and never through a host order equality or a hidden normed-lattice quotient.*

Proof. Unfold the classifier of Definition 3620.1. Its comparison coordinates are exactly the vector-space row, lattice join and meet row, norm or seminorm compatibility row, positive-cone row, replay row, provenance row, and local naming row.

The vector component transports through the $\mathsf{VecSpace}^{\uparrow}$ comparison, and the lattice component transports through the displayed join and meet comparisons. The norm or seminorm row then moves along the same transported vector and lattice data.

The positive-cone row is carried componentwise as well: positive part, negative part, cone membership, scalar positivity, and reconstruction of the original vector all remain inside the visible ledger. Hence every norm-facing or order-facing consumer reads a transported finite certificate, not a host order equality or a hidden quotient construction. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RieszSpace}^{\uparrow}$ packet is generated from vector-space rows, lattice join and meet rows, norm or seminorm compatibility rows, positive-cone decomposition data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RieszSpace}\uparrow}$, seed)

Scope closed: Definition 3620.1, Definition 3620.2, and Definition 3620.3 seed the finite ordered vector-lattice certificate over VecSpaceUp, LatticeUp, NormUp, PositiveRealUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RieszSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host order primitives, supremum completion, Banach-lattice completeness, pointwise function representation, quotient by order ideals, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, vector-space compatibility, lattice join and meet exactness, norm or seminorm compatibility, positive-cone decomposition, transport, replay, provenance, and local naming for BEDC.Derived.RieszSpaceUp.

Chapter 3621

A Concrete Naming Certificate for ArzelaAscoliFiniteWindowDiagonalBridge$^{\uparrow}$

Following Arzela and Ascoli, the ArzelaAscoliFiniteWindowDiagonalBridge$^{\uparrow}$ packet names the finite-window bridge between the diagonal extraction surface of chapter 2219 and the compact family interface of chapter 412. It consumes the equicontinuity ledger of chapter 413, the compact source rows of chapter 129, the target completion rows of chapter 128, the finite window names of chapter 126, the rational readback rows of chapter 301, and the pointwise seal of chapter 38. The chapter records a finite BEDC NameCert bridge; it does not assert an ambient compact-open topology, a host sequence-space compactness theorem, or a choice-selected subsequence.

Definition 3621.1 (Arzela-Ascoli finite-window diagonal bridge)**.** *An* ArzelaAscoliFiniteWindowDiagonalBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, E, Y, D, W, R, S, H, C, P, N)$$

with the following visible rows:

1. *K records the compact source net rows read from* CompactMetric$^{\uparrow}$*, including the finite probe windows and coverage witnesses consumed by the diagonal route;*
2. *E records the* EquicontinuityFamily$^{\uparrow}$ *ledger that binds every requested target tolerance to a displayed source-radius row uniformly over the family ledger;*
3. *Y records the* CompleteMetric$^{\uparrow}$ *target surface through which finite-window target reads are sealed;*
4. *D records the accepted* AscoliDiagonal$^{\uparrow}$ *carrier whose diagonal extraction rows are being exposed to the Arzela-Ascoli consumer;*
5. *W records the finite diagonal* StreamName$^{\uparrow}$ *windows, with each window naming the source-net points, family indices, and target reads currently inspected;*
6. *R records* RegSeqRat$^{\uparrow}$ *readback rows for the rational tolerances and target-distance witnesses visible on W;*
7. *S records the* Real$^{\uparrow}$ *seal that repacks each finite readback into the target-side pointwise boundary;*
8. *H records componentwise* hsame *transport for K, E, Y, D, W, R, S and the structural rows;*
9. *C records displayed* Cont *replay through AscoliDiagonal, EquicontinuityFamily, CompactMetric, CompleteMetric, StreamName, RegSeqRat, Real, and local NameCert reads;*

10. *P is the* Pkg *provenance over* ArzelaAscoliFiniteWindowDiagonalBridge$^{\uparrow}$, AscoliDiagonal$^{\uparrow}$, ArzelaAscoli$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompleteMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* NameCert$_{\text{ArzelaAscoliFiniteWindowDiagonalBridge}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite-window diagonal bridge data. It has no coordinate for an unbounded subsequence selector, an ambient compact-open topology, or an open-cover compactness principle.

Lean4 ✓ `BEDC.Derived.ArzelaAscoliFiniteWindowDiagonalBridgeUp.ArzelaAscoliFiniteWindowDiagonalBridgeTas`
`single carrier alignment`

Theorem 3621.2 (Finite-window diagonal bridge route)**.** *Every bridge read from an accepted* ArzelaAscoliFiniteWindowDiagonalBridge$^{\uparrow}$ *carrier factors through the finite route*

$$\text{AscoliDiagonal}^{\uparrow} \longrightarrow (\text{EquicontinuityFamily}^{\uparrow}, \text{CompactMetric}^{\uparrow}) \longrightarrow \text{CompleteMetric}^{\uparrow} \longrightarrow \text{StreamName}^{\uparrow} \longrightarrow \text{RegSeqRa}$$

The route first reads the accepted AscoliDiagonal carrier, then the compact source nets and equicontinuity ledger, then the complete target surface, then the finite diagonal StreamName windows, then RegSeqRat readback and the Real seal. The exported surface is a finite NameCert bridge and no choice-selected subsequence or host function-space compactness object.

Proof. Let $B = (K, E, Y, D, W, R, S, H, C, P, N)$ be an accepted carrier. Project D first. Its accepted AscoliDiagonal$^{\uparrow}$ row fixes the diagonal extraction surface before any Arzela-Ascoli consumer can inspect a target read.

Next project K and E. The compact source row supplies finite net windows, and the equicontinuity-family row supplies the shared tolerance-to-radius ledger used by those windows.

Project Y to read the complete-metric target boundary. The bridge can then inspect only the finite StreamName$^{\uparrow}$ windows recorded in W, so each target read is tied to displayed source-net points and displayed family indices.

The readback row R records the corresponding RegSeqRat$^{\uparrow}$ tolerance and distance data, and the seal row S repacks the finite readback as the visible Real$^{\uparrow}$ boundary. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve exactly those rows.

Since the carrier contains no unbounded subsequence selector, no ambient compact-open topology, and no host function-space compactness coordinate, every bridge read factors through the displayed finite route and exports nothing beyond it. □

Closure status for NameCert$_{\text{ArzelaAscoliFiniteWindowDiagonalBridge}^{\uparrow}}$ **.**

Constructive story: An ArzelaAscoliFiniteWindowDiagonalBridge$^{\uparrow}$ packet is generated from an accepted AscoliDiagonal carrier, compact source-net rows, equicontinuity-family rows, complete-metric target rows, finite StreamName diagonal windows, RegSeqRat readback rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ArzelaAscoliFiniteWindowDiagonalBridge}^{\uparrow}}$, seed)

Scope closed: Definition 3621.1 and Definition 3621.2 seed the finite-window diagonal bridge from AscoliDiagonal data to the Arzela-Ascoli compact family interface.

Formal verification: FormalStatus(NameCert$_{\text{ArzelaAscoliFiniteWindowDiagonalBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a choice-selected subsequence, ambient compact-open topology, open-cover compactness, host sequence-space compactness, or a standard bridge.

Upgrade path: Obligation closure requires Lean carrier admission, classifier transport, finite-window route extraction, readback sealing, and non-escape rows for BEDC.Derived.ArzelaAscoliFiniteWindowDiagonalBridgeUp.

Chapter 3622

A Concrete Naming Certificate for $\mathsf{BishopCauchySequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchySequence}^{\uparrow}$ packet records the textbook sequence-level Cauchy surface that mediates between regular rational names and the sealed Real object. It sits after the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational name packet of chapter 301, and the uniqueness route of chapter 3390, while feeding the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a finite carrier for Cauchy sequence evidence; it does not assert quotient streams, selected limits, countable choice, or ambient Real completeness.

Definition 3622.1 (Bishop Cauchy sequence carrier)**.** *A* $\mathsf{BishopCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, D, X, U, R, H, C, P, N)$$

with the following visible rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposing the requested rational sequence entries;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, comparison budget, and rational-distance rows used by the Cauchy test;*
3. *X is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row that certifies the sequence entries respect the displayed tolerance discipline;*
4. *U is the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *comparison row used only to compare accepted regular names at the same displayed tolerance surface;*
5. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, D, X, U have been displayed;*
6. *H stores componentwise* hsame *transport for the stream window, dyadic ledger, regularity row, uniqueness comparison, seal row, continuation route, package row, and local naming row;*
7. *C records displayed* Cont *replay of the route*

$$S, D \longmapsto X \longmapsto U \longmapsto R;$$

8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $S, D, X, U, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, ambient Real completeness, or a host equality oracle for Real values.

Lean4 ✓ `BEDC.Derived.BishopCauchySequenceUp.BishopCauchySequenceUpTasteGate single carrier alignment`

Theorem 3622.2 (Bishop Cauchy sequence NameCert obligations)**.** *For an accepted* $\mathsf{BishopCauchySequence}^{\uparrow}$ *carrier*

$$B = (S, D, X, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchySequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row,* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *comparison row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier stability under the same displayed rows; tolerance exactness through D; regularity handoff through X; uniqueness comparison through U; and Real-seal boundary control through R.*

Proof. Carrier admission is projection from Definition 3622.1. The projection exposes exactly the stream window, dyadic tolerance ledger, regular rational sequence evidence, uniqueness comparison, Real seal, and structural rows.

Classifier stability follows row by row because the classifier has no coordinate beyond $S, D, X, U, R, H, C, P, N$. Tolerance exactness is the projection of D, and regularity handoff is the projection of X with the same displayed tolerance row.

The uniqueness row U compares only accepted regular names at the displayed surface. The Real seal row R is downstream from S, D, X, U, so no consumer can read a sealed Real object without first passing through the finite Bishop Cauchy sequence packet. □

Theorem 3622.3 (Bishop Cauchy sequence regularity handoff)**.** *Every accepted* $\mathsf{BishopCauchySequence}^{\uparrow}$ *packet hands its stream-window and tolerance data to a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row before the uniqueness comparison or Real seal is available. The handoff route is the finite chain*

$$S, D \longmapsto X \longmapsto U \longmapsto R,$$

preserved by H, C, P, N and not by quotient stream equality, a selected limiting object, countable choice, or an ambient completeness theorem.

Proof. Project the carrier and read the continuation route C. The route opens the finite stream window S and dyadic tolerance ledger D before the regularity row X.

The comparison row U is downstream from the regularity row. Since U is a $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ row, it compares accepted regular names through the displayed sequence and tolerance data rather than through a quotient stream.

The Real seal row R occurs at the end of the displayed route. The transport, provenance, and naming rows preserve that order, while no carrier coordinate supplies a selected limit, countable-choice principle, or ambient completeness argument. □

Theorem 3622.4 (Bishop Cauchy sequence Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{BishopCauchySequence}^{\uparrow}$ *packet factors through the finite rows S, D, X, U before it reaches the seal row R. The packet therefore exposes a sequence-level route from rational windows and dyadic tolerances to the Real seal, while withholding quotient streams, selected limits, countable choice, and ambient Real completeness.*

Proof. Start from a Real-facing read and project the carrier. The only seal row is R, and the continuation route places it after the stream window, tolerance ledger, regularity row, and uniqueness comparison.

Use Definition 3622.3 to bind the regularity row to the same stream and dyadic tolerance data. Then use the uniqueness row U only as a displayed comparison between accepted regular names.

The coordinate list of Definition 3622.1 exhausts the packet. Since it contains no quotient stream, selected limit, countable choice, or ambient-completeness coordinate, no consumer can derive such data from the Real seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchySequence}^{\uparrow}$ packet is generated from finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat regularity evidence, a RegularCauchyUniqueness comparison row, a Real seal, transport data, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3622.1, Definition 3622.2, Definition 3622.3, and Definition 3622.4 name the L10 sequence-level carrier between regular rational streams and the Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, ambient Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, tolerance exactness, regularity handoff, uniqueness comparison, and Real-seal boundary rows for the displayed Bishop Cauchy sequence packet.

Chapter 3623

A Concrete Naming Certificate for $\mathsf{MeirKeelerContraction}^{\uparrow}$

Following Meir and Keeler's fixed point theorem and Bishop–Bridges constructive metric analysis, the $\mathsf{MeirKeelerContraction}^{\uparrow}$ packet records the finite epsilon-to-delta contraction ledger that sits between ordinary contraction data and completion-facing fixed-point consumers. It reads the metric carrier of chapter 57, the fixed-point route of chapter 3607, the iteration ledger of chapter 2383, the endpoint-admission surface of chapter 128, and the Banach fixed-point packet of chapter 396. It also sits beside the Lipschitz and nonexpansive surfaces of chapter 410, chapter 2328, and chapter 2105, while refusing to replace the Meir–Keeler ledger by a single host Lipschitz constant.

Definition 3623.1 (Meir–Keeler contraction carrier)**.** *A* $\mathsf{MeirKeelerContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, d, T, E, I, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted* $\mathsf{Met}^{\uparrow}$ *carrier row for the source points.*
2. *d is the metric-distance readback row used by all comparison requests.*
3. *T is the self-map graph row for the candidate contraction.*
4. *E is the Meir–Keeler epsilon-to-delta contraction ledger: for each displayed positive tolerance request it stores a displayed response window forcing a strictly smaller image distance whenever the source distance lies in the named annulus.*
5. *I is the fixed-point iteration row, recording the finite Picard-style orbit segments and adjacent comparison reads used by downstream consumers.*
6. *L is the Cauchy handoff ledger, listing the finite tail requests that the Meir–Keeler row transfers to the complete-metric endpoint surface.*
7. *H records componentwise* hsame *transport for metric rows, distance reads, self-map graph rows, epsilon-to-delta ledger rows, iteration rows, Cauchy handoff rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a contraction request through $X, d, T, E, I, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MeirKeelerContraction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContractionPrinciple}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MeirKeelerContraction}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $X, d, T, E, I, L, H, C, P, N$. It has no coordinate for a global Lipschitz constant, a selected endpoint, quotient completion equality, host function extensionality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MeirKeelerContractionUp.MeirKeelerContractionTasteGate single carrier alignment`

Theorem 3623.2 (Meir–Keeler contraction NameCert obligations)**.** *For an accepted* $\mathsf{MeirKeelerContraction}^{\uparrow}$ *carrier $M = (X, d, T, E, I, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MeirKeelerContraction}^{\uparrow}}$ *surface consists exactly of metric-carrier admission, distance-readback visibility, self-map graph admission, epsilon-to-delta ledger exactness, fixed-point iteration visibility, Cauchy handoff visibility, componentwise transport, displayed replay, provenance, and local naming. These obligations bind the Meir–Keeler route without adding a global contraction constant, endpoint selection, quotient completion equality, host fixed-point equality, countable choice, or ambient completeness.*

Proof. Project the carrier of Definition 3623.1. The displayed rows $X, d, T, E, I, L, H, C, P, N$ are the whole local surface, so every obligation must be one of their admissions, transports, or replay checks.

The contraction content is carried by T and E. The self-map row fixes the map being iterated, while the epsilon-to-delta row supplies the strict Meir–Keeler comparison at each displayed tolerance window. No single Lipschitz bound is extracted from this row.

The iteration and completion-facing content is carried by I and L. These rows expose finite orbit segments and finite tail requests before any complete-metric endpoint can be consumed by another chapter.

Finally H, C, P, N keep the same rows stable under classifier transport, replay, provenance, and local naming. Since the excluded host objects are not carrier coordinates, the NameCert surface cannot export them. □

Theorem 3623.3 (Meir–Keeler contraction Cauchy handoff)**.** *Every fixed-point or completion-facing read of an accepted* $\mathsf{MeirKeelerContraction}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow},\ d,\ T,\ E,\ \mathsf{FixedPointIteration}^{\uparrow},\ L,\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The read uses the Meir–Keeler epsilon-to-delta ledger to feed finite iteration-tail requests into the complete-metric endpoint surface. It never exposes a selected limit, a quotient representative, a host global Lipschitz constant, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the metric and map rows. A consumer first reads X, d, T, so the source carrier, comparison relation, and self-map graph are fixed before the Meir–Keeler ledger is inspected.

Next consume E. The epsilon-to-delta ledger answers each displayed tolerance request by a finite annulus response, which is the contraction data available to the iteration route. This is weaker than a global Lipschitz constant but strong enough for the displayed tail comparisons.

Then read I and L. The iteration row supplies the finite orbit comparisons, and the Cauchy handoff row packages the resulting tail requests for the $\mathsf{CompleteMetric}^{\uparrow}$ endpoint surface.

The structural rows H, C, P, N transport and replay the same route. Because no endpoint selector, quotient equality, host Lipschitz constant, or ambient completeness row occurs in the carrier, every downstream read remains inside the finite handoff just described. □

Falsifiable prediction: Every accepted $\mathsf{MeirKeelerContraction}^{\uparrow}$ read factors through one MetricUp carrier row, one distance readback row, one self-map row, one Meir–Keeler epsilon-to-delta ledger, one fixed-point iteration row, one Cauchy handoff ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any completion-facing fixed-point consumer can read it.

Independence witness: metric, contraction-principle, fixed-point-iteration, completemetric, banach-fixed-point, lipschitzmap, regular-cauchy-nonexpansive-map: none is bijective with $\mathsf{MeirKeelerContraction}^{\uparrow}$ because the packet jointly stores the metric carrier, self-map graph, epsilon-to-delta contraction ledger, finite iteration route, Cauchy handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MeirKeelerContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{MeirKeelerContraction}^{\uparrow}$ packet is generated from a MetricUp carrier, distance readback, self-map graph, Meir–Keeler epsilon-to-delta contraction ledger, fixed-point iteration row, Cauchy handoff ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MeirKeelerContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3623.1, Definition 3623.2, and Definition 3623.3 seed the finite Meir–Keeler contraction packet and its completion-facing Cauchy handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MeirKeelerContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global Lipschitz constant, selected endpoint, quotient completion equality, host fixed-point equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, epsilon-to-delta ledger exactness, fixed-point iteration visibility, Cauchy handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.MeirKeelerContractionUp.

Chapter 3624

A Concrete Naming Certificate for $\mathsf{IntervalHalvingModulus}^{\uparrow}$

Beginning from Bishop–Bridges constructive interval bisection, the $\mathsf{IntervalHalvingModulus}^{\uparrow}$ packet records the finite halving schedule used by L10 interval and Cauchy constructions before any completed point or ambient real-completeness principle is exposed. It consumes the located interval surface of chapter 1709, the dyadic tolerance ladder of chapter 3525, the finite observation windows of chapter 126, the regular located-rational modulus route of chapter 3532, the dyadic arithmetic core of chapter 291, and the terminal real-name boundary of chapter 38. The packet gives bisection, nested-interval, and regular-Cauchy extraction chapters a shared finite modulus object rather than a compactness or choice principle.

Definition 3624.1 (Interval halving modulus carrier)**.** *An* $\mathsf{IntervalHalvingModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, L, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row. It records the inspected interval window, endpoint location data, inclusion rows, and nonempty finite evidence visible to a halving consumer.*
2. *L is the* $\mathsf{DyadicToleranceLadder}^{\uparrow}$ *row. It records the finite tolerance requests and the displayed halving relation between successive dyadic scales.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names the finite interval, endpoint, midpoint, and tolerance observations that may be opened by the route.*
4. *R is the* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ *handoff row. It records the located-rational regular Cauchy modulus extracted from scheduled interval halves and tolerance requests.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for midpoint formation, endpoint comparison, diameter comparison, and dyadic tolerance readback.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after I, L, S, R, D have displayed the finite halving route.*
7. *H records componentwise* hsame *transport for interval windows, tolerance ladders, stream schedules, located-modulus handoffs, dyadic ledgers, real seals, replay rows, provenance, and local naming.*

8. *C records displayed* Cont *replay from an interval-halving request through I, L, S, R, D, E and then through the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{IntervalHalvingModulus}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicToleranceLadder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalHalvingModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten displayed rows. It has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, a selected limit, countable choice, trichotomy, quotient interval equality, host interval equality, or bridge checking.*

Lean4 ✓ `BEDC.Derived.IntervalHalvingModulusUp.TasteGate.IntervalHalvingModulusTasteGate single carrier alignment`

Theorem 3624.2 (Interval halving modulus NameCert obligations)**.** *For every accepted* $\mathsf{IntervalHalvingModulus}^{\uparrow}$ *carrier*

$$M = (I, L, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalHalvingModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, dyadic tolerance ladder L, finite stream schedule S, regular located-rational modulus handoff R, dyadic arithmetic ledger D, real-seal boundary E, componentwise transport H, continuation replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3624.1. The projection exposes one finite interval row, one dyadic tolerance ladder, one stream schedule, one located-rational modulus handoff, one dyadic arithmetic ledger, one real-seal boundary, and the structural rows.

The interval and tolerance obligations are I and L. The finite schedule S states which interval endpoints, midpoints, and tolerance requests are opened, while D supplies the arithmetic comparisons needed by those observations.

The handoff row R is downstream from the displayed interval, ladder, schedule, and dyadic rows. It exports only the regular located-rational modulus read from those finite observations.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no extra coordinate for completeness, selected limits, countable choice, trichotomy, quotient interval equality, or host interval equality, the displayed rows exhaust the NameCert obligations. □

Theorem 3624.3 (Interval halving modulus ladder handoff)**.** *Let $M = (I, L, S, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{IntervalHalvingModulus}^{\uparrow}$ *carrier. Every bisection, nested-interval, or regular-Cauchy consumer of M factors through the finite route*

$$I, L \longmapsto S, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the consumer receives a displayed halving modulus and located-rational Cauchy handoff before any $\mathsf{Real}^{\uparrow}$ *seal can be read.*

Proof. Start with the located interval row I and the dyadic tolerance ladder L. They provide the only interval window and halving-scale data available to the consumer.

The schedule row S selects the finite observations to open, and the dyadic ledger D checks midpoint formation, endpoint order, diameter bounds, and tolerance comparisons for those observations.

The row R repacks exactly this scheduled data as the regular located-rational modulus. The real-facing row E is therefore downstream from the finite halving route rather than an external source of completeness.

The rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Hence bisection, nested-interval, and regular-Cauchy consumers cannot leave the finite ladder handoff without leaving the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalHalvingModulus}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalHalvingModulus}^{\uparrow}$ packet is generated from located interval rows, dyadic tolerance ladders, StreamName schedules, regular located-rational modulus handoffs, dyadic arithmetic ledgers, Real seal boundaries, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalHalvingModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3624.1, Definition 3624.2, and Definition 3624.3 seed the finite halving schedule used by interval bisection, nested interval, and regular-Cauchy extraction routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalHalvingModulus}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.IntervalHalvingModulusUp.TasteGate.IntervalHalvingModulusTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter refuses $\mathsf{Real}^{\uparrow}$ completeness, selected limits, countable choice, trichotomy, quotient interval equality, host interval equality, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval exposure, tolerance-ladder exactness, schedule compatibility, dyadic midpoint and diameter exactness, regular located-rational modulus handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.IntervalHalvingModulusUp.

Chapter 3625

A Concrete Naming Certificate for $\mathsf{PostMedianGateShell}^{\uparrow}$

The $\mathsf{PostMedianGateShell}^{\uparrow}$ packet realizes the post-median gate-shell object of Definition 9462.1490 as finite BEDC NameCert data. It reads the six-boundary-tile vision through codon-shell rows, Boolean-coordinate rows, spectral-optimum rows, first-exit rows, transport, replay, provenance, and local naming. The packet is a science-facing finite certificate: it does not treat the observed shell as a universal genetic-code law, an unbounded evolutionary optimizer, or an oracle for unseen codon tables.

Falsifiable prediction: Every accepted $\mathsf{PostMedianGateShell}^{\uparrow}$ read must display the six shell rows CAR, CCR, GUR, the median gate M, the first-exit target layer, and the retained CUR exit-closing row before any spectral-optimum claim is exported.

Independence witness: six-boundary-tile-coverage, window-coverage-trigger-algebra, punctured-cube-skeleton, wrr-state-phase-space, median-closure-structure: six-boundary-tile coverage names the codon-window partition, window-coverage trigger algebra names activation gates, the punctured-cube skeleton names cube geometry, WRR state phase space names replay states, and median closure structure names the median set. None is bijective to $\mathsf{PostMedianGateShell}^{\uparrow}$ because this packet binds post-median shell rows, Boolean coordinates, first-exit rows, spectral optimality, transport, replay, provenance, and local naming in one accepted surface.

The shell route consumes the finite boundary-tile coverage row of chapter 3470 and the trigger-algebra row of chapter 3478 before the median gate and first-exit rows are read. These sibling rows provide the boundary support and activation surface; the present packet adds the post-median shell ledger, spectral row, first-exit row, transport, replay, provenance, and local naming.

Definition 3625.1 (Post-median gate shell carrier)**.** *A* $\mathsf{PostMedianGateShell}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, B, S, F, T, C, P, N)$$

with the following displayed rows:

1. *K is the codon-shell row. It records the median gate M, the shell rows* CAR*,* CCR*,* GUR*, the retained* CUR *exit-closing row, and the finite read request.*
2. *B is the Boolean-coordinate row. It records the six-boundary tile coordinates used to read the shell as a finite yes-or-no window rather than as a host-level biological assertion.*
3. *S is the spectral-optimum row. It records the killed-walk Perron-root comparison for the displayed shell rows and refuses to export an optimizer outside the finite comparison table.*

4. *F is the first-exit row. It records that* CAR, CCR, *and* GUR *are read as the top first-exit target layer after the median gate.*
5. *T records componentwise* hsame *transport for codon-shell rows, Boolean coordinates, spectral rows, first-exit rows, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from the post-median gate-shell request through K, B, S, F, T, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{PostMedianGateShell}^{\uparrow}$*, the six-boundary-tile coverage, the window-coverage trigger algebra, the punctured-cube skeleton, the WRR state phase space, the median closure structure,* BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PostMedianGateShell}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eight rows. It has no coordinate for arbitrary codon-table optimality, global evolutionary selection, unseen-window extrapolation, host biochemical causality, or bridge checking.

Lean4 ✓ `BEDC.Derived.PostMedianGateShellUp.PostMedianGateShellTasteGate single carrier alignment`

Theorem 3625.2 (Post-median gate shell NameCert obligations)**.** *For every accepted* $\mathsf{PostMedianGateShell}^{\uparrow}$ *carrier*

$$G = (K, B, S, F, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PostMedianGateShell}^{\uparrow}}$ *surface consists exactly of carrier admission for the codon-shell row K, Boolean-coordinate row B, spectral-optimum row S, first-exit row F, componentwise transport T, continuation replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3625.1. The projection exposes one finite codon-shell row, one Boolean-coordinate row, one spectral row, one first-exit row, and the structural rows.

The codon and coordinate obligations are K and B. They force every read to display the six shell rows and the finite boundary-tile coordinates before the shell can be compared spectrally.

The spectral and first-exit obligations are S and F. The spectral row is tied to the displayed finite comparison table, while the first-exit row ties CAR, CCR, and GUR to the post-median target layer.

Finally T, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for arbitrary codon-table optimality, global evolutionary selection, unseen-window extrapolation, or host biochemical causality, the displayed rows exhaust the NameCert obligations. □

Theorem 3625.3 (Post-median gate shell accepted-read frontier)**.** *Every accepted read of a* $\mathsf{PostMedianGateShell}^{\uparrow}$ *packet factors through*

$$K, B \longmapsto S, F \longmapsto T, C, P, N.$$

Thus a consumer may export the post-median shell only after the six shell rows, Boolean-coordinate window, finite spectral comparison, and first-exit target layer have all been displayed.

Proof. Begin with the shell row K and Boolean-coordinate row B. These rows display the median gate, CAR, CCR, GUR, CUR, and the finite six-boundary coordinates available to the read.

The spectral row S then records the finite Perron-root comparison for that displayed shell. The first-exit row F records the route from the median gate to the top target layer, so the consumer cannot replace the shell by an unrelated codon orbit.

The rows T, C, P, N preserve the same finite surface under transport, replay, provenance, and local naming. Any read that claims an unbounded optimizer, unseen-window extrapolation, global evolutionary selection, or host biochemical causality leaves the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PostMedianGateShell}^{\uparrow}}$.

Constructive story: A $\mathsf{PostMedianGateShell}^{\uparrow}$ packet is generated from finite codon-shell rows, Boolean-coordinate rows, spectral-optimum rows, first-exit rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PostMedianGateShell}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3625.1, Definition 3625.2, and Definition 3625.3 seed the finite post-median shell certificate over displayed codon, Boolean-coordinate, spectral, and first-exit rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PostMedianGateShell}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary codon-table optimality, global evolutionary selection, unseen-window extrapolation, host biochemical causality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, six-row shell exposure, Boolean-coordinate exactness, spectral-optimum exactness, first-exit exactness, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.PostMedianGateShellUp.TasteGate.

Chapter 3626

A Concrete Naming Certificate for MetaCICDependentCodomainStabilityBoundary$^{\uparrow}$

The MetaCICDependentCodomainStabilityBoundary$^{\uparrow}$ packet realizes the dependent-codomain barrier of subsection 9386.7.1 as finite NameCert data. It reads the inversion boundary of chapter 781, the closure-preservation packet of chapter 804, the subject-reduction boundary of chapter 721, and the closed-normal consistency boundary of chapter 733. The packet names the stability row required before a dependent-codomain application branch can be routed to subject reduction; it does not assert unconditional subject reduction.

Definition 3626.1 (MetaCIC dependent-codomain stability boundary carrier)**.** *A* MetaCICDependentCodomainSta *carrier is a finite* BHist *packet*

$$S = (A, D, R, I, V, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the application-argument reduction row whose codomain may observe the reducing argument.*
2. *D is the dependent-codomain readback row, displaying the pre-step and post-step codomain observations.*
3. *R is the subject-reduction discharge request row that asks for the application branch of the MetaCIC interface.*
4. *I is the dependent-codomain inversion-boundary row.*
5. *V is the closure-preservation transport row available before typing preservation is requested.*
6. *Q is the obstruction row recording that subject reduction is unavailable unless the dependent-codomain stability row is supplied.*
7. *L is the stability ledger: it records the exact row that a later bundle witness must fill to make the dependent codomain readback stable under the application-argument step.*
8. *H records componentwise* hsame *transport for application, codomain readback, discharge request, inversion, closure-preservation, obstruction, stability-ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the MetaCIC open-problem boundary through $A, D, R, I, V, Q, L, H, P, N$.*

10. *P is the* Pkg *provenance over* MetaCICDependentCodomainStabilityBoundary$^{\uparrow}$, DependentCodomainInversionBoun DependentCodomainClosurePreservation$^{\uparrow}$, MetaCICSubjectReductionBoundaryUp, ClosedNormalConsistencyBound SubjectReductionDischargeBundle, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, D, R, I, V, Q, L, H, C, P, N$. It has no coordinate for unconditional subject reduction, conversion completeness, closed consistency, ambient normalization, or a hidden discharge witness.

Theorem 3626.2 (MetaCIC dependent-codomain stability boundary obligations)**.** *For an accepted* MetaCICDependentCodomainStabilityBoundary$^{\uparrow}$ *carrier $S = (A, D, R, I, V, Q, L, H, C, P, N)$, the local* NameCert$_{\text{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}}$ *surface consists exactly of application-argument reduction admission, dependent-codomain readback visibility, subject-reduction discharge-request visibility, inversion-boundary routing, closure-preservation transport, obstruction recording, stability-ledger exactness, componentwise transport, displayed replay, provenance, and local naming. A downstream Lean follow-up must supply the corresponding 'Nontrivial' and 'FieldFaithful' instances before this boundary can be consumed as a checked discharge row.*

Lean4 ✓ `BEDC.Derived.MetaCICDependentCodomainStabilityBoundaryUp.TasteGate.MetaCICDependentCodomainStab`
`single carrier alignment`

Proof. Project the carrier. The rows $A, D, R, I, V, Q, L, H, C, P, N$ are the only displayed coordinates, so the local NameCert obligations are their admission, compatibility, and replay checks.

The codomain-sensitive part is A, D, R. These rows record that the reduction branch is an application-argument branch and that the codomain readback can observe the reducing argument before the subject-reduction request is made.

The boundary part is I, V, Q, L. The inversion row and closure-preservation row provide the available finite data, the obstruction row records why they are insufficient by themselves, and the stability ledger names the missing row rather than discharging it.

Finally H, C, P, N transport, replay, source, and name the same finite packet. The required Lean 'Nontrivial' and 'FieldFaithful' instances belong to the later bundle witness because no hidden instance coordinate occurs in this carrier. □

Theorem 3626.3 (MetaCIC dependent-codomain stability handoff)**.** *Every subject-reduction-facing read of an accepted* MetaCICDependentCodomainStabilityBoundary$^{\uparrow}$ *carrier factors through the finite route*

DependentCodomainInversionBoundary$^{\uparrow}$, DependentCodomainClosurePreservation$^{\uparrow}$, MetaCICSubjectReductionBound

The handoff exposes the stability ledger that a later bundle witness must fill. It does not turn the dependent-codomain application case into unconditional subject reduction and does not promote closed-normal consistency to full closed consistency.

Proof. Begin with A, D, R. The read is subject-reduction-facing only because it has first displayed the application-argument step, the dependent-codomain readback, and the discharge request.

Next consume I, V, Q. The inversion boundary and closure-preservation packet give the available codomain and closedness data, while the obstruction row records that this data does not yet type the post-step codomain.

The ledger L is then the only exported positive handoff. It names the dependent-codomain stability row that a later bundle witness must supply, including the instance obligations recorded in the carrier theorem.

Finally H, C, P, N replay the route without adding theorem strength. Thus a consumer receives a precise boundary packet and a setup-facing row, not an unconditional subject-reduction theorem. □

Theorem 3626.4 (AppArgTypeStable boundary row)**.** *For an accepted* MetaCICDependentCodomainStabilityBoun *carrier* $S = (A, D, R, I, V, Q, L, H, C, P, N)$*, the ledger row* L *is the AppArgTypeStable-facing boundary: any application-argument reduction read must display the pre-step and post-step codomain observations in* D *before it can feed the subject-reduction discharge request* R*.*

Proof. Project the rows A, D, R, L from the accepted carrier. The row A identifies the read as an application-argument reduction, while D displays the dependent codomain before and after that step.

Apply Definition 3626.3. The only positive row exported toward the subject-reduction request is L, and the handoff reaches it only after A, D, R have been displayed.

Thus L names the AppArgTypeStable-facing boundary for the later discharge witness. It records the required codomain-stability row without claiming unconditional subject reduction. □

Falsifiable prediction: Any $\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}$ packet lacking the dependent-codomain stability row L cannot discharge the application-argument branch of subject reduction through the displayed MetaCIC discharge interface.

Independence witness: dependentcodomaininversionboundary, dependentcodomainclosurepreservation, metacicsubjectreductionboundary, closed-normal-consistency-boundary, metacic-open-problems: none is bijective with $\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}$ because this packet jointly stores application-argument reduction, dependent codomain readback, discharge request, inversion boundary, closure-preservation transport, obstruction row, stability ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}$ packet is generated from application-argument reduction, dependent-codomain readback, subject-reduction discharge request, inversion-boundary, closure-preservation, obstruction, stability-ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3626.1, Definition 3626.2, and Definition 3626.3 seed the finite dependent-codomain stability boundary packet for MetaCIC subject-reduction consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unconditional subject reduction, conversion completeness, full closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked application-argument admission, dependent-codomain readback visibility, inversion-boundary routing, closure-preservation transport, obstruction recording, stability-ledger exactness, and the required witness instances for BEDC.Derived.MetaCICDependentCodomainStabilityBoundaryUp.

Chapter 3627

A Concrete Naming Certificate for $\mathsf{DyadicSandwich}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicSandwich}^{\uparrow}$ packet records the finite squeeze surface by which lower and upper dyadic rows trap a regular rational tail before a Real-facing consumer can read the seal. It sits over the dyadic tolerance core of chapter 291, the finite schedules of chapter 126, the regular rational readback route of chapter 301, the dyadic tail ball boundary of chapter 1633, and the terminal Real packet of chapter 38. The packet names the squeeze route as finite certificate data; it is not a quotient-real equality theorem, a selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 3627.1 (DyadicSandwich carrier)**.** *A* $\mathsf{DyadicSandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, U, S, D, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower dyadic row, listing the inspected lower endpoints and their finite-window order witnesses.*
2. *U is the upper dyadic row, listing the inspected upper endpoints and the matching containment witnesses.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing only the windows on which L and U are compared.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the dyadic radii, order comparisons, and residual budgets for the sandwich.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-tail row whose displayed values remain between the lower and upper dyadic rows at the scheduled windows.*
6. *H records componentwise* hsame *transport for lower rows, upper rows, schedules, dyadic ledgers, regular tails, replay rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from the dyadic lower and upper rows through the schedule, tolerance ledger, regular tail, and Real-facing handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicSandwich}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicTailBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicSandwich}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $L, U, S, D, R, H, C, P, N$. It has no coordinate for quotient equality of regular names, selected limits, trichotomy, countable choice, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 3627.2 (DyadicSandwich NameCert obligations)**.** *For every accepted* $\mathsf{DyadicSandwich}^{\uparrow}$ *carrier $Q = (L, U, S, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicSandwich}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the lower dyadic row, upper dyadic row, StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat regular-tail row, transport, replay, provenance, and local naming;*
2. *lower/upper order, requiring each displayed lower row to lie below the matching upper row through the dyadic comparison data in D;*
3. *tail containment, requiring the regular-tail values in R to remain inside the displayed dyadic interval at every window named by S;*
4. *classifier stability, requiring any accepted comparison of packets to transport $L, U, S, D, R, H, C, P, N$ componentwise and to preserve the displayed containment route;*
5. *squeeze handoff, requiring every* $\mathsf{DyadicTailBall}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer to read the schedule, dyadic ledger, and regular-tail row before the terminal seal is available;*
6. *provenance exhaustion, requiring all accepted reads to be sourced by P and locally named by N, with no hidden quotient, selected-limit, trichotomy, countable-choice, or ambient-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.DyadicSandwichUp.DyadicSandwichTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3627.1. The visible coordinates are exactly $L, U, S, D, R, H, C, P, N$, so carrier admission and provenance exhaustion are read from those rows.

The order and containment obligations are the two analytic faces of the same displayed dyadic ledger. The lower and upper rows are compared through D, while the regular-tail row R is inspected only at windows named by S.

Classifier stability follows componentwise through H and by replay through C. Since the replay route names the same lower row, upper row, schedule, dyadic ledger, and regular tail after transport, a classifier comparison cannot replace the sandwich with a quotient class or a selected limiting object.

Finally the consumer handoff is downstream of S, D, R. A $\mathsf{DyadicTailBall}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read therefore reaches the terminal boundary only after the finite squeeze rows have been displayed, and the carrier list supplies no trichotomy, countable-choice, or ambient-completeness datum. □

Theorem 3627.3 (DyadicSandwich regular Cauchy squeeze route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{DyadicSandwich}^{\uparrow}$ *packet factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicTailBall}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The route first reads the dyadic lower and upper endpoints with their tolerance ledger, then the finite schedule, then the regular-tail row, then the dyadic tail-ball boundary, and only then the Real seal. It exports no quotient equality, selected limit, trichotomy, countable-choice principle, or ambient completeness theorem.

Proof. Start from an accepted packet $Q = (L, U, S, D, R, H, C, P, N)$. The dyadic information is exhausted by L, U, D, so every lower/upper comparison and tolerance request is first reduced to the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

The schedule row S fixes the finite windows on which the squeeze is inspected. The regular-tail row R is attached to those windows, so a consumer cannot read a tail value outside the displayed schedule.

The dyadic tail-ball boundary is then obtained by replaying the same lower, upper, schedule, dyadic-ledger, and regular-tail rows through C and transporting them through H. The provenance row P and local naming row N package that route for the terminal $\mathsf{Real}^{\uparrow}$ read.

No remaining carrier coordinate can supply quotient equality, a selected limit, trichotomy, countable choice, or ambient completeness. Hence every Real-facing read factors through the displayed constructive squeeze route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicSandwich}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicSandwich}^{\uparrow}$ packet is generated from a lower dyadic row, an upper dyadic row, a finite StreamName schedule, a DyadicRatCore tolerance ledger, a RegSeqRat regular-tail row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicSandwich}^{\uparrow}}$, seed)

Scope closed: Definition 3627.1, Definition 3627.2, and Definition 3627.3 seed the constructive finite squeeze route from dyadic tail windows to Real-facing reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicSandwich}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower/upper order, tail containment, classifier stability, squeeze handoff, and provenance exhaustion for BEDC.Derived.DyadicSandwichUp.

Chapter 3628

A Concrete Naming Certificate for $\mathsf{CauchyCompletionRecursor}^{\uparrow}$

Following Bishop and Bridges on constructive completion and uniformly continuous extension, the $\mathsf{CauchyCompletionRecursor}^{\uparrow}$ packet records the elimination principle by which a completion-facing consumer reads a completed object only through a displayed dense source, a modulus-controlled map, an extension handoff, and a uniqueness row. It sits after the regular completion carrier of chapter 1639, the source admission row of chapter 1527, the uniformly continuous extension packet of chapter 769, and the terminal Real seal of chapter 38. The recursor is an elimination route for displayed completion data; it is not a selected limit, quotient stream, countable-choice principle, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 3628.1 (CauchyCompletionRecursor carrier)**.** *A* $\mathsf{CauchyCompletionRecursor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, f, m, E, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the dense source row, read through the Bishop regular Cauchy completion carrier and the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *source-admission route.*
2. *T is the completion target row, exposing only the completion-facing boundary consumed by the recursor.*
3. *f is the source map row, visible only on the displayed dense source S.*
4. *m is the uniform modulus row controlling the source map before any completion-facing read is admitted.*
5. *E is the extension handoff row supplied by the uniformly continuous extension route.*
6. *U is the uniqueness row, requiring any two admitted extension reads with the same source restriction and modulus ledger to agree through the displayed completion and Real seal rows.*
7. *H records componentwise* hsame *transport for the dense source, target, source map, modulus, extension handoff, uniqueness row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-facing request through S, f, m, E, U and then to the terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionRecursor}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionRecursor}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for selected limits, quotient stream representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionRecursorUp.CauchyCompletionRecursorTasteGate single carrier alignment`

Theorem 3628.2 (CauchyCompletionRecursor NameCert obligations)**.** *For every accepted* CauchyCompletionRecu *carrier $R = (S, T, f, m, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionRecursor}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dense source, completion target, source map, modulus ledger, extension handoff, uniqueness row, transport, replay, provenance, and local naming rows;*
2. *source restriction, requiring f to be read only on the displayed dense source S admitted by the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *route;*
3. *modulus preservation, requiring every extension read to preserve the same uniform modulus row m before the target row T is consumed;*
4. *extension handoff, requiring E to be supplied through the uniformly continuous extension route and not by a selected limit or host completion theorem;*
5. *uniqueness, requiring U to identify any two admitted extension reads with the same source restriction, modulus ledger, and completion target route;*
6. *ledger non-escape, requiring H, C, P, N to replay and name only the displayed rows and to export no selected limit, quotient stream, countable-choice selector, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3628.1. The visible packet consists exactly of the dense source row S, target row T, source map row f, modulus row m, extension handoff E, uniqueness row U, and structural rows H, C, P, N.

Source restriction follows from the placement of S before f. The source map can be inspected only after the dense source has been displayed through the Bishop regular completion and $\mathsf{CauchyCompletionUnit}^{\uparrow}$ routes.

Modulus preservation and extension handoff are read through m and E. The uniformly continuous extension route consumes the same modulus ledger before it exposes an extension row, so no selected limit or ambient completion theorem can replace the displayed handoff.

Uniqueness is exactly the role of U. Once the source restriction, modulus ledger, target row, and extension handoff agree, the local uniqueness row identifies the two recursor reads through the displayed completion-facing route.

Finally, H, C, P, N exhaust the ledger. They transport, replay, source, and name the displayed rows only, so there is no carrier coordinate from which quotient streams, selected limits, countable choice, host real equality, or ambient Real completeness can be exported. □

Theorem 3628.3 (CauchyCompletionRecursor universal route)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyCompletionRecursor}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BishopRegularCauchyCompletion}^{\uparrow} \longmapsto \mathsf{CauchyCompletionUnit}^{\uparrow} \longmapsto \mathsf{UniformContinuousExtension}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer first reads the displayed dense source S, then the source map f and modulus ledger m, then the extension handoff E, then the uniqueness row U, and only then the terminal Real seal. The route contains no selected limit, countable choice, quotient stream, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with an accepted packet $R = (S, T, f, m, E, U, H, C, P, N)$. The dense source row S is the only source coordinate available to the consumer, and it is admitted through the Bishop regular completion and $\mathsf{CauchyCompletionUnit}^{\uparrow}$ routes.

Replay the continuation row C. A completion-facing request reaches f only after S is displayed, and it reaches E only after the modulus ledger m has been read. Thus the extension handoff is modulus-controlled rather than limit-selected.

The uniqueness row U is read before the terminal Real seal. It forces any two admitted extension reads with the same source restriction, modulus ledger, and target route to share the same completion-facing output row.

The structural rows H, C, P, N preserve this order under transport, replay, provenance, and naming. Since the carrier has no coordinate for selected limits, countable choice, quotient streams, host real equality, or ambient Real completeness, no completion-facing consumer can export any of those data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionRecursor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionRecursor}^{\uparrow}$ packet is generated from a dense source row, completion target row, source map, uniform modulus ledger, extension handoff, uniqueness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionRecursor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3628.1, Definition 3628.2, and Definition 3628.3 seed the finite elimination route from displayed dense source data through modulus-controlled extension and uniqueness into the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionRecursor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient streams, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source restriction, modulus preservation, extension handoff, uniqueness, replay stability, provenance exhaustion, and Real seal nonescape for BEDC.Derived.CauchyCompletionRecursorUp.

Chapter 3629

A Concrete Naming Certificate for $\mathsf{DedekindReal}^{\uparrow}$

Following Dedekind and Bishop–Bridges constructive analysis, the $\mathsf{DedekindReal}^{\uparrow}$ packet records a real name by a displayed located cut together with the finite Cauchy readback surface that lets completion-facing consumers compare cut data with regular rational Cauchy names. It sits beside the located-cut carrier of chapter 404, the tight cut boundary of **??**, the regular rational sequence route of chapter 301, the finite stream interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the cut-versus-Cauchy comparison surface; it is not a quotient of cuts, a selected supremum, trichotomy on rationals, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 3629.1 (DedekindReal carrier)**.** *A* $\mathsf{DedekindReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, C, T, R, S, Q, E, H, K, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *row exposing the lower and upper rational probes and the locatedness witness available to the cut.*
2. *C is the* $\mathsf{CauchyCut}^{\uparrow}$ *row tying finite Cauchy windows to the same cut boundary.*
3. *T is the* $\mathsf{TightLocatedCut}^{\uparrow}$ *row recording the no-gap compatibility between lower and upper probes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row used as the Cauchy name readback.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting the inspected rational approximants.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare cut probes and Cauchy windows at one displayed budget.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, C, T, R, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for cut, Cauchy-cut, tightness, sequence, stream, tolerance, Real-seal, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a cut-facing or Cauchy-facing request through L, C, T, R, S, Q and then to E.*

10. *P is the* Pkg *provenance over* $\mathsf{DedekindReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{CauchyCut}^{\uparrow}$, $\mathsf{TightLocatedCut}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient cut equality, a selected supremum, a detached Cauchy limit, rational trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DedekindRealUp.DedekindRealTasteGate single carrier alignment`

Theorem 3629.2 (DedekindReal NameCert obligations)**.** *For every accepted* $\mathsf{DedekindReal}^{\uparrow}$ *carrier* $D = (L, C, T, R, S, Q, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DedekindReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, located-cut exposure through L, Cauchy-cut compatibility through C, tight no-gap checking through T, regular rational readback through R, finite stream-window exposure through S, dyadic tolerance comparison through Q, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.*

Every Real and Completion consumer that treats a Dedekind-style cut as a real name must read the finite route

$$\mathsf{LocatedCut}^{\uparrow} \longrightarrow \mathsf{CauchyCut}^{\uparrow} \longrightarrow \mathsf{TightLocatedCut}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Re}$$

before exporting any real-facing row.

Proof. Project the carrier of Definition 3629.1. The accepted packet exposes only the located cut, Cauchy-cut, tightness, regular rational sequence, stream window, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

The cut side is forced by L, C, T. Locatedness supplies rational probes on both sides of the boundary, the Cauchy-cut row ties those probes to finite Cauchy windows, and the tight row records that no displayed gap remains between the lower and upper faces.

The Cauchy side is forced by R, S, Q, E. The regular rational sequence supplies the finite approximants, the stream row selects the inspected windows, the dyadic ledger fixes the comparison budget, and the Real seal can be reached only after those rows have been consumed.

Finally H, K, P, N exhaust the structural surface. They transport, replay, source, and name the displayed rows only, so quotient cut equality, selected suprema, detached limits, rational trichotomy, countable choice, and ambient Real completeness have no export coordinate in the local certificate. □

Theorem 3629.3 (DedekindReal cut–Cauchy comparison)**.** *Let $D = (L, C, T, R, S, Q, E, H, K, P, N)$ be an accepted* $\mathsf{DedekindReal}^{\uparrow}$ *carrier. A cut-facing read and a Cauchy-facing read compare only when both are routed through the same tolerance ledger Q and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal E. In particular, every admitted comparison between the Dedekind cut surface and the regular Cauchy real-name surface factors through*

$$(L, C, T) \longmapsto Q \longleftarrow (R, S)$$

and then through E, H, K, P, N.

The comparison contains no quotient of cuts, no selected supremum, no selected Cauchy limit, no trichotomy branch, no countable-choice selector, and no appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted packet. A cut-facing read can inspect only L, C, T, while a Cauchy-facing read can inspect only R, S before the common dyadic tolerance row is reached.

The row Q is the only displayed comparison budget. Therefore a lower-or-upper rational probe from L and a regular rational approximant from R, S can be compared only after both sides have entered the same dyadic ledger.

The terminal seal E is downstream of that shared ledger. Transport and replay through H and K preserve the same order, and P, N package only the resulting finite route.

Since no carrier coordinate stores quotient cut equality, a supremum selector, a detached limit, trichotomy, countable choice, or ambient completeness, the comparison is exactly the finite cut-versus-Cauchy route displayed above. □

Falsifiable prediction: Every accepted $\mathsf{DedekindReal}^{\uparrow}$ consumer that claims a cut-versus-Cauchy real-name comparison must exhibit locatedcut, cauchycut, tightlocatedcut, regseqrat, streamname, dyadicratcore, real, transport, replay, provenance, and local namecert rows. A consumer omitting any one of those rows refutes the packet.

Independence witness: locatedcut, cauchycut, tightlocatedcut, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the whole packet $D = (L, C, T, R, S, Q, E, H, K, P, N)$, because each sibling contributes only cut probes, Cauchy compatibility, tightness, rational sequence data, finite windows, tolerance budgets, or terminal real sealing while this chapter binds them as one finite comparison certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindReal}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindReal}^{\uparrow}$ packet is generated from a LocatedCut row, CauchyCut compatibility row, TightLocatedCut no-gap row, RegSeqRat readback, StreamName finite windows, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3629.1, Definition 3629.2, and Definition 3629.3 seed the finite cut-versus-Cauchy real-name route from located cut probes through Cauchy compatibility, tightness, regular rational readback, finite stream windows, dyadic tolerance, and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient cut equality, selected suprema, selected Cauchy limits, rational trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cut exposure, Cauchy-cut compatibility, tight no-gap checking, regular rational readback, finite-window exposure, dyadic tolerance comparison, terminal Real seal routing, and ledger nonescape for BEDC.Derived.DedekindRealUp.

Chapter 3630

A Concrete Naming Certificate for $\mathsf{ObservableDiameterDecay}^{\uparrow}$

The $\mathsf{ObservableDiameterDecay}^{\uparrow}$ packet realizes the compact finite-net and uniform-modulus route of chapter 9237 as a finite diameter ledger. It consumes the compact source of chapter 129, the pointwise graph and radius data of chapter 130, the finite radius ledger of chapter 452, the uniform-modulus consumer of chapter 369, and the source-to-target triangle estimate of chapter 1159. The packet exposes observable diameter decay as NameCert data rather than as a narrative compactness bridge.

Definition 3630.1 (Observable diameter decay carrier)**.** *An* $\mathsf{ObservableDiameterDecay}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, F, L, T, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the inspected centers and source-radius windows.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise graph and local-modulus row for the displayed map on those centers.*
3. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius row binding the finite compact cover to one positive radius ledger.*
4. *T is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *triangle row that turns source-radius bounds and pointwise target estimates into a target-diameter bound.*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, read only after K, F, L, T have been displayed.*
6. *H records componentwise* hsame *transport for compact-net, continuous-map, radius-ledger, triangle-estimate, uniform-modulus, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from finite-net source windows through pointwise estimates, the finite Lebesgue-number row, the triangle estimate, and the uniform-modulus handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{ObservableDiameterDecay}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ObservableDiameterDecay}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, L, T, M, H, C, P, N$. It has no coordinate for open-cover compactness, host semantic continuity, selected centers outside the displayed finite net, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ObservableDiameterDecayUp.ObservableDiameterDecayTasteGate` single carrier alignment

Theorem 3630.2 (Observable diameter decay NameCert obligations)**.** *For every accepted* ObservableDiameterDeca *carrier $O = (K, F, L, T, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ObservableDiameterDecay}^{\uparrow}}$ *surface consists exactly of carrier admission; compact finite-net coverage through K; pointwise-modulus compatibility through F; finite Lebesgue-number radius exactness through L; triangle-estimate diameter control through T; uniform-modulus handoff through M; componentwise transport and displayed replay through H and C; and provenance exhaustion through P and N.*

Proof. Project the carrier of Definition 3630.1. The visible coordinates are exactly the compact finite-net row, continuous-map row, finite radius ledger, triangle estimate, uniform-modulus handoff, and structural rows.

Coverage is read from K, and pointwise-modulus compatibility is read from F. The finite Lebesgue-number row L binds those local source-radius windows to a single positive radius ledger.

The triangle row T converts the shared source-radius bound and pointwise target estimates into the displayed target-diameter control. The uniform-modulus row M is downstream from K, F, L, T, so the handoff cannot be inspected before the finite diameter-decay route is exposed.

Transport and replay through H and C preserve exactly those rows, while P and N source and name them. Since the carrier contains no open-cover compactness, host semantic continuity, external center selector, or ambient completeness coordinate, the listed rows exhaust the NameCert obligations. □

Lean4 ✓ `BEDC.Derived.ObservableDiameterDecayUp.ObservableDiameterDecayNamecertObligations`

Theorem 3630.3 (Observable diameter decay compact-uniform route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read from an accepted* $\mathsf{ObservableDiameterDecay}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{FiniteLebesgueNumber}^{\uparrow} \longrightarrow \mathsf{MetricTriangleUniformEstimate}^{\uparrow} \longrightarrow \mathsf{Uniform}$$

The route measures diameter decay on displayed compact-net cells, transports pointwise target estimates along the finite Lebesgue-number radius row, and seals the result as a uniform-modulus handoff. It exports no open-cover compactness, host semantic continuity, selected center outside the packet, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.ObservableDiameterDecayUp.ObservableDiameterDecayCompactUniformRoute`

Proof. Begin with an accepted packet $O = (K, F, L, T, M, H, C, P, N)$. The compact source data are exactly the finite-net centers and source-radius windows recorded in K.

Read the continuous-map row F at those displayed centers. These pointwise target estimates are tied to the same finite source windows that the compact-net row exposes.

The radius row L supplies the finite Lebesgue-number ledger needed to make the source-radius request uniform over the inspected compact-net cells. The triangle row T then turns the source bounds and pointwise target estimates into a target-diameter bound.

Only after that route is replayed through C and transported through H can the uniform-modulus handoff M be read. The provenance and naming rows P, N package the same route, and no carrier coordinate supplies open-cover compactness, host semantic continuity, external center selection, or ambient completeness. □

Falsifiable prediction: Removing the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ radius row from an accepted $\mathsf{ObservableDiameterDec}$ carrier breaks the $\mathsf{UniformModulus}^{\uparrow}$ handoff, because the compact finite-net source row and pointwise $\mathsf{ContinuousMap}^{\uparrow}$ estimates no longer share one displayed positive-radius ledger.

Independence witness: compactuniformcontinuity, finitelebesguenumber, metrictriangleuniformestimate, uniformmodulus, compactmetric: none is bijective to $\mathsf{ObservableDiameterDecay}^{\uparrow}$ because this packet jointly carries compact-net coverage, pointwise continuous-map estimates, the finite Lebesgue-number radius ledger, triangle-estimate diameter control, uniform-modulus handoff, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ObservableDiameterDecay}^{\uparrow}}$.

Constructive story: An $\mathsf{ObservableDiameterDecay}^{\uparrow}$ packet is generated from a CompactMetric finite-net row, a ContinuousMap pointwise-modulus row, a FiniteLebesgueNumber radius ledger, a MetricTriangleUniformEstimate diameter-control row, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservableDiameterDecay}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3630.1, Definition 3630.2, and Definition 3630.3 seed the finite compact-net diameter-decay route consumed by uniform-modulus reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservableDiameterDecay}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host semantic continuity, selected centers outside the displayed finite net, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net coverage, pointwise-modulus compatibility, finite radius exactness, triangle-estimate diameter control, uniform-modulus handoff, transport and replay stability, and provenance exhaustion for BEDC.Derived.ObservableDiameterDecayUp.

Chapter 3631

A Concrete Naming Certificate for $\mathsf{FastCauchyNormalForm}^{\uparrow}$

Bishop–Bridges constructive Cauchy completion treats a real number as regular approximation data rather than as a quotient object selected by an ambient limit operation. The $\mathsf{FastCauchyNormalForm}^{\uparrow}$ packet records the finite normal-form surface by which dyadic rational cores, finite stream names, regular rational sequences, terminal Real rows, and Cauchy-rate comparisons are read as one L10 completion-facing NameCert object. It is not quotient real equality, selected representative choice, countable choice, trichotomy, or an ambient completeness oracle.

The sibling dependency is part of the carrier: D imports the dyadic tolerance carrier of chapter 291, S imports the finite-window stream surface of chapter 126, R imports the regular rational route of chapter 301, E imports the terminal seal of chapter 38, and C imports the rate comparison surface of chapter 1671. The normal-form packet binds those sibling rows before any completion consumer can treat a regular name as fast normalized.

Definition 3631.1 (Real fast Cauchy normal-form carrier)**.** *A* $\mathsf{FastCauchyNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, E, C, H, Q, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic tolerance row, carrying the finite endpoint, radius, distance, and budget data used by the normal form.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the inspected stream observations and the omitted-tail ledger.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row whose modulus is being normalized.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *C is the* $\mathsf{CauchyRateComparison}^{\uparrow}$ *row comparing the displayed regular sequence against the fast dyadic rate demanded by the packet.*
6. *H records componentwise* hsame *transport for dyadic tolerance, stream window, regular-sequence, Real-seal, Cauchy-rate, replay, provenance, and local naming rows.*
7. *Q records displayed* Cont *replay from a fast-normal-form request through D, S, R, E, C.*
8. *P is the* Pkg *provenance over* $\mathsf{FastCauchyNormalForm}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRateComparison}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{FastCauchyNormalForm}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, R, E, C, H, Q, P, N$ and their displayed replay route. It has no coordinate for quotient real equality, selected representatives, detached limit choice, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FastCauchyNormalFormUp.FastCauchyNormalFormTasteGate single carrier alignment`

Theorem 3631.2 (Real fast Cauchy normal-form NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchyNormalForm}^{\uparrow}$ *carrier $F = (D, S, R, E, C, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FastCauchyNormalForm}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet, classifier stability under componentwise* hsame*, dyadic tolerance nonescape through D, finite-window exposure through S, regular-sequence admission through R, terminal seal routing through E, fast-rate comparison through C, displayed replay through Q, provenance through P, and local naming through N.*

Every completion-facing consumer that treats a regular rational sequence as fast-normalized must read the finite route

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{CauchyRateComparison}^{\uparrow}$$

before exporting any normal-form row.

Proof. Project the carrier of Definition 3631.1. The accepted packet exposes only the dyadic tolerance row, finite stream window, regular rational sequence, terminal Real seal, Cauchy-rate comparison, transport, replay, provenance, and local naming rows.

The analytic route is forced by D, S, R, E, C. The dyadic ledger supplies the displayed tolerance budgets, the stream row records the finite observations, the regular sequence row supplies the Cauchy data, the Real row seals only that displayed route, and the comparison row checks the fast rate against those same finite rows.

The structural rows H, Q, P, N preserve this route under componentwise transport and replay. Since no accepted coordinate stores quotient real equality, a selected representative, detached limit choice, countable choice, trichotomy, or ambient completeness, none of those objects belongs to the NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{FastCauchyNormalForm}^{\uparrow}$ consumer that claims fast Cauchy normal form must exhibit the dyadic tolerance row, finite stream window, regular rational sequence row, terminal Real seal row, Cauchy-rate comparison row, componentwise transport, displayed replay, provenance, and local naming row. A consumer omitting dyadicratcore, streamname, regseqrat, real, cauchyratecomparison, or namecert sibling slugs refutes the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchyratecomparison: no listed sibling supplies the whole packet $F = (D, S, R, E, C, H, Q, P, N)$, because each sibling contributes only tolerances, finite observations, regular sequence data, terminal sealing, or rate comparison while this chapter binds all five analytic faces as one finite normal-form certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyNormalForm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FastCauchyNormalForm}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat regular-sequence data, a terminal RealUp seal, a CauchyRateComparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FastCauchyNormalForm}^{\uparrow}}$, seed)

Scope closed: Definition 3631.1 and Definition 3631.2 seed the finite fast Cauchy normal-form route over dyadic tolerance data, finite stream names, regular rational sequences, terminal Real sealing, Cauchy-rate comparison, transport, replay, provenance, and local NameCert data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FastCauchyNormalForm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, detached limit choice, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic tolerance nonescape, finite-window exposure, regular-sequence admission, terminal-seal routing, fast-rate comparison, and FieldFaithful FastCauchyNormalFormUp for BEDC.Derived.FastCauchyNormalFormUp.

The $\mathsf{Calculus}^{\uparrow}$ dossier consumes the finite $\mathsf{Limit}^{\uparrow}$ route of chapter 1678 and the regular-Cauchy diagonal meet of chapter 909 before derivative and integral rows are read.

Chapter 3632

A Concrete Naming Certificate for $\mathsf{Calculus}^{\uparrow}$

Following Cartan's local differential calculus and the Bishop–Bridges constructive treatment of limits, derivatives, and integrals, the $\mathsf{Calculus}^{\uparrow}$ packet records the finite analysis root used by later derivative and integration chapters. Its derivative/integral local-linearization carrier consumes the $\mathsf{ContinuousMap}^{\uparrow}$ modulus surface of chapter 130, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ error ledger of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It sits beside the real-name boundary of chapter 38, the generic limit route of chapter 1678, the continuous-map surface used throughout the analysis region, the derivative carrier of chapter 122, the integral carrier, and the regular rational readback of chapter 301. The packet names the common calculus substrate without importing a host function space, a global limit operator, quotient equality of functions, or an ambient completeness theorem.

Definition 3632.1 (Calculus local-linearization carrier)**.** *A* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier is a finite* BHist *packet*

$$\Lambda = (E, R, D, L, J, H, C, P, N)$$

whose rows are the terminal $\mathsf{Real}^{\uparrow}$ *seal* E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{Derivative}^{\uparrow}$ *finite difference-quotient row* L*, the* $\mathsf{RiemannIntegral}^{\uparrow}$ *finite tagged-sum row* J*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N*. The classifier compares accepted packets only through these rows. It has no coordinate for a host differentiability theorem, selected antiderivative, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusLocalLinearizationCarrier`
Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLocalLinearizationCarrier admission`

Theorem 3632.2 (Calculus derivative continuation obligation)**.** *Every accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier* $\Lambda = (E, R, D, L, J, H, C, P, N)$ *exposes a derivative-facing continuation only after the* $\mathsf{Real}^{\uparrow}$ *seal* E*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{Derivative}^{\uparrow}$ *difference-quotient row* L*,* hsame *transport* H*,* Cont *replay* C*, provenance* P*, and local NameCert row* N *have been displayed. The read cannot export a host differentiability theorem, quotient real equality, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusDerivativeContinuationObligation`

Proof. Project the carrier of Definition 3632.1. The derivative-facing row is L, and its tolerance and value data are visible only together with the real seal E, regular-rational readback R, and dyadic ledger D.

The structural rows H, C, P, N transport, replay, source, and name that same finite packet. Since none of those rows contains a host differentiability theorem or quotient real equality, the continuation remains a displayed finite difference-quotient route.

The Riemann row J may coexist in the packet, but it does not supply derivative data. Thus every derivative consumer must read through E, R, D, L, H, C, P, N before any derivative-facing conclusion is public. □

Theorem 3632.3 (Calculus integral finite-sum obligation)**.** *Every accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier* $\Lambda = (E, R, D, L, J, H, C, P, N)$ *exposes an integral-facing read only through the* $\mathsf{RiemannIntegral}^{\uparrow}$ *finite tagged-sum row* J *together with the* $\mathsf{Real}^{\uparrow}$ *seal* E*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, componentwise transport, replay, provenance, and local naming. The read does not select an antiderivative and does not import quotient real equality or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusIntegralFiniteSumObligation`

Proof. Read J from the carrier. It records the partition, tags, finite sum, and endpoint handoff as displayed calculus data, so an integral consumer cannot bypass the finite-sum route.

The rows E, R, D provide the real-facing seal, regular-rational comparison, and dyadic tolerance ledger used to interpret that sum. The structural rows H, C, P, N preserve the same finite route under accepted transport and replay.

The derivative row L remains separate. Because no coordinate of Λ contains a selected antiderivative, host integration functional, quotient real equality, or ambient completeness theorem, the integral obligation is exactly the finite-sum route through J and the displayed support rows. □

Theorem 3632.4 (Calculus limit real-seal obligation)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing limit read exported by an accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, derivative row* L *or Riemann finite-sum row* J*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*,* hsame *transport,* Cont *replay, provenance, and local NameCert rows. No such read may use a host limit theorem, quotient real equality, selected antiderivative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local data.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLimitRealSealObligation`

Proof. Start from a Real-facing calculus read. The carrier exposes E as the only terminal real seal, so every such read must arrive at E through the displayed regular-rational and dyadic rows R, D.

There are two calculus sources for that seal. A derivative read uses L and the finite difference-quotient route; an integral read uses J and the finite tagged-sum route. Both sources are transported and replayed only by H and C, with provenance and local naming recorded by P and N.

Since the carrier has no coordinate for host limits, quotient real equality, selected antiderivatives, or ambient completeness, the real-seal obligation is confined to the displayed BEDC rows. □

Definition 3632.5 (Calculus root public package)**.** *The* $\mathsf{Calculus}^{\uparrow}$ *root public package of an accepted carrier is the finite packet*

$$\Pi_{\mathsf{Calculus}^{\uparrow}} = (E, R, D, L, J, H, C, P, N; C_{\mathrm{root}}, D_{\mathrm{root}}, I_{\mathrm{root}}, L_{\mathrm{root}}, R_{\mathrm{root}}, Q_{\mathrm{root}}, Y_{\mathrm{root}}, H_{\mathrm{root}}, T_{\mathrm{root}}, P_{\mathrm{root}}, N_{\mathrm{root}})$$

obtained by reading the local-linearization rows $E, R, D, L, J, H, C, P, N$ *together with the root rows* $C_{\mathrm{root}}, D_{\mathrm{root}}, I_{\mathrm{root}}, L_{\mathrm{root}}, R_{\mathrm{root}}, Q_{\mathrm{root}}, Y_{\mathrm{root}}, H_{\mathrm{root}}, T_{\mathrm{root}}, P_{\mathrm{root}}, N_{\mathrm{root}}$ *of Definition 3632.43. Its public surface is the derivative row, Riemann finite-sum row,* $\mathsf{Limit}^{\uparrow}$ *row,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-replay row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming.*

The package compares accepted calculus reads only through those rows. It has no coordinate for a host function space, selected antiderivative, selected derivative operator, quotient equality of functions, host limit operator, host integral functional, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusRootPublicPackage`

Definition 3632.6 (Calculus root obligation surface)**.** *The* $\mathsf{Calculus}^{\uparrow}$ *root obligation surface is the ordered read of* $\Pi_{\mathsf{Calculus}^{\uparrow}}$ *through the derivative row, integral finite-sum row,* $\mathsf{Limit}^{\uparrow}$ *row,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-replay row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, and the transport, replay, provenance, and local naming rows. It is the same finite packet as Definition 3632.5, read as downstream obligations rather than as a public package.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusRootObligationSurface`

Theorem 3632.7 (Calculus root limit derivative integral route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *root read for limits, derivatives, integrals, continuous-map replay,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, or* $\mathsf{Real}^{\uparrow}$ *sealing passes through the obligation surface of Definition 3632.6. The consumer may choose the relevant operation row, but the shared route remains* $\Pi_{\mathsf{Calculus}^{\uparrow}}$.

Proof. Read the obligation surface as the public package with its rows ordered by consumer. Derivative, integral, and limit consumers select D_{root}, I_{root}, or L_{root}, respectively, while continuous-map replay, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and naming remain common rows.

Apply the existing root package readiness theorem. It already forces each listed consumer through $\Pi_{\mathsf{Calculus}^{\uparrow}}$, so reading the same packet as an obligation surface gives the stated L10 route. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootLimitDerivativeIntegralRoute`

Theorem 3632.8 (Calculus root L10 nonescape)**.** *The obligation surface of Definition 3632.6 exports no host function space, quotient function equality, selected antiderivative, host limit operator, host integral functional, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every L10 calculus consumer stays inside the displayed limit, derivative, integral, continuous-map, dyadic-rational, regular-rational, Real-seal, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootL10Nonescape`

Proof. Compare the refused objects with the row inventory of Definition 3632.6. None is a row of the displayed obligation surface.

Use Definition 3632.7 for the positive route and Definition 3632.10 for the boundary. Together they exhaust the public calculus read through $\Pi_{\mathsf{Calculus}^{\uparrow}}$ and leave no coordinate for the refused host objects. □

Theorem 3632.9 (Calculus root public package readiness)**.** *Every downstream* $\mathsf{Calculus}^{\uparrow}$ *consumer of derivative, integral, limit, continuous-map, or Real-facing data factors through the root public*

package of Definition 3632.5. A derivative consumer reads the derivative rows and the shared graph, dyadic, regular-rational, Real, transport, replay, provenance, and naming rows; an integral consumer reads the Riemann finite-sum rows and the same support; a limit consumer reads the $\mathsf{Limit}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *rows and the same support. No downstream calculus consumer obtains a public conclusion from a row outside* $\Pi_{\mathsf{Calculus}^{\uparrow}}$.

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootPublicPackageReadiness`

Proof. Start with the local-linearization obligations. The derivative, integral, and limit real-seal statements above force every local read through $E, R, D, L, J, H, C, P, N$ before a public conclusion is visible.

Now project the root carrier of Definition 3632.43. Its public operation rows are $C_{\mathrm{root}}, D_{\mathrm{root}}, I_{\mathrm{root}}, L_{\mathrm{root}}, R_{\mathrm{root}}, Q$

Use Definition 3632.44, Definition 3632.45, and Definition 3632.48. They place derivative, integral, and limit consumers behind the graph row, the relevant operation row, and the common regular-rational, dyadic, Real, transport, replay, provenance, and naming support.

The package $\Pi_{\mathsf{Calculus}^{\uparrow}}$ is exactly the union of those local and root rows. Since the cited obligations exhaust the operation ledger, a downstream consumer has no remaining coordinate from which to read calculus data outside the package. □

Theorem 3632.10 (Calculus root package nonescape)**.** *The* $\mathsf{Calculus}^{\uparrow}$ *root public package exports no host function space, selected antiderivative, selected derivative operator, quotient real equality of functions, host limit operator, host integral functional, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every public derivative, integral, limit, continuous-map, or Real-facing read remains inside the derivative, Riemann finite-sum,* $\mathsf{Limit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *transport, replay, provenance, and local naming rows of* $\Pi_{\mathsf{Calculus}^{\uparrow}}$.

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootPackageNonescape`

Proof. Read the excluded objects against Definition 3632.5. None is a row of $\Pi_{\mathsf{Calculus}^{\uparrow}}$, and the package comparison only inspects the displayed local and root rows.

For derivative and integral reads, apply Definition 3632.13 and Definition 3632.45. They keep derivative and Riemann finite-sum data in separate source rows and refuse a host fundamental theorem or selected antiderivative.

For limit, continuous-map, and Real-facing reads, apply Definition 3632.4, Definition 3632.42, and Definition 3632.46. These place the read behind the continuous-map, limit, regular-rational, dyadic, and Real-seal rows before anything is public.

Thus every exported calculus conclusion is obtained through the package rows. The excluded host structures remain absent, so the package cannot supply them by projection. □

Theorem 3632.11 (Calculus RegSeqRat dyadic error route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *Real-facing error estimate exposed by an accepted local-linearization carrier* $\Lambda = (E, R, D, L, J, H, C, P, N)$ *passes through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is consumed. The route is finite packet readback and not a host analytic estimate, quotient real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRegSeqRatDyadicErrorRoute`

Proof. Project the local-linearization carrier. The rows R and D are the only coordinates that record rational readback and dyadic tolerance data for a Real-facing calculus estimate.

The derivative source row L and the Riemann finite-sum source row J both sit before the terminal seal E. Their estimates can be transported and replayed only by the displayed structural rows H, C, P, N.

Thus any accepted Real-facing error estimate must read R, D before E. Since the carrier has no coordinate for host analysis, quotient real equality, or ambient completeness, no other route can supply the estimate. □

Theorem 3632.12 (Calculus ContinuousMap limit route)**.** *Every continuous-map limit read exposed by an accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier must display the graph and pointwise replay data of* $\mathsf{ContinuousMap}^{\uparrow}$ *before any* $\mathsf{Limit}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is consumed. In the local-linearization packet this means the derivative or Riemann source row is read only after its graph data has been routed through* R, D, H, C, P, N *toward* E*.*

Proof. Read the carrier rows in order. The local-linearization packet has no separate host function-space coordinate; graph and pointwise replay data can appear only through the displayed calculus source rows and their replay row C.

The real-seal obligation already confines limit-facing reads to the regular-rational row R, dyadic tolerance row D, one of the calculus source rows L, J, and the seal E. Therefore a continuous-map consumer cannot reach the Limit or Real seal without first displaying the graph data attached to that source row.

The transport, provenance, and local naming rows preserve the same dependency order. Hence the route is a finite ContinuousMap-to-Limit-to-Real read, not an ambient continuity theorem or a hidden limit operator. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusContinuousMapLimitRoute`

Theorem 3632.13 (Calculus Riemann derivative separation)**.** *In every accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier* $\Lambda = (E, R, D, L, J, H, C, P, N)$*, the* $\mathsf{Derivative}^{\uparrow}$ *row* L *and the* $\mathsf{RiemannIntegral}^{\uparrow}$ *finite-sum row* J *remain separate consumers of the common displayed support* E, R, D, H, C, P, N*. The shared support does not identify derivative and integral conclusions and does not supply a host fundamental theorem between them.*

Proof. Project the carrier. The derivative data is stored in L, and the finite tagged-sum data is stored in J; these are distinct coordinates of the finite packet.

Both rows may use the same real seal, rational readback, dyadic tolerance, transport, replay, provenance, and local naming support. Sharing those support rows only records common BEDC infrastructure; it does not turn one source row into the other.

Since the carrier contains no coordinate for a host fundamental theorem, selected antiderivative, quotient function equality, or ambient real completeness, derivative and Riemann finite-sum consumers remain separated after projection. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRiemannDerivativeSeparation`

Theorem 3632.14 (Calculus Real-seal error budget)**.** *Every derivative, integral, or limit read exported by an accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier* $\Lambda = (E, R, D, L, J, H, C, P, N)$ *exposes a source graph or finite-sum row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any calculus conclusion is public. The exposed route is one of*

$$C, L, R, D, E, H, P, N \qquad \text{or} \qquad C, J, R, D, E, H, P, N,$$

according to whether the consumer asks for a derivative/limit read or a Riemann finite-sum read, and it has no coordinate for host limits, quotient function equality, selected antiderivatives, or ambient real completeness.

Proof. Project the local-linearization carrier. Its calculus-facing source rows are the derivative row L, the Riemann finite-sum row J, the continuous-map graph row implicit in C, the regular-rational readback row R, the dyadic tolerance row D, and the real seal E.

Apply Definition 3632.2 to derivative-shaped reads and Definition 3632.3 to integral-shaped reads. Apply Definition 3632.30 and Definition 3632.12 for limit and continuous-map reads.

The real-seal route is then forced by Definition 3632.4. The separating theorem Definition 3632.13 prevents the finite-sum row from supplying derivative data and prevents the derivative row from supplying integral data.

The structural rows H, C, P, N transport, replay, source, and name the same exposed inventory. Since the carrier lacks the excluded host coordinates, the listed rows form the full public error budget before any calculus conclusion is read. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealSealErrorBudget`

Theorem 3632.15 (Calculus source-window obligation)**.** *For an accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier, every derivative, integral, and limit consumer must display the finite source window on which the read depends before it reaches a public conclusion. A derivative read displays a difference-quotient window, an integral read displays a partition and tagged finite-sum window, and a limit read displays the* $\mathsf{Limit}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *window rows, all with* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming.*

Proof. Start from the carrier rows of Definition 3632.21 and the local-linearization rows of Definition 3632.1. They display the finite source rows D, I, L, J together with the regular-rational, dyadic, Real, transport, replay, provenance, and naming support.

For derivative reads, use Definition 3632.2 and Definition 3632.33. The conclusion remains behind the displayed difference-quotient source, the continuous-map route, the regular-rational readback, and the dyadic tolerance data.

For integral reads, use Definition 3632.3 and Definition 3632.41. The finite partition, tagged-sum, endpoint, and readback rows are visible before the Real boundary is consumed.

For limit reads, use Definition 3632.30, Definition 3632.12, and Definition 3632.42. These force the continuous-map and limit windows to remain inside the displayed BEDC route. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusSourceWindowObligation`

Theorem 3632.16 (Calculus root-unblock limit window scope)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *limit consumer that exports a* $\mathsf{Real}^{\uparrow}$*-facing conclusion must expose the* $\mathsf{Limit}^{\uparrow}$ *window row, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-replay row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming before the conclusion is public. The consumer cannot replace those rows by a host limit operator, quotient real equality, selected function-space theorem, or ambient completeness principle.*

Proof. Project the carrier rows of Definition 3632.21. The limit route is L, the continuous-map route is C, the regular-rational readback is Q, the terminal real boundary is R, and the structural rows are H, T, P, N.

Use Definition 3632.15 to require the finite source window before any public read. For a limit-shaped consumer, Definition 3632.30 and Definition 3632.12 identify the required $\mathsf{Limit}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ rows.

Finally apply Definition 3632.42 and Definition 3632.46. They keep the read behind the regular-rational, dyadic, transport, replay, provenance, naming, and Real-seal rows. Since the excluded host objects are absent from the carrier, the listed rows form the full limit-window scope. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootUnblockLimitWindowScope`

Theorem 3632.17 (Calculus root-unblock finite-sum handoff)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *integral consumer that exports a* $\mathsf{Real}^{\uparrow}$*-facing conclusion must pass through the* $\mathsf{RiemannIntegral}^{\uparrow}$ *finite-sum row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the conclusion is public. The consumer cannot bypass the finite-sum row by selecting an antiderivative, a host integration functional, quotient equality of functions, or ambient real completeness.*

Proof. Project Definition 3632.21. The integral source is I, the common regular-rational readback is Q, the terminal Real boundary is R, and the transport, replay, provenance, and naming rows are H, T, P, N.

Apply Definition 3632.15 and Definition 3632.3. Together they force the partition, tagged finite sum, endpoint handoff, regular-rational readback, dyadic tolerance data, and structural rows to be displayed before any Real-facing integral read is exported.

The handoff is separated from derivative data by Definition 3632.45. The Real seal is then controlled by Definition 3632.41 and Definition 3632.46, so the public conclusion remains a finite-sum-to-regular-rational-to-Real route. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootUnblockFiniteSumHandoff`

Theorem 3632.18 (Calculus root-unblock continuous derivative window)**.** *Every derivative-facing* $\mathsf{Calculus}^{\uparrow}$ *root read that reaches a public* $\mathsf{Real}^{\uparrow}$*-facing conclusion must expose the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, the* $\mathsf{Derivative}^{\uparrow}$ *difference row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming before the derivative conclusion is public. It cannot replace those rows by a host function space, quotient equality of functions, selected derivative operator, selected antiderivative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3632.21. The continuous-map route is C, the derivative source is D, the regular-rational readback is Q, the terminal Real boundary is R, and the structural rows are H, T, P, N.

Use Definition 3632.15 to force the finite derivative source window before any public read. Then apply Definition 3632.2, Definition 3632.33, and Definition 3632.12 to keep the derivative read behind the displayed graph and difference rows.

The dyadic and Real boundary is supplied by Definition 3632.11, Definition 3632.4, and Definition 3632.46. Since Definition 3632.52 excludes the host coordinates, the listed rows form the full continuous derivative window. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootUnblockContinuousDerivativeWindow`

Theorem 3632.19 (Calculus root-unblock Riemann endpoint readback)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *endpoint read consumed by a* $\mathsf{Calculus}^{\uparrow}$ *root integral conclusion must expose the finite tagged-sum row, the endpoint* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any integral conclusion is public. The endpoint read is a finite sum and readback route, not a host integration functional or selected antiderivative.*

Proof. Project the integral route of Definition 3632.21. The integral source is I, the shared regular-rational readback is Q, the Real boundary is R, and the transport, replay, provenance, and naming rows are H, T, P, N.

Apply Definition 3632.3, Definition 3632.41, and Definition 3632.17. These theorems place partition, tag, endpoint, finite-sum, regular-rational, dyadic, and Real-seal data before the public integral read.

Finally use Definition 3632.13 and Definition 3632.10. They prevent the endpoint read from being supplied by derivative data, a host integral functional, a selected antiderivative, quotient equality, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootUnblockRiemannEndpointReadback`

Theorem 3632.20 (Calculus root-unblock RegSeqRat Real-seal factorization)**.** *Every derivative, integral, and limit consumer exported by the* $\mathsf{Calculus}^{\uparrow}$ *root package factors first through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route and then through the terminal* $\mathsf{Real}^{\uparrow}$ *seal. No such consumer may use a host function space, quotient equality of functions, selected antiderivative, selected derivative operator, host limit operator, host integration functional, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness in place of the* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *factorization.*

Proof. Read the common carrier rows from Definition 3632.21 and the root package rows from Definition 3632.5. In both inventories, derivative, integral, and limit data reach a Real-facing conclusion only through the regular-rational row and the Real boundary row.

For derivative reads, apply Definition 3632.18. For integral reads, apply Definition 3632.17 and Definition 3632.19. For limit reads, apply Definition 3632.16.

The common factorization is then exactly the one recorded by Definition 3632.11, Definition 3632.4, and Definition 3632.46. The nonescape statements Definition 3632.52 and Definition 3632.10 exclude every listed host replacement. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootUnblockRegSeqRatRealSealFactorization`

Definition 3632.21 (Calculus carrier)**.** *A* $\mathsf{Calculus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, L, C, D, I, Q, H, T, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar boundary used by all endpoint values, tolerances, finite sums, and error estimates.*
2. *L is the* $\mathsf{Limit}^{\uparrow}$ *route for displayed convergence windows and downstream real seals.*
3. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the finite graph, pointwise continuity, and replay windows available to calculus consumers.*
4. *D is the* $\mathsf{Derivative}^{\uparrow}$ *local difference-quotient row, including the source point, target read, and remainder ledger.*

5. *I is the* $\mathsf{Integral}^{\uparrow}$ *finite-sum row, exposing the partition, tagged-read, and endpoint handoff data used by integration consumers.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row shared by the limit, derivative, and integral ledgers.*
7. *H records componentwise* hsame *transport for real, limit, continuous-map, derivative, integral, regular-rational, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from real reads to limits, from limits to continuous maps, from finite difference quotients to derivative reads, and from finite sums to integral handoffs.*
9. *P is the* Pkg *provenance over* $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Limit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row.*

The classifier reads only $R, L, C, D, I, Q, H, T, P, N$. It has no coordinate for a host function space, a selected global derivative operator, an unbounded integration functional, quotient equality of functions, an open-cover compactness principle, or ambient real completeness.

Theorem 3632.22 (Calculus NameCert obligations)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier $K = (R, L, C, D, I, Q, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *surface consists exactly of carrier admission, real-boundary exposure, limit-window readback, continuous-map replay, local-linear approximation routing, finite difference quotient readback, integral finite-sum handoff, regular-rational readback, componentwise transport, displayed replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3632.21. The rows $R, L, C, D, I, Q, H, T, P, N$ are the full finite inventory available to a calculus consumer.

The local-linear approximation route is carried by D and is read only after the real boundary R, limit route L, continuous-map row C, and regular-rational readback Q have supplied the displayed point, tolerance, and remainder data. Thus a derivative-facing consumer sees a finite difference quotient route rather than a hidden global derivative operator.

The integral handoff is carried by I. Its partition, finite-sum, and endpoint rows are exposed before any real-facing value is consumed, and the same Q row supplies the rational readback needed to compare finite sums with limit and derivative windows.

Finally H, T, P, N transport, replay, source, and name exactly the displayed rows. Since no coordinate contains host function-space equality, ambient completeness, a selected derivative operator, or an unbounded integral functional, every accepted read remains inside the finite calculus packet. □

Definition 3632.23 (Calculus completion-source envelope)**.** *The* $\mathsf{Calculus}^{\uparrow}$ *completion-source envelope is the finite row inventory read jointly from Definition 3632.21 and Definition 3632.1. It consists of the displayed BEDC rows*

$$\mathsf{Real}^{\uparrow},\ \mathsf{Limit}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Derivative}^{\uparrow},\ \mathsf{Integral}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The $\mathsf{Real}^{\uparrow}$ *row is the terminal seal for endpoint values and tolerances. The* $\mathsf{Limit}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *rows expose convergence windows and graph replay. The* $\mathsf{Derivative}^{\uparrow}$ *and* $\mathsf{Integral}^{\uparrow}$ *rows expose finite difference-quotient, remainder, partition, tagged-sum, and endpoint handoff data. The* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows carry rational readback and dyadic tolerance data before any Real-facing seal is consumed. The remaining* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows transport, replay, source, and name exactly this finite packet.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusCompletionSourceEnvelope`

Theorem 3632.24 (Calculus completion-source envelope obligations)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier and every accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier, any derivative, integral, or limit consumer must expose the completion-source envelope rows of Definition 3632.23 before it reaches a public calculus conclusion. Thus a calculus conclusion may read only through displayed Real, Limit, ContinuousMap, Derivative, Integral, RegSeqRat, DyadicRatCore,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and not through a host limit operator, quotient function equality, selected global derivative operator, unbounded integration functional, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusCompletionSourceEnvelopeObligations`

Proof. Project the finite rows of Definition 3632.21 and Definition 3632.1. Together they expose the Real boundary, limit route, continuous-map replay, derivative source, integral source, regular-rational readback, dyadic tolerance data, transport, replay, provenance, and local naming listed in Definition 3632.23.

Apply Definition 3632.22. It identifies carrier admission, real-boundary exposure, limit-window readback, continuous-map replay, local-linear approximation routing, finite difference-quotient readback, integral finite-sum handoff, regular-rational readback, componentwise transport, displayed replay, provenance, and naming as the local NameCert surface.

Now apply Definition 3632.15. Derivative, integral, and limit consumers must display their finite source windows with the regular-rational, dyadic, transport, replay, provenance, and naming rows before any public conclusion is read. The excluded host objects have no row in either carrier, so the envelope is the full public route. □

Theorem 3632.25 (Calculus completion-source real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing calculus read from an accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier or accepted* $\mathsf{Calculus}^{\uparrow}$ *local-linearization carrier factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows of Definition 3632.23 before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. In particular, derivative, integral, and limit reads may hand a value to the Real boundary only after the displayed regular-rational readback and dyadic tolerance route have been exposed inside the finite BEDC packet.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusCompletionSourceRealReadback`

Proof. Use Definition 3632.11. It forces every Real-facing error estimate in the local-linearization carrier through the regular-rational readback row and dyadic tolerance ledger before the terminal Real seal is read.

Use Definition 3632.14. The derivative, integral, and limit routes expose a source graph or finite-sum row together with regular-rational readback, dyadic tolerance data, and the Real seal before any calculus conclusion is public.

Finally apply Definition 3632.52. Public local operation reads cannot replace the displayed packet by a host function space, host limit operator, quotient equality of functions, selected derivative operator, selected antiderivative, or ambient Real completeness. Therefore every Real-facing calculus read factors through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ before reaching $\mathsf{Real}^{\uparrow}$. □

Theorem 3632.26 (Calculus continuous-map graph replay obligation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$*, a continuous-map read is public only after the consumer has displayed the* $\mathsf{Real}^{\uparrow}$ *boundary* R*, the* $\mathsf{Limit}^{\uparrow}$ *window route* L*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* C*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*, provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N*. A derivative or integral consumer using that continuous-map read must therefore factor through* R, L, C, Q, H, T, P, N *before reading* D *or* I*.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusContinuousMapGraphReplayObligation`

Proof. Project the carrier of Definition 3632.21. The only row that names a continuous-map graph is C, and its endpoint values are typed by the real boundary R and compared through the regular-rational readback Q.

The limit route L supplies the finite convergence windows through which the graph row is replayed. The rows H, T, P, N transport, replay, source, and name the same displayed graph data.

Now apply Definition 3632.22. Since the derivative row D and integral row I are later consumers of the continuous-map graph, neither can use C until the route through R, L, C, Q, H, T, P, N is visible. □

Theorem 3632.27 (Calculus derivative-integral separation obligation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$*, the derivative row* D *and the integral row* I *are separate finite rows. The row* D *may expose local difference-quotient and remainder data only through* R, L, C, Q, H, T, P, N*, while the row* I *may expose finite-sum and endpoint handoff data only through those same support rows. Neither row supplies the other's conclusion, and the carrier contains no host fundamental theorem connecting them.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusDerivativeIntegralSeparationObligation`

Proof. Project Definition 3632.21. The derivative data is stored in D, and the integral data is stored in I; they are distinct coordinates of the finite packet.

Use Definition 3632.2 for the derivative-facing route and Definition 3632.3 for the integral-facing route. Each theorem reads its own calculus row together with the real, limit, continuous-map, regular-rational, transport, replay, provenance, and naming support.

Definition 3632.22 lists the full local surface and includes no coordinate for a host fundamental theorem. Hence a consumer cannot derive an integral conclusion from D, cannot derive a derivative conclusion from I, and cannot import a global theorem to identify the two reads. □

Theorem 3632.28 (Calculus RegSeqRat readback root obligation)**.** *Every real-facing value exported by an accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$ *must display the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *together with the* $\mathsf{Real}^{\uparrow}$ *boundary* R *and the dyadic tolerance route inherited by the regular-rational readback. This readback is required before any limit, derivative, or integral read is exported from* L*,* D*, or* I*.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRegSeqRatReadbackRootObligation`

Proof. Begin with the carrier of Definition 3632.21. The terminal real boundary is R, and the common rational readback row is Q; no other coordinate converts limit, derivative, or integral data into a real-facing value.

The earlier real-seal theorem Definition 3632.4 already forces Real-facing limit reads through regular-rational and dyadic tolerance data. The derivative and integral obligations similarly keep their finite quotient and finite-sum reads attached to the displayed real and rational support rows.

Finally use Definition 3632.22. The local NameCert surface lists regular-rational readback as a root obligation, so every export from L, D, I must first pass through Q with R and the underlying dyadic tolerance route visible. □

Theorem 3632.29 (Calculus root regular readback obligation)**.** *Every derivative, integral, or limit export from an accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$ *must expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *and the inherited* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route before the terminal*

$\mathsf{Real}^{\uparrow}$ *seal R is consumed. The export is a displayed calculus packet read and not a host analytic estimate, quotient real equality, or ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootRegularReadbackObligation`

Proof. Project the carrier in Definition 3632.21. The limit row is L, the derivative row is D, the integral row is I, the common regular-rational readback row is Q, and the terminal Real boundary is R.

Apply Definition 3632.28. It already requires every real-facing value exported from L, D, I to display Q together with R and the dyadic tolerance route inherited by the regular-rational readback.

Apply Definition 3632.30. It forces a continuous-map graph read and a limit-window read to remain visible before any Real seal is exported, with Q supplying the readback used by R.

Thus no derivative, integral, or limit consumer can replace the displayed readback by a host analytic estimate, quotient real equality, or ambient Real completeness. The root obligation is exactly the route through Q and its dyadic tolerance data before R is consumed. □

Theorem 3632.30 (Calculus continuous-limit carrier budget)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier $K = (R, L, C, D, I, Q, H, T, P, N)$, a continuous-map graph read and a limit-window read must both be displayed before any* $\mathsf{Real}^{\uparrow}$ *seal is exported. The graph row C supplies the named finite graph and pointwise replay windows, the limit row L supplies the convergence windows, and the regular-rational row Q supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback used by the terminal real boundary R. Thus a real-facing calculus export cannot bypass C, L, Q or treat Real completeness as an ambient carrier.*

Proof. Project the carrier of Definition 3632.21. The only continuous-map graph coordinate is C, the only limit-window coordinate is L, and the only regular-rational readback coordinate is Q.

Use Definition 3632.26. It requires R, L, C, Q, H, T, P, N before a derivative or integral consumer can read the continuous-map graph.

Use Definition 3632.28. Every real-facing export from L, D, I must expose Q together with R and the dyadic tolerance route. Hence the Real seal is downstream of the displayed graph, limit, and readback rows rather than an ambient completeness principle. □

Theorem 3632.31 (Calculus derivative-integral source separation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier $K = (R, L, C, D, I, Q, H, T, P, N)$, the derivative row D and integral row I remain separated even when they share the source rows R, L, C, Q, H, T, P, N. A derivative consumer must read local difference-quotient and remainder data from D, while an integral consumer must read partition, tagged-sum, and endpoint handoff data from I; no shared support row identifies the two sources or exports a host fundamental theorem.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusDerivativeIntegralSourceSeparation`

Proof. Project Definition 3632.21. The derivative source is the coordinate D, and the integral source is the coordinate I.

Apply Definition 3632.27. That theorem already records that the two rows use the same finite support but do not supply each other's conclusions.

The carrier list contains no coordinate for quotient function equality, a selected antiderivative, or a host fundamental theorem. Therefore shared support through R, L, C, Q, H, T, P, N preserves source separation rather than collapsing D and I. □

Theorem 3632.32 (Calculus real RegSeqRat error handoff)**.** *Every real-facing error estimate exported by an accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$ *must first display the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *and the dyadic rational tolerance route inherited by that readback. Limit, derivative, and integral consumers may then hand the estimate to the* $\mathsf{Real}^{\uparrow}$ *boundary* R*, but only after the regular-rational and dyadic data have been read inside the finite packet.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealRegseqratErrorHandoff`

Proof. Begin with Definition 3632.28. It makes Q mandatory before any real-facing value is exported from L, D, I.

The derivative and integral routes use the same readback discipline. Their finite quotient, remainder, partition, tagged-sum, and endpoint rows are compared through regular-rational data before a Real-facing estimate is named.

Finally apply Definition 3632.22. The local NameCert surface contains $R, L, C, D, I, Q, H, T, P, N$ and no ambient Real-completeness or host error functional. Thus the handoff to R is downstream of $\mathsf{RegSeqRat}^{\uparrow}$ and dyadic readback data in Q. □

Theorem 3632.33 (Calculus derivative-limit root obligation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$*, a derivative-limit read is public only after the* $\mathsf{Real}^{\uparrow}$ *seal row* R*, the* $\mathsf{Limit}^{\uparrow}$ *route* L*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row* C*, the* $\mathsf{Derivative}^{\uparrow}$ *quotient row* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the dyadic tolerance ledger inherited by* Q*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N *have all been displayed. The read exports a finite BEDC derivative-limit route and not a host function space, quotient equality of functions, selected derivative operator, selected antiderivative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusDerivativeLimitObligation`

Proof. Project the carrier of Definition 3632.21. The derivative source is the row D, while the limit-facing route is L and the graph replay available to a derivative consumer is C.

Use Definition 3632.26. It places every derivative consumer behind R, L, C, Q, H, T, P, N, so the graph and pointwise replay are visible before the derivative row is consumed.

Use Definition 3632.28. The regular-rational readback Q carries the dyadic tolerance route required before any Real-facing value reaches R.

The remaining rows H, T, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a host function space, quotient function equality, selected derivative operator, selected antiderivative, or ambient completeness, the derivative-limit obligation is exactly this displayed route. □

Theorem 3632.34 (Calculus integral-sum root obligation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$*, an integral read may consume the* $\mathsf{Integral}^{\uparrow}$ *finite-sum row* I *only after the* $\mathsf{Real}^{\uparrow}$ *boundary* R*,* $\mathsf{Limit}^{\uparrow}$ *route* L*,* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row* C*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, dyadic tolerance ledger, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N *are visible. The finite-sum row records partition, tag, sum, and endpoint handoff data; it does not export a host integration functional, quotient equality of functions, a selected antiderivative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusIntegralSumObligation`

Proof. Read the carrier K and isolate the integral source row I. The statement of Definition 3632.22 lists integral finite-sum handoff as one local NameCert obligation, so I is a displayed row rather than a host integral object.

Apply Definition 3632.3. It keeps the partition, tag, finite-sum, and endpoint data attached to the real boundary, regular-rational readback, dyadic tolerance ledger, transport, replay, provenance, and local naming rows.

Apply Definition 3632.26. If the integral consumer reads graph data, it reaches that graph through R, L, C, Q, H, T, P, N before the finite-sum handoff is public.

The derivative row D remains separate by Definition 3632.31. Thus the integral-sum obligation is the finite route through I and the displayed support rows, with no selected antiderivative, host function space, quotient equality, or ambient Real-completeness coordinate. □

Theorem 3632.35 (Calculus continuity real-readback root obligation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$*, a continuity-shaped Real read must display the* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row* C*, the* $\mathsf{Limit}^{\uparrow}$ *route* L*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the dyadic tolerance ledger inherited by* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R *before derivative or integral data is consumed. The structural rows* H, T, P, N *preserve this same route through* hsame*,* Cont*,* Pkg*, and* NameCert*, and no host continuity theorem, function-space equality, quotient real equality, selected antiderivative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness is exported.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusContinuityRealReadbackObligation`

Proof. Start with Definition 3632.30. It identifies C, L, Q as mandatory displayed rows before any $\mathsf{Real}^{\uparrow}$ seal is exported from the calculus carrier.

Use Definition 3632.32. The real-facing estimate must pass through Q and the dyadic rational tolerance route before it reaches R.

Derivative and integral reads remain downstream consumers. The row D supplies only finite difference-quotient data, and the row I supplies only finite-sum data, so neither can replace the continuity-to-limit-to-readback route.

Finally read H, T, P, N. These rows give componentwise transport, displayed continuation replay, package provenance, and local naming for the same packet. The carrier therefore exports a finite continuity real-readback route and no host continuity theorem, function-space equality, quotient real equality, selected antiderivative, or ambient completeness principle. □

Theorem 3632.36 (Calculus root chain-rule window obligation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, a chain-rule-shaped read for composed local maps must display the outer and inner* $\mathsf{ContinuousMap}^{\uparrow}$ *graph windows in* C*, the two* $\mathsf{Derivative}^{\uparrow}$ *difference-quotient windows in* D*, the* $\mathsf{Limit}^{\uparrow}$ *route* L*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming* N *before the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R *is consumed. The read is a finite window-composition obligation, not a host chain-rule theorem over an ambient function space.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootChainRuleWindowObligation`

Proof. Project the root carrier of Definition 3632.43. The graph data for a composed read can only be displayed through C, while derivative data can only be read through D.

Use Definition 3632.44 to place every derivative, integral, or limit consumer behind the $\mathsf{ContinuousMap}^{\uparrow}$ graph row. Use Definition 3632.33 to keep the derivative-limit read behind $R, L, C, D, Q, H, T, P, N$.

The regular-rational and dyadic rows Q, Y supply the comparison window before R is consumed. The structural rows H, T, P, N transport, replay, source, and name the same finite packet.

Thus the chain-rule-shaped obligation is a displayed composition of two local derivative windows. Since the carrier has no coordinate for host function-space equality or a global derivative operator, no ambient chain-rule theorem is exported. □

Theorem 3632.37 (Calculus root fundamental-theorem refusal boundary)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, a consumer that reads both the* $\mathsf{Derivative}^{\uparrow}$ *row* D *and the* $\mathsf{Integral}^{\uparrow}$ *row* I *must keep them as separate boundary rows over the common* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Limit}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *support. The packet may expose compatible finite source windows, but it does not identify* D *with* I*, select an antiderivative, or claim the full fundamental theorem of calculus.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootFtcBoundaryRefusal`

Proof. Project D and I from Definition 3632.43. The derivative source and integral source are distinct coordinates of the same finite BHist packet.

Apply Definition 3632.45. It states that D and I remain separate over $C, L, Q, Y, R, H, T, P, N$ and that neither row supplies the other's conclusion.

The real-facing support is controlled by Definition 3632.46. Any value read from either source must pass through Q, Y before reaching R.

Therefore the carrier records a refusal boundary: derivative and integral rows can share finite support without becoming a fundamental-theorem certificate. Selected antiderivatives, quotient equality of functions, and a host theorem relating all derivatives and integrals are absent from the packet. □

Theorem 3632.38 (Calculus root local-linearity composition)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, a local-linearity composition read must route the source* $\mathsf{ContinuousMap}^{\uparrow}$ *graph windows through* C*, the two local* $\mathsf{Derivative}^{\uparrow}$ *difference-quotient rows through* D*, the comparison windows through* $\mathsf{Limit}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows* L, Q, Y*, and the terminal value through the* $\mathsf{Real}^{\uparrow}$ *boundary* R*, with componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming* N*. The conclusion is only that the finite local-linear windows compose inside the displayed BEDC packet.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootLocalLinearityComposition`

Proof. Begin with the graph route. By Definition 3632.44, every local operation consumer must display C before reading derivative, integral, or limit data.

For the local-linear source, use Definition 3632.36. It gives the two derivative windows and their limit/readback support through D, L, Q, Y before R is consumed.

The rows H, T, P, N then transport, replay, source, and name this composed finite window. No row of G supplies a host function space, quotient equality of functions, selected global derivative operator, or ambient Real completeness theorem.

Thus local linearity composes only as a finite BEDC dependency route: graph windows, derivative windows, regular-rational and dyadic comparison windows, and the terminal Real boundary remain visible in the same packet. □

Definition 3632.39 (Calculus root derivative-integral carrier)**.** *A* $\mathsf{Calculus}^{\uparrow}$ *root derivative-integral carrier is the carrier*

$$K = (R, L, C, D, I, Q, H, T, P, N)$$

of Definition 3632.21 read with the following root dependency rows singled out:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *boundary for endpoint, value, error, derivative, integral, and limit readback.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the rational comparison and error schedule used before R is consumed.*
3. *the dyadic tolerance data inherited by Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dependency row for denominator, radius, and comparison reads;*
4. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise replay row used before derivative, integral, or limit consumers read function data;*
5. *D, I, L, H, T, P, N are respectively the derivative source row, integral finite-sum row, limit route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row.*

The root classifier compares accepted packets only through these displayed BHist, hsame, Cont, NameCert, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{ContinuousMap}^{\uparrow}$ *rows. It has no coordinate for a host function space, quotient equality of functions, a selected derivative operator, a selected antiderivative, or ambient real completeness.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusRootDerivativeIntegralCarrier`

Theorem 3632.40 (Calculus root derivative real handoff)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root derivative-integral carrier $K = (R, L, C, D, I, Q, H, T, P, N)$, a derivative-facing real read must expose the* $\mathsf{ContinuousMap}^{\uparrow}$ *row C, the* $\mathsf{Derivative}^{\uparrow}$ *row D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data inherited by Q, componentwise* hsame *transport H, displayed* Cont *replay T,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row N before the* $\mathsf{Real}^{\uparrow}$ *boundary R is consumed.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootDerivativeRealHandoff`

Proof. Project the root carrier of Definition 3632.39. The derivative source is D, but D is public only as part of the same BHist packet as the graph row C, readback row Q, transport row H, replay row T, provenance row P, and local naming row N.

Use Definition 3632.33. It already places every derivative-limit read behind the $\mathsf{ContinuousMap}^{\uparrow}$ graph row, the regular-rational readback, the dyadic tolerance route, and the structural rows.

The terminal real boundary is R. Since no coordinate of the root carrier contains quotient function equality, a selected derivative operator, or ambient real completeness, the derivative-facing handoff reaches R only through the displayed finite route. □

Theorem 3632.41 (Calculus root integral RegSeqRat handoff)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root derivative-integral carrier $K = (R, L, C, D, I, Q, H, T, P, N)$, an integral-facing read through the* $\mathsf{Integral}^{\uparrow}$ *row I must first display the* $\mathsf{ContinuousMap}^{\uparrow}$ *row C, the finite-sum and endpoint handoff data in I, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route inherited by Q, componentwise* hsame *transport H, displayed* Cont *replay T,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row N. Only after this readback may the consumer reach the* $\mathsf{Real}^{\uparrow}$ *boundary R.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootIntegralRegSeqRatHandoff`

Proof. Read the integral source row I from Definition 3632.39. Its partition, tag, finite-sum, and endpoint data are displayed inside the same finite BHist packet as C, Q, H, T, P, N.

Apply Definition 3632.34. That obligation forces the integral row through the real boundary, limit route, continuous-map replay, regular-rational readback, dyadic tolerance ledger, transport, replay, provenance, and local naming rows.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff is therefore not optional. The consumer cannot replace Q by a host integration functional, selected antiderivative, quotient function equality, or ambient completeness theorem before reading R. □

Theorem 3632.42 (Calculus root limit nonescape)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root derivative-integral carrier* $K = (R, L, C, D, I, Q, H, T, P, N)$*, each limit-shaped read exported by* L *must remain inside the route through the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* C*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route inherited by* Q*, the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N*. It cannot escape to a host limit operator, quotient equality of functions, selected derivative operator, selected antiderivative, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootLimitNonescape`

Proof. Project the limit row L from the root carrier. By construction, L is not a standalone host limit object; it is stored together with C, Q, R, H, T, P, N in the displayed calculus packet.

Use Definition 3632.30. A continuous-map graph read and a limit-window read must both be displayed before any real-facing seal is exported, and the regular-rational row Q supplies the readback used by R.

The structural rows preserve the same route through hsame, Cont, Pkg, and $\mathsf{NameCert}$. Since the carrier has no coordinate for the excluded host principles, every limit-shaped read remains confined to the listed BEDC dependency rows. □

Definition 3632.43 (Calculus root carrier)**.** *A* $\mathsf{Calculus}^{\uparrow}$ *root carrier is a finite* BHist *packet*

$$G = (C, D, I, L, R, Q, Y, H, T, P, N)$$

whose rows are the $\mathsf{ContinuousMap}^{\uparrow}$ *graph and replay surface* C*, the* $\mathsf{Derivative}^{\uparrow}$ *difference-quotient row* D*, the* $\mathsf{Integral}^{\uparrow}$ *finite-sum row* I*, the* $\mathsf{Limit}^{\uparrow}$ *window row* L*, the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and denominator ledger* Y*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N*. The root classifier compares accepted packets only through these finite rows. It has no coordinate for a host limit operator, quotient equality of functions, a selected derivative operator, a selected antiderivative, or ambient Real completeness.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusRootCarrier`
Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootCarrier admission`

Theorem 3632.44 (Calculus root ContinuousMap handoff)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, any derivative, integral, or limit consumer must display the* $\mathsf{ContinuousMap}^{\uparrow}$ *row* C *before it reads* D*,* I*, or* L *and before it consumes the* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *rows. The handoff is a finite graph-and-replay read through* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows, not an ambient function space or host continuity theorem.*

Proof. Project the root carrier of Definition 3632.43. The only coordinate that names graph and pointwise replay data is the row C, so calculus consumers cannot read derivative, integral, or limit data as graph data unless C is visible.

Use Definition 3632.26. It already places derivative and integral consumers behind the continuous-map graph route of the calculus packet.

The rows H, T, P, N preserve that same graph route under transport, replay, provenance, and local naming. Since G has no coordinate for a host function space or host continuity theorem, the handoff remains the displayed $\mathsf{ContinuousMap}^{\uparrow}$ row. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootContinuousMapHandoff`

Theorem 3632.45 (Calculus root derivative-integral boundary)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, the* $\mathsf{Derivative}^{\uparrow}$ *row* D *and the* $\mathsf{Integral}^{\uparrow}$ *row* I *are separate boundary rows over the common support* $C, L, Q, Y, R, H, T, P, N$*. A derivative read may use finite difference-quotient data from* D*, and an integral read may use finite-sum data from* I*, but neither row supplies the other's conclusion or a host fundamental theorem.*

Proof. Read the two source rows from Definition 3632.43. The derivative source is D, and the integral source is I; they are distinct coordinates of the finite packet.

Apply Definition 3632.31. It states that derivative and integral sources remain separated even when they share the real, limit, continuous-map, regular-rational, transport, replay, provenance, and local naming support.

The dyadic tolerance row Y and readback row Q only provide comparison data before the terminal Real boundary R is consumed. They do not identify D with I and do not contain a selected antiderivative, quotient function equality, or host fundamental theorem. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootDerivativeIntegralBoundary`

Theorem 3632.46 (Calculus root Real-seal nonescape)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, every Real-facing export from derivative, integral, or limit data must pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y *before the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R *is consumed. The export remains inside the displayed finite packet and cannot escape to host limit operators, quotient function equality, or ambient Real completeness.*

Proof. Start with the root carrier. The terminal Real boundary is R, while Q and Y are the only regular-rational and dyadic tolerance rows available before that boundary is read.

Use Definition 3632.28. It requires every real-facing value exported from the calculus limit, derivative, and integral rows to display regular-rational readback before the Real boundary is consumed.

Use Definition 3632.42 for limit-shaped reads and Definition 3632.45 for derivative and integral source separation. Together they keep the route inside $C, D, I, L, Q, Y, R, H, T, P, N$.

Because the root carrier has no coordinate for host limit operators, quotient function equality, selected derivative or antiderivative operators, or ambient Real completeness, no Real-facing export can bypass Q, Y on the way to R. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootRealSealNonescape`

Definition 3632.47 (Calculus root operation ledger)**.** *The* $\mathsf{Calculus}^{\uparrow}$ *root operation ledger attached to an accepted carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$ *is the displayed row inventory*

$$\mathsf{OpLedger}_{\mathsf{Calculus}^{\uparrow}}(G) = (C, D, I, L, R, Q, Y, H, T, P, N).$$

Here C *is the continuous-map graph and replay row,* D *is the derivative difference-quotient row,* I *is the integral finite-sum row,* L *is the limit-window row,* R *is the terminal* $\mathsf{Real}^{\uparrow}$ *boundary,* Q *is*

the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* Y *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* H *is componentwise* hsame *transport,* T *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row. The ledger has no row for a host function space, quotient equality of functions, a selected antiderivative, a selected derivative operator, or ambient completeness.*

Lean4 (definition) `BEDC.Derived.CalculusUp.CalculusRootOperationLedger`

Theorem 3632.48 (Calculus root operation ledger exhaustion)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, every derivative, integral, limit, or Real-facing operation read is exhausted by the operation ledger of Definition 3632.47. A consumer may read derivative data only through* $C, D, Q, Y, R, H, T, P, N$*, integral data only through* $C, I, Q, Y, R, H, T, P, N$*, and limit data only through* $C, L, Q, Y, R, H, T, P, N$*. No operation read may replace those rows by a host function space, quotient equality of functions, selected antiderivatives, selected derivative operators, or ambient completeness.*

Proof. Begin with the root carrier of Definition 3632.43. It displays exactly the rows $C, D, I, L, R, Q, Y, H, T, P, N$, and Definition 3632.47 only repackages that same finite inventory as the operation ledger.

Apply Definition 3632.44. Every derivative, integral, and limit consumer must display C before reading D, I, or L.

For derivative and integral reads, apply Definition 3632.45. It keeps D and I as separate source rows over the common support and refuses a host fundamental theorem or selected antiderivative.

For limit and Real-facing reads, apply Definition 3632.42 and Definition 3632.46. They force the read through Q, Y before R is consumed and leave no coordinate for host limits, quotient function equality, selected derivative or antiderivative operators, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootOperationLedgerExhaustion`

Theorem 3632.49 (Calculus root unblock Real operation ledger)**.** *The root* $\mathsf{Calculus}^{\uparrow}$ *operation ledger unblocks downstream derivative, integral, limit, and completion consumers only as the finite BEDC route*

$$C, D, I, L, R, Q, Y, H, T, P, N.$$

Any downstream consumer that asks for a Real-facing calculus value must display the relevant operation row D*,* I*, or* L*, the graph row* C*, the regular-rational readback* Q*, the dyadic tolerance ledger* Y*, the terminal Real boundary* R*, and the structural rows* H, T, P, N*. The ledger does not export ambient function spaces, quotient equality, selected antiderivatives, selected derivative operators, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Read the operation ledger from Definition 3632.47. The only public rows available to a downstream consumer are the displayed finite rows $C, D, I, L, R, Q, Y, H, T, P, N$.

Use the derivative-integral boundary of Definition 3632.45 for operation separation. It prevents the derivative row from supplying integral conclusions and prevents the integral row from supplying derivative conclusions.

Use the Real-seal nonescape theorem Definition 3632.46. It requires every Real-facing export from derivative, integral, or limit data to pass through Q, Y before R is consumed.

Finally apply Definition 3632.48. The exhaustion statement identifies the ledger as the full consumer-facing route, so the root unblock surface is a finite operation ledger and not a host analytic structure or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootUnblockRealOperationLedger`

Theorem 3632.50 (Calculus root Real-completion operation handoff)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, any consumer that combines derivative, integral, or limit rows with a Real-facing value must route through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N *before reading the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R*. The handoff is the Phase Real and Completion route of the finite root carrier, not an ambient completion or host analytic-value principle.*

Proof. Apply Definition 3632.45 to keep the derivative and integral rows separate over the common support.

Use Definition 3632.46 and Definition 3632.48. These force every derivative, integral, limit, or Real-facing read through Q, Y before R is public.

Finally apply Definition 3632.51 for the completion-facing derivative window. The structural rows H, T, P, N preserve the same finite route, so the consumer reaches Phase Real and Completion only through the displayed root ledger. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootRealCompletionOperationHandoff`

Theorem 3632.51 (Calculus root local linearization Cauchy handoff)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, a local-linearization consumer that asks for a Cauchy-facing derivative window must display the* BHist *derivative row* D*, the continuous graph row* C*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *row* N *before the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R *is consumed. The handoff is a finite derivative-to-regular-readback route and not a host differentiability theorem, quotient equality of functions, or ambient Cauchy completeness claim.*

Proof. Project the root operation ledger. The derivative source for local linearization is the displayed row D, and any graph data used by that derivative source is routed through C.

Apply Definition 3632.40. It places every derivative-facing real read behind C, D, Q, H, T, P, N before R is consumed. Apply Definition 3632.46 to keep the same read behind the dyadic tolerance ledger Y and the regular-rational row Q.

The structural rows H, T, P, N preserve the same finite packet under hsame, Cont, Pkg, and local naming. Because the carrier has no coordinate for host differentiability, quotient function equality, or ambient completion, the Cauchy-facing handoff is exactly the displayed derivative, readback, tolerance, and Real-seal route. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootLocalLinearizationCauchyHandoff`

Theorem 3632.52 (Calculus local operation nonescape)**.** *Every public* $\mathsf{Calculus}^{\uparrow}$ *local operation read is confined to the displayed* BHist *rows for source graph data or finite sums,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming. No derivative, integral, or limit conclusion may replace those rows by a host function space, host limit operator, quotient equality of functions, selected derivative operator, selected antiderivative, or ambient Real completeness theorem.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLocalOperationNonescape`

Proof. Read the carrier inventory from Definition 3632.21. The local operations are stored only in the derivative, integral, and limit rows, and all Real-facing reads pass through the regular-rational and dyadic rows before the terminal seal is consumed.

Apply Definition 3632.44 to keep every operation behind its graph-and-replay row. Apply Definition 3632.45 and Definition 3632.13 to keep derivative and integral sources distinct.

The Real-facing boundary is controlled by Definition 3632.46 together with Definition 3632.14. The source-window requirement is exactly Definition 3632.15.

Thus each operation is exported only through the displayed BEDC packet. The excluded host and quotient objects are absent from the carrier, so there is no accepted escape route outside the finite local operation surface. □

Theorem 3632.53 (Calculus root continuity composition ledger)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, a continuity-composition read for derivative, integral, or limit consumers must first display the* BHist *continuous-map row* C*, the operation row among* D, I, L*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y*, the terminal* $\mathsf{Real}^{\uparrow}$ *row* R*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming* N*. The composition ledger exports no host continuity theorem, function-space equality, selected operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the continuous-map row C from the root carrier. By Definition 3632.44, every derivative, integral, or limit consumer must expose C before it reads D, I, or L.

For the operation side, apply Definition 3632.48. It separates derivative reads through D, integral reads through I, and limit reads through L, while keeping all three behind the common regular-rational, dyadic, Real, transport, replay, provenance, and naming rows.

The Real-facing portion is controlled by Definition 3632.46. Hence the continuity-composition ledger is a finite route through $C, D, I, L, Q, Y, R, H, T, P, N$, with no extra coordinate from which a host continuity theorem or ambient function-space equality could be read. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootContinuityCompositionLedger`

Theorem 3632.54 (Calculus root Riemann-sum Real seal)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, R, Q, Y, H, T, P, N)$*, a Riemann-sum-facing integral read must display the* BHist *finite-sum row* I*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *row* C*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, local* $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$ *naming* N*, and the terminal* $\mathsf{Real}^{\uparrow}$ *boundary* R *before any integral value is public. The seal is a finite Riemann row over L10 readback data and not a selected antiderivative, host integral functional, quotient equality of functions, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootRiemannSumRealSeal`

Proof. Project the integral source row I from the root carrier. It is the only row carrying finite-sum and endpoint handoff data for an integral-shaped read.

Apply Definition 3632.41. It forces the integral row through C, I, Q, H, T, P, N and then through the terminal Real boundary R. Apply Definition 3632.46 to keep the same route behind the dyadic tolerance ledger Y before R is consumed.

The derivative row D and limit row L remain separate by Definition 3632.45 and Definition 3632.48. Thus the Riemann-sum Real seal is exactly the finite route through $I, C, Q, Y, H, T, P, N, R$, with no selected antiderivative, host integration functional, quotient equality, or ambient completeness row. □

Theorem 3632.55 (Calculus root limit-derivative-integral triad)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, Q, Y, R, H, T, P, N)$*, the derivative row* D*, integral row* I*, and limit row* L *form one finite root triad over the continuous-map source* C*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Y*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R*, and the structural rows* H, T, P, N*. A consumer of any one of* D, I, L *must expose the whole route* $C, D, I, L, Q, Y, R, H, T, P, N$ *before exporting a Real-facing calculus value.*

Proof. Apply Definition 3632.44. It places every derivative, integral, and limit read behind the shared continuous-map row C.

Apply Definition 3632.45 to keep the derivative and integral coordinates distinct, and use Definition 3632.48 for the limit coordinate and the common ledger inventory.

Finally apply Definition 3632.54 and Definition 3632.46. The integral and Real-seal routes force the same Q, Y, R, H, T, P, N readback boundary, so the triad is the displayed finite carrier surface and not an ambient analytic operator family. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootLimitDerivativeIntegralTriad`

Theorem 3632.56 (Calculus root common Real readback)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, Q, Y, R, H, T, P, N)$*, derivative, integral, and limit consumers share the same Real readback route: the chosen operation row among* D, I, L *is read only together with* C, Q, Y, R, H, T, P, N*. No operation row exports a Real value through a separate quotient representative, selected limiting object, or host completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootCommonRealReadback`

Proof. Start from Definition 3632.46. It requires every Real-facing calculus export to pass through Q, Y before the terminal row R is consumed.

Use Definition 3632.44 to attach that readback to C, and use Definition 3632.48 to identify the only operation rows as D, I, L.

The Riemann-sum boundary of Definition 3632.54 supplies the integral case, while Definition 3632.45 prevents that case from being reused as derivative data. The shared readback is therefore $C, D, I, L, Q, Y, R, H, T, P, N$ with the selected operation coordinate named by the consumer. □

This common readback consumes the Real and completion chain through chapter 38, chapter 301, and chapter 291. Those sibling rows provide the terminal seal, regular rational readback, and tolerance ledger for the calculus root route, while importing no ambient Real completeness theorem or host function space.

Theorem 3632.57 (Calculus root operation separation)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, Q, Y, R, H, T, P, N)$*, the derivative, integral, and limit obligations are separated by the operation rows* D, I, L *while remaining tied to the same continuous-map, regular-rational, dyadic, Real, transport, replay, provenance, and naming rows* C, Q, Y, R, H, T, P, N*. Thus no accepted calculus consumer may infer a derivative claim from* I *or* L*, an integral claim from* D *or* L*, or a limit claim from* D *or* I *without reopening the displayed finite route.*

Proof. Apply Definition 3632.45. It already separates derivative reads through D from integral reads through I.

Apply Definition 3632.48. The exhaustion ledger adds the limit row L to the same separated inventory and gives no hidden coordinate from which one operation can supply another.

Use Definition 3632.44 and Definition 3632.46 to keep all three operation rows attached to C, Q, Y, R, H, T, P, N. The carrier route is therefore common at the readback boundary and separated at the operation boundary. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootOperationSeparation`

Theorem 3632.58 (Calculus root chain-rule ContinuousMap RegSeqRat scope)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, Q, Y, R, H, T, P, N)$*, a composable pair of local-linearization ledgers whose graph replay is accepted by* $\mathsf{ContinuousMap}^{\uparrow}$ *through* C *and whose dyadic error budgets descend through* $\mathsf{RegSeqRat}^{\uparrow}$ *via* Q, Y *produces a* $\mathsf{Real}^{\uparrow}$ *readback scope for the chain-rule window. The consumer may read only the finite route* $C, D, Q, Y, R, H, T, P, N$ *together with the two composable local-linearization rows; it may not infer the full fundamental theorem of calculus, a global derivative operator, a selected antiderivative, quotient equality of functions, or ambient Real completeness.*

Proof. Begin with the calculus root ContinuousMap handoff of Definition 3632.44. It forces the graph replay for each local-linearization row through the displayed continuous-map coordinate C before the derivative row D is consumed.

Use the derivative-integral boundary of Definition 3632.45. The chain-rule window remains on the derivative side of the root carrier and does not borrow an integral row or a host antiderivative claim.

Next apply the regular-rational and dyadic readback route supplied by Definition 3632.53 and Definition 3632.56. These keep the error budgets in Q, Y before any terminal $\mathsf{Real}^{\uparrow}$ readback row R is exposed.

Finally use Real-seal nonescape, Definition 3632.46. The resulting scope is the displayed finite route through $C, D, Q, Y, R, H, T, P, N$ for the composable local-linearization pair, not the full fundamental theorem of calculus or any ambient analytic completeness principle. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootChainRuleContinuousMapRegSeqRatScope`

Theorem 3632.59 (Calculus root operation readback tail chain-rule boundary)**.** *For every accepted* $\mathsf{Calculus}^{\uparrow}$ *root carrier* $G = (C, D, I, L, Q, Y, R, H, T, P, N)$*, any chain-rule readback that uses the derivative row* D *must retain the common route* $C, D, Q, Y, R, H, T, P, N$*. The derivative evidence cannot be supplied by the integral row* I *or the limit row* L*; those rows remain available only through their own integral and limit obligations.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRootOperationReadbackTailChainRuleBoundary`

Proof. Apply Definition 3632.58. It fixes the chain-rule window on the displayed derivative route through $C, D, Q, Y, R, H, T, P, N$ together with the composable local-linearization rows.

Next use Definition 3632.57. The separated operation ledger prevents an integral row I or a limit row L from being consumed as derivative evidence without reopening the corresponding operation obligation.

Finally apply Definition 3632.56. The Real-facing readback is the common finite BEDC route through the continuous-map, derivative, regular-rational, dyadic, Real, transport, replay, provenance, and naming rows. By Real-seal nonescape this route is not a host analytic chain-rule operator, selected integral, selected limit, quotient function equality, or ambient completeness principle. □

Lemma 3632.60 (Calculus derivative and Riemann-integral dependency route)**.** *Every substantive* $\mathsf{Calculus}^{\uparrow}$ *consumer of a derivative or integral conclusion reads the derivative branch through chapter 122, the Riemann finite-sum branch through chapter 1526, and the shared endpoint readback through the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows. The route is therefore a displayed BEDC dependency through derivative windows, tagged Riemann sums, regular rational readback, and real-name sealing; it is not a host function space, a host measure-space integral, a selected antiderivative, or quotient equality of functions.*

Proof. Project the $\mathsf{Calculus}^{\uparrow}$ local-linearization and root carrier rows already named in Definition 3632.1 and Definition 3632.5. Their derivative-facing coordinates are the $\mathsf{Derivative}^{\uparrow}$ rows, and their integral-facing coordinates are the $\mathsf{RiemannIntegral}^{\uparrow}$ or finite-sum rows.

The shared numerical readback is not supplied by a host analytic object. It passes through the regular rational and real-name rows before a public endpoint value is exposed.

The existing nonescape theorems in the chapter exclude host function spaces, host integration functionals, selected antiderivatives, quotient equality of functions, and ambient completeness. Hence the dependency route for calculus consumers is the finite $\mathsf{Derivative}^{\uparrow}$–$\mathsf{RiemannIntegral}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ route stated above. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRiemannIntegralDependencyRoute`

Theorem 3632.61 (Calculus derivative-integral dependency factorization)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *consumer that combines a derivative conclusion with a Riemann-integral conclusion factors its public read through the* $\mathsf{Derivative}^{\uparrow}$*,* $\mathsf{RiemannIntegral}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before exposing endpoint equality or an estimate. In the notation of Definition 3632.1 and Definition 3632.5, the derivative branch consumes the displayed derivative rows, the integral branch consumes the displayed finite-sum rows, and the common endpoint readback consumes the regular rational and real-name rows before any equality or estimate is public.*

Proof. Start with the dependency route of Definition 3632.60. It already separates derivative-facing reads through chapter 122 from Riemann finite-sum reads through chapter 1526.

The local-linearization carrier Definition 3632.1 supplies the derivative-side window, while the root public package Definition 3632.5 supplies the shared public rows. Thus a consumer combining the two conclusions must first read the derivative and integral branches as displayed BEDC rows.

The endpoint or estimate then passes through the regular rational readback and terminal Real seal. This is the same nonescape boundary used by Definition 3632.52, Definition 3632.10, and Definition 3632.46.

Those nonescape statements exclude host function spaces, selected antiderivatives, quotient function equality, host integration functionals, and ambient completeness. Hence no combined derivative-integral conclusion can expose an endpoint equality or estimate before the finite $\mathsf{Derivative}^{\uparrow}$–$\mathsf{RiemannIntegral}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ factorization has been consumed. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRiemannIntegralDependencyFactorization`

Theorem 3632.62 (Calculus finite-limit seal dependency)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *consumer that turns derivative or integral endpoint data into a limit-facing read must first pass through the finite* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *route*

$$M, W, R, D, E$$

of Definition 5722.5. The calculus consumer may read derivative windows through $\mathsf{Derivative}^{\uparrow}$ *and finite tagged sums through* $\mathsf{RiemannIntegral}^{\uparrow}$*, but its public endpoint handoff is limit-facing only*

after the displayed modulus, window, readback, tolerance, and terminal real-seal rows have been consumed.

Proof. Begin with Definition 3632.60. It separates the derivative branch, the Riemann finite-sum branch, and the shared regular-rational and real-name readback before any calculus endpoint is public.

Use Definition 3632.61 to combine the derivative and integral branches. The factorization leaves the endpoint read behind the same $\mathsf{Derivative}^{\uparrow}$–$\mathsf{RiemannIntegral}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ support, not behind a host function space or selected antiderivative.

Finally apply Definition 5722.5. Its finite route M, W, R, D, E is the Real-facing limit seal. Therefore a calculus consumer that turns the endpoint into a limit-facing read must expose that seal before the endpoint can be consumed as public limit data. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusFiniteLimitSealDependency`

Theorem 3632.63 (Calculus finite-limit seal public handoff)**.** *Any public* $\mathsf{Calculus}^{\uparrow}$ *endpoint equality or estimate that combines derivative and Riemann-integral branches may be exported only after the* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *route*

$$M, W, R, D, E$$

of Definition 5722.5, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal have all been exposed. The exported handoff is therefore the displayed finite route through* $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *and not a host function space, selected antiderivative, host integration functional, quotient function equality, or ambient completeness assertion.*

Proof. Start from the dependency route of Definition 3632.60. It already places derivative reads, Riemann finite-sum reads, regular-rational readback, and real-name sealing on displayed BEDC rows.

Apply Definition 3632.61. Any combined endpoint equality or estimate must first factor through the derivative branch, the Riemann-integral branch, and the shared $\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ readback before it is public.

Now use Definition 3632.62. When that endpoint read becomes limit-facing, the finite route M, W, R, D, E of the $\mathsf{FiniteLimitSeal}^{\uparrow}$ seal is exposed before export.

The non-escape boundary is unchanged: the handoff supplies no host function space, selected antiderivative, host integration functional, quotient function equality, or ambient completeness principle. Hence later calculus statements can consume only the public finite-limit-seal handoff displayed above. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusFiniteLimitSealPublicHandoff`

The $\mathsf{Calculus}^{\uparrow}$ plane-boundary branch reads vector-calculus integration through the Green theorem certificate before treating the result as a calculus-facing Riemann-integral dependency. This keeps the planar region, boundary curve, differential-form row, scalar curl or divergence row, and tagged integration handoff visible as a finite route.

Thus any $\mathsf{Calculus}^{\uparrow}$ consumer of plane boundary integration passes through chapter 7971 and chapter 5720 before reading the $\mathsf{RiemannIntegral}^{\uparrow}$ packet of chapter 1526.

Lemma 3632.64 (Calculus finite-limit seal route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *endpoint consumer that turns derivative, integral, or root limit data into a limit-facing read must pass through chapter 5722 and the finite* M, W, R, D, E *route of Definition 5722.5 before the public* $\mathsf{Real}^{\uparrow}$ *endpoint is exposed.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusFiniteLimitSealDependencyRoute`

Proof. Start with the derivative and integral dependency route of Definition 3632.60. It already forces calculus endpoint reads through the displayed $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Now read the finite-limit seal route. Theorem Definition 5722.5 supplies the M, W, R, D, E handoff for real-facing limit reads, so the calculus endpoint consumer must expose that seal before treating the endpoint as public limit-facing data. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusFiniteLimitSealRoute`

The $\mathsf{Calculus}^{\uparrow}$ packet supplies the local difference-quotient and derivative-window route consumed by chapter 5135, chapter 6674, and chapter 6763. These sibling certificates read the same finite calculus window before exporting finite-difference tables, Taylor-polynomial coefficient rows, or mean-value comparison data. The $\mathsf{Calculus}^{\uparrow}$ derivative-facing route reads finite computations through chapter 5135 before using the derivative carrier of chapter 122. Its Real-facing rows remain tied to the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Consequently the finite-difference derivative route is a downstream consumer of the L10 real-completion spine before any derivative endpoint is read: the dyadic tolerance rows of chapter 291 feed the regular rational sequence rows of chapter 301, and those rows feed the real-completion seal of chapter 38. The derivative carrier may inspect finite differences only after that spine has supplied the tolerance-visible $\mathsf{Real}^{\uparrow}$ endpoint. The $\mathsf{Calculus}^{\uparrow}$ packet supplies derivative and limit local-linearization rows to the located-compact boundary only after the finite-net and real-readback routes are visible. A $\mathsf{LocatedCompact}^{\uparrow}$ consumer of a calculus window must first read the local-linearization carrier of Definition 3632.1 and the Cauchy-facing derivative handoff of Definition 3632.51; it then receives the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, the $\mathsf{ContinuousMap}^{\uparrow}$ graph replay row, and the terminal $\mathsf{Real}^{\uparrow}$ seal before any compactness-facing finite-net row may be consumed.

Theorem 3632.65 (Calculus located-compact dependency route)**.** *Every* $\mathsf{LocatedCompact}^{\uparrow}$ *consumer of a* $\mathsf{Calculus}^{\uparrow}$ *derivative, limit, or local-linearization row factors through the finite calculus route displayed by Definition 3632.1, Definition 3632.51,* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before it reaches the located-compact packet of chapter 1488. The handoff exports a finite graph-and-readback window for compactness use, not open-cover compactness, a selected finite subcover, quotient function equality, or ambient Real completeness.*

Proof. Project the calculus local-linearization carrier. Its derivative and limit rows expose graph data through $\mathsf{ContinuousMap}^{\uparrow}$, regular rational readback through $\mathsf{RegSeqRat}^{\uparrow}$, and endpoint values through the $\mathsf{Real}^{\uparrow}$ boundary.

Use Definition 3632.51 for the Cauchy-facing derivative window. That route displays the derivative row, graph row, readback row, dyadic tolerance ledger, transport, replay, provenance, and local naming before the Real boundary is consumed.

Only after those rows are visible may the consumer enter chapter 1488. The located-compact packet therefore receives finite calculus data suitable for its finite-net and locatedness rows, with no host compactness theorem or selected subcover coordinate added by the calculus route. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLocatedCompactDependencyRoute`

The $\mathsf{Calculus}^{\uparrow}$ packet consumes the Cauchy and real-completion route before derivative, integral, or limit rows can expose a real-valued endpoint. Its root carrier therefore sits downstream of the regular rational readback of chapter 301, the terminal real boundary of chapter 38, and the generic limit packet of chapter 1678.

Theorem 3632.66 (Calculus Cauchy dependency route)**.** *Every* Calculus$^{\uparrow}$ *derivative, integral, or limit read that exposes a real-valued limit factors through the finite Cauchy route displayed by the local-linearization carrier of Definition 3632.1 and the root local-linearization Cauchy handoff of Definition 3632.51. In particular, the read must display the* RegSeqRat$^{\uparrow}$ *readback row and the terminal* Real$^{\uparrow}$ *seal before any calculus operation can export a real-valued endpoint. The route supplies finite Cauchy-window data for the* Limit$^{\uparrow}$ *consumer, not an ambient completeness theorem, a host limit operator, quotient equality of functions, or a selected real representative.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusCauchyDependencyRoute`

Proof. Project the calculus local-linearization carrier. Its derivative, integral, and limit rows are interpreted only together with the regular rational readback row and the terminal real seal.

Apply the root local-linearization Cauchy handoff. That theorem keeps the derivative-facing calculus window behind the displayed Cauchy rows, dyadic tolerance ledger, transport, replay, provenance, and local naming before any Real$^{\uparrow}$ endpoint is public.

Finally read the sibling route through chapter 301, chapter 38, and chapter 1678. These chapters supply the finite readback, real boundary, and limit consumer rows consumed by calculus; none supplies an ambient host completeness or quotient-function equality coordinate. □

Theorem 3632.67 (Calculus Cauchy dependency real-completion readback)**.** *Every accepted* Calculus$^{\uparrow}$ *real-valued derivative, integral, or limit endpoint read exposes the* RegSeqRat$^{\uparrow}$ *readback row, the terminal* Real$^{\uparrow}$ *seal, and the* Limit$^{\uparrow}$ *consumer row in that order. The route exports only finite Cauchy-window data from the local-linearization carrier and never exports an ambient Real-completion theorem, a selected limit, quotient equality of functions, or a host endpoint object.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusCauchyDependencyRealCompletionReadback`

Proof. Project the local-linearization carrier of Definition 3632.1. Its derivative, integral, and limit endpoints are visible only through the displayed Cauchy-window rows, so no endpoint can bypass the finite route.

Apply Definition 3632.66. It already places every real-valued calculus read behind the regular rational readback and the terminal Real seal before any endpoint is public.

Now read the sibling routes in order. The RegSeqRat$^{\uparrow}$ chapter supplies the regular rational readback row, the Real$^{\uparrow}$ chapter supplies the terminal seal, and the Limit$^{\uparrow}$ chapter consumes the resulting finite Cauchy-window data as a limit-facing row. Since those are the only exposed rows, the readback cannot import host completeness, selected representatives, quotient-function equality, or an ambient endpoint. □

The Calculus$^{\uparrow}$ packet consumes the shared finite limit route whenever a derivative or integral read exposes a limiting value. This route is the same public route recorded by chapter 1678, not a host limit operator or a selected real representative.

Theorem 3632.68 (Calculus Limit dependency route)**.** *Every* Calculus$^{\uparrow}$ *finite derivative or integral read that consumes a limiting value must pass through the shared* Limit$^{\uparrow}$ *route of chapter 1678, together with the* RegSeqRat$^{\uparrow}$ *readback rows of chapter 301, the* StreamName$^{\uparrow}$ *schedule rows of chapter 126, the* DyadicRatCore$^{\uparrow}$ *tolerance ledgers of chapter 291, and the downstream* Real$^{\uparrow}$ *seal rows of chapter 38. The calculus carrier cannot replace that route by host limit operators, quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLimitDependencyRoute`

Proof. Project a calculus read that asks for a derivative or integral endpoint. The endpoint is not read as a host real value; it is routed through the finite limit consumer surface.

Apply the public $\mathsf{Limit}^{\uparrow}$ handoff of Definition 1678.3, Definition 1678.4, and Definition 1678.8. These theorems force the same StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming route before a limiting value can be consumed.

The surrounding calculus rows can then read derivative and integral data through that shared route. Since the route contains no host limit operator, quotient stream equality, selected representative, host real equality, countable-choice selector, or ambient-completeness coordinate, no calculus consumer can export one by bypassing $\mathsf{Limit}^{\uparrow}$. □

Theorem 3632.69 (Calculus Limit dependency refusal boundary)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *derivative or integral endpoint read that omits one of the* $\mathsf{Limit}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *seal rows is outside the BEDC calculus limit-consumer surface. Such a read cannot be retyped as an accepted calculus limit consumer by replacing the missing row with a host limit operator, quotient stream equality, a selected representative, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLimitDependencyRefusalBoundary`

Proof. Apply Definition 3632.68. It requires every finite derivative or integral endpoint read that consumes a limiting value to pass through the public $\mathsf{Limit}^{\uparrow}$ route and its RegSeqRat, StreamName, DyadicRatCore, and Real handoffs.

If one of those seal rows is absent, the route supplied by Definition 1678.3, Definition 1678.4, and Definition 1678.8 is not available. The attempted endpoint read therefore lacks the displayed finite limit source that the calculus carrier consumes.

The omitted row cannot be supplied by the host side. The cited handoffs exclude host limit operators, quotient stream equality, selected representatives, countable-choice selectors, and ambient completeness rows from the accepted $\mathsf{Limit}^{\uparrow}$ route, so the calculus consumer has no alternate BEDC row through which to retype the missing dependency. □

The $\mathsf{Calculus}^{\uparrow}$ limit route is read only after the real-completion display has fixed its readback rows. The child route below records the sibling order used by derivative, integral, and endpoint consumers: $\mathsf{Limit}^{\uparrow}$ supplies the limit-facing consumer surface, while $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ supply the terminal seal, regular rational readback, and schedule rows that make the limit read finite.

Theorem 3632.70 (Calculus Limit real handoff)**.** *Every accepted* $\mathsf{Calculus}^{\uparrow}$ *derivative, integral, or endpoint consumer that cites the* $\mathsf{Limit}^{\uparrow}$ *route must first display the* $\mathsf{Real}^{\uparrow}$ *terminal seal, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{StreamName}^{\uparrow}$ *schedule row used by that limit route. The handoff is the finite dependency lattice through chapter 1678, chapter 38, chapter 301, and chapter 126; it is not a host limit operator, quotient stream equality, selected representative, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLimitRealHandoff`

Proof. Start with the existing calculus limit dependency route of Definition 3632.68. It already places every derivative or integral endpoint read behind the shared $\mathsf{Limit}^{\uparrow}$ consumer surface.

Now read the sibling rows that make this consumer surface finite. The $\mathsf{StreamName}^{\uparrow}$ schedule names the displayed stream positions, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies the terminal seal consumed by the limit-facing row.

The calculus packet can therefore cite $\mathsf{Limit}^{\uparrow}$ only after those readback rows are visible. Since the route contains no coordinate for a host limit operator, quotient stream equality, selected representative, or ambient completeness theorem, the handoff remains a finite BEDC dependency route. □

This terminal-export theorem is the canonical public handoff consumed by the $\mathsf{Calculus}^{\uparrow}$ closure ledger, so the ledger points to this route without changing the independent verification grade recorded for the chapter.

Theorem 3632.71 (Calculus Limit real derivative readback)**.** *Every accepted* $\mathsf{Calculus}^{\uparrow}$ *derivative endpoint consumer that exports a Real-facing derivative value must pass through* $\mathsf{Limit}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *before the endpoint may be read as a* $\mathsf{Real}^{\uparrow}$ *value. The derivative readback is the finite BEDC route through limit consumption, stream scheduling, regular rational readback, dyadic rational coordinates, and terminal Real sealing; it is not a host limit operator, quotient stream equality, selected representative, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLimitRealDerivativeReadback`

Proof. Start with the real handoff of Definition 3632.70. It already places derivative endpoint reads behind the $\mathsf{Limit}^{\uparrow}$ consumer surface together with $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Now include the existing calculus limit dependency route of Definition 3632.68. Its endpoint schedule is read through rational coordinates, so the $\mathsf{DyadicRatCore}^{\uparrow}$ row must be visible before the regular readback can be sealed as a Real-facing derivative value.

The route therefore exposes only the displayed limit, stream, dyadic rational, regular readback, and Real seal rows. Since no coordinate supplies a host limit operator, quotient stream equality, selected representative, or ambient completeness theorem, the derivative endpoint remains a finite BEDC readback. □

Theorem 3632.72 (Calculus Limit real terminal export)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *derivative, integral, or endpoint theorem that exports a Real-facing value through the* $\mathsf{Limit}^{\uparrow}$ *route must display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any downstream calculus consumer may read that value. The export composes the real handoff of Definition 3632.70, the derivative readback of Definition 3632.71, and the limit dependency route of Definition 3632.68; it is not a host limit, quotient stream equality, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLimitRealTerminalExport`

Proof. Begin with Definition 3632.70. It places every derivative, integral, or endpoint consumer behind the $\mathsf{Limit}^{\uparrow}$ surface together with the StreamName schedule, RegSeqRat readback, and terminal Real seal.

Apply Definition 3632.71 to the Real-facing endpoint case. That theorem inserts the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row before the regular readback is sealed as a Real-facing value.

Finally use Definition 3632.68 to identify the common calculus limit route consumed by derivative, integral, and endpoint theorems. The same displayed limit surface is the only route by which those consumers can reach a Real-facing value.

The terminal export is therefore the finite row order $\mathsf{Limit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Because none of the composed routes contains a host limit operator, quotient stream equality, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, no downstream calculus consumer can bypass the displayed rows. □

The $\mathsf{Calculus}^{\uparrow}$ product-distance route is read through the Cauchy product metric packet before derivative-product or endpoint consumers expose any paired Real data. This child route records that the calculus hub uses the finite product-metric surface of chapter 3551 rather than a host product metric.

Theorem 3632.73 (Calculus product metric forward link)**.** *Every accepted* $\mathsf{Calculus}^{\uparrow}$ *derivative-product, endpoint, or paired-distance consumer that uses product-distance data must first display the* $\mathsf{CauchyProductMetric}^{\uparrow}$ *packet through* $\mathsf{CauchyProduct}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before reading either component as a* $\mathsf{Real}^{\uparrow}$ *value. The route supplies the finite product-distance ledger, paired stream windows, regular rational readbacks, dyadic tolerance coordinates, metric distance row, and componentwise terminal Real seals. It supplies no host product metric, quotient stream equality, selected product limit, detached Real carrier, detached Real pair, or ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricForwardLink`

Proof. Begin with the real handoff of Definition 3632.70. It already forces endpoint reads through $\mathsf{Limit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before a calculus consumer may expose a Real-facing value.

Now insert the product-distance sibling. The $\mathsf{CauchyProductMetric}^{\uparrow}$ carrier of chapter 3551 reads two $\mathsf{CauchyProduct}^{\uparrow}$ rows, the $\mathsf{Met}^{\uparrow}$ distance row, paired stream windows, regular rational readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ product-distance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The terminal Real seal is componentwise. A paired-distance read may expose the left component and the right component only after the product-metric sibling has displayed the two carried streams, their dyadic comparison ledger, and the Real-facing seals for those same coordinates. It cannot replace that route by a detached host product metric or a selected product limit whose components are later read as independent Real values.

Therefore a derivative-product, endpoint, or paired-distance consumer can use product-distance data only after that finite route is visible. Since no row in the calculus packet or the product-metric sibling carries a host product metric, quotient stream equality, selected product limit, detached Real carrier, detached Real pair, or ambient completeness theorem, the forward link remains a BEDC dependency route. □

Theorem 3632.74 (Calculus product metric seal pairing)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *derivative-product, endpoint, or paired-distance consumer that exposes two component* $\mathsf{Real}^{\uparrow}$ *seals must read both seals through the same* $\mathsf{CauchyProductMetric}^{\uparrow}$ *packet and the shared route*

$$\mathsf{CauchyProduct}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow}.$$

The paired seals are therefore componentwise but not detached: the consumer may inspect the left and right $\mathsf{Real}^{\uparrow}$ *rows only as terminal rows of one displayed product-metric packet. It has no route through detached Real pairs, host product metrics, selected product limits, quotient stream equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricSealPairing`

Proof. Start with the forward link of Definition 3632.73. It places every derivative-product, endpoint, or paired-distance consumer behind the $\mathsf{CauchyProductMetric}^{\uparrow}$ packet before either component Real value is read.

Next apply the finite modulus route of Definition 3632.75. This identifies the common route through the two $\mathsf{CauchyProduct}^{\uparrow}$ source rows, the $\mathsf{Met}^{\uparrow}$ distance row, paired $\mathsf{StreamName}^{\uparrow}$ windows,

paired $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ product-distance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seals.

Finally use the handoff theorem Definition 3632.76. The handoff keeps both component seals downstream of the same product-metric packet, so a calculus consumer cannot split the pair into detached Real data and later attach a host product metric, selected product limit, quotient stream equality, or ambient completeness witness. □

Theorem 3632.75 (Calculus product metric finite modulus route)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *paired-distance read that reaches component* $\mathsf{Real}^{\uparrow}$ *seals must expose the finite product-metric modulus rows before those component seals are read. Concretely, the read factors through the* $\mathsf{CauchyProductMetric}^{\uparrow}$ *route of chapter 3551, the two* $\mathsf{CauchyProduct}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-distance ledger, the* $\mathsf{Met}^{\uparrow}$ *distance row, and only then the terminal component* $\mathsf{Real}^{\uparrow}$ *seals. It does not factor through a host product metric, quotient stream equality, ambient completeness, or a detached product Real.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricForwardModulusRoute`

Proof. Start with the forward link of Definition 3632.73. It already makes the product-distance sibling visible before any calculus derivative-product, endpoint, or paired-distance consumer can inspect component Real data.

Next read the product-metric sibling through Definition 3551.4. That boundary orders the route by the two product sources, paired stream windows, regular rational readbacks, dyadic product-distance ledger, metric row, and terminal Real seal. Thus the finite modulus rows are not optional decoration: they are the rows through which the paired distance is displayed before the component seals are available.

The excluded coordinates are the same on both sides of the handoff. Neither the calculus route nor the $\mathsf{CauchyProductMetric}^{\uparrow}$ route contains a host product metric, quotient stream equality, selected product limit, detached product Real, or ambient completeness witness. Therefore every accepted paired-distance read keeps the finite modulus route visible before it reads the component $\mathsf{Real}^{\uparrow}$ seals. □

Theorem 3632.76 (Calculus product metric modulus handoff)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *consumer that reads a derivative-product, endpoint, or paired-distance conclusion must read the product-metric modulus handoff through*

$$\mathsf{CauchyProductMetric}^{\uparrow},\quad \mathsf{CauchyProduct}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

before either component $\mathsf{Real}^{\uparrow}$ *seal is exposed. The handoff supplies only the displayed product-distance packet, paired source rows, metric row, finite stream windows, regular rational readbacks, dyadic tolerance ledger, and terminal component seals. It supplies no host product metric, quotient stream equality, detached Real pair, selected product limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricModulusHandoff`

Proof. Start with Definition 3632.73. It places every derivative-product, endpoint, or paired-distance consumer after the $\mathsf{CauchyProductMetric}^{\uparrow}$ packet and before any component Real-facing value can be inspected.

Refine the route by Definition 3632.75. That theorem identifies the finite modulus rows: the $\mathsf{CauchyProduct}^{\uparrow}$ sources, $\mathsf{Met}^{\uparrow}$ distance row, paired $\mathsf{StreamName}^{\uparrow}$ windows, paired $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ product-distance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seals.

Finally use the $\mathsf{CauchyProductMetric}^{\uparrow}$ real-seal boundary of Definition 3551.4. The boundary keeps the component seals downstream of the product-metric route, so a calculus consumer cannot detach the two Real rows and later pretend that their product distance came from a host product metric.

The excluded principles have no row in the composed display. Quotient stream equality, detached Real pairs, selected product limits, host product metrics, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not generated by the calculus packet or by the product-metric sibling, so the modulus handoff is the only accepted route to the paired-distance read. □

Theorem 3632.77 (Calculus product metric regulated-integral handoff)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *paired-distance or derivative-product consumer that feeds a* $\mathsf{RegulatedIntegral}^{\uparrow}$ *endpoint must first expose the shared route*

$$\mathsf{CauchyProductMetric}^{\uparrow},\quad \mathsf{CauchyProduct}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

and then the $\mathsf{RegulatedIntegral}^{\uparrow}$ *finite ledger*

$$I,\ G,\ A,\ S,\ D,\ R,\ E,\ H,\ C,\ P,\ N$$

before any integral endpoint is public. The route supplies product-metric Real endpoints and the regulated finite-sum handoff through the same L10 Real-completion path. It supplies no host product metric, selected product limit, measure completion, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricRegulatedIntegralHandoff`

Proof. Start with Definition 3632.76. It forces any derivative-product, endpoint, or paired-distance conclusion to expose the $\mathsf{CauchyProductMetric}^{\uparrow}$ packet, the $\mathsf{CauchyProduct}^{\uparrow}$ source rows, the $\mathsf{Met}^{\uparrow}$ distance row, the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seals.

Next feed the terminal Real-facing data into the regulated-integral route of Definition 1557.7. That route keeps the integral endpoint behind the same L10 Real-completion interface rather than behind a host integral or a detached completed Real object.

Finally apply the public interface theorem Definition 1557.10. The public regulated-integral endpoint is readable only through the finite ledger $I, G, A, S, D, R, E, H, C, P, N$, so the calculus product-metric route and the regulated-integral finite-sum handoff meet at the displayed Real-completion boundary.

The excluded objects have no coordinate in the composed route. Host product metrics, selected product limits, measure completion, quotient function equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are therefore not available to the consumer before the regulated endpoint is exposed. □

Theorem 3632.78 (Calculus product metric regulated-endpoint route)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *consumer exporting regulated integral endpoints from paired-distance or derivative-product data must factor through* $\mathsf{CauchyProductMetric}^{\uparrow}$*,* $\mathsf{CauchyProduct}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and then the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *endpoint ledger. The route first exposes the shared product-metric rows*

$$\mathsf{CauchyProductMetric}^{\uparrow},\quad \mathsf{CauchyProduct}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

and then reads the regulated endpoint ledger

$$I,\ G,\ A,\ S,\ D,\ R,\ E,\ H,\ C,\ P,\ N.$$

It supplies no host product metric, measure completion, quotient function equality, selected product limit, detached endpoint pair, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Begin with the product metric handoff of Definition 3632.76. It places every derivative-product, endpoint, or paired-distance conclusion behind the CauchyProductMetric$^{\uparrow}$ packet, the CauchyProduct$^{\uparrow}$ source rows, the Met$^{\uparrow}$ distance row, finite StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readbacks, the DyadicRatCore$^{\uparrow}$ tolerance ledger, and the terminal Real$^{\uparrow}$ seals.

Refine the route by the finite modulus theorem Definition 3632.75. That theorem keeps the paired-distance data attached to the product-metric packet before either component Real seal can be read, so the endpoint source is not a detached product limit.

Now apply the regulated-integral handoff of Definition 3632.77. It feeds the terminal product-metric Real data into the regulated endpoint ledger $I, G, A, S, D, R, E, H, C, P, N$ rather than into a host integral or a measure-completion object.

Finally use the public interface theorem Definition 1557.10. The public endpoint is readable only through the displayed regulated-integral rows, and the preceding product-metric rows supply its Real-facing inputs. Since neither route contains a host product metric, measure completion, quotient function equality, selected product limit, detached endpoint pair, or ambient completeness principle, every exported endpoint factors through the finite route stated above. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricRegulatedEndpointRoute`

Theorem 3632.79 (Calculus product metric Real route)**.** *Any* Calculus$^{\uparrow}$ *paired-distance consumer that exports a* Real$^{\uparrow}$*-facing derivative or endpoint read factors through the same finite route: the* CauchyProductMetric$^{\uparrow}$ *packet, two* CauchyProduct$^{\uparrow}$ *rows, paired* StreamName$^{\uparrow}$ *windows, paired* RegSeqRat$^{\uparrow}$ *readbacks, the* DyadicRatCore$^{\uparrow}$ *product-distance ledger, the* Met$^{\uparrow}$ *distance row, the modulus handoff row, and then the terminal* Real$^{\uparrow}$ *seals. The route exports no host product metric, quotient stream equality, detached Real pair, selected product limit, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricRealRoute`

Proof. Start with the forward link of Definition 3632.73. It forces every derivative-product, endpoint, or paired-distance consumer that uses product-distance data to display the CauchyProductMetric$^{\uparrow}$ packet before reading component Real values.

Use the seal pairing theorem of Definition 3632.74. It keeps the two terminal Real$^{\uparrow}$ seals componentwise but attached to one shared product-metric packet rather than to a detached Real pair.

Refine the shared packet by Definition 3632.75 and Definition 3632.76. These rows expose the two CauchyProduct$^{\uparrow}$ sources, paired StreamName$^{\uparrow}$ windows, paired RegSeqRat$^{\uparrow}$ readbacks, the DyadicRatCore$^{\uparrow}$ product-distance ledger, the Met$^{\uparrow}$ distance row, and the handoff before the terminal seals are read.

Since each cited route excludes host product metrics, quotient stream equality, selected product limits, detached Real pairs, and ambient completeness, their composition gives exactly the finite Real-facing route stated above. □

Theorem 3632.80 (Calculus product metric forward-link export)**.** *Any public* Calculus$^{\uparrow}$ *paired-distance or derivative-product export factors through the product-metric route before it may feed regulated-integral or endpoint consumers. The export must display the existing* CauchyProductMetric$^{\uparrow}$ *route,* CauchyProduct$^{\uparrow}$ *rows, the* Met$^{\uparrow}$ *distance row,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, and terminal* Real$^{\uparrow}$ *seals as one finite Real-completion path.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusProductMetricForwardLinkExport`

Proof. Start with Definition 3632.73. It places every paired-distance or derivative-product consumer behind the product-metric route before component Real-facing data can be read.

Use Definition 3632.74, Definition 3632.75, and Definition 3632.76. These rows keep the paired seals attached to one $\mathsf{CauchyProductMetric}^{\uparrow}$ packet, expose the product rows, metric row, stream windows, regular readbacks, and dyadic tolerance ledger, and prevent a detached Real pair or host product metric from entering the export.

Finally apply Definition 3632.79. The Real route is already terminal for the component seals, so the public export can feed regulated-integral or endpoint consumers only through that same displayed Real-completion path. □

Theorem 3632.81 (Calculus Peano dependency route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *read that is used as an ODE-facing derivative row or local-flow row must consume the Peano and initial-value surfaces after the Real and continuous-map rows have already been displayed. Concretely, such a read is routed through the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and modulus rows, chapter 3530, and chapter 3979 before it may be exported as an ODE existence consumer.*

Lean4 ✓ `BEDC.Derived.CalculusUp.PeanoDependencyRoute.CalculusPeanoDependencyRoute`

Proof. The hub spine fixes $\mathsf{Calculus}^{\uparrow}$ as a packet over Real-facing limits, local operations, and continuous-map readback. The existing Real handoff and finite-difference routes make any derivative read visible only after the terminal $\mathsf{Real}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ rows have been named.

An ODE-facing consumer needs more than that derivative row. It must also expose the local existence packet of chapter 3530 and the initial-data packet of chapter 3979, since those chapters bind the interval source, vector-field row, local window, and solution-read surface used by the existence request.

Thus the calculus derivative or local-flow read is not a detached host derivative. It is an additive child route from the already displayed Real and continuous-map rows through Peano existence and initial-value data before any ODE existence consumer is public. □

The $\mathsf{Calculus}^{\uparrow}$ real-completion route is read as a child of the existing limit handoff. The endpoint surface of Definition 3632.70 and Definition 3632.72 already fixes the finite readback order through $\mathsf{Limit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any calculus consumer can export a Real-facing value.

Theorem 3632.82 (Calculus Real-completion forward link)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *Real-facing endpoint export that consumes a* $\mathsf{Limit}^{\uparrow}$ *row must pass through the* $\mathsf{Real}^{\uparrow}$ *terminal seal, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row displayed by Definition 3632.70 and Definition 3632.72. The forward link is the finite L10 route from calculus limits into the Real-completion spine of chapter 38; it is not a host limit operator, quotient stream equality, selected representative, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealCompletionForwardLink`

Proof. Read the endpoint export through Definition 3632.70. That theorem already places every derivative, integral, or endpoint consumer behind the $\mathsf{Limit}^{\uparrow}$ surface together with the $\mathsf{Real}^{\uparrow}$ terminal seal, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{StreamName}^{\uparrow}$ schedule rows.

Now apply Definition 3632.72. It inserts the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row before the regular readback is sealed as a Real-facing value, so the downstream calculus export cannot skip the displayed real-completion readback order.

Since the route has no coordinate for a host limit operator, quotient stream equality, selected representative, or ambient completeness theorem, the child link records only the finite L10 dependency lattice already visible in the sibling handoff theorems. □

Theorem 3632.83 (Calculus real-completion sibling route)**.** *Every accepted* $\mathsf{Calculus}^{\uparrow}$ *derivative, integral, or limit consumer that reaches Real-facing completion data must route through the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *completion stack, with the* $\mathsf{StreamName}^{\uparrow}$ *naming surface available when the consumer reads a displayed sequence. The route is witnessed by chapter 38, chapter 301, and chapter 126. It is not an appeal to ambient Real completeness, host quotient completion, or selected limits outside the accepted completion stack.*

Proof. Read the accepted $\mathsf{Calculus}^{\uparrow}$ consumer through its derivative, integral, or limit interface. A Real-facing completion request first has to expose the $\mathsf{Real}^{\uparrow}$ certificate surface rather than a host completeness object.

The completion data then factors through the regular rational naming route supplied by $\mathsf{RegSeqRat}^{\uparrow}$. When the consumer carries a sequential name, the visible stream component is the $\mathsf{StreamName}^{\uparrow}$ naming surface, so the read remains inside the displayed completion stack.

Thus the horizontal dependency is exactly the sibling route through Real, regular rational sequences, and StreamName names. Since no carrier row in the local route names ambient Real completeness, host quotient completion, or selected limits, those endpoints are not exported by the calculus consumer. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealCompletionSiblingRoute`

Theorem 3632.84 (Calculus regulated-integral forward link)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *integration-facing consumer that reads a regulated integral first exposes the regulated-integral finite step route of chapter 1557 before it may use* $\mathsf{Real}^{\uparrow}$ *endpoint seals. In the root package of Definition 3632.5, the integral branch reads the calculus finite-sum row, then the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *interval, regulated-function, step approximation, finite step-sum, Darboux/Riemann compatibility, error, transport, replay, provenance, and local NameCert rows, and only then consumes the Real-facing endpoint.*

The forward link is therefore a sibling dependency from the accepted $\mathsf{Calculus}^{\uparrow}$ *root package to the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *route. It does not supply a host integral functional, selected antiderivative, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRegulatedIntegralForwardLink`

Proof. Start from the $\mathsf{Calculus}^{\uparrow}$ root public package of Definition 3632.5. Its integration-facing branch contains the finite-sum row and the structural rows that transport, replay, source, and locally name the accepted calculus read.

Route that branch through chapter 1557. The regulated-integral packet exposes its interval, regulated-function, dyadic step approximation, finite step-sum, Darboux/Riemann compatibility, error, transport, replay, provenance, and local NameCert rows before a Real-facing handoff is public.

The terminal endpoint seal is then read through $\mathsf{Real}^{\uparrow}$ and the existing calculus Real-completion sibling route. Since neither the calculus root package nor the regulated-integral sibling carries a coordinate for host integration, selected antiderivatives, quotient function equality, measure completion, or ambient completeness, the forward link remains the displayed finite route. □

Theorem 3632.85 (Calculus real and continuous-map dependency route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *derivative, integral, or limit-facing consumer that reads a scalar endpoint or function-value row must*

expose the Real$^{\uparrow}$ *seal of chapter 38 and the* ContinuousMap$^{\uparrow}$ *modulus-and-evaluation surface of chapter 130 before the calculus packet can replay the read through its local* NameCert *row. Thus the calculus hub records a substantive L10-to-analysis edge through Real names and continuous-map data rather than a detached kernel-only route.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealContinuousDependencyRoute`

Theorem 3632.86 (Calculus Real-completion orphan lattice route)**.** *Every* Calculus$^{\uparrow}$ *regulated-integral or limit-facing consumer that reads an endpoint seal must first pass through the L10 Real-completion source lattice of chapter 38, chapter 301, and chapter 126. In particular, the consumer may use the* RegulatedIntegral$^{\uparrow}$ *handoff of Definition 3632.84 only after the source stream window, regular rational readback, and terminal Real seal are visible as the displayed completion route. It exports no host completion theorem, selected representative of a Cauchy stream, quotient real equality, detached endpoint seal, or ambient integration functional.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealCompletionOrphanLatticeRoute`

Proof. Start with the Calculus$^{\uparrow}$ root package. Its regulated-integral and limit-facing rows are accepted only as finite BEDC reads through the calculus carrier, transport, replay, provenance, and local naming rows.

Use the regulated-integral forward link. It routes endpoint reads through the displayed RegulatedIntegral$^{\uparrow}$ ledger rather than through a host integral or detached endpoint object.

Finally compose this handoff with the Real-completion source lattice. The StreamName$^{\uparrow}$ window supplies the finite source, RegSeqRat$^{\uparrow}$ supplies regular rational readback, and Real$^{\uparrow}$ supplies the terminal seal, so every such endpoint read remains inside the L10 completion lattice. □

Theorem 3632.87 (Calculus real-completion CauchySpace dependency link)**.** *Every accepted* Calculus$^{\uparrow}$ *derivative, integral, or limit consumer that reaches Real-facing completion data must pass through the* CauchySpace$^{\uparrow}$ *filter-uniform and regular-sequence boundary before the terminal* Real$^{\uparrow}$ *seal is read. Concretely, the existing route through Definition 3632.83 factors through the Cauchy-space consumer surface of chapter 1847: the* CauchyFilter$^{\uparrow}$ *and* UniformSpace$^{\uparrow}$ *rows expose the completion request, the* RegSeqRat$^{\uparrow}$ *row supplies the regular rational readback, the* StreamName$^{\uparrow}$ *row supplies any displayed sequential name, and only then may the* Real$^{\uparrow}$ *seal be consumed.*

Proof. Start with a Real-facing Calculus$^{\uparrow}$ consumer and read it through Definition 3632.83. That route already forces the endpoint through the Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and StreamName$^{\uparrow}$ completion stack rather than through ambient completeness.

Now insert the Cauchy-space boundary supplied by chapter 1847. Its Real-consumer rows require the displayed filter, uniform, regular-name, precompletion, transport, replay, provenance, and local naming data before a Real-facing consumer can inspect completion data.

Thus the calculus endpoint cannot jump directly from a local derivative, integral, or limit row to a Real seal. It first traverses the Cauchy-space filter-uniform and regular-sequence interface, and the route exports no host quotient completion, selected limit, countable-choice selector, or ambient Real$^{\uparrow}$ completeness theorem. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusRealCompletionDependencyLink`

Theorem 3632.88 (Calculus pointwise stream metric dependency route)**.** *Every accepted* Calculus$^{\uparrow}$ *derivative, integral, or local-error consumer that compares real-valued stream data must first read the pointwise metric-stream packet of chapter 4139. The comparison route consumes the displayed*

StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* RegSeqRat$^{\uparrow}$ *readback, terminal* Real$^{\uparrow}$ *seal, and metric row before derivative or integral estimates may treat the local error as a real-valued bound. Interval-local derivative or integral consumers also read the compact interval endpoint and finite-net route of chapter 5553 before treating a local error bound as a calculus estimate on a compact real interval.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusPointwiseStreamMetricDependencyRoute`

Proof. Project the calculus consumer through its derivative, integral, or local limit row. A local error comparison needs a pointwise distance before it can be read as a Real-facing estimate.

Use chapter 4139. Its carrier displays the stream source, finite pointwise windows, dyadic tolerance ledger, regular-rational readback, terminal Real seal, and metric row before any downstream completion or calculus consumer receives the distance packet.

Use chapter 5553 for interval-local estimates. The CompactRealInterval$^{\uparrow}$ packet supplies endpoint Real seals and finite interval-net rows, so the pointwise metric stream comparison is anchored to a displayed compact interval packet rather than to an ambient host interval.

Thus the calculus route reads pointwise stream metric control before derivative and integral consumers compare real-valued local errors. The dependency exports no host function equality, quotient stream equality, selected representative, countable-choice schedule, or ambient Real$^{\uparrow}$ completeness principle. □

Theorem 3632.89 (Calculus L10 Real and Completion dependency)**.** *Every* Calculus$^{\uparrow}$ *certificate that exports derivative, integral, or limit-facing clauses to the Real and Completion route must first read the L10 substrate through chapter 38, chapter 301, chapter 126, and chapter 130. The calculus row therefore consumes terminal real seals, regular rational readbacks, finite stream windows, and displayed continuous-map evidence before derivative or integral clauses may be used as public BEDC obligations.*

Proof. Read the finite observation schedule through the StreamName certificate. This fixes the inspected windows before any regular rational or real-facing calculus row is exported.

Use the RegSeqRat and Real certificates next. They attach regular rational readback and terminal real sealing to the same windows.

Finally read the ContinuousMap certificate for displayed function evidence. With those four sibling certificates present, the derivative, integral, and limit-facing calculus clauses have a visible L10 dependency route rather than a kernel-only carrier island. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusL10RealCompletionDependency`

Theorem 3632.90 (Calculus L10 dependency route)**.** *Every accepted* Calculus$^{\uparrow}$ *consumer reads derivative and integral data only after the displayed* Real$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* Limit$^{\uparrow}$*, and* ContinuousMap$^{\uparrow}$ *style rows have been exposed. The route is therefore horizontal through chapter 38, chapter 301, chapter 126, chapter 1678, and chapter 130; it is not a host differentiability oracle, a selected antiderivative, an ambient completeness principle, or a quotient of function germs.*

Proof. Project an accepted Calculus$^{\uparrow}$ packet through the existing dependency routes in this hub. The Real-facing row supplies the scalar seal, the regular rational and stream-name rows supply finite approximation schedules, the limit row supplies the local convergence boundary, and the continuous-map row supplies the function readback surface.

Derivative and integral reads occur only after those rows are displayed. The packet may replay them through its structural BHist, hsame, Cont, Pkg, and NameCert rows, but those rows preserve the displayed dependencies rather than adding a host-level analytic oracle.

Thus an L10 consumer sees calculus data as a finite dependency route through the sibling chapters named above. No row exports selected antiderivatives, ambient completeness, quotient germs, or an untyped host computation. □

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusL10DependencyRoute`

The $\mathsf{Calculus}^{\uparrow}$ limit and endpoint consumers that reuse a Real-completion diagonal estimate read the shared-threshold packet of chapter 909 before exporting a Real-facing calculus row. That sibling packet exposes the route through the shared modulus, regular-Cauchy tail meet, witness envelope, diagonal-window coverage, and comparison row; calculus therefore receives a displayed finite diagonal-meet boundary rather than a detached host limit, quotient stream equality, or selected completion witness. The $\mathsf{Calculus}^{\uparrow}$ hub consumes its Real-facing dependency route through the existing BEDC name certificates for chapter 38, chapter 301, chapter 126, and chapter 291. Its paired-distance consumers enter the product-metric child route of Definition 3632.73 before exposing any derivative-product, endpoint, or component $\mathsf{Real}^{\uparrow}$ seal, so the hub records a horizontal dependency on those finite route packets rather than a bare list of local children.

The $\mathsf{Calculus}^{\uparrow}$ endpoint and derivative-product reads also pass through the finite Cauchy real completion interface of chapter 1844 before any completion-facing consumer may inspect a terminal $\mathsf{Real}^{\uparrow}$ seal.

Lemma 3632.91 (Calculus lower-envelope Real-facing route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$ *derivative, integral, or variation consumer that reads a lower-envelope regularization as a Real-facing value must route first through chapter 1536, then through chapter 6224, then through the regular rational readback of chapter 301, and finally through the terminal seal of chapter 38. Thus the calculus packet sees the lower-envelope value only after the finite lower-semicontinuity, epigraph, regular-rational, and Real rows are displayed, with no route through host suprema, quotient functions, selected minimizers, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLowerEnvelopeRealFacingRoute`

Proof. Read the lower-envelope request as a calculus-facing value. The lower-semicontinuity row supplies the admissible lower-envelope boundary, and the epigraph row supplies the displayed value/lower-bound comparison used by that boundary.

Next pass to regular rational data. The $\mathsf{RegSeqRat}^{\uparrow}$ route records the finite readback through visible windows, so the calculus consumer has a concrete value surface before it can inspect any Real seal.

Finally read the $\mathsf{Real}^{\uparrow}$ seal. Since the route has already passed through the displayed lower-semicontinuity, epigraph, and regular-rational rows, no derivative or integral consumer can replace it by a host supremum, quotient-function equality, selected minimizer, or ambient completeness principle. □

Theorem 3632.92 (Calculus lower-envelope regularization handoff)**.** *Any* $\mathsf{Calculus}^{\uparrow}$ *derivative, integral, or variation consumer that imports lower-envelope regularization must preserve the finite route*

$$\mathsf{LowerSemicontinuous}^{\uparrow}, \mathsf{Epigraph}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before any calculus operation reads the regularized value. The consumer first displays the lower-semicontinuity obligation and epigraph comparison rows, then reads the regular rational approximation together with the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and only then consumes the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports no host supremum, quotient function, selected minimizer, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CalculusUp.CalculusLowerEnvelopeRegularizationHandoff`

Proof. Begin with the route lemma above. It already forces a calculus-facing lower-envelope value through $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{Epigraph}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the value is visible to a derivative, integral, or variation consumer.

Next use the lower-envelope regularization packet of chapter 7792. Its NameCert obligations keep the finite lower-envelope ledger between the epigraph row and the regular-rational readback, while its L10 handoff keeps the regularized value inside the displayed envelope route.

Finally insert the shared dyadic tolerance discipline. The regularization carrier records the finite comparison ledger read by the regular-rational row, and downstream calculus consumers must retain that $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance surface before they read the $\mathsf{Real}^{\uparrow}$ seal.

The resulting handoff is the listed finite route. Since the cited rows contain no coordinate for host suprema, quotient functions, selected minimizers, or ambient completeness, no calculus operation can recover those objects from the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Calculus}^{\uparrow}$ packet is generated from Real, Limit, ContinuousMap, Derivative, Integral, RegSeqRat, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$, maturePackageClosed)

Scope closed: The bridge-facing export surface is the finite source-window calculus route over $\mathsf{Real}^{\uparrow}$, $\mathsf{Limit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Calculus}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CalculusUp.CalculusLimitRealTerminalExport`

Bridge status: none

Not claimed: This chapter does not close bridge checking, a host function space, global differentiability, an ambient integration operator, quotient function equality, or real completeness beyond the displayed Real row.

Upgrade path: Further work is standard-bridge verification over the checked limit-real terminal export without adding host function spaces, global differentiability, ambient integration, quotient function equality, or extra real completeness.

Chapter 3633

A Concrete Naming Certificate for $\mathsf{ChainRule}^{\uparrow}$

Following Bishop and Bridges and standard calculus treatments, the $\mathsf{ChainRule}^{\uparrow}$ packet records a finite derivative-composition read as NameCert data inside the L10 calculus boundary. It sits beside the calculus root surface of chapter 3632, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names the displayed composition window through derivative and continuity rows; it is not a host theorem over an ambient function space, quotient equality of maps, a selected representative, countable choice, or an appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3633.1 (Chain-rule carrier)**.** *A* $\mathsf{ChainRule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D_0, C_i, D_o, W, Q, E, H, T, P, N)$$

with the following displayed rows:

1. D_0 *is the source* $\mathsf{Derivative}^{\uparrow}$ *row naming the derivative observation for the inner displayed map at the inspected source window.*
2. C_i *is the inner* $\mathsf{ContinuousMap}^{\uparrow}$ *row that carries the graph window needed to feed the outer derivative row.*
3. D_o *is the outer* $\mathsf{Derivative}^{\uparrow}$ *row naming the derivative observation at the displayed image window.*
4. W *is the composition-window row recording the finite source, image, tolerance, and endpoint requests common to* D_0, C_i, D_o*.*
5. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational derivative and error values inspected through* W*.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after* D_0, C_i, D_o, W, Q *have been displayed.*
7. H *records componentwise* hsame *transport for the derivative, continuous-map, composition-window, readback, real-seal, replay, provenance, and local naming rows.*
8. T *records displayed* Cont *replay from a chain-rule request through* $D_0, C_i, D_o, W, Q, E, H, P, N$*.*
9. P *is the* Pkg *provenance over* $\mathsf{ChainRule}^{\uparrow}$*,* $\mathsf{Calculus}^{\uparrow}$*,* $\mathsf{Derivative}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{ChainRule}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D_0, C_i, D_o, W, Q, E, H, T, P, N$. It has no coordinate for host function equality, quotient equality of maps, a selected representative, countable choice, a global derivative operator, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 3633.2 (Chain-rule NameCert obligations)**.** *For every accepted* $\mathsf{ChainRule}^{\uparrow}$ *carrier* $G = (D_0, C_i, D_o, W, Q, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChainRule}^{\uparrow}}$ *surface consists exactly of carrier admission for the source derivative row, inner continuous-map row, outer derivative row, composition-window row, regular rational readback, real-name seal, componentwise transport, displayed replay, package provenance, and local naming. Every derivative-composition read must pass through the* $\mathsf{Calculus}^{\uparrow}$*,* $\mathsf{Derivative}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *sibling rows before a consumer reads the resulting Real-facing value.*

Proof. Project the carrier of Definition 3633.1. The only analytic rows available to the classifier are D_0, C_i, D_o, W, Q, E: the inner derivative observation, inner graph window, outer derivative observation, shared composition window, regular rational readback, and terminal Real seal.

The calculus root surface of chapter 3632 supplies the L10 boundary in which those rows are inspected. The source and outer derivative rows remain displayed $\mathsf{Derivative}^{\uparrow}$ observations, and the inner graph row remains a $\mathsf{ContinuousMap}^{\uparrow}$ observation; none of them is replaced by a host function-space equality or a global derivative operator.

Readback and sealing are downstream of the same composition window. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q records the finite rational values and tolerances exposed by W, and the $\mathsf{Real}^{\uparrow}$ row E is consumed only after those values have been displayed.

Finally, H, T, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no row for quotient map equality, selected representatives, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3633.3 (Chain-rule L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{ChainRule}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{Calculus}^{\uparrow},\ \mathsf{Derivative}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Thus a derivative-composition read can be cited by later calculus, completion, and real-readback chapters as a named finite packet. The handoff exports no host function equality, quotient function space, selected representative, countable-choice schedule, global derivative operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the obligation surface of Definition 3633.2. It fixes the derivative-composition request inside the $\mathsf{Calculus}^{\uparrow}$ boundary and exposes the two derivative rows together with the inner continuous-map row before any Real-facing read is allowed.

The regular rational and real-name siblings then determine the endpoint of the read. By chapter 301, the values visible to the consumer are rational-window readbacks, and by chapter 38, the terminal row is a sealed Real-facing name rather than an ambient completeness principle.

Transport and replay preserve the same finite route through H and T, while P and N record provenance and local naming. Therefore the L10 handoff is exactly the displayed BEDC route, with the excluded host equalities, representatives, choice principles, and ambient completeness objects absent from the packet. □

Falsifiable prediction: Every accepted $\mathsf{ChainRule}^{\uparrow}$ read must expose source derivative data, inner ContinuousMap graph data, outer Derivative data, a finite composition window, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance,

and local naming before any calculus or completion consumer may read the derivative-composition value.

Independence witness: calculus, derivative, continuousmap, regseqrat, real: $\mathsf{ChainRule}^{\uparrow}$ is not bijective to any listed sibling because it binds two derivative observations and one inner continuousmap graph row through one composition-window read before the rational and Real-facing rows are consumed.

Closure status for $\mathsf{NameCert}_{\mathsf{ChainRule}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChainRule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3633.1, Definition 3633.2, and Definition 3633.3 seed the finite derivative-composition carrier and its L10 Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChainRule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host analytic chain-rule theorem, quotient equality of functions, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-window exactness, inner continuousmap exposure, composition-window exactness, regular-readback boundary, Real-seal boundary, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.ChainRuleUp.

Constructive story: A $\mathsf{ChainRule}^{\uparrow}$ packet is generated from a source Derivative row, inner ContinuousMap row, outer Derivative row, finite composition-window row, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3634

A Concrete Naming Certificate for $\mathsf{FrechetDerivative}^{\uparrow}$

Following Cartan-style differential calculus on normed spaces, the $\mathsf{FrechetDerivative}^{\uparrow}$ packet records the local linear approximation surface as finite NameCert data. It sits beside the norm carrier of chapter 89, the linear-map obligations of chapter 48, the calculus route named by $\mathsf{Calculus}^{\uparrow}$, and the terminal real-name seal of chapter 38. The packet names a displayed derivative read through norm, linearity, and dyadic remainder control; it is not a host function-space derivative, not a selected tangent map outside the carrier, and not an ambient theorem about differentiability.

Definition 3634.1 (Frechet derivative carrier)**.** *A* $\mathsf{FrechetDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, A, L, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the normed source row, carrying the domain and codomain norm data through which difference vectors and error sizes are read.*
2. *A is the point-and-window row, recording the base point, admissible neighbourhood window, and finite comparison requests visible to the derivative packet.*
3. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the linear approximation admitted at the displayed point and over the same source and target norm rows.*
4. *R is the dyadic remainder-modulus row. It records a finite tolerance schedule that bounds the residual after the linear read L has been subtracted from the local step read.*
5. *H records componentwise* hsame *transport for X, A, L, R and the structural rows.*
6. *C records displayed* Cont *replay from a derivative request through the normed source, point window, linear map, and dyadic remainder-modulus rows.*
7. *P is the* Pkg *provenance over* $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host function equality, a global function-space topology, an unrecorded derivative operator, quotient tangent germs, or classical differentiability primitives outside the displayed finite route.

Lean4 ✓ `BEDC.Derived.FrechetDerivativeUp.TasteGate.FrechetDerivativeTasteGate single carrier alignment`

Theorem 3634.2 (Frechet derivative NameCert obligations)**.** *For every accepted* $\mathsf{FrechetDerivative}^{\uparrow}$ *carrier* $D = (X, A, L, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FrechetDerivative}^{\uparrow}}$ *surface consists exactly of carrier admission for the normed source row, point-and-window row, linear-map row, dyadic remainder-modulus row, componentwise transport, displayed replay, provenance, and local naming; linear approximation of the local step through* L*; remainder-modulus control through* R *over the same window* A *and norm row* X*; classifier stability under* hsame *transport of all displayed rows; and ledger non-escape from host function equality, global function-space topology, unrecorded derivative operators, quotient tangent germs, and classical differentiability primitives outside the packet.*

Proof. Project the carrier of Definition 3634.1. The tuple X, A, L, R, H, C, P, N is the whole accepted packet, so carrier admission for the named rows is a direct read from the finite history.

The linear approximation clause is the read of L over the source row X and the point window A. Because L is a $\mathsf{LinMap}^{\uparrow}$ row in the same packet, the approximation is not detached into a host tangent map.

The remainder-modulus clause is the read of R. Its dyadic tolerance schedule is attached to the same X and A, so the residual bound is compared through the displayed norm and window rows rather than through an external limit predicate.

Classifier stability is the componentwise transport row H, replay is the continuation row C, and source accounting is the package row P. Since no coordinate names any excluded host object, the local certificate exports only the displayed Frechet-derivative route. □

Theorem 3634.3 (Frechet derivative linear-remainder handoff)**.** *Every derivative read of an accepted* $\mathsf{FrechetDerivative}^{\uparrow}$ *carrier factors through the ordered finite route*

$$\mathsf{Norm}^{\uparrow},\ \mathsf{LinMap}^{\uparrow},\ \mathsf{Calculus}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The linear approximation row and dyadic remainder-modulus row are exposed before any consumer may read the derivative as public BEDC data. Thus the packet supplies a traditional analysis neighbour for later derivative and implicit-function certificates without importing a host derivative operator.

Proof. Read a derivative request through the continuation row C. The replay first exposes the normed source row X and point window A, so the request is already tied to displayed source, target, and local neighbourhood data.

Next read the $\mathsf{LinMap}^{\uparrow}$ row L and the dyadic remainder-modulus row R. The first row supplies the linear approximation, while the second supplies the finite tolerance ledger that keeps the residual under the displayed norm comparison.

The package row P records the dependency route through $\mathsf{Norm}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. The local naming row N exports only that route, with no host function-space derivative, selected tangent germ, quotient equality, or ambient differentiability theorem. □

Falsifiable prediction: Every accepted $\mathsf{FrechetDerivative}^{\uparrow}$ packet must expose $\mathsf{Norm}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows before any derivative read is public.

Independence witness: norm, linearmap, calculus, real: $\mathsf{FrechetDerivative}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a normed source row, point-and-window row, linear approximation row, dyadic remainder-modulus row, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetDerivative}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3634.1, Definition 3634.2, and Definition 3634.3 seed the finite Frechet derivative route over Norm, LinearMap, Calculus, Real, BHist, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host differentiability, global function-space topology, quotient tangent germs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, linear approximation, remainder-modulus control, classifier stability, derivative handoff stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.FrechetDerivative

Constructive story: A $\mathsf{FrechetDerivative}^{\uparrow}$ packet is generated from a normed source row, a point-and-window row, a LinearMap approximation row, a dyadic remainder-modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 3635

A Concrete Naming Certificate for $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Riemann–Darboux treatment of bounded intervals, the $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ packet records a finite subdivision surface for a displayed bounded $\mathsf{Real}^{\uparrow}$ interval. It sits after the dyadic rational core of chapter 291, the finite StreamName windows of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the located partition surface of chapter 2248. The packet supplies a reusable finite subdivision carrier for $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, and $\mathsf{RegulatedIntegral}^{\uparrow}$ consumers; it does not supply open-cover compactness, selected limits, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3635.1 (Bounded real interval partition carrier)**.** *A* $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, S, M, T, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *E is the bounded interval endpoint row, carrying lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint seals together with the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used to observe them.*
2. *S is the ordered subdivision row, listing finitely many subdivision nodes between the displayed endpoints and the adjacent cell ledger they generate.*
3. *M is the dyadic mesh-bound row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording a rational precision budget, finite cell-width bounds, and the endpoint-to-cell comparison rows.*
4. *T is the tag-window row, assigning each cell a finite tag window and recording only the displayed containment evidence for that tag.*
5. *Q is the regular rational readback row for the subdivision nodes, tag windows, mesh bounds, and endpoint comparisons.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the endpoint and subdivision observations, reached only after E, S, M, T, Q have been displayed.*
7. *L is the integration-consumer ledger, recording that* $\mathsf{RiemannIntegral}^{\uparrow}$*,* $\mathsf{DarbouxIntegral}^{\uparrow}$*,* $\mathsf{RiemannStieltjes}^{\uparrow}$*, and* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumers may read the finite partition only through the rows E, S, M, T, Q, R.*

8. *H records componentwise* hsame *transport for endpoints, subdivision nodes, dyadic mesh bounds, tag windows, regular readbacks, real seals, consumer ledgers, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from endpoint observations to ordered cells, from cells to tag windows, and from mesh bounds to the consumer ledger.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealIntervalPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed endpoint, subdivision, mesh-bound, tag-window, readback, seal, consumer-ledger, transport, replay, provenance, and local naming rows. It has no coordinate for an open-cover compactness proof, selected limiting partition, quotient real equality, host interval partition, countable choice, or ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.BoundedRealIntervalPartitionUp.TasteGate.BoundedRealIntervalPartitionTasteGate single carrier alignment`

Theorem 3635.2 (Bounded real interval partition NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ *carrier* $B = (E, S, M, T, Q, R, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedRealIntervalPartitio}}$ *surface consists exactly of carrier admission; bounded endpoint exposure through E; ordered subdivision exposure through S; dyadic mesh-bound exposure through M; tag-window containment through T;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q; terminal* $\mathsf{Real}^{\uparrow}$ *sealing through R; integration-consumer routing through L; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Thus a Riemann, Darboux, Riemann–Stieltjes, or regulated-integral consumer receives a finite subdivision surface only after the endpoint, cell, mesh-bound, tag-window, readback, and seal rows have all been displayed.

Proof. Project the carrier of Definition 3635.1. The tuple lists the only available rows: endpoints, ordered subdivision nodes, dyadic mesh bounds, tag windows, regular readbacks, real seals, consumer routing, transport, replay, provenance, and local naming.

The endpoint stage is E. Its $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and $\mathsf{Real}^{\uparrow}$ seals supply bounded endpoint observations before a cell can be inspected.

The finite subdivision stage is S, M, T, Q. The ordered row S supplies the cells, the dyadic row M records the mesh budget and cell-width bounds, the tag row T confines each tag to a displayed window, and the regular readback row Q reads those finite observations.

The consumer stage is R, L, H, C, P, N. The terminal seal R is reached only through the displayed rows, while L records the permitted $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, and $\mathsf{RegulatedIntegral}^{\uparrow}$ reads. The structural rows transport, replay, package, and name exactly this route, so the listed obligations exhaust the local NameCert surface. □

Theorem 3635.3 (Bounded real interval partition mesh consumer readiness)**.** *Let* $B = (E, S, M, T, Q, R, L, H, C, P$ *be an accepted* $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ *carrier. The ordered subdivision row S and dyadic mesh row M are read as a bounded refinement of the located partition surface of chapter 2248 before any* $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, *or* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer may inspect the integration-consumer ledger L. The consumer therefore receives a located finite partition with bounded dyadic mesh evidence, not an isolated mesh code or host interval partition.*

Proof. Project the carrier of Definition 3635.1. The endpoint row E supplies the bounded Real interval, and the subdivision row S lists ordered cells over that same endpoint surface.

Apply Definition 3635.2. The dyadic mesh-bound row M is not a separate object; it is read after S and compares adjacent cells by the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ budget.

The located partition dependency is therefore substantive. The rows S and M refine the located interval partition of chapter 2248 by adding bounded endpoint access and dyadic mesh bounds before the regular readback Q and real seal R are exposed.

Only then may the ledger L route the packet to Riemann, Darboux, Riemann–Stieltjes, or regulated-integral consumers. Since the carrier contains no host partition coordinate, every such consumer reads the bounded refinement route rather than a free-standing subdivision code. □

Theorem 3635.4 (Bounded real interval partition transport stability)**.** *Let $B = (E, S, M, T, Q, R, L, H, C, P, N)$ and $B' = (E', S', M', T', Q', R', L', H', C', P', N')$ be accepted* $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ *carriers classified together by componentwise* hsame *transport. If S' is read as the transported ordered subdivision over the transported bounded endpoint row E', then the mesh-bound row, tag-window row, regular readback row, real-seal row, and integration-consumer ledger are all read through the same finite transported subdivision route.*

The transported carrier therefore preserves the finite partition surface without adding open-cover compactness, selected limits, quotient real equality, a host interval partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the endpoint row. Componentwise transport carries E to E', including the finite StreamName windows, RegSeqRat readbacks, and Real seals attached to the lower and upper endpoints.

Read the transported subdivision through S'. Since its cells are displayed over E', every later mesh or tag read remains attached to the same bounded interval route.

The rows M', T', Q', R' are downstream of that route. The dyadic mesh bounds compare transported adjacent cells, the tag windows remain cell-local, the regular readbacks observe only the displayed finite windows, and the Real seal is reached after those observations.

Finally L', H', C', P', N' carry the same route to the integration consumers and name it. No additional coordinate exists in the carrier, so the transported packet cannot export any of the excluded compactness, selection, quotient, host-partition, choice, or completeness data. □

Theorem 3635.5 (Bounded real interval partition consumer nonescape)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$*,* $\mathsf{DarbouxIntegral}^{\uparrow}$*,* $\mathsf{RiemannStieltjes}^{\uparrow}$*, or* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ *packet receives only the finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BoundedRealIntervalPartition}^{\uparrow}.$$

The route exposes endpoint rows, ordered subdivision rows, dyadic mesh bounds, tag windows, readbacks, terminal seals, componentwise transport, displayed replay, provenance, and local naming. It exports no open-cover compactness theorem, selected limiting partition, quotient real equality, host interval partition, measure-completion object, or ambient real-completeness principle.

Proof. Apply Definition 3635.2. It makes $E, S, M, T, Q, R, L, H, C, P, N$ the entire public surface of the packet.

Apply Definition 3635.4. Any transported or refined consumer read must preserve the same endpoint-to-subdivision-to-mesh route before the consumer ledger L is available.

Now inspect the consumers named in L. A Riemann or Darboux read may use the displayed cells and mesh bounds; a Riemann–Stieltjes read may additionally pair those cells with its own

integrator row; and a regulated-integral read may use the same finite subdivision as a step surface. In each case the consumer receives only the listed finite rows and their structural provenance.

Since the carrier contains no row for compactness, selected limits, quotient equality, host partitions, measure completion, or ambient real completeness, none of those objects can escape through the consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealIntervalPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealIntervalPartition}^{\uparrow}$ packet is generated from bounded Real endpoint seals, ordered subdivision rows, dyadic mesh bounds, tag windows, RegSeqRat readbacks, integration-consumer routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealIntervalPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3635.1, Definition 3635.2, Definition 3635.4, and Definition 3635.5 seed the bounded real interval partition boundary over $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, and $\mathsf{RegulatedIntegral}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealIntervalPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected limits, quotient real equality, host interval partitions, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, ordered subdivision exactness, dyadic mesh-bound stability, tag-window containment, RegSeqRat readback, Real seal nonescape, integration-consumer routing, transport, replay, provenance, and local naming for BEDC.Derived.BoundedRealIntervalPartitionUp.

Chapter 3636

A Concrete Naming Certificate for $\mathsf{CauchySequenceOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchySequenceOrder}^{\uparrow}$ packet records the finite constructive-order route by which two regular rational Cauchy source rows are compared before any $\mathsf{Real}^{\uparrow}$ consumer reads an ordered boundary. It sits over the binary algebra packet of chapter 3708, the regular source surface of chapter 301, the finite observation windows of chapter 126, the dyadic comparison ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives completion and ordered-Real consumers one finite comparison surface for Cauchy sequence algebra; it does not import trichotomy, quotient Cauchy classes, selected limits, countable choice, host real order, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3636.1 (Cauchy sequence order carrier)**.** *A* $\mathsf{CauchySequenceOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, Y, A, W, D, L, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations supply the left and right comparison inputs.*
2. *A is the upstream* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *row that fixes the shared binary Cauchy-algebra source from which the comparison is read.*
3. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite pairs of observations where X and Y are inspected at the same requested tolerance scale.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison-budget row. It stores the displayed dyadic radius, rational endpoint differences, slack conversions, strict-gap tests, and non-strict comparison checks used by the accepted order request.*
5. *L is the apartness row. It records only displayed positive-gap evidence between the two regular names, with the gap budget read through D and the windows read through W.*
6. *Q is the non-strict order row. It records only displayed tolerance domination evidence, again through the same W and D rows.*
7. *R is the comparison replay row, exposing whether a downstream consumer requested apartness, non-strict order, or the boundary case where no displayed comparison row is accepted.*

8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is exposed only after the requested comparison row has displayed its regular-source and dyadic-budget dependencies.*

9. *H records componentwise* hsame *transport for the two source rows, algebra row, synchronized windows, dyadic budget, apartness row, non-strict order row, replay row, Real seal, continuation route, provenance, and local naming row.*

10. *C records displayed* Cont *replay from a constructive order request through $X, Y, A, W, D, L, Q, R, S, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceOrder}^{\uparrow}$, $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceOrder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, A, W, D, L, Q, R, S, H, C, P, N$. The carrier has no coordinate for trichotomy, quotient-stream equality, a selected limit, host real order, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceOrderUp.CauchySequenceOrderTasteGate single carrier alignment`

Theorem 3636.2 (Cauchy sequence order NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceOrder}^{\uparrow}$ *carrier*

$$O = (X, Y, A, W, D, L, Q, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceOrder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, upstream* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *row, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison budget, apartness row, non-strict order row, comparison replay row,* $\mathsf{Real}^{\uparrow}$ *seal, transport, continuation, provenance, and local naming;*

2. *source-window synchronization, requiring every comparison request to inspect X and Y through the same displayed window row W before any dyadic comparison is read;*

3. *dyadic-budget exactness, requiring every apartness or non-strict order row to consume only the displayed radius, difference, slack, strict-gap, and domination entries of D;*

4. *comparison-row separation, requiring L to carry only positive-gap apartness evidence and Q to carry only non-strict domination evidence, while both rows consume the same source, algebra, window, and dyadic-budget rows;*

5. *Real seal handoff, requiring S to be exposed only after the requested comparison row has displayed its regular-source and dyadic-budget dependencies;*

6. *transport and replay stability, requiring H and C to preserve the full route $X, Y, A, W, D, L, Q, R, S, P, N$ without adding trichotomy, quotient equality, selected limits, host real order, countable choice, or ambient completeness.*

No Cauchy sequence order NameCert obligation is stored outside these rows.

Proof. Carrier exposure is row projection from Definition 3636.1. The displayed coordinates are exactly the two source rows X, Y, algebra row A, synchronized windows W, dyadic budget D, comparison rows L, Q, R, Real seal S, and structural rows H, C, P, N.

Source-window synchronization is forced by the single window coordinate W. Both source reads must pass through that coordinate before the comparison budget is available, so the carrier has no second observation service for either input.

Dyadic-budget exactness and comparison-row separation are read from D, L, Q. The row D supplies the finite arithmetic comparisons, the row L consumes those comparisons for positive-gap apartness, and the row Q consumes them for non-strict domination. Since L and Q are distinct rows with the same upstream inputs, neither row can import a hidden order oracle.

Finally, the replay, seal, and structural rows close the finite route. The row R records which comparison request is being replayed, the seal S is downstream of the displayed comparison dependency, and H, C, P, N only transport, replay, package, and name the listed rows. The excluded trichotomy, quotient, selected-limit, host-order, choice, and ambient-completeness data have no carrier coordinate. □

Theorem 3636.3 (Cauchy sequence order dyadic budget exactness)**.** *Every apartness or non-strict order fact exported from an accepted* $\mathsf{CauchySequenceOrder}^{\uparrow}$ *carrier reads its comparison budget through the displayed route*

$$X, Y, A \longmapsto W \longmapsto D \longmapsto L, Q, R \longmapsto S \longmapsto H, C, P, N.$$

Consequently the exported fact obtains synchronized regular-source observations, dyadic radius and slack data, strict-gap or domination evidence, the terminal Real seal handoff, transport, continuation, provenance, and local naming, and obtains no trichotomy datum, quotient Cauchy class, selected limit, host real order, countable-choice datum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Begin with a downstream comparison request. By Definition 3636.1, the only source coordinates are X and Y, and the upstream algebra row is A.

The finite observation surface is then forced through W. The dyadic comparison budget is forced through D, whose rows record the displayed radius, endpoint differences, slack conversions, strict-gap tests, and domination checks.

Apartness reads the route row L, non-strict order reads the route row Q, and replay reads the route row R. Each of these rows is downstream of the same sources, algebra row, windows, and dyadic budget named in Definition 3636.2.

The Real-facing handoff is last. A $\mathsf{Real}^{\uparrow}$ consumer can read S only after the requested comparison row has displayed its dependencies, and the rows H, C, P, N preserve that same finite route. No coordinate remains from which trichotomy, quotient equality, selected limits, host order, choice, or ambient completeness could be exported. □

Theorem 3636.4 (Cauchy sequence order non-escape)**.** *Let* $O = (X, Y, A, W, D, L, Q, R, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceOrder}^{\uparrow}$ *carrier. Any order-facing fact exported from* O *is a rowwise consequence of the displayed regular source rows, algebra row, synchronized windows, dyadic comparison budget, apartness row, non-strict order row, replay row, Real seal, transport, continuation, provenance, and local naming rows. It is not a trichotomy principle, quotient Cauchy class, selected limit, host real-order fact, countable-choice datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The data-bearing coordinates are exactly $X, Y, A, W, D, L, Q, R, S$, and the structural coordinates are exactly H, C, P, N.

An exported apartness fact must use L after the source, algebra, window, and dyadic-budget rows have been displayed. An exported non-strict order fact must use Q after the same upstream rows have been displayed. A replayed comparison must pass through R, and any Real-facing boundary then passes through the seal row S.

The structural rows preserve only that route. Componentwise hsame transport and displayed Cont replay cannot create trichotomy, quotient equality, selected limits, host order, choice, or

ambient completeness, while provenance and local naming record only the finite packet. Thus every exported order-facing fact is confined to the listed rows, and each excluded principle has no entry point. □

Closure status for NameCert$_{CauchySequenceOrderUp}$.

Theory closure: TheoryGate(NameCert$_{CauchySequenceOrderUp}$, seed)

Scope closed: Definition 3636.1, Definition 3636.2, Definition 3636.3, and Definition 3636.4 seed the finite constructive-order route over CauchySequenceAlgebra$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{CauchySequenceOrderUp}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient Cauchy classes, selected limits, host real order, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-window synchronization, dyadic-budget exactness, comparison-row separation, Real seal handoff, transport, continuation, provenance, local naming, and non-escape for BEDC.Derived.CauchySequenceOrderUp.

Constructive story: A CauchySequenceOrder$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, an upstream CauchySequenceAlgebra$^{\uparrow}$ row, synchronized StreamName$^{\uparrow}$ windows, one DyadicRatCore$^{\uparrow}$ comparison-budget ledger, apartness and non-strict order rows, a comparison replay row, a Real$^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3637

A Concrete Naming Certificate for $\mathsf{NoetherianRing}^{\uparrow}$

Following Emmy Noether's ascending-chain formulation, the $\mathsf{NoetherianRing}^{\uparrow}$ packet records finite ideal-chain stabilization data over a commutative-ring source and an ideal source. In BEDC form it sits after $\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}$ (chapter 44) and $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$ (chapter 81), supplies a reusable finitary algebra row for the reduction surface of chapter 2197, and exposes the Noetherian component later consumed by chapter 172.

3637.1 Carrier definition

Definition 3637.1 (Noetherian ring carrier)**.** *A* $\mathsf{NoetherianRing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{NoethRing}(C, I, A, G, H, Q, P, N).$$

The row C is the $\mathsf{CommRing}^{\uparrow}$ *source surface. The row I is the* $\mathsf{Ideal}^{\uparrow}$ *source surface over the same classifier. The row A is the ascending-chain stabilization witness: every displayed chain of ideal rows over C and I carries a finite stage after which all later ideal endpoints classify with that stage. The row G is the finite-generator witness used by algebraic consumers that read Noetherianity through finitely generated ideal data. The row H is componentwise* hsame *transport for the commutative-ring, ideal, stabilization, and generator rows. The row Q is displayed* Cont *replay for the chain and generator certificates. The row P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}$ *naming row.*

Lean4 ✓ `BEDC.Derived.NoetherianRingUp.NoetherianRingTasteGate single carrier alignment`

Theorem 3637.2 (Noetherian ring NameCert obligations)**.** *For an accepted* $\mathsf{NoetherianRing}^{\uparrow}$ *carrier* $\mathsf{NoethRing}(C, I, A, G, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}$ *surface consists exactly of carrier admission for the eight displayed rows, source compatibility with* $\mathsf{CommRing}^{\uparrow}$ *and* $\mathsf{Ideal}^{\uparrow}$*, finite stabilization access through A, finite-generator access through G, componentwise classifier transport through H, displayed continuation replay through Q, provenance non-escape through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.NoetherianRingUp.NoetherianRingCarrier namecert obligations`

Proof. Project the eight rows of Definition 3637.1. The source rows C and I fix the shared commutative-ring and ideal classifier before any chain is inspected.

The stabilization row A and generator row G are then read over that classifier. Componentwise transport H carries each displayed row through hsame, while Q replays the corresponding continuations without replacing the source surface.

Finally, P and N repack the same finite inventory as the local naming certificate. No quotient ideal space, maximal ideal selection, or Hilbert basis proof is introduced by this packet. □

Theorem 3637.3 (Noetherian ascending-chain stability)**.** *Let* $\mathsf{NoethRing}(C, I, A, G, H, Q, P, N)$ *be an accepted* $\mathsf{NoetherianRing}^{\uparrow}$ *carrier. For every displayed ascending chain of ideal rows over the shared* $\mathsf{CommRing}^{\uparrow}$ *and* $\mathsf{Ideal}^{\uparrow}$ *classifier, the witness A supplies a finite stabilization stage, and H transports that stabilization along the same classifier. Thus any downstream consumer may use* $\mathsf{NoetherianRing}^{\uparrow}$ *as a finite ideal-chain certificate without re-proving stabilization inside its own packet.*

Proof. Begin with the source compatibility rows from Definition 3637.2. They force the chain to be read over the commutative-ring and ideal classifier already present in C and I.

Apply the stabilization witness A to obtain a finite stage for the displayed chain. If the accepted packet is transported through a classified replacement, use the componentwise transport row H to move both the chain entries and the stabilization witness through the shared classifier.

The transported stage remains a stage for the same finite chain surface because Q replays only the displayed continuation data and P prevents provenance escape. The conclusion is therefore a reusable finite ideal-chain certificate for later algebra chapters. □

Closure status for $\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}$.

Constructive story: A $\mathsf{NoetherianRing}^{\uparrow}$ packet is generated from a $\mathsf{CommRing}^{\uparrow}$ source, an $\mathsf{Ideal}^{\uparrow}$ source over the same classifier, an ascending-chain stabilization witness, a finite-generator witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3637.1, Definition 3637.2, and Definition 3637.3 seed the finite ideal-chain stabilization interface over CommRingUp, IdealUp, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient ideal spaces, maximal ideal choice, Hilbert basis proof, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, finite stabilization access, finite-generator access, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.NoetherianRingUp.

Chapter 3638

A Concrete Naming Certificate for $\mathsf{LeviCivitaConnection}^{\uparrow}$

Following Kobayashi and Nomizu, the $\mathsf{LeviCivitaConnection}^{\uparrow}$ packet records the finite NameCert surface that ties a Riemannian metric to the unique torsion-free metric-compatible connection visible to curvature consumers. It is grounded in the source-fibre metric packet of chapter 133, the connection packet of chapter 134, and the curvature boundary surface of chapter 135. The packet exports only displayed rows and certificate ledgers; it does not import an ambient smooth connection operator, coordinate Christoffel symbols, or a host-level uniqueness theorem.

Definition 3638.1 (Levi-Civita connection carrier)**.** *A* $\mathsf{LeviCivitaConnection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, C, T, M, R, H, K, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{RiemannianMetric}^{\uparrow}$ *row whose source-fibre surface supplies the metric data on the displayed tangent fibres.*
2. *C is the* $\mathsf{Connection}^{\uparrow}$ *row carrying the base, fibre, section, tangent-direction, derivative endpoint, and connection provenance visible to the packet.*
3. *T is the torsion-free boundary row, recording that the two displayed tangent-direction orders have no residual antisymmetric endpoint outside the connection ledger.*
4. *M is the metric-compatibility row, recording that the connection derivative preserves the displayed* $\mathsf{RiemannianMetric}^{\uparrow}$ *inner-product row along the inspected tangent window.*
5. *R is the* $\mathsf{Curvature}^{\uparrow}$ *compatibility row, exposing the curvature boundary obtained from the connection row after the torsion-free and metric-compatibility rows have been displayed.*
6. *H records componentwise* hsame *transport for G, C, T, M, R and their dependency rows.*
7. *K records the displayed* Cont *replay from the metric row and connection row through torsion-free verification, metric compatibility, and curvature compatibility.*
8. *P is the* Pkg *provenance over* $\mathsf{LeviCivitaConnection}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, $\mathsf{Connection}^{\uparrow}$, $\mathsf{Curvature}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LeviCivitaConnection}^{\uparrow}}$ *row.*

The carrier therefore packages a displayed Riemannian metric together with a displayed connection whose torsion-free, metric-compatible, and curvature-facing rows are all visible in the same finite certificate. It does not contain a coordinate formula for Christoffel symbols, a selected smooth atlas, a global geodesic theorem, or a host-level equality between possible connections.

Lean4 ✓ `BEDC.Derived.LeviCivitaConnectionUp.LeviCivitaConnectionTasteGate single carrier alignment decode encode`

Theorem 3638.2 (Levi-Civita connection NameCert obligations)**.** *For an accepted* $\mathsf{LeviCivitaConnection}^{\uparrow}$ *carrier* $L = (G, C, T, M, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LeviCivitaConnection}^{\uparrow}}$ *surface is exhausted by the following finite obligations:*

1. *carrier admission for the displayed metric and connection rows* G *and* C*;*
2. *torsion-free exposure for the boundary row* T*;*
3. *metric-compatibility exposure for the row* M*;*
4. *curvature-facing compatibility for the row* R*;*
5. *componentwise transport for* G, C, T, M, R *through* H*;*
6. *replay exactness for the route recorded by* K*;*
7. *provenance and local naming through* P *and* N*.*

No obligation asks for an unlogged covariant derivative, a coordinate chart calculation, a selected geodesic flow, or a host-level uniqueness principle.

Proof. Project the carrier of Definition 3638.1. The rows G and C are the only metric and connection sources available to the local certificate, and their dependency surfaces are already the public rows of $\mathsf{RiemannianMetric}^{\uparrow}$ and $\mathsf{Connection}^{\uparrow}$.

The torsion-free and metric-compatibility clauses are the two displayed boundary rows T and M. They are read after the connection row has exposed tangent-direction and derivative-endpoint data and after the metric row has exposed the fibrewise inner-product surface.

The curvature-facing clause is exactly R. It can be consumed only after the connection and compatibility rows have been replayed by K, so the downstream $\mathsf{Curvature}^{\uparrow}$ read receives a finite boundary route rather than a detached tensor object.

Transport and replay exactness are then componentwise projections from H and K. The package row P and local name row N repack these rows as the whole local NameCert surface, leaving no coordinate for the excluded ambient objects. □

Theorem 3638.3 (Levi-Civita connection curvature compatibility)**.** *Every* $\mathsf{Curvature}^{\uparrow}$ *consumer of an accepted* $\mathsf{LeviCivitaConnection}^{\uparrow}$ *carrier reads curvature through the finite route*

$$G \longmapsto C \longmapsto T \longmapsto M \longmapsto R.$$

Thus the curvature row is downstream of the displayed $\mathsf{RiemannianMetric}^{\uparrow}$ *metric packet, the displayed* $\mathsf{Connection}^{\uparrow}$ *derivative packet, the torsion-free boundary, and the metric-compatibility row. It cannot be read as an independent coordinate curvature tensor, a host connection form, or a curvature object detached from the metric-compatible connection certificate.*

Proof. Start with a curvature-facing request. The carrier has only one curvature coordinate, namely R, and R is declared as a compatibility row over the displayed connection row C.

The connection row C is not detached from the metric. The torsion-free row T and metric-compatibility row M sit between C and R in the replay row K, while G supplies the metric source that M preserves.

Apply the connection curvature-boundary surface from Definition 134.5 and the curvature source obligations of chapter 135. These existing rows explain how a connection boundary becomes consumable by $\mathsf{Curvature}^{\uparrow}$.

Repacking the projected rows gives the displayed route $G \mapsto C \mapsto T \mapsto M \mapsto R$. Since no coordinate curvature tensor, host connection form, or detached curvature object appears in the carrier, no such object is exported to the consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{LeviCivitaConnection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LeviCivitaConnection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3638.1, Definition 3638.2, and Definition 3638.3 seed the displayed metric-compatible torsion-free connection route from $\mathsf{RiemannianMetric}^{\uparrow}$ and $\mathsf{Connection}^{\uparrow}$ rows through torsion-free, metric-compatible, curvature-facing, transport, replay, provenance, and local naming boundaries over $\mathsf{Curvature}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LeviCivitaConnection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close coordinate Christoffel symbols or formulae, selected smooth atlases, global geodesic theorems or flows, host-level connection uniqueness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, torsion-free exposure, metric-compatibility exposure, curvature-facing compatibility, transport, replay, provenance, and local naming for BEDC.Derived.LeviCivitaConnectionUp.

Constructive story: A $\mathsf{LeviCivitaConnection}^{\uparrow}$ packet is generated from displayed Riemannian metric and connection rows, torsion-free and metric-compatibility boundary rows, a curvature-facing compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3639

A Concrete Naming Certificate for $\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}$ packet records completion as a finite transformation of metric names rather than as an ambient quotient or selected limit. It sits on the dyadic endpoint discipline of chapter 291, the finite observation route of chapter 126, the regular rational sequence row of chapter 301, the terminal real-name seal of chapter 38, the regular-Cauchy completion packet of chapter 1639, the functor rows of chapter 423, and the extension-uniqueness surface of chapter 397.

Definition 3639.1 (Bishop Cauchy completion functor carrier)**.** *A* $\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, R, E, F, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric row, containing the named points, displayed distance observations, and finite tolerance ledger read by the source classifier.*
2. *T is the target metric row, containing the metric surface into which transported Cauchy data are read.*
3. *R is the regular-Cauchy family row, exposing the* $\mathsf{RegSeqRat}^{\uparrow}$ *schedules and stream windows used by the completion handoff.*
4. *E is the completion seal row, recording the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *boundary reached from S and R.*
5. *F is the transported map row, storing the displayed map action on source rows and the finite replay by which regular-Cauchy families are sent to target completion rows.*
6. *U is the extension-uniqueness row, read through the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *surface and tied to the same source, target, regular-Cauchy, and seal rows.*
7. *H records componentwise* hsame *transport for source, target, regular-Cauchy, completion seal, transported map, extension, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for a completion-facing consumer from S, T, R through E, F, U and back to the local naming row.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BishopRegularCauchyCompletio CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}}$ *evidence.*

The carrier contains no quotient completion, no selected limit, no countable-choice schedule, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopCauchyCompletionFunctorUp.BishopCauchyCompletionFunctorTasteGate`
`single carrier alignment`

Theorem 3639.2 (Bishop Cauchy completion functor NameCert obligations)**.** *For every accepted carrier $Q = (S, T, R, E, F, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}}$ *surface consists of six finite obligation rows: carrier admission for $S, T, R, E, F, U, H, C, P, N$; classifier stability by componentwise* hsame *transport; functorial map transport through the displayed source, target, regular-Cauchy, and seal rows; unit handoff from source metric points into the completion seal; extension uniqueness through the row U; and non-escape from quotient completions, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is coordinate projection from Definition 3639.1. The packet exposes the source and target metric rows, regular-Cauchy family row, completion seal, transported map row, extension row, and the structural rows H, C, P, N as one finite history.

Classifier stability is componentwise. The row H supplies the only equality-like transport, and C replays the same completion-facing route through S, T, R, E, F, U whenever a consumer replaces one accepted packet by a classified mate.

Functorial map transport and unit handoff are sibling-row compositions. The source row S and regular-Cauchy row R feed the completion seal E; the transported map row F carries that route to the target row T; and the unit read is the special case in which a displayed source point enters the same seal route without naming a host limit.

Extension uniqueness is read only from U after E and F have been fixed. Since no carrier coordinate stores a quotient completion, selected representative, choice schedule, or ambient Real-completeness theorem, coordinate exhaustion gives the non-escape clauses. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}}$.

Constructive story: A BishopCauchyCompletionFunctor$^{\uparrow}$ packet is generated from source and target metric rows, a regular-Cauchy family row, a completion seal row, a transported map row, an extension-uniqueness row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}}$, seed)

Scope closed: Definition 3639.1 and Definition 3639.2 bind the seed carrier and its finite obligation rows over the displayed completion-functor surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not assert quotient completion construction, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, functorial map transport, unit handoff, extension uniqueness, and non-escape rows for the displayed Bishop completion-functor packet.

Chapter 3640

A Concrete Naming Certificate for $\mathsf{RealLocatedOrder}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealLocatedOrder}^{\uparrow}$ packet names located comparison for two displayed real names by reading only regular Cauchy data, finite stream windows, dyadic tolerance budgets, a located comparison row, and an apartness handoff before any completion-facing consumer sees an order claim. It consumes the terminal $\mathsf{Real}^{\uparrow}$ seals of chapter 38, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the positive-separation boundary of chapter 304, and the finite located-order test of chapter 2112. The packet is a public constructive located-order certificate over $\mathsf{Real}^{\uparrow}$ names; it is not host trichotomy, host real equality, quotient stream equality, selected limits, countable choice, or ambient real completeness.

Definition 3640.1 (Real located-order carrier)**.** *A* $\mathsf{RealLocatedOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, R, S, D, O, A, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{Real}^{\uparrow}$ *seal rows whose order relation is being read.*
2. *R stores the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks for the two real names.*
3. *S stores the shared* $\mathsf{StreamName}^{\uparrow}$ *finite windows used to inspect the paired approximants.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that fixes the visible precision budget.*
5. *O is the located comparison row imported from the* $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$ *surface.*
6. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *handoff row, present only when the comparison exposes positive separation.*
7. *H stores componentwise* hsame *transport for the two real seals, readbacks, windows, dyadic tolerances, located comparison, apartness handoff, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from Real-name reads through regular Cauchy readbacks, stream windows, dyadic tolerances, located comparison, and apartness handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{RealLocatedOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyRealLocatedOrderTest}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLocatedOrder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, R, S, D, O, A, H, C, P, N$. It has no coordinate for host trichotomy, host real equality, quotient stream equality, selected limits, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.RealLocatedOrderUp.RealLocatedOrderTasteGate single carrier alignment`

Theorem 3640.2 (Real located-order NameCert obligations)**.** *For every accepted* $\mathsf{RealLocatedOrder}^{\uparrow}$ *carrier* $L = (X, Y, R, S, D, O, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLocatedOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{Real}^{\uparrow}$ *seals, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, shared* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget, located comparison row, optional* $\mathsf{ApartnessReal}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.RealLocatedOrderUp.RealLocatedOrderCarrier namecert obligations`

Proof. Project the carrier of Definition 3640.1. The two real names are visible only as the seal rows X, Y, and their numerical reads pass through the paired regular rational row R.

The finite windows S and dyadic tolerance ledger D are then the only inspection surface available to the located comparison row O. Thus the local NameCert reads order evidence as the displayed CauchyRealLocatedOrderTest route rather than as a host order theorem.

Finally read A, H, C, P, N. The apartness row is a handoff when positive separation is displayed, while the structural rows transport, replay, source, and name the same finite route. Since no remaining coordinate stores trichotomy, host equality, quotient stream equality, selected limits, choice, or ambient completeness, the listed rows exhaust the obligation surface. □

Theorem 3640.3 (Real located-order apartness handoff)**.** *For every accepted* $\mathsf{RealLocatedOrder}^{\uparrow}$ *carrier* $L = (X, Y, R, S, D, O, A, H, C, P, N)$*, an apartness-facing consumer may read positive separation only through the route*

$$X, Y \longmapsto R \longmapsto S \longmapsto D \longmapsto O \longmapsto A$$

together with H, C, P, N*. The handoff exports an* $\mathsf{ApartnessReal}^{\uparrow}$ *row when the located comparison displays a positive gap, but it exports no host real equality test, quotient-stream equality, trichotomy, selected limit, countable-choice selector, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.RealLocatedOrderUp.RealLocatedOrderCarrier apartness handoff`

Proof. Start with the located comparison row in Definition 3640.1. The row O is downstream of the two Real seals, paired regular readbacks, finite windows, and dyadic tolerance ledger.

Use the apartness clause of the carrier. The row A is not an independent equality or order oracle; it is the ApartnessReal handoff available only when the displayed located comparison has exposed positive separation.

The structural rows H, C, P, N preserve this same packet route. Therefore a consumer can export the apartness handoff, but cannot bypass the displayed rows to obtain host equality, quotient stream equality, trichotomy, selected limits, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RealLocatedOrder}^{\uparrow}$ consumer must exhibit two RealUp seals, paired RegSeqRat readbacks, StreamName finite windows, a DyadicRatCore tolerance budget, a CauchyRealLocatedOrderTest row, an ApartnessReal handoff when positive separation is claimed, componentwise transport, displayed replay, provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore, apartnessreal, cauchy-real-located-order-test: no listed sibling carries the whole packet $L = (X, Y, R, S, D, O, A, H, C, P, N)$

because each sibling supplies only real sealing, rational readback, finite windows, tolerance budgets, apartness handoff, or located comparison while this chapter binds all rows as one Real-facing located-order certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLocatedOrder}\uparrow}$.

Constructive story: A $\mathsf{RealLocatedOrder}^{\uparrow}$ packet is generated from two RealUp seals, paired RegSeqRat readbacks, StreamName finite windows, a DyadicRatCore tolerance budget, a CauchyRealLocatedOrderTest located comparison row, an ApartnessReal handoff when positive separation is displayed, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLocatedOrder}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3640.1, Definition 3640.2, and Definition 3640.3 seed the finite constructive located-order certificate over two displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLocatedOrder}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, host real equality, quotient stream equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, apartness handoff, and TasteGate field faithfulness for BEDC.Derived.RealLocatedOrderUp.

Chapter 3641

A Concrete Naming Certificate for $\mathsf{RealSequenceSpace}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of sequences of real numbers, the $\mathsf{RealSequenceSpace}^{\uparrow}$ packet records a real-valued sequence carrier as finite BEDC route data rather than as a quotient of streams or a completed function space. It sits between the finite stream windows of chapter 126, the regular rational names of chapter 301, the dyadic tolerance core of chapter 291, the finite real-name boundary of chapter 38, and the Cauchy convergence handoff of chapter 1509.

Definition 3641.1 (RealSequenceSpace carrier)**.** *A* $\mathsf{RealSequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, R, D, E, K, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the finite sequence windows visible to the carrier.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row supplying regular rational names for the inspected real-valued coordinates.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those inspected coordinates.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the scheduled regular rows and dyadic tolerances have been displayed.*
5. *K is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *handoff row for consumers that ask for Cauchy behavior of the displayed real-valued sequence.*
6. *H records componentwise* hsame *transport for the stream schedule, regular names, dyadic ledger, Real seal, Cauchy handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each finite window request through S, R, D, E, K.*
8. *P is the* Pkg *provenance over* $\mathsf{RealSequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSequenceSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealSequenceSpaceUp.RealSequenceSpaceTasteGate single carrier alignment`

Theorem 3641.2 (RealSequenceSpace NameCert obligations)**.** *For every accepted* $\mathsf{RealSequenceSpace}^{\uparrow}$ *carrier* $Q = (S, R, D, E, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealSequenceSpace}^{\uparrow}}$ *surface consists exactly of finite* BHist *packet rows over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$*:*

1. *carrier admission for the displayed stream schedule, regular rational coordinate names, dyadic tolerance ledger, Real seal, Cauchy-criterion handoff, transport, replay, provenance, and local name;*
2. *finite-window classification, requiring every coordinate read to pass through the* $\mathsf{StreamName}^{\uparrow}$ *row* S*;*
3. *regular-coordinate admission, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *to be read only at windows named by* S*;*
4. *tolerance admission, requiring the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *to accompany every displayed regular coordinate request;*
5. *Real-seal ordering, requiring the* $\mathsf{Real}^{\uparrow}$ *row* E *to be downstream of* S, R, D*;*
6. *Cauchy-handoff ordering, requiring the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *row* K *to consume only the same displayed* S, R, D, E *route;*
7. *transport and replay stability through* H, C, P, N*.*

No obligation supplies quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness.

Proof. Project the carrier of Definition 3641.1. The packet exposes only the stream schedule, regular rational coordinate rows, dyadic tolerance ledger, Real seal, Cauchy-criterion handoff, and structural rows.

The finite-window obligations are then forced. A coordinate read has no source except S, the regular name row R is read only at those windows, and the dyadic ledger D records the tolerance data attached to the same request.

The Real and Cauchy rows are downstream. The seal E is reached only after the displayed S, R, D route, and the handoff K reuses that same route when a Cauchy-facing consumer reads the sequence.

Finally the rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier definition contains none of the excluded host-side data, the listed rows exhaust the local NameCert surface. □

Theorem 3641.3 (RealSequenceSpace Cauchy criterion handoff)**.** *Every* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealSequenceSpace}^{\uparrow}$ *carrier* $Q = (S, R, D, E, K, H, C, P, N)$ *reads a finite* BHist *packet route over*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{CauchyConvergenceCriterion}^{\uparrow}$$

in the ordered form

$$S \longrightarrow R \longrightarrow D \longrightarrow E \longrightarrow K.$$

Thus a convergence-facing read may inspect only scheduled finite windows, regular rational coordinate rows, dyadic tolerance rows, the finite Real seal, and the displayed Cauchy handoff. It cannot extract quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness from the sequence-space packet.

Proof. Start from an accepted convergence-facing read. By Definition 3641.2, the read first enters the finite $\mathsf{StreamName}^{\uparrow}$ schedule and then the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ coordinate rows.

The tolerance and seal rows are fixed by the same packet. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D records the precision budget for the inspected coordinates, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of S, R, D.

The $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ row K consumes only that displayed route. The structural rows H, C, P, N preserve and name the same finite packet, so no quotient-stream representative, selected limit, countable-choice family, trichotomy branch, host real equality, or ambient completeness theorem is available to the consumer. □

Theorem 3641.4 (RealSequenceSpace finite-window classifier determinacy)**.** *Let*

$$Q = (S, R, D, E, K, H, C, P, N) \qquad \textit{and} \qquad Q' = (S', R', D', E', K', H', C', P', N')$$

be accepted $\mathsf{RealSequenceSpace}^{\uparrow}$ *carriers. If Q and Q' display the same* $\mathsf{StreamName}^{\uparrow}$ *schedule, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinate rows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{Real}^{\uparrow}$ *seal, the same* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *handoff, and componentwise matching* hsame *and* Cont *rows, then their public classifier reads are the same. Conversely, any public classifier disagreement between Q and Q' must occur in one of those displayed finite rows; it cannot be hidden in quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness.*

Proof. Project both carriers through Definition 3641.1. The only classifier coordinates exposed by either packet are the stream schedule, regular rational coordinate rows, dyadic tolerance ledger, Real seal, Cauchy handoff, transport, replay, provenance, and local naming rows.

Apply Definition 3641.2 to both packets. The theorem fixes the ordering of finite-window admission, regular-coordinate admission, tolerance admission, Real-seal ordering, Cauchy-handoff ordering, and transport stability, so matching displayed rows force matching public reads at every permitted coordinate.

It remains to exclude hidden disagreement. By Definition 3641.3, every convergence-facing read factors through the same ordered route

$$S \longrightarrow R \longrightarrow D \longrightarrow E \longrightarrow K.$$

Thus no quotient stream, selected limit, countable-choice family, trichotomy branch, host real equality, or ambient completeness theorem can supply an additional classifier coordinate. Any disagreement must therefore be visible in one of the displayed finite rows. □

Theorem 3641.5 (RealSequenceSpace window-seal obligation closure)**.** *For every accepted* $\mathsf{RealSequenceSpace}^{\uparrow}$ *carrier $Q = (S, R, D, E, K, H, C, P, N)$, the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinate row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal row,* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *handoff,* hsame *transport,* Cont *replay, provenance, and local* $\mathsf{NameCert}$ *jointly close the local obligation surface. Every sequence-space consumer must read*

$$S \longrightarrow R \longrightarrow D \longrightarrow E \longrightarrow K$$

before any public sequence-space classifier is exported, and any classifier disagreement must appear in one displayed finite row rather than in a quotient stream, selected limit, countable-choice family, trichotomy branch, host real equality, or ambient Real completeness theorem.

Proof. Project the carrier of Definition 3641.1. The projection exposes exactly the window schedule S, coordinate row R, tolerance ledger D, Real seal E, Cauchy handoff K, and structural rows H, C, P, N.

Apply Definition 3641.2. This fixes the row ordering from finite-window admission through regular-coordinate admission, dyadic tolerance admission, Real-seal ordering, Cauchy-handoff ordering, and transport stability.

Apply Definition 3641.3 for convergence-facing reads. Such a consumer can inspect only the ordered route $S \longrightarrow R \longrightarrow D \longrightarrow E \longrightarrow K$, so the Cauchy side receives no additional host equality or completeness coordinate.

Finally apply Definition 3641.4. Matching displayed rows force matching public reads, and any remaining classifier disagreement is therefore visible in one displayed finite row rather than hidden in a quotient-stream or host-equality layer. □

Theorem 3641.6 (RealSequenceSpace tail-zero subspace route)**.** *Let $Q = (S, R, D, E, K, H, C, P, N)$ be an accepted* $\mathsf{RealSequenceSpace}^{\uparrow}$ *carrier equipped with a displayed dyadic tail modulus T whose entries are read through the same* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinate rows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger as S, R, D. Then every tail-zero subspace consumer factors through the route*

$$S \longrightarrow R \longrightarrow D \longrightarrow E \longrightarrow K$$

before it exports the tail-zero surface. The extra tail claim is visible only as the displayed D, K-facing ledger T; it does not add quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 3641.1. The sequence source, regular coordinate readback, dyadic tolerance rows, Real seal, and Cauchy handoff are already the rows S, R, D, E, K, and the tail modulus T is displayed over the same finite windows.

Apply Definition 3641.2 and Definition 3641.3. These results force every Real-facing or Cauchy-facing read to reuse the ordered route through S, R, D, E, K before any public sequence-space conclusion is exported.

The tail-zero subspace surface therefore adds no new equality coordinate. It records that the dyadic tail requests in T are ledger entries facing D and K, while the structural rows H, C, P, N transport and name the same finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSequenceSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSequenceSpace}^{\uparrow}$ packet is generated from a finite $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ coordinate rows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal row, a $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSequenceSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3641.1, Definition 3641.2, and Definition 3641.3 seed the real-valued sequence-space carrier over finite StreamName, RegSeqRat, DyadicRatCore, Real, and Cauchy convergence rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSequenceSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window classification, regular-coordinate admission, dyadic tolerance admission, Real-seal ordering, Cauchy-handoff ordering, and transport stability for the same displayed packet.

Chapter 3642

A Concrete Naming Certificate for $\mathsf{FrechetUrysohn}^{\uparrow}$

Following Frechet and Urysohn's sequential analysis of closure in topology, the $\mathsf{FrechetUrysohn}^{\uparrow}$ packet records the finite data by which a point is certified as sequentially reachable from a displayed subset rather than assuming an ambient topological closure operator. It sits between the finite real-valued sequence surface of chapter 3641, the sequential compactness packet of chapter 2372, and the finite stream windows of chapter 126.

Definition 3642.1 (Frechet-Urysohn carrier)**.** *A* $\mathsf{FrechetUrysohn}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, S, W, R, A, X, H, C, P, N)$$

with the following displayed rows:

1. *T is the topology carrier row, containing the named point, the displayed subset, and the finite neighborhood probes used by the closure read.*
2. *S is the sequence-space row over* $\mathsf{RealSequenceSpace}^{\uparrow}$*, recording the accepted real-valued or chart-valued sequence route used to approach the named point.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for the finite initial segments and tail windows visible to the classifier.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the coordinate reads that witness convergence through S and W.*
5. *A is the closure-witness row, displaying that every inspected tail window lies in the named subset and that the limit read is the named point.*
6. *X is the transport row for the topology probes, sequence-space rows, StreamName windows, Real seal, closure witness, replay, provenance, and local naming data.*
7. *H records componentwise* hsame *transport along the same displayed rows.*
8. *C records displayed* Cont *replay from a closure request through T, S, W, R, A, X.*
9. *P is the* Pkg *provenance over* $\mathsf{FrechetUrysohn}^{\uparrow}$, $\mathsf{RealSequenceSpace}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetUrysohn}^{\uparrow}}$ *row.*

The classifier has no coordinate for arbitrary nets, choice-selected sequences, host closure equality, excluded middle over neighborhoods, or an ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.FrechetUrysohnUp.FrechetUrysohnTasteGate single carrier alignment`

Theorem 3642.2 (Frechet-Urysohn NameCert obligations)**.** *For every accepted* $\mathsf{FrechetUrysohn}^{\uparrow}$ *carrier* $Q = (T, S, W, R, A, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FrechetUrysohn}^{\uparrow}}$ *surface consists exactly of finite* BHist *rows for topology admission, sequence-space admission, StreamName windowing, Real-seal ordering, closure-witness display, transport, replay, provenance, and local naming. Every sequential-closure classifier read must pass through* $T, S, W, R, A, X, H, C, P, N$ *in that order, and any disagreement between two accepted packets must be visible in one of those displayed rows.*

Proof. Project the carrier of Definition 3642.1. The packet exposes the topology row, the real sequence-space row, the finite StreamName windows, the Real seal, and the closure-witness row before any structural replay is available.

The NameCert obligations are therefore row-local. Topology admission is read from T, the sequence route from S, the finite windows from W, the coordinate seal from R, and the sequential closure witness from A.

The structural rows X, H, C, P, N then transport, compare, replay, source, and name the same finite packet. Since the carrier contains none of the excluded host-side coordinates, a classifier disagreement cannot be hidden outside the displayed rows. □

Theorem 3642.3 (Frechet-Urysohn sequential closure handoff)**.** *Every consumer that reads a point as belonging to the sequential closure of a displayed subset through an accepted* $\mathsf{FrechetUrysohn}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealSequenceSpace}^{\uparrow}, \qquad \mathsf{SequentialCompact}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

and then through the closure-witness row A*. The handoff exports only the finite sequence windows, the accepted sequence-space route, the Real seal, and the displayed tail-in-subset witness; it does not export arbitrary nets, countable choice, host closure equality, or ambient topological compactness.*

Proof. Start with an accepted sequential-closure read. By Definition 3642.2, the read first enters the topology row T and then the sequence-space row S with its displayed StreamName window schedule W.

The Real seal R and the closure-witness row A are downstream of the same sequence route. The witness can therefore certify only the inspected tail windows and the displayed limit read named by the packet.

The sequential compactness reference is consumed as a finite comparison boundary rather than as an ambient compactness theorem. The structural rows X, H, C, P, N preserve this same route, so the consumer receives a sequential handoff but no hidden net, selected sequence, host equality, or external closure principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetUrysohn}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetUrysohn}^{\uparrow}$ packet is generated from a topology carrier row, a real sequence-space row, StreamName windows, a Real seal, a closure-witness row, transport, componentwise hsame rows, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetUrysohn}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3642.1, Definition 3642.2, and Definition 3642.3 seed the sequential-closure carrier over finite topology, sequence-space, window, Real, and witness rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetUrysohn}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FrechetUrysohnUp.FrechetUrysohnTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim arbitrary nets, countable choice, host closure equality, excluded middle over neighborhoods, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence-space admission, finite-window ordering, Real-seal ordering, closure-witness display, and transport stability for the same packet.

Chapter 3643

A Concrete Naming Certificate for $\mathsf{HyperbolicBoundaryPhaseAudit}^{\uparrow}$

The $\mathsf{HyperbolicBoundaryPhaseAudit}^{\uparrow}$ packet realizes the boundary-phase audit face of chapter 9463 as finite NameCert data. It sits after the observer-expansion ledger of chapter 3486, the boundary-geodesic route of chapter 3491, the horocycle packet of chapter 3534, the phase-ledger horocycle packet of chapter 3591, and the boundary-fixed disk transport route of chapter 3500. The packet names an audit row for checking that a visible boundary-phase read has passed through the displayed hyperbolic ledger, boundary, horocycle, and transport surfaces; it is not a second horocycle carrier, not a host ideal-boundary quotient, and not a physical observer trajectory.

Falsifiable prediction: Every accepted $\mathsf{HyperbolicBoundaryPhaseAudit}^{\uparrow}$ read factors through displayed $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, transport, replay, provenance, and local $\mathsf{NameCert}$ rows before it exports a boundary-phase audit verdict.

Independence witness: hyperbolic-expansion-ledger, hyperbolic-geodesic-boundary, hyperbolic-horocycle, phase-ledger-horocycle, poincare-boundary-fixed-transport: the expansion ledger records records-side growth without a boundary-phase audit verdict; the geodesic-boundary packet records far-end incidence without horocycle phase accounting; the horocycle packet records boundary tangency without focused phase-ledger provenance; the phase-ledger horocycle packet records the boundary-transport route without a separate audit verdict; and the boundary-fixed transport packet records preserved disk transport without ledger-phase coverage. None is bijective to $\mathsf{HyperbolicBoundaryPhaseAudit}^{\uparrow}$.

Definition 3643.1 (Hyperbolic boundary-phase audit carrier)**.** *A* $\mathsf{HyperbolicBoundaryPhaseAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, G, Q, L, T, V, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$ *observer-expansion ledger row.*
2. *G is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *boundary-geodesic incidence row.*
3. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *boundary-tangent row.*
4. *L is the* $\mathsf{PhaseLedgerHorocycle}^{\uparrow}$ *focused phase-ledger route.*

5. *T is the* PoincareBoundaryFixedTransport$^{\uparrow}$ *boundary-preserving disk-transport row.*
6. *V is the audit verdict row, recording that the visible boundary-phase read has consumed X, G, Q, L, T before any public verdict is exported.*
7. *H records componentwise* hsame *transport for the expansion ledger, boundary-geodesic, horocycle, phase-ledger, transport, audit, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the same ordered audit route.*
9. *P is the* Pkg *provenance over* HyperbolicBoundaryPhaseAudit$^{\uparrow}$, HyperbolicExpansionLedger$^{\uparrow}$, HyperbolicGeodesicB HyperbolicHorocycle$^{\uparrow}$, PhaseLedgerHorocycle$^{\uparrow}$, PoincareBoundaryFixedTransport$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{HyperbolicBoundaryPhaseAudit}^{\uparrow}}$ *row.*

The carrier exports no host hyperbolic plane, quotient ideal-boundary equality, selected boundary representative, global clock, physical observer path, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.HyperbolicBoundaryPhaseAuditUp.HyperbolicBoundaryPhaseAuditTasteGate`
`single carrier alignment`

Theorem 3643.2 (Hyperbolic boundary-phase audit NameCert obligations)**.** *For every accepted* HyperbolicBoundaryPhaseAudit$^{\uparrow}$ *carrier $A = (X, G, Q, L, T, V, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicBoundaryPhaseAu}}$ *surface consists exactly of observer-expansion ledger admission, boundary-geodesic incidence, horocycle boundary tangency, focused phase-ledger route admission, boundary-fixed transport, audit verdict exposure, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the accepted carrier. The analytic route begins with the expansion ledger X, then reads the boundary-geodesic row G, the horocycle row Q, the phase-ledger horocycle row L, and the boundary-fixed transport row T.

The audit verdict V is downstream of those five rows. It therefore cannot certify a boundary-phase read unless the expansion, boundary, horocycle, phase-ledger, and transport surfaces have already been displayed.

The structural rows H, C, P, N preserve and name that route. Since the carrier has no coordinate for a host hyperbolic plane, quotient boundary equality, selected boundary representative, global clock, physical observer path, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 3643.3 (Hyperbolic boundary-phase audit route nonescape)**.** *Every boundary-phase audit verdict exported by an accepted* HyperbolicBoundaryPhaseAudit$^{\uparrow}$ *packet factors through*

$$\text{HyperbolicExpansionLedger}^{\uparrow} \longmapsto \text{HyperbolicGeodesicBoundary}^{\uparrow} \longmapsto \text{HyperbolicHorocycle}^{\uparrow} \longmapsto \text{PhaseLedgerHorocycle}$$

before the audit verdict row is visible. The verdict exports only the finite audit route carried by $A = (X, G, Q, L, T, V, H, C, P, N)$, not a host ideal-boundary quotient, a selected boundary representative, a physical observer trajectory, a global clock, or a completed hyperbolic surface.

Proof. Start with the NameCert obligations of Definition 3643.2. They place the expansion ledger, boundary-geodesic row, horocycle row, phase-ledger horocycle route, and boundary-fixed transport before the audit verdict.

Read the sibling packets in order. Definition 3486.3 supplies the records-side expansion route, Definition 3491.3 supplies the boundary-geodesic handoff, Definition 3534.2 supplies the horocycle boundary-tangency route, and Definition 3591.2 supplies the focused phase-ledger route.

Finally consume the boundary-fixed transport row and the structural rows H, C, P, N. Because no other carrier coordinate exists, the audit verdict cannot escape to host boundary equality, selected representatives, physical observer motion, global clocks, or completed hyperbolic geometry. □

The Lean follow-up for this packet must provide explicit Nontrivial HyperbolicBoundaryPhaseAudit$^{\uparrow}$ and FieldFaithful HyperbolicBoundaryPhaseAudit$^{\uparrow}$ TasteGate instances. Those instances must keep $X, G, Q, L, T, V, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for NameCert$_{\text{HyperbolicBoundaryPhaseAudit}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicBoundaryPhaseAudit}^{\uparrow}}$, seed)

Scope closed: Definition 3643.1, Definition 3643.2, and Definition 3643.3 seed the finite boundary-phase audit route over expansion-ledger, boundary-geodesic, horocycle, phase-ledger, boundary-fixed transport, audit, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicBoundaryPhaseAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host hyperbolic geometry, quotient ideal-boundary equality, selected boundary representatives, physical observer trajectories, global clocks, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, expansion-ledger routing, boundary-geodesic handoff, horocycle incidence, phase-ledger coverage, boundary-fixed transport, audit verdict exactness, TasteGate nontriviality, FieldFaithful coverage, and local naming for BEDC.Derived.HyperbolicBoundaryPhaseAuditUp.

Constructive story: A HyperbolicBoundaryPhaseAudit$^{\uparrow}$ packet is generated from a HyperbolicExpansionLedger row, HyperbolicGeodesicBoundary row, HyperbolicHorocycle row, PhaseLedgerHorocycle route, PoincareBoundaryFixedTransport row, audit verdict row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3644

A Concrete Naming Certificate for $\mathsf{SardTheoremFiniteJet}^{\uparrow}$

Following Sard and the finite-jet presentation of differential topology, the $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ packet records the displayed local data by which a smooth map is inspected through finitely many derivative, chart, rank, and critical-value rows. It sits after the Frechet derivative surface of chapter 3634, the local inverse-function route of chapter 2055, the comparison discipline of chapter 1912, and the charted carrier of chapter 96. The packet names a finite jet certificate for critical-value exclusion windows; it is not the classical full measure-zero Sard theorem, not a transversality theorem, not a choice-selected regular-value principle, and not a standard bridge.

Definition 3644.1 (Sard theorem finite-jet carrier)**.** *A* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, F, D, R, V, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *chart row naming the source and target chart windows in which the finite jet is read.*
2. *F is the displayed map row, containing only the finite map observations inspected by the packet.*
3. *D is the* $\mathsf{FrechetDerivative}^{\uparrow}$ *jet row, recording the derivative orders and finite remainder windows consumed by the critical-value test.*
4. *R is the rank-defect row, displaying which derivative minors are inspected and where the finite packet records criticality.*
5. *V is the candidate value-window row, naming the finite output windows whose regular-value status is being tested.*
6. *L is the local inverse or mean-value ledger supplied through* $\mathsf{InverseFunction}^{\uparrow}$ *and* $\mathsf{MeanValueTheorem}^{\uparrow}$ *when a displayed noncritical branch is certified.*
7. *H records componentwise* hsame *transport for the chart, map, derivative, rank, value-window, ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite value-window request through the chart, map, derivative, rank, and local ledger rows.*
9. *P is the* Pkg *provenance over* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$, $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{InverseFunction}^{\uparrow}$, $\mathsf{MeanValueTheorem}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SardTheoremFiniteJet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for ambient measure zero, global transversality, choice-selected regular values, host smooth-function spaces, or a standard bridge.

Lean4 ✓ `BEDC.Derived.SardTheoremFiniteJetUp.TasteGate.SardTheoremFiniteJetTasteGate single carrier alignment`

Theorem 3644.2 (Sard theorem finite-jet NameCert obligations)**.** *For every accepted* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ *carrier* $J = (M, F, D, R, V, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SardTheoremFiniteJet}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *charted carrier admission through* $\mathsf{Manifold}^{\uparrow}$ *for the source and target windows;*
2. *finite derivative admission through* $\mathsf{FrechetDerivative}^{\uparrow}$ *for the displayed jet orders and remainders;*
3. *rank-defect and value-window inspection through R and V;*
4. *noncritical local handoff through* $\mathsf{InverseFunction}^{\uparrow}$ *and* $\mathsf{MeanValueTheorem}^{\uparrow}$ *when the packet records a regular finite window;*
5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

Every accepted finite-jet regularity read factors through these five rows, and any disagreement between two accepted packets is visible in one of them.

Proof. Project the carrier of Definition 3644.1. The rows $M, F, D, R, V, L, H, C, P, N$ are the whole accepted packet, so the chart, map, derivative, rank, value-window, and local ledger reads are finite BHist data.

The critical-value boundary is read only from D, R, V. The derivative row supplies the inspected jet windows, the rank-defect row records the displayed minors, and the value row records the finite output windows under consideration.

When a noncritical branch is exposed, the local ledger L records the inverse-function and mean-value handoff. That handoff is local to the same chart and derivative rows, so it does not choose a global regular value or import a host transversality principle.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row stores ambient measure-zero data, global transversality, selected regular values, host smooth-function spaces, or bridge data, the five obligation rows exhaust the NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ packet must expose $\mathsf{Manifold}^{\uparrow}$, $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{InverseFunction}^{\uparrow}$, $\mathsf{MeanValueTheorem}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows before any finite-jet regularity read is public.

Independence witness: frechet-derivative, inverse-function, mean-value-theorem, manifold: no listed sibling is bijective to $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ because the Sard finite-jet packet jointly binds chart windows, map observations, derivative jets, rank-defect rows, value windows, local regularity ledger, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SardTheoremFiniteJet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ packet is generated from Manifold chart rows, displayed map observations, Frechet derivative jet rows, rank-defect rows, finite value-window rows, an inverse-function and mean-value local ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SardTheoremFiniteJet}\uparrow}$, seed)

Scope closed: Definition 3644.1 and Definition 3644.2 seed the finite Sard jet certificate over chart, derivative, rank, value-window, local regularity, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SardTheoremFiniteJet}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the classical full measure-zero Sard theorem, transversality, choice-selected regular values, host smooth-function spaces, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite derivative admission, rank-defect inspection, value-window inspection, local inverse-function and mean-value handoff, and transport stability for BEDC.Derived.SardTheoremFiniteJetU

Chapter 3645

A Concrete Naming Certificate for $\mathsf{BusemannBoundary}^{\uparrow}$

Following Busemann and Bridson–Haefliger, the $\mathsf{BusemannBoundary}^{\uparrow}$ packet records boundary reads by finite distance-difference rows rather than by a completed host ideal-boundary quotient. It sits after the metric-read surface of chapter 3474, the geodesic far-end carrier of chapter 3491, the boundary-fixed transport route of chapter 3500, and the disk-coordinate surface of chapter 377.

Definition 3645.1 (Busemann boundary carrier)**.** *A* $\mathsf{BusemannBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, o, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *source row, exposing the metric carrier from which all distance-difference reads are taken.*
2. *o is the basepoint row, recording the named origin point and its admission through the same metric source.*
3. *R is the geodesic-ray window row, displaying the finite ray segments and endpoint probes supplied by* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$*.*
4. *D is the dyadic distance-difference ledger for the inspected values $d(x, \gamma(t)) - d(o, \gamma(t))$ over the displayed windows.*
5. *L is the boundary-read row, classifying the finite Busemann read against the visible ideal-boundary data of* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$*,* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*, and* $\mathsf{UnitDisk}^{\uparrow}$*.*
6. *H records componentwise* hsame *transport for the metric source, basepoint, ray windows, dyadic ledger, boundary-read row, replay, provenance, and local naming data.*
7. *C records displayed* Cont *replay from a boundary request through X, o, R, D, L.*
8. *P is the* Pkg *provenance over* $\mathsf{BusemannBoundary}^{\uparrow}$*,* $\mathsf{HyperbolicMetric}^{\uparrow}$*,* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$*,* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*,* $\mathsf{UnitDisk}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BusemannBoundary}^{\uparrow}}$ *row.*

The classifier has no coordinate for an arbitrary compactification, a host quotient of ideal points, a globally chosen geodesic representative, classical sequential compactness at infinity, or an ambient visual boundary not displayed by the packet.

Lean4 ✓ `BEDC.Derived.BusemannBoundaryUp.BusemannBoundaryTasteGate single carrier alignment`

Theorem 3645.2 (Busemann boundary NameCert obligations)**.** *For every accepted* $\mathsf{BusemannBoundary}^{\uparrow}$ *carrier* $B = (X, o, R, D, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BusemannBoundary}^{\uparrow}}$ *surface consists exactly of finite* BHist *rows for carrier admission, ray-window exactness, metric-read stability, boundary classifier laws, and nonescape from the host ideal-boundary quotients. Every boundary consumer must read* X, o, R, D, L *before transport, replay, provenance, and local naming are available, and any disagreement between accepted Busemann reads must occur in one of those displayed rows.*

Proof. Project the carrier of Definition 3645.1. The packet exposes a hyperbolic metric source, a basepoint, geodesic-ray windows, a dyadic distance-difference ledger, and a boundary-read row before any structural replay is present.

Carrier admission is therefore row-local. Ray-window exactness is read from R, metric-read stability from the shared X, o source, and boundary classifier laws from L against the displayed geodesic, transport, and disk rows.

The structural rows H, C, P, N then preserve, replay, source, and name the same finite surface. Since the carrier contains no coordinate for a completed host quotient or an unrecorded compactification, the read cannot escape the displayed ideal-boundary data. □

Theorem 3645.3 (Busemann boundary nonescape)**.** *Every accepted boundary read exported by a* $\mathsf{BusemannBoundary}^{\uparrow}$ *carrier factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \quad \mathsf{HyperbolicGeodesicBoundary}^{\uparrow}, \quad \mathsf{PoincareBoundaryFixedTransport}^{\uparrow}, \quad \mathsf{UnitDisk}^{\uparrow}$$

and then through the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of the same packet. The exported read is therefore a finite distance-difference boundary certificate; it is not a host compactification point, a quotient class of rays, or an ambient visual-boundary object.*

Proof. Begin with an accepted boundary read. By Definition 3645.2, the read first enters the $\mathsf{HyperbolicMetric}^{\uparrow}$ row X and the basepoint row o, so each distance-difference entry is tied to the same displayed metric source.

The ray-window and boundary rows then force the read through $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, and $\mathsf{UnitDisk}^{\uparrow}$. The ledger D records only the finite dyadic distance-difference values attached to those windows, and L classifies only against the displayed boundary data.

Finally H, C, P, N transport, replay, source, and name this same route. No additional coordinate remains for a host ideal-boundary quotient, a global ray representative, or an ambient compactification, so every exported Busemann boundary read stays inside the named packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BusemannBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BusemannBoundary}^{\uparrow}$ packet is generated from a HyperbolicMetric source row, a basepoint row, geodesic-ray windows, a dyadic distance-difference ledger, a boundary-read row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BusemannBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3645.1, Definition 3645.2, and Definition 3645.3 seed the Busemann boundary carrier over finite metric, basepoint, ray-window, distance-difference, and boundary-read rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BusemannBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary compactifications, host ideal-boundary quotients, global geodesic representatives, classical compactness at infinity, ambient visual boundaries, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ray-window exactness, metric-read stability, boundary classifier laws, nonescape from host ideal-boundary quotients, transport, replay, provenance, and local naming for the same displayed packet.

Chapter 3646

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$

Following Bishop and Bridges on constructive completion, the $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$ packet records the unit route from displayed regular Cauchy source data into the completion-facing seal. It sits between the regular-name source of chapter 371, the unit map of chapter 1527, the monadic completion surface of chapter 378, and the real completion boundary of chapter 360. Its finite reads pass through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as exposed in chapter 126, chapter 301, chapter 291, and chapter 38. The packet names the source-to-completion unit as finite BEDC data; it is not quotient completion equality, a selected Cauchy representative, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3646.1 (RegularCauchyCompletionUnit carrier)**.** *A* $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (G, R, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the source row, read either as a* $\mathsf{RegularCauchyName}^{\uparrow}$ *packet or as the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy row already visible to a completion consumer.*
2. *R is the unit-admission row stating that the displayed source row is admitted as the unit image before any completion-facing seal is consumed.*
3. *S is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows through which the source row is inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those source windows and precision requests.*
5. *E is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after G, R, S, D have been displayed.*
6. *H stores componentwise* hsame *transport for the source, unit-admission row, stream windows, dyadic tolerance ledger, seal handoff, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from source inspection through unit admission, finite windows, tolerance readback, and seal handoff.*
8. *P records* Pkg *provenance over* $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUnit}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, a selected regular-Cauchy representative, countable-choice schedules, host sequence equality, an ambient completion theorem, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionUnitUp.RegularCauchyCompletionUnitTasteGate single carrier alignment`

Theorem 3646.2 (RegularCauchyCompletionUnit NameCert obligations)**.** *For an accepted* RegularCauchyComplet *carrier $U = (G, R, S, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUnit}^{\uparrow}}$ *surface consists exactly of source admission through G, unit-route admission through R, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance readback through D,* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3646.1. Its displayed source row is G, and the unit-admission row is R.

The finite observation surface is S, D. The stream windows expose only scheduled source reads, and the dyadic ledger records only the tolerance data needed before completion-facing consumption.

The seal handoff E is downstream of those rows. The structural rows H, C, P, N transport, replay, source, and name the same route, so the local certificate is exhausted by the listed fields. □

Theorem 3646.3 (RegularCauchyCompletionUnit seal handoff)**.** *Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* RegularCauchyCompletionUnit *packet reaches the seal row E only through the route*

$$G \longmapsto R \longmapsto S \longmapsto D \longmapsto E$$

together with H, C, P, N. Thus the unit image is consumed as displayed regular Cauchy source data with finite windows and dyadic tolerance readback, not as a quotient class or selected completion representative.

Proof. Begin with a completion-facing consumer. By the carrier definition, the only source row available to the consumer is G, and the only unit-admission row is R.

The consumer must next pass through the finite windows S and the dyadic tolerance ledger D. These rows are the displayed readback route inherited from the regular-name and regular-rational source surfaces.

Only after that route is available can E be read. The rows H, C, P, N attach transport, replay, provenance, and local naming to the same route, so the seal handoff is the displayed unit route and not a hidden completion object. □

Theorem 3646.4 (RegularCauchyCompletionUnit non-escape)**.** *No accepted* $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$ *packet exports data outside $G, R, S, D, E, H, C, P, N$. In particular, it cannot be used to recover quotient completion equality, a selected regular-Cauchy representative, countable-choice schedules, host sequence equality, an ambient completion theorem, analytic closure of the monad, or completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Inspect the carrier. The source, unit-admission, window, tolerance, seal, transport, replay, provenance, and local-name rows are the only fields.

Apply Definition 3646.2. Every accepted obligation is a projection of those rows or a structural transport, replay, provenance, or naming row for them.

Finally use Definition 3646.3. All completion-facing consumers pass through $G, R, S, D, E, H, C, P, N$, so no excluded quotient, choice, host, monadic closure, or completeness object can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUnit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$ packet is generated from a RegularCauchyName or RegSeqRat source row, unit admission, finite StreamName windows, a DyadicRatCore tolerance ledger, a RealCauchyCompletion or RealUp seal handoff, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3646.1, Definition 3646.2, Definition 3646.3, and Definition 3646.4 seed the finite source-to-completion unit route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion equality, selected representatives, countable choice, host sequence equality, monadic analytic closure, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, unit-route admission, finite window exposure, dyadic tolerance readback, seal handoff, transport stability, provenance, and non-escape for the displayed packet.

Chapter 3647

A Concrete Naming Certificate for $\mathsf{SobolevTrace}^{\uparrow}$

Following Lions–Magenes and Adams–Fournier, the $\mathsf{SobolevTrace}^{\uparrow}$ packet records finite BEDC boundary trace data for Sobolev carriers. It sits next to the weak-derivative packet of chapter 440, consumes the boundary-control route of chapter 2329, uses the compact-window handoff of chapter 2218, and reads scalar and metric data through chapter 38, chapter 57, and chapter 128. The packet names only the displayed boundary restriction surface; it does not claim a host trace operator on a completed Sobolev quotient.

Definition 3647.1 (Sobolev trace carrier)**.** *A* $\mathsf{SobolevTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, D, B, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, exposing the weak-derivative, integrability, codomain, transport, replay, provenance, and local naming rows already admitted by the Sobolev packet.*
2. *D is the boundary-domain row. It records the finite boundary chart, collar, normal-window, or boundary-read ledger on which the trace is inspected.*
3. *B is the Poincare-facing boundary-control row from* $\mathsf{PoincareInequality}^{\uparrow}$*, used only to keep constant or zero-boundary escape from entering the trace read.*
4. *R is the Rellich–Kondrachov compact-window row, recording the finite compactness or subsequence-window handoff consumed by boundary convergence tests.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *row that supplies the finite distance and Cauchy-readback surface for the boundary values.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for boundary magnitudes, radii, and norm estimates.*
7. *H stores componentwise* hsame *transport for S, D, B, R, M, E and the structural rows.*
8. *C stores the displayed* Cont *replay from a trace request through the Sobolev source, boundary row, Poincare row, compact-window row, metric row, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{SobolevTrace}^{\uparrow}$*,* $\mathsf{Sobolev}^{\uparrow}$*,* $\mathsf{PoincareInequality}^{\uparrow}$*,* $\mathsf{RellichKondrachov}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SobolevTrace}^{\uparrow}}$ *row.*

The classifier has no coordinate for an ambient trace operator, quotient equality of boundary functions, selected representative, distributional boundary value, open-cover compactness theorem, or global completeness theorem for the real line.

Lean4 ✓ `BEDC.Derived.SobolevTraceUp.sobolevTraceChapterTasteGate`

Theorem 3647.2 (Sobolev trace NameCert obligations)**.** *For every accepted* $\mathsf{SobolevTrace}^{\uparrow}$ *carrier* $T = (S, D, B, R, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SobolevTrace}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the displayed Sobolev source, boundary-domain row, Poincare control row, Rellich–Kondrachov compact-window row, metric or complete-metric row, real seal, transport, replay, provenance, and local naming data;*
2. *source compatibility, requiring every trace request to enter through the* $\mathsf{Sobolev}^{\uparrow}$ *weak-derivative ledger before any boundary row is read;*
3. *boundary-control exactness, requiring* D *and* B *to supply the boundary restriction and normalization data consumed by the trace;*
4. *compact and complete-metric handoff, requiring* R *and* M *to expose only finite convergence, compact-window, distance, and Cauchy-readback rows;*
5. *scalar readback and transport, requiring* E, H, C, P, N *to preserve, replay, source, and name the same finite trace route.*

Proof. Project the carrier. The accepted packet exposes only the rows $S, D, B, R, M, E, H, C, P, N$, so carrier admission is row-local.

The source compatibility row is forced by S. A trace request first reads the $\mathsf{Sobolev}^{\uparrow}$ weak-derivative and magnitude ledger, then reaches the boundary-domain row D and the Poincare control row B.

The compact and complete-metric handoff is similarly row-local. The Rellich–Kondrachov row R supplies only finite compact-window data, and M supplies only the displayed metric or complete-metric readback surface.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier contains no ambient trace operator, host quotient, selected representative, or distributional boundary coordinate, the local NameCert obligations are exhausted by the five displayed rows. □

Lean4 ✓ `BEDC.Derived.SobolevTraceUp.SobolevTraceNamecertObligationSurface`

Theorem 3647.3 (Sobolev trace boundary readback)**.** *Every boundary value read exported by an accepted* $\mathsf{SobolevTrace}^{\uparrow}$ *packet factors through*

$$\mathsf{Sobolev}^{\uparrow} \longmapsto \mathsf{PoincareInequality}^{\uparrow} \longmapsto \mathsf{RellichKondrachov}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

and then through the displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the same packet. The exported object is a finite boundary readback certificate; it is not a host boundary function, quotient trace class, distributional trace, or selected representative.*

Proof. Start with an accepted trace read. By Definition 3647.2, the read first enters the Sobolev source row S, so it inherits only the weak-derivative and magnitude data visible in the source packet.

The boundary rows D and B then restrict the request to the displayed boundary ledger and Poincare-facing control surface. These rows determine which boundary observations are available before any compactness or completion-facing datum is consumed.

The remaining analytic read passes through R, M, E. Thus compact-window information, metric or complete-metric readback, and scalar magnitude are all finite rows of the same packet.

The structural rows H, C, P, N merely preserve, replay, source, and name this route. No carrier coordinate remains from which a host boundary function, quotient class, distributional trace, or selected representative could be read. □

Theorem 3647.4 (Sobolev trace complete-metric handoff)**.** *Any* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *PDE, variational, or boundary-analysis consumer citing an accepted* $\mathsf{SobolevTrace}^{\uparrow}$ *carrier receives only the complete-metric handoff displayed by* M*, the real scalar seal displayed by* E*, and the upstream rows* S, D, B, R*. In particular, a complete-metric consumer may request Cauchy-readback data for the boundary trace only after the Sobolev source, boundary-control, Poincare, and Rellich–Kondrachov rows have been read.*

Proof. Project a downstream consumer request. The carrier places M after S, D, B, R, so the complete-metric surface cannot be reached before the Sobolev source, boundary row, boundary-control row, and compact-window row are fixed.

The real scalar seal is read through E. It records the displayed boundary magnitudes and radii used by M, not a host completeness theorem for all real-valued boundary functions.

The transport, replay, provenance, and local naming rows keep this handoff inside the same BHist packet. Hence the complete-metric consumer receives only the finite Cauchy-readback route displayed by the trace carrier. □

Falsifiable prediction: Every $\mathsf{SobolevTrace}^{\uparrow}$ boundary read factors through displayed SobolevUp, PoincareInequalityUp, RellichKondrachovUp, MetricUp, CompleteMetricUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows before any downstream trace consumer receives it.

Independence witness: sobolev, poincare-inequality, rellich-kondrachov, metric, completemetric, real: $\mathsf{SobolevTrace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a Sobolev source, boundary-domain row, boundary-control row, compact-window row, complete-metric boundary readback, scalar seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevTrace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SobolevTrace}^{\uparrow}$ packet is generated from a Sobolev source row, boundary-domain row, Poincare control row, Rellich–Kondrachov compact-window row, metric or complete-metric readback row, real scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SobolevTrace}^{\uparrow}}$, seed)

Scope closed: Definition 3647.1, Definition 3647.2, Definition 3647.3, and Definition 3647.4 seed the finite boundary trace route over Sobolev, Poincare, Rellich–Kondrachov, metric, complete-metric, and real neighbours.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SobolevTrace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host trace operator, quotient equality of boundary functions, selected representatives, distributional boundary values, open-cover compactness, real-line completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, boundary-control exactness, compact and complete-metric handoff, scalar readback, componentwise transport, replay, provenance, and local naming.

Chapter 3648

A Concrete Naming Certificate for $\mathsf{NoetherianModule}^{\uparrow}$

Following Emmy Noether and standard module theory, the $\mathsf{NoetherianModule}^{\uparrow}$ packet records finite submodule-chain stabilization data over a displayed module source. In BEDC form it sits after $\mathsf{NameCert}_{\mathsf{Module}^{\uparrow}}$ (chapter 46), the commutative scalar source of $\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}$ (chapter 44), the ideal-side Noetherian surface of $\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}$ (chapter 3637), and the ideal carrier of $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$ (chapter 81). The packet supplies the module-side finite-chain row consumed by algebraic reduction and kernel-image arguments; it does not assert quotient-module classification, selected bases, maximal-submodule choice, or a host Noetherian theorem.

3648.1 Carrier definition

Definition 3648.1 (Noetherian module carrier)**.** *A* $\mathsf{NoetherianModule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{NoethMod}(M, R, I, A, G, H, Q, P, N).$$

The row M is the $\mathsf{Module}^{\uparrow}$ *source surface. The row R is the scalar* $\mathsf{CommRing}^{\uparrow}$ *source read from the module certificate. The row I is the* $\mathsf{Ideal}^{\uparrow}$ *comparison surface used when scalar-generated submodule rows are inspected. The row A is the ascending-chain stabilization witness: every displayed chain of submodule rows over M carries a finite stage after which all later submodule endpoints classify with that stage. The row G is the finite-generator witness used by algebraic consumers that read the module through finitely generated submodule data. The row H is componentwise* hsame *transport for the module, scalar, ideal-comparison, stabilization, and generator rows. The row Q is displayed* Cont *replay for the submodule-chain and generator certificates. The row P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{NoetherianModule}^{\uparrow}}$ *naming row.*

Lean4 ✓ `BEDC.Derived.NoetherianModuleUp.TasteGate.NoetherianModuleTasteGate single carrier alignment`

Theorem 3648.2 (Noetherian module NameCert obligations)**.** *For an accepted* $\mathsf{NoetherianModule}^{\uparrow}$ *carrier* $\mathsf{NoethMod}(M, R, I, A, G, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NoetherianModule}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, source compatibility with* $\mathsf{Module}^{\uparrow}$*,* $\mathsf{CommRing}^{\uparrow}$*,* $\mathsf{NoetherianRing}^{\uparrow}$*, and* $\mathsf{Ideal}^{\uparrow}$*, finite submodule-chain stabilization access through A, finite-generator access through G, componentwise classifier transport through H, displayed continuation replay through Q, provenance non-escape through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.NoetherianModuleUp.NoetherianModuleCarrier namecert obligations`

Proof. Project the nine rows of Definition 3648.1. The module row M fixes the additive carrier, scalar action, and module classifier before any submodule chain is inspected.

The scalar and ideal comparison rows R and I bind the chain to the same commutative-ring and ideal surfaces used by chapter 3637. Thus the $\mathsf{NoetherianRing}^{\uparrow}$ dependency supplies only the scalar-side finite-chain context; it does not replace the module chain by an ideal chain.

The stabilization row A and generator row G are then read over the displayed module classifier. Componentwise transport H carries the same rows through hsame, while Q replays only the displayed continuations.

Finally, P and N repack this inventory as the local naming certificate. Since no quotient-module classifier, basis selector, maximal-submodule choice, or host Noetherian principle occurs in the carrier, none can occur among the local obligations. □

Theorem 3648.3 (Noetherian submodule-chain stability)**.** *Let* $\mathsf{NoethMod}(M, R, I, A, G, H, Q, P, N)$ *be an accepted* $\mathsf{NoetherianModule}^{\uparrow}$ *carrier. For every displayed ascending chain of submodule rows over the* $\mathsf{Module}^{\uparrow}$ *classifier of* M*, the witness* A *supplies a finite stabilization stage, and* H *transports that stabilization along the same classifier. Thus any downstream algebraic consumer may use* $\mathsf{NoetherianModule}^{\uparrow}$ *as a finite submodule-chain certificate without importing quotient-module classification, selected bases, maximal-submodule choice, or a host Noetherian theorem.*

Proof. Begin with the source compatibility rows from Definition 3648.2. They force the chain to be read over the module classifier already present in M, while R and I keep the scalar and ideal comparison surfaces visible.

Apply the stabilization witness A to the displayed submodule chain. The result is a finite stage inside the same module classifier, not an external quotient or selected basis.

If the accepted packet is transported through a classified replacement, use the componentwise transport row H to move the chain entries and the stabilization witness together. The replay row Q preserves only the displayed continuation data, and the provenance row P prevents an ambient Noetherian principle from entering the route.

The transported stage is therefore a reusable finite submodule-chain certificate for later module consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{NoetherianModule}^{\uparrow}}$.

Constructive story: A $\mathsf{NoetherianModule}^{\uparrow}$ packet is generated from a $\mathsf{Module}^{\uparrow}$ source, a scalar $\mathsf{CommRing}^{\uparrow}$ source, a $\mathsf{NoetherianRing}^{\uparrow}$ scalar-side chain context, an $\mathsf{Ideal}^{\uparrow}$ comparison surface, a submodule-chain stabilization witness, a finite-generator witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NoetherianModule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3648.1, Definition 3648.2, and Definition 3648.3 seed the finite submodule-chain stabilization interface over ModuleUp, NoetherianRingUp, CommRingUp, IdealUp, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NoetherianModule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-module classification, selected bases, maximal-submodule choice, host Noetherian module theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, finite submodule-chain stabilization access, finite-generator access, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.NoetherianModuleUp.

Chapter 3649

A Concrete Naming Certificate for $\mathsf{LaplaceTransform}^{\uparrow}$

Following classical Laplace transform theory in analysis, the $\mathsf{LaplaceTransform}^{\uparrow}$ packet records only the finite constructive transform interface visible to BEDC consumers. It sits after the coefficient and convergence rows of chapter 1583, the integral carrier of chapter 123, the graph discipline of chapter 130, the real seal of chapter 38, the regular rational readback of chapter 301, the finite observation discipline of chapter 126, and the dyadic tolerance core of chapter 291. The chapter records finite exponential-kernel, integral-window, transform-output, transport, replay, provenance, and local NameCert rows; it does not assert host analytic continuation, a global function-space quotient, selected improper integrals, or ambient real completeness.

Definition 3649.1 (Laplace transform carrier)**.** *A* $\mathsf{LaplaceTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, I, F, W, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the exponential-kernel row, read through* $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *data for the finitely inspected values of e^{-st}.*
2. *I is the* $\mathsf{Integral}^{\uparrow}$ *window row naming the displayed interval, mesh or tagged integration data, and tolerance budget used by the transform read.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *input-function row restricted to the finite source observations consumed by I.*
4. *W is the finite product-read window combining the kernel row K with the input row F before the integral row I is consumed.*
5. *O is the transform-output row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff reached only through K, F, W, I.*
6. *H records componentwise* hsame *transport for the kernel, integral window, input function, product reads, output handoff, provenance, and local name.*
7. *C records displayed* Cont *replay from kernel and function reads through the integral window into the output row.*
8. *P is the* Pkg *provenance over* $\mathsf{LaplaceTransform}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{LaplaceTransform}^\uparrow}$ *row.*
The classifier compares accepted carriers only through $K, I, F, W, O, H, C, P, N$. It has no coordinate for host analytic continuation, quotient equality of functions, selected improper limits, unbounded integration outside the displayed window, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.LaplaceTransformUp.LaplaceTransformTasteGate single carrier alignment`

Theorem 3649.2 (Laplace transform NameCert obligations)**.** *For an accepted* $\mathsf{LaplaceTransform}^\uparrow$ *carrier $L = (K, I, F, W, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LaplaceTransform}^\uparrow}$ *surface consists exactly of carrier admission, exponential-kernel admission, integral-window exactness, input-function read compatibility, product-window replay, transform-output handoff, componentwise transport, continuation replay, provenance, and ledger non-escape. These obligations are discharged along the finite route*

$$K, F \longmapsto W \longmapsto I \longmapsto O$$

together with H, C, P, N.

Proof. Carrier admission is projection from Definition 3649.1. The kernel row K, input-function row F, product-read window W, integral row I, and output row O are stored coordinates before any downstream consumer reads the transform.

The exponential-kernel obligation is confined to the displayed $\mathsf{RealPowerSeries}^\uparrow$ and real-read rows inside K. The input-function obligation is confined to the finite $\mathsf{ContinuousMap}^\uparrow$ observations in F, and the product-window obligation records exactly which paired reads enter the integration window.

Integral-window exactness is the row I. It consumes only the paired reads in W and the displayed tolerance and mesh data carried by the integral interface, so the calculation is a finite BHist route rather than an improper-integral assertion.

The rows H and C transport and replay the same route componentwise. The provenance row P and local name N source the packet, while O is downstream of K, F, W, I. Since none of the excluded host objects appears as a carrier coordinate, the listed obligations exhaust the certificate surface. □

Theorem 3649.3 (Laplace transform exponential-kernel window)**.** *Every accepted* $\mathsf{LaplaceTransform}^\uparrow$ *read of the exponential factor passes through the finite kernel row K before it can enter the product window W and the integral row I. The kernel read is therefore a displayed* $\mathsf{RealPowerSeries}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{StreamName}^\uparrow$, *and* $\mathsf{DyadicRatCore}^\uparrow$ *window over the inspected s, t values, not a host exponential-function oracle and not an analytic-continuation principle.*

Proof. Project the kernel row K from the carrier of Definition 3649.1. The row records only the finitely inspected real and regular-rational reads needed for the exponential kernel.

The product window W consumes K together with the input-function row F. Thus an integral read cannot reach the kernel through any route except the displayed finite kernel row and its stored transport and replay data.

Finally the integral row I consumes W rather than a host exponential function. The transform output O is downstream of this route, so no consumer can replace the kernel window by analytic continuation or an unrecorded exponential oracle. □

Theorem 3649.4 (Laplace transform real seal nonescape)**.** *The output row O of an accepted* $\mathsf{LaplaceTransform}^{\uparrow}$ *packet exports to* $\mathsf{Real}^{\uparrow}$ *only after the displayed route*

$$K, F \longmapsto W \longmapsto I$$

has been transported and replayed through H and C. The real seal records the finite transform-output handoff already present in the packet, and it does not export host analytic continuation, global function-space equality, selected improper limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The output row O is a carrier coordinate, but Definition 3649.1 places it downstream of the kernel row, input-function row, product-read window, and integral row. A $\mathsf{Real}^{\uparrow}$ consumer therefore receives only the output handoff obtained from the displayed finite route.

Componentwise transport through H preserves the same coordinates, and continuation replay through C rebuilds the same dependency route. The package row P and local name N record provenance without adding analytic structure.

The excluded objects are absent from the carrier. There is no host analytic-continuation row, no quotient function-space coordinate, no selected improper-integral limit, no countable-choice selector, and no ambient completeness witness. Hence the real seal is nonescaping. □

Closure status for $\mathsf{NameCert}_{\mathsf{LaplaceTransform}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LaplaceTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3649.1, Definition 3649.2, Definition 3649.3, and Definition 3649.4 seed the finite exponential-kernel and integral-window transform boundary over $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LaplaceTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host analytic continuation, global function-space equality, selected improper limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exponential-kernel admission, integral-window exactness, product-window replay, transform-output handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.LaplaceTransformUp.

Constructive story: A $\mathsf{LaplaceTransform}^{\uparrow}$ packet is generated from a finite exponential-kernel row, an input-function row, a product-read window, an Integral window, a RegSeqRat and Real output handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 3650

A Concrete Naming Certificate for $\mathsf{LipschitzExtension}^{\uparrow}$

Following McShane, Whitney, and Bishop–Bridges constructive metric analysis, the $\mathsf{LipschitzExtension}^{\uparrow}$ packet records the reusable finite certificate by which a displayed Lipschitz map on a displayed subcarrier is read as an extension candidate on an ambient metric carrier. It sits above the map-level surface of chapter 410, the metric carrier of chapter 57, the continuity handoff of chapter 130, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the formula-specific McShane–Whitney certificate of chapter 1941. The chapter isolates the extension interface itself: source inclusion, bound ledger, candidate graph, restriction agreement, continuity handoff, transport, replay, provenance, and local naming.

Definition 3650.1 (Lipschitz extension carrier)**.** *A* $\mathsf{LipschitzExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, A, L, B, F, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *row naming the source metric observations available to the extension request.*
2. *A is the displayed subcarrier row, including membership evidence and inclusion routes into X.*
3. *L is the source* $\mathsf{LipschitzMap}^{\uparrow}$ *row on A, carrying the finite graph window and displayed Lipschitz constant.*
4. *B is the* $\mathsf{RegSeqRat}^{\uparrow}$ *bound row that records the rational tolerance and constant reads used by the extension certificate.*
5. *F is the candidate extension graph row, exposed only as finite ambient graph observations.*
6. *R is the restriction-agreement row, requiring each candidate read over an admitted source point to replay the source* $\mathsf{LipschitzMap}^{\uparrow}$ *read through A, L, B.*
7. *Q is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row for the candidate extension on the displayed ambient window.*
8. *H records componentwise* hsame *transport for the metric, subcarrier, source map, bound, candidate graph, restriction, continuity handoff, provenance, and local name rows.*
9. *C records displayed* Cont *replay from an ambient extension request through $X, A, L, B, F, R, Q, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{McShaneExtension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzExtension}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host function equality, quotient function spaces, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LipschitzExtensionUp.LipschitzExtensionTasteGate single carrier alignment`

Theorem 3650.2 (Lipschitz extension NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzExtension}^{\uparrow}$ *carrier* $E = (X, A, L, B, F, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LipschitzExtension}^{\uparrow}}$ *surface consists exactly of carrier admission, subcarrier inclusion, source Lipschitz-map admission, rational bound readback, candidate graph admission, restriction-agreement exactness, continuity handoff, componentwise transport, displayed replay, provenance, and ledger non-escape. The finite route is*

$$X, A \longmapsto L \longmapsto B \longmapsto F \longmapsto R, Q \longmapsto H, C, P, N.$$

No obligation is discharged by a host extension formula or by equality of ambient functions.

Proof. Carrier admission is projection from Definition 3650.1. The rows $X, A, L, B, F, R, Q, H, C, P, N$ are the complete visible inventory of an accepted packet.

The subcarrier and source-map clauses read A and L. A source value can enter the extension certificate only after the membership and inclusion row A has been displayed and the $\mathsf{LipschitzMap}^{\uparrow}$ row L has exposed the finite graph and bound data.

The rational bound and candidate graph clauses read B and F. The bound is a regular-rational ledger, and the candidate graph is a finite ambient observation row, so neither row selects a global function object or an unrecorded real limit.

Restriction exactness is the row R, while continuity handoff is the row Q. The transport and replay rows H and C preserve the same route componentwise, and P, N source and name it. Since no excluded host object occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3650.3 (Lipschitz extension restriction handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{McShaneExtension}^{\uparrow}$ *consumer of an accepted* $\mathsf{LipschitzExtension}^{\uparrow}$ *packet must read the restriction route*

$$A, L, B \longmapsto R$$

before it can treat the candidate graph row F as an extension of the source Lipschitz row. The handoff exports the displayed agreement between source and ambient rows, not a quotient function equality, not a selected representative, and not an ambient completeness theorem.

Proof. Start with a consumer asking whether the candidate extends the source map. The subcarrier row A is read first, because the question is meaningful only for points admitted by the displayed inclusion route.

Next read the source Lipschitz row L and the rational bound row B. These rows supply the finite source graph and tolerance data against which the candidate graph will be checked.

The restriction-agreement row R then compares the candidate graph row F with the source route over the admitted point. The continuity row Q and structural rows H, C, P, N replay and source the same comparison without adding a host function-space coordinate.

Thus a McShane–Whitney certificate may instantiate the interface, but the interface itself exports only the finite restriction handoff displayed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzExtension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3650.1, Definition 3650.2, and Definition 3650.3 seed the finite reusable Lipschitz extension surface over displayed metric, Lipschitz-map, continuity, regular-rational, real, and McShane-extension rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient function spaces, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subcarrier inclusion, source Lipschitz admission, rational bound readback, candidate graph admission, restriction exactness, continuity handoff, transport, replay, provenance, and non-escape for BEDC.Derived.LipschitzExtensionUp.

Constructive story: A $\mathsf{LipschitzExtension}^{\uparrow}$ packet is generated from an ambient Metric row, a displayed subcarrier row, a source LipschitzMap row, a regular rational bound ledger, a candidate extension graph, a restriction-agreement row, a ContinuousMap handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3651

A Concrete Naming Certificate for $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$

The $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$ packet realizes the anchor-subcube trigger theorem of Definition 9462.1519 as finite NameCert data. It records the displayed anchor, boundary-tile span, coverage-rank, trigger-algebra, blocker, transport, replay, provenance, and local naming rows that let a DNA-window consumer read the median closure route without importing a global codon geometry oracle or a host powerset calculation. The packet consumes the boundary-tile carrier of chapter 3393 and the trigger-algebra route of chapter 3478 before exposing the median-closure read.

Definition 3651.1 (Anchor subcube trigger carrier)**.** *An* $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, S, R, G, K, H, C, P, N)$$

with the following displayed rows:

1. *A is the anchor row naming the* CUY *boundary anchor and the admitted coordinate window.*
2. *B is the boundary-tile row listing the outside Y-halfspace observations inspected by the packet.*
3. *S is the subcube-span row recording the axis-aligned span generated by the anchor and the projected outside observations.*
4. *R is the coverage-rank row, including the displayed value of the span dimension used by the trigger theorem.*
5. *G is the trigger-algebra row recording the finite median-closure operations allowed by the packet.*
6. *K is the blocker row excluding closure reads outside the generated anchor subcube.*
7. *H records componentwise* hsame *transport for anchor, boundary-tile, span, rank, trigger-algebra, blocker, provenance, and local name rows.*
8. *C records displayed* Cont *replay from a trigger request through $A, B, S, R, G, K, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, anchored in Definition 9462.1519.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AnchorSubcubeTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for a host codon powerset, a global median algebra, an unbounded closure engine, or equality of biological interpretations outside the displayed trigger window.

Lean4 ✓ `BEDC.Derived.AnchorSubcubeTriggerUp.AnchorSubcubeTriggerTasteGate single carrier alignment`

Theorem 3651.2 (Anchor subcube trigger NameCert obligations)**.** *For every accepted* $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$ *carrier* $T = (A, B, S, R, G, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AnchorSubcubeTrigger}^{\uparrow}}$ *surface consists exactly of anchor admission, boundary-tile admission, subcube-span calculation, coverage-rank readback, trigger-algebra replay, blocker non-escape, componentwise transport, displayed continuation replay, provenance, and local naming. The finite route is*

$$A, B \longmapsto S \longmapsto R \longmapsto G, K \longmapsto H, C, P, N.$$

No obligation is discharged by a host median-closure oracle or by an unrecorded codon-space equality.

Proof. Project the accepted carrier. The rows $A, B, S, R, G, K, H, C, P, N$ are the complete packet, so anchor admission and boundary-tile admission are direct finite reads.

The span row S records the axis-aligned subcube generated by the anchor and the outside boundary observations. The rank row R then reads the displayed span dimension, so the trigger threshold is a certificate row rather than a host calculation over all codon subsets.

The trigger-algebra row G replays the finite median operations that generate the subcube, while the blocker row K prevents reads outside the displayed span. Transport through H and replay through C preserve this same route componentwise.

The provenance and local naming rows P, N source the packet in the anchor-subcube trigger theorem. Since no carrier coordinate names a global codon powerset or an ambient closure engine, the listed rows exhaust the local NameCert obligations. □

Theorem 3651.3 (Anchor subcube trigger replay boundary)**.** *Every consumer of an accepted* $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$ *packet that reads a trigger conclusion must first traverse the displayed route*

$$A, B, S, R, G, K.$$

The replay exposes the anchor-relative subcube span and its coverage rank before the trigger is public. It exports no closure claim for boundary tiles outside B*, no radial trigger not carried by* S*, and no codon equality outside the finite rows named by the packet.*

Proof. Begin with a trigger read. The anchor row A and boundary-tile row B fix the finite observation window before any span or rank claim is available.

Read the span and rank rows S and R. These rows are the only source of the generated subcube and its dimension, so a consumer cannot substitute an external radial or global closure calculation.

The trigger-algebra row G then replays the median operations licensed by the span, and the blocker row K records the boundary beyond which the packet refuses closure reads. The structural rows H, C, P, N transport, replay, source, and name the same route without adding further codon geometry. □

Closure status for $\mathsf{NameCert}_{\mathsf{AnchorSubcubeTrigger}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AnchorSubcubeTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3651.1, Definition 3651.2, and Definition 3651.3 seed the finite anchor, boundary-tile, span, rank, trigger-algebra, blocker, transport, replay, provenance, and NameCert surface for anchor-subcube triggers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AnchorSubcubeTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host codon powersets, global median algebra, radial trigger claims outside the displayed span, biological equality outside the packet, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked anchor admission, boundary-tile admission, span calculation, rank readback, trigger-algebra replay, blocker non-escape, transport, replay, provenance, and local naming for BEDC.Derived.AnchorSubcubeTrigger

Constructive story: An AnchorSubcubeTrigger$^{\uparrow}$ packet is generated from a displayed anchor row, boundary-tile row, anchor-relative span row, coverage-rank row, trigger-algebra row, blocker row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 3652

A Concrete Naming Certificate for $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$

Following Fourier's heat-equation analysis and the Courant–Friedrichs–Lewy finite-difference tradition, the $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ packet records only the finite constructive stencil interface visible to BEDC consumers. It sits after the partial-differential-equation row of chapter 194, the derivative row of chapter 122, the integral row of chapter 123, the transform handoff of chapter 3649, the real seal of chapter 38, the regular rational readback of chapter 301, the stream-window discipline of chapter 126, and the dyadic tolerance core of chapter 291. The chapter records heat-equation finite-stencil data as a local NameCert surface; it does not assert analytic solution existence, global PDE well-posedness, host function spaces, measure theory, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3652.1 (Heat-equation finite-stencil carrier)**.** *A* $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, T, X, B, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite source-function window row, read through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *observations of the finitely inspected source values.*
2. *T is the time-step row containing the displayed dyadic time width, time-index schedule, and local tolerance budget.*
3. *X is the spatial stencil row containing the displayed dyadic mesh width, nearest-neighbour or finite-radius stencil weights, and inspected spatial index schedule.*
4. *B is the boundary row containing only the boundary values and boundary classifier reads requested by the finite stencil.*
5. *Q is the finite replay row that records how source, time-step, spatial-stencil, and boundary reads produce the next displayed heat row.*
6. *R is the real-seal row reached through* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks for the finitely inspected stencil values.*
7. *H records componentwise* hsame *transport for F, T, X, B, Q, R, P, N and for the local certificate rows.*

8. *C records displayed* Cont *replay from the source-function windows through time-step, spatial-stencil, boundary, and real-seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{LaplaceTransform}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HeatEquationFiniteStencil}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, T, X, B, Q, R, H, C, P, N$. It has no coordinate for analytic solution existence, global parabolic well-posedness, host function-space equality, measure-theory integration, infinite mesh limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HeatEquationFiniteStencilUp.HeatEquationFiniteStencilTasteGate single carrier alignment`

Theorem 3652.2 (Heat-equation finite-stencil NameCert obligations)**.** *For an accepted* $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ *carrier $E = (F, T, X, B, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeatEquationFiniteStencil}^{\uparrow}}$ *surface consists exactly of carrier admission, source-window admission, time-step exactness, spatial-stencil exactness, boundary-row exactness, finite replay, real-seal handoff, componentwise transport, displayed continuation replay, provenance, and local naming. These obligations are discharged along the finite route*

$$F, T, X, B \longmapsto Q \longmapsto R$$

together with H, C, P, N.

Proof. Carrier admission is projection from Definition 3652.1. The projection exposes the source-function windows, time-step row, spatial-stencil row, boundary row, finite replay row, real-seal row, transport rows, replay rows, provenance row, and local name.

The source-window, time-step, spatial-stencil, and boundary obligations are the rows F, T, X, B. They record only finite stream positions, regular rational readbacks, dyadic mesh and time budgets, and boundary reads already displayed in the packet.

The finite replay obligation is Q. It consumes F, T, X, B before the real seal R is read, so the heat row is a displayed stencil calculation rather than a host PDE solution.

Finally H transports the same rows componentwise, C replays the same route, and P, N source and name the packet. Since the carrier contains no row for analytic existence, global well-posedness, host function spaces, measure theory, infinite mesh limits, or ambient real completeness, the listed rows exhaust the local certificate surface. □

Theorem 3652.3 (Heat-equation finite-stencil Laplace-PDE handoff)**.** *Every accepted* $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ *handoff to a* $\mathsf{Pde}^{\uparrow}$ *or* $\mathsf{LaplaceTransform}^{\uparrow}$ *consumer passes first through the displayed finite stencil route*

$$F, T, X, B \longmapsto Q \longmapsto R.$$

The $\mathsf{Pde}^{\uparrow}$ *read receives only the derivative-relation and boundary rows visible through the stencil packet, while the* $\mathsf{LaplaceTransform}^{\uparrow}$ *read receives only the finite transform-window handoff after R has been displayed. Neither consumer obtains analytic solution existence, global heat-kernel semantics, selected improper limits, host function-space equality, measure theory, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $E = (F, T, X, B, Q, R, H, C, P, N)$. The PDE-facing data are not independent host equations; they are the derivative-relation, time-step, spatial-stencil, and boundary reads already present in T, X, B, Q.

For a $\mathsf{Pde}^{\uparrow}$ consumer, replay C from the source windows through the time and spatial rows into Q. The consumer can inspect only the finite relation and boundary rows that the replay exposes, transported by H and sourced by P, N.

For a $\mathsf{LaplaceTransform}^{\uparrow}$ consumer, the transform-window handoff is available only after the real-seal row R has been reached through the same route. The read therefore consumes finite stream, regular rational, and dyadic rows before it reaches any transform output.

The excluded analytic objects are not fields of the carrier. The handoff is therefore a finite NameCert route from stencil data to PDE and Laplace interfaces, not a claim of global heat-equation solvability or host analytic semantics. □

Falsifiable prediction: An accepted $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ consumer that reaches a $\mathsf{Pde}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{LaplaceTransform}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed $\mathsf{StreamName}^{\uparrow}$ source windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ mesh and tolerance rows, finite stencil replay, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: pde, derivative, integral, laplacetransform, real, regseqrat, streamname, dyadicratcore: no listed sibling supplies the whole heat finite-stencil packet $E = (F, T, X, B, Q, R, H, C, P, N)$, because each sibling contributes only a PDE relation, derivative read, integral window, transform handoff, real seal, regular rational readback, stream schedule, or dyadic tolerance ledger while this chapter binds them into one finite replay and local naming route.

Closure status for $\mathsf{NameCert}_{\mathsf{HeatEquationFiniteStencil}^{\uparrow}}$.

Constructive story: A $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ packet is generated from finite source-function windows, a displayed time-step row, a displayed spatial-stencil row, boundary rows, finite replay rows, a Real-seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeatEquationFiniteStencil}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3652.1, Definition 3652.2, and Definition 3652.3 seed the finite constructive heat-equation stencil boundary over $\mathsf{Pde}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{LaplaceTransform}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeatEquationFiniteStencil}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim analytic solution existence, global PDE well-posedness, host function spaces, measure theory, infinite mesh convergence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface and Laplace-PDE handoff.

Chapter 3653

A Concrete Naming Certificate for $\mathsf{HausdorffDistance}^{\uparrow}$

Following the Hausdorff–Kuratowski compact-set metric reading, the $\mathsf{HausdorffDistance}^{\uparrow}$ packet records the scalar finite-distance certificate between two displayed nonempty compact subsets of one compact metric source. It sits next to the host hyperspace route of chapter 2086, consumes the compact-metric finite-net surface of chapter 129, and seals the resulting value through the real-name interface of chapter 38. The packet names the distance value as a finite BEDC carrier rather than treating $\mathsf{HausdorffMetric}^{\uparrow}$ itself as the only available consumer object.

Definition 3653.1 (Hausdorff distance finite carrier)**.** *A* $\mathsf{HausdorffDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, H, N_X, N_Y, D, E, R, T, C, P, L)$$

with the following displayed rows:

1. *A and B are the two nonempty compact-subset rows over the same compact metric source.*
2. *H is the* $\mathsf{HausdorffMetric}^{\uparrow}$ *ledger row that records the finite directed comparisons already admitted by the neighbouring Hausdorff-metric certificate.*
3. *N_X and N_Y are finite net rows for the two compact-subset names, read from the* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *sources.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling the displayed mesh, directed bound, and symmetric slack.*
5. *E is the symmetric bound-exactness row, recording that the two directed finite-net estimates determine the same scalar tolerance window.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *distance seal reached only after the ledger, nets, and dyadic tolerance rows have been displayed.*
7. *T records componentwise* hsame *transport for $A, B, H, N_X, N_Y, D, E, R, C, P, L$.*
8. *C records displayed* Cont *replay of the route from compact-subset rows through finite nets, symmetric bounds, and the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{HausdorffDistance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, H, N_X, N_Y, D, E, R, T, C, P, L$. It has no coordinate for a host hyperspace point, quotient subset equality, selected nearest point, open-cover compactness, or ambient supremum formation.

Lean4 ✓ `BEDC.Derived.HausdorffDistanceUp.HausdorffDistanceTasteGate single carrier alignment`

Theorem 3653.2 (Hausdorff distance NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffDistance}^{\uparrow}$ *carrier*

$$Q = (A, B, H, N_X, N_Y, D, E, R, T, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffDistance}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the two compact-subset rows, HausdorffMetric ledger, finite nets, dyadic tolerance row, symmetric bound row, Real seal, transport, replay, provenance, and local naming row;*
2. *symmetric bound exactness, requiring the directed finite-net estimates in H and E to share the dyadic tolerance budget recorded by D;*
3. *finite-net witness stability, requiring N_X and N_Y to remain attached to the same* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *sources under componentwise transport;*
4. *Real seal nonescape, requiring every scalar distance read to pass through R after H, N_X, N_Y, D, E have been displayed;*
5. *ledger nonescape, requiring C, P, L to replay, source, and name only the displayed finite route and to export no host hyperspace point, quotient subset equality, selected nearest point, open-cover compactness, or ambient supremum row.*

No scalar Hausdorff distance obligation is stored outside these rows.

Theorem 3653.3 (Hausdorff distance scalar handoff)**.** *Every Gromov–Hausdorff-facing, Vietoris-facing, or compact-subset consumer of an accepted* $\mathsf{HausdorffDistance}^{\uparrow}$ *packet reads the scalar value only through the finite route*

$$A, B, H, N_X, N_Y, D, E \longmapsto R \longmapsto T, C, P, L.$$

Thus the consumer receives a $\mathsf{Real}^{\uparrow}$ *distance seal for the two displayed compact-subset rows without receiving a host hyperspace metric object, quotient subset equality, selected nearest point, open-cover compactness theorem, or ambient supremum principle.*

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffDistance}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HausdorffDistance}^{\uparrow}$ packet is generated from two nonempty compact-subset rows, a HausdorffMetricUp ledger, finite CompactMetricUp and TotallyBoundedUp net rows, a DyadicRatCore tolerance row, symmetric bound exactness, a RealUp distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HausdorffDistance}^{\uparrow}}$, seed)

Scope closed: Definition 3653.1, Definition 3653.2, and Definition 3653.3 seed the finite scalar Hausdorff distance certificate consumed by compact-metric downstream routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HausdorffDistance}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host hyperspaces, quotient subset equality, selected nearest points, open-cover compactness, ambient supremum formation, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, symmetric bound exactness, finite-net witness stability, RealUp seal nonescape, and ledger nonescape for BEDC.Derived.HausdorffDistanceUp.

Chapter 3654

A Concrete Naming Certificate for $\mathsf{BoundedVariationRealFunction}^{\uparrow}$

Following Jordan's bounded variation theorem and Bishop–Bridges constructive analysis, the $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ packet records a real-valued function on a displayed real interval through finite partition windows and variation budgets. It sits between the real-valued sequence interface of chapter 3641, the finite partition carrier of chapter 1863, the stream-name observation route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet names the finite BEDC surface needed by later regulated-integration and Jordan-decomposition consumers without selecting a total variation supremum or importing ambient real completeness.

Definition 3654.1 (BoundedVariationRealFunction carrier)**.** *A* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, F, W, R, D, B, J, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval and partition window row supplied by* $\mathsf{DyadicPartition}^{\uparrow}$*, listing the finite dyadic subdivision on which variation is inspected.*
2. *F is the displayed real-valued function row, exposed only through* $\mathsf{RealSequenceSpace}^{\uparrow}$ *coordinate requests over the partition endpoints.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row scheduling the finite endpoint windows and adjacent-pair probes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the values of F at the endpoints named by W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *variation-budget ledger, recording absolute-difference budgets, partial variation sums, and the displayed bound attached to the current partition window.*
6. *B is the bounded-variation acceptance row, asserting that the inspected partition window is admitted only when its dyadic variation sum is witnessed below the displayed budget in D.*
7. *J is the Jordan-route row, naming the finite positive and negative variation ledgers available to a later Jordan-decomposition consumer without selecting a global decomposition.*
8. *H records componentwise* hsame *transport for the partition, function, observation, readback, variation-budget, bounded-variation, Jordan-route, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a bounded-variation request through I, F, W, R, D, B, J.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{RealSequenceSpace}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for total variation as a host supremum, quotient equality of functions, a selected Jordan decomposition, measure integration, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedVariationRealFunctionUp.TasteGate.BoundedVariationRealFunctionTasteGate single carrier alignment`

Theorem 3654.2 (BoundedVariationRealFunction NameCert obligations)**.** *For every accepted* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *carrier $V = (I, F, W, R, D, B, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationRealFun}}$ *surface consists exactly of finite* BHist *rows for carrier admission, partition-window exposure, real-value readback, variation-budget exactness, bounded-variation acceptance, Jordan-route availability, componentwise transport, replay, provenance, and local naming:*

1. *carrier admission requires the displayed* $\mathsf{DyadicPartition}^{\uparrow}$ *row,* $\mathsf{RealSequenceSpace}^{\uparrow}$ *function row,* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets, bounded-variation row, Jordan-route row, transport, replay, provenance, and local name;*

2. *partition exposure requires every variation request to pass through the finite dyadic row I before any endpoint value is read;*

3. *value readback requires the endpoint values of F to be inspected only through W and R, and then sealed as* $\mathsf{Real}^{\uparrow}$ *data through the provenance row P;*

4. *variation-budget exactness requires the partial sums and displayed bound in D to mediate every acceptance read by B;*

5. *Jordan-route availability requires J to expose only finite positive and negative variation ledgers downstream of the same I, F, W, R, D, B route;*

6. *transport and replay stability require H, C, P, N to preserve and name the same finite surface.*

No obligation supplies total variation as a host supremum, quotient equality of functions, a selected Jordan decomposition, measure integration, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3654.1. The packet exposes a dyadic partition window, a displayed real-valued function row, finite observation windows, regular rational readbacks, a dyadic variation ledger, a bounded-variation acceptance row, and a Jordan-route row before any structural replay is available.

The local obligations are therefore row-local. A variation request first enters the $\mathsf{DyadicPartition}^{\uparrow}$ row I; endpoint values of F are then read only through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows W and R; and every absolute-difference or partial-sum comparison is mediated by the $\mathsf{DyadicRatCore}^{\uparrow}$ row D.

The bounded-variation and Jordan-facing rows are downstream of the same route. The acceptance row B can certify only the displayed partition window and budget, while J can expose only finite positive and negative variation ledgers built from that accepted data.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a host supremum, quotient function equality, selected decomposition, measure integration, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3654.3 (BoundedVariationRealFunction Jordan route)**.** *Every Jordan-facing consumer of an accepted* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *carrier* $V = (I, F, W, R, D, B, J, H, C, P, N)$ *reads the ordered finite route*

$$\mathsf{DyadicPartition}^{\uparrow} \longrightarrow \mathsf{RealSequenceSpace}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through $I, F, W, R, D, B, J, H, C, P, N$*. The consumer may use the finite positive and negative variation ledgers exposed by* J*, but it cannot extract total variation as a host supremum, quotient equality of functions, a selected Jordan decomposition, measure integration, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Start with a Jordan-facing read of an accepted carrier. By Definition 3654.2, the read first passes through the finite $\mathsf{DyadicPartition}^{\uparrow}$ row and the displayed $\mathsf{RealSequenceSpace}^{\uparrow}$ function row, so every inspected endpoint value is tied to the same partition window.

The observation and readback rows then fix the value interface. The $\mathsf{StreamName}^{\uparrow}$ row schedules the endpoint probes, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational readbacks, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row records the variation-budget comparisons used by the bounded-variation acceptance row.

The Jordan route J is downstream of that accepted data. It may expose finite positive and negative variation ledgers for the displayed window, and the structural rows H, C, P, N transport, replay, source, and name the route.

No additional carrier coordinate remains for a host supremum of all partitions, quotient equality of real-valued functions, a selected Jordan decomposition, measure integration, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every Jordan-facing read factors through the displayed finite route. □

Theorem 3654.4 (BoundedVariationRealFunction partition-refinement induction)**.** *Let* $V = (I, F, W, R, D, B, J, H$ *be an accepted* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *carrier. Suppose that* I *displays a finite dyadic partition window and that a finite refinement spine is obtained by repeatedly inserting one dyadic endpoint into an already displayed adjacent interval. Then primitive induction over that spine preserves the variation-budget row: at every stage each inserted endpoint is read through the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *route* W, R*, the two adjacent absolute-difference budgets replacing the old interval budget are recorded in the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*, and the refined partial variation ledger is accepted by the same bounded-variation row* B*.*

Proof. Use induction on the finite refinement spine displayed over I. In the base case the spine has no inserted endpoint, so the current ledger is exactly the partition row already accepted by B through the budget comparisons recorded in D.

For the successor step, assume that the current displayed ledger is accepted by B and insert one dyadic endpoint inside a single adjacent interval. The endpoint observation is scheduled by the $\mathsf{StreamName}^{\uparrow}$ row W and read back by the $\mathsf{RegSeqRat}^{\uparrow}$ row R, so no value of F is inspected outside the carrier route.

The $\mathsf{DyadicRatCore}^{\uparrow}$ row D then replaces the old interval budget by the two adjacent absolute-difference budgets and updates the displayed partial variation sum. Since the induction hypothesis already identifies every unchanged interval with its accepted budget row, this replacement is the only local comparison required for the refined window.

Finally H, C, P, N transport, replay, source, and name the refined packet without changing the carrier rows. The acceptance row B therefore reads the refined ledger through the same finite packet, and the induction preserves bounded-variation acceptance along the whole refinement spine. □

Theorem 3654.5 (BoundedVariationRealFunction ledger handoff)**.** *Every accepted* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *carrier whose partition window is read as a* $\mathsf{BoundedVariation}^{\uparrow}$ *packet must expose*

$$I, F, W, R, D, B, J, H, C, P, N$$

first. The finite partition, endpoint, and dyadic-variation ledger recorded by I, W, R, D, B *is precisely the input consumed by chapter 398; the Jordan row* J *only routes the same accepted ledger to later positive and negative variation consumers.*

Proof. Start with the NameCert obligations of Definition 3654.2. They require carrier admission, partition-window exposure, value readback, variation-budget exactness, bounded-variation acceptance, and Jordan-route availability to be read through the same tuple $I, F, W, R, D, B, J, H, C, P, N$.

The Jordan route theorem Definition 3654.3 keeps J downstream of the accepted partition and variation-budget rows. Thus the positive and negative variation ledgers do not replace the bounded-variation input; they are read only after I, F, W, R, D, B have been displayed.

Finally apply the refinement induction of Definition 3654.4. It shows that endpoint insertions preserve the dyadic variation ledger through the same W, R, D, B route, so the reusable $\mathsf{BoundedVariation}^{\uparrow}$ chapter consumes exactly this finite ledger and no host supremum, quotient function equality, selected Jordan decomposition, or ambient completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariationRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ packet is generated from finite $\mathsf{DyadicPartition}^{\uparrow}$ windows, a displayed $\mathsf{RealSequenceSpace}^{\uparrow}$ function row, $\mathsf{StreamName}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{DyadicRatCore}^{\uparrow}$ variation-budget ledger, a bounded-variation acceptance row, a finite Jordan-route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedVariationRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3654.1, Definition 3654.2, Definition 3654.3, Definition 3654.4, and Definition 3654.5 seed the finite bounded-variation real-function surface over partition windows, real-valued sequence rows, finite observations, regular readbacks, dyadic variation budgets, refinement ledgers, bounded-variation handoff, and local Jordan-route ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedVariationRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim total variation as a host supremum, quotient equality of functions, a selected Jordan decomposition, measure integration, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-window exposure, real-value readback, variation-budget exactness, bounded-variation acceptance, finite Jordan-route availability, componentwise transport, replay, provenance, and local naming for the same displayed packet.

Chapter 3655

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$ packet records the finite modulus evidence that turns regular Cauchy rational windows into located real-name reads. It sits between the dyadic arithmetic substrate of chapter 291, the stream observation surface of chapter 126, the regular rational sequence packet of chapter 301, the located comparison rows of chapter 1730, and the sealed real-name handoff of chapter 38.

3655.1 Located modulus carrier

Definition 3655.1 (Regular Cauchy located modulus carrier)**.** *A* $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$ *carrier is a finite packet* $(D, S, Q, L, U, M, H, C, P, N)$ *with the following displayed rows:*

1. D*, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger whose positive rows name the dyadic error budgets used by the modulus;*
2. S*, a* $\mathsf{StreamName}^{\uparrow}$ *observation window for the rational name under inspection;*
3. Q*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the regular Cauchy rational values visible on* S*;*
4. L *and* U*, lower and upper located comparison rows tied to the same finite window and the same dyadic precision ledger;*
5. M*, a finite modulus row assigning to each displayed dyadic precision a window depth after which the* Q*-values stay inside the* L, U *located bracket;*
6. H*, the componentwise* hsame *transport rows for the dyadic ledger, stream window, regular readback, located comparison rows, and modulus row;*
7. C*, the displayed* Cont *replay routes preserving the finite window and modulus reads under transport;*
8. P*, the* Pkg *provenance rows for the dyadic ledger, stream window, regular readback, located comparison evidence, and modulus ledger;*
9. N*, the local* $\mathsf{NameCert}$ *row binding these nine rows as one located modulus certificate.*

The carrier contains no quotient equality of Cauchy names, no selected limit point, no host real order predicate, and no ambient completeness principle.

Lean4 ✓ BEDC.Derived.RegularCauchyLocatedModulusUp.RegularCauchyLocatedModulusTasteGate single carrier alignment

Theorem 3655.2 (Regular Cauchy located modulus NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedM}}$ *surface for Definition 3655.1 consists of six finite obligations:*

1. *carrier admission: the rows* $(D, S, Q, L, U, M, H, C, P, N)$ *occur in the same finite* BHist *packet;*
2. *window alignment:* S *is the only observation window read by* Q*, by the located comparison rows* L, U*, and by the modulus row* M*;*
3. *dyadic precision exactness: every modulus query in* M *consumes a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget displayed in* D*;*
4. *regular readback confinement: all rational values inspected by* M *come through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *and not through an external sequence selector;*
5. *located bracket handoff: the lower and upper comparison rows* L, U *are the only located evidence exported toward* $\mathsf{LocatedRealComparison}^{\uparrow}$*;*
6. *transport stability:* hsame, Cont, Pkg*, and* NameCert *move the dyadic ledger, window, readback, located brackets, and modulus row componentwise.*

These obligations certify a finite located-modulus route for regular Cauchy names. They do not certify quotient equality of names, chosen limits, total order, or real completeness.

Proof. Project the carrier of Definition 3655.1. The projection exposes the dyadic precision ledger D, the stream window S, the regular readback Q, the located comparison rows L, U, and the modulus row M.

Window alignment and dyadic precision exactness are read directly from those rows. Since M has no coordinate except the displayed D, S, Q, L, U data, each precision query is evaluated against the same finite observation window and the same regular Cauchy readback.

The located bracket handoff is componentwise. The L, U rows are already the displayed $\mathsf{LocatedRealComparison}^{\uparrow}$ evidence, and the transport rows H, C replay them together with D, S, Q, M.

Finally P and N record the provenance and local certificate for exactly these rows. No extra coordinate can supply quotient stream equality, a selected limit, a host real order predicate, or ambient completeness. □

Theorem 3655.3 (Regular Cauchy located modulus Real-seal handoff)**.** *Every accepted* RegularCauchyLocatedMod *packet exports toward* $\mathsf{Real}^{\uparrow}$ *only the sealed read obtained from its* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* S*, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger* D*, located comparison rows* L, U*, and modulus row* M*. The handoff preserves the same* $D, S, Q, L, U, M, H, C, P, N$ *carrier rows and supplies no quotient equality of Cauchy names, selected limit point, trichotomy, host real order predicate, or ambient completeness principle.*

Proof. Start with an accepted carrier and read the regular Cauchy name through Q on the displayed window S. The dyadic budgets used to test locatedness are the positive rows of D, and the lower and upper comparison evidence is precisely L, U.

The modulus row M turns each displayed precision into a finite window-depth claim over those same rows. Thus the Real-facing read has the data needed for a sealed $\mathsf{Real}^{\uparrow}$ handoff without selecting a representative limit.

Transport is confined to H and replayed by C. These rows preserve the dyadic ledger, stream window, regular readback, located brackets, and modulus ledger componentwise, while P, N record provenance and local naming.

The carrier has no quotient, trichotomy, host order, selected limit, or completeness coordinate. Hence the Real-seal consumer receives exactly the finite located-modulus evidence stated above. □

Theorem 3655.4 (Regular Cauchy located modulus finite-window nonescape)**.** *Every* $\mathsf{LocatedRealComparison}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$ *packet must pass through the displayed dyadic ledger* D, $\mathsf{StreamName}^{\uparrow}$ *window* S, $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q, *lower and upper located comparison rows* L, U, *modulus row* M, *transport rows* H, *replay rows* C, *provenance rows* P, *and local* $\mathsf{NameCert}$ *row* N. *A strengthened finite-window read can refine these rows only by reading the same carrier coordinates; it cannot bypass them by using quotient Cauchy equality, selected limits, trichotomy, host order, or ambient completeness.*

Proof. Project the carrier of Definition 3655.1. The projection exposes exactly $D, S, Q, L, U, M, H, C, P, N$ as the finite rows available to a consumer.

Apply Definition 3655.2. Window alignment, dyadic precision exactness, regular readback confinement, located bracket handoff, and transport stability force each accepted read through the displayed ledger, window, readback, brackets, modulus, transport, replay, provenance, and local naming rows.

Apply Definition 3655.3 for the Real-facing case. The same $D, S, Q, L, U, M, H, C, P, N$ route is preserved at the seal, so a strengthened finite-window read remains a refinement of the displayed packet route.

The refused objects are absent carrier coordinates. Therefore quotient Cauchy equality, selected limits, trichotomy, host order, and ambient completeness cannot be used to bypass the finite-window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$ packet is generated from a dyadic precision ledger, a StreamName observation window, a RegSeqRat readback, located comparison brackets, a finite modulus row, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3655.1, Definition 3655.2, and Definition 3655.3 name the seed carrier, finite NameCert obligation surface, and Real-seal handoff for located moduli of regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of Cauchy names, selected limits, trichotomy, host real order, ambient completeness, or a standard bridge.

Upgrade path: To reach obligationClosure, the carrier, finite modulus obligations, and Real-seal handoff must be checked as BEDC packet obligations.

Chapter 3656

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$

Following Bishop and Bridges and Mac Lane, the $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$ packet records the L10 completion reflector as one finite NameCert surface. It reads the reflector rows of chapter 1585, the functor rows of chapter 423, the extension-and-uniqueness rows of chapter 397, and the reflective-inclusion rows of chapter 1793. The chapter names the reflector boundary consumed by completion arguments; it does not assert quotient completions, choose limit representatives, identify host completions, import countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3656.1 (CauchyCompletionUniversalReflector carrier)**.** *A* $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, R, F, E, J, W, G, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric and name-data row, including the displayed metric classifier, finite source observations,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *reads, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger available before completion is consumed.*
2. *R is the reflector row read through* $\mathsf{CauchyCompletionReflector}^{\uparrow}$*, naming the source-to-completion admission and completed-object surface without exposing a quotient carrier or selected host limit.*
3. *F is the functor row read through* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$*, recording the finite action on displayed completion-facing source maps and continuation schedules.*
4. *E is the universal-extension row read through* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*, carrying extension existence, extension uniqueness, and finite-window consumer factorization after R and F have been displayed.*
5. *J is the reflective-inclusion row read through* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$*, exposing completed objects only through the public reflective boundary.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row attached to the source and completed-name reads.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row used by the source and completion-facing sequences.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-accounting row used by S, W, G, R, F, E, J.*

9. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *name row reached only after the stream, regular-rational, dyadic, reflector, functor, universal-extension, and reflective-inclusion rows have been displayed.*

10. *H records componentwise* hsame *transport for the source metric/name data, reflector row, functor row, universal-extension row, reflective-inclusion row, StreamName row, RegSeqRat row, DyadicRatCore row, Real row, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from source observations through $W, G, D, R, F, E, J, Q, H$.*

12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}}$ *row.*

The carrier exposes only this finite reflector surface. It has no coordinate for a quotient completion, chosen limit, host-level completion equality, countable-choice schedule, ambient completeness theorem, or full completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.CauchyCompletionUniversalReflectorUp`
Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalReflectorUp.CauchyCompletionUniversalReflectorTasteGate`
`single carrier alignment`

Theorem 3656.2 (CauchyCompletionUniversalReflector NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$ *carrier $U = (S, R, F, E, J, W, G, D, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source metric/name data, reflector, functor, universal-extension, reflective-inclusion, stream-window, regular-rational, dyadic-tolerance, real-name, transport, replay, provenance, and local naming rows;*

2. *reflector admission, requiring each completion-facing object read to pass through R as in chapter 1585;*

3. *functorial action, requiring each source-map continuation to pass through F as in chapter 423;*

4. *universal-extension factorization, requiring each finite-window consumer to pass through E as in chapter 397;*

5. *reflective-inclusion exposure, requiring completed-object access to pass through J as in chapter 1793;*

6. *local StreamName, RegSeqRat, DyadicRatCore, and Real discipline, requiring W, G, D, Q to be read as the only name and tolerance rows;*

7. *ledger nonescape, requiring P and N to export no quotient completion, selected limit, host completion equality, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3656.1. The packet displays the source row, reflector row, functor row, universal-extension row, reflective-inclusion row, local StreamName-RegSeqRat-DyadicRatCore-Real rows, transport, replay, provenance, and local name.

The reflector and functor obligations are the first completion-facing projections. The row R is read through chapter 1585, and the row F is read through chapter 423; no consumer reaches completion data before those rows are visible.

The universal-extension and reflective-inclusion obligations follow the same displayed route. The row E cites chapter 397, while J cites chapter 1793; both are projected from the same finite packet.

Finally W, G, D, Q, H, C, P, N transport, replay, package, and name only the displayed rows. Since quotient completions, selected limits, host completion equality, countable choice, ambient completeness, and full $\mathsf{Real}^{\uparrow}$ completeness are absent as coordinates, no NameCert obligation can export them. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalReflectorUp.CauchyCompletionUniversalReflectorNamecertOb`

Theorem 3656.3 (CauchyCompletionUniversalReflector extension factorization)**.** *Let $U = (S, R, F, E, J, W, G, D,$ be an accepted* $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$ *carrier. Every accepted completion-extension read factors through the finite route*

$$S, W, G, D \longmapsto R \longmapsto F \longmapsto E \longmapsto J \longmapsto Q \longmapsto H, C, P, N.$$

Thus a finite-window source consumer can reach an extension row only after the source metric/name data, reflector row, functor row, universal-property row, reflective-inclusion row, and local StreamName-RegSeqRat-DyadicRatCore-Real rows have all been projected from the same carrier.

Lean4 ✓ `BEDC.Derived.CauchyCompletionUniversalReflectorUp.CauchyCompletionUniversalReflectorCarrier extension factorization`

Proof. Begin with an accepted completion-extension read and project the carrier of Definition 3656.1. The source metric/name data and the local W, G, D rows supply the only finite observations and tolerance accounting available to the read.

Apply the reflector and functor projections. The reflector row R is the public entry into completion-facing data, and the functor row F is the only displayed action row for source-map continuations.

Apply the universal-property projection from E. By chapter 397, the extension and uniqueness read is downstream of the displayed completion rows rather than an independent host function.

The reflective-inclusion row J and real-name row Q close the route. The structural rows H, C, P, N preserve exactly the same route, so the extension factorization has no coordinate from which to read quotient completions, selected limits, host completion equality, choice, or ambient completeness. □

Theorem 3656.4 (CauchyCompletionUniversalReflector nonescape)**.** *Every public L10 completion read exported by an accepted* $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$ *packet is exhausted by the rows $S, R, F, E, J, W, G, D, Q, H, C, P, N$. In particular, the read cannot replace the reflector by* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *alone, the functor by* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *alone, the extension by* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *alone, the public completed-object boundary by* $\mathsf{CauchyCompletionReflectiveSubcateg}$ *alone, or the local name route by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *alone.*

Proof. Project P first. It names the available sibling packets: $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctc}$ $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 3656.2. Each sibling is assigned to one row of the carrier, so a consumer that keeps only one sibling loses the displayed relation between source data, reflector entry, functor action, universal extension, reflective inclusion, and local name data.

Apply Definition 3656.3. The extension route is finite and ordered, and the structural rows H, C, P, N preserve that order. Therefore no public L10 completion read can leave the packet surface to obtain a quotient completion, selected limit, host equality, choice schedule, ambient completeness theorem, or full $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}$ packet is generated from source metric/name data, reflector rows, functor rows, universal-extension rows, reflective-inclusion rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, Real name rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3656.1, Definition 3656.2, Definition 3656.3, and Definition 3656.4 seed the finite universal-reflector boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUniversalReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host completion equality, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector admission, functorial action, universal-extension factorization, reflective-inclusion exposure, local name-route discipline, and ledger nonescape for BEDC.Derived.CauchyCompletionUn

Chapter 3657

A Concrete Naming Certificate for $\mathsf{TriggerHypergraphReliability}^{\uparrow}$

The $\mathsf{TriggerHypergraphReliability}^{\uparrow}$ packet realizes the trigger-hypergraph reliability surface of Definition 9462.1556 as finite BEDC NameCert data. It sits over the six-boundary-tile coverage route of chapter 3470, the window-coverage trigger algebra of chapter 3478, the cellular window trace of chapter 3481, the dyadic tolerance ladder of chapter 3525, and the trigger-hypergraph reliability theorem of Definition 9462.1564. The packet names accepted reliability reads as finite trigger-edge and budget rows; it is not a stochastic oracle, polynomial-ring equality, quotient codon semantics, infinite trigger search, or hidden probability model.

Definition 3657.1 (TriggerHypergraphReliability carrier)**.** *A* $\mathsf{TriggerHypergraphReliability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, E, R, L, W, D, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the six-boundary-tile coverage row naming the finite boundary positions whose trigger behavior is read.*
2. *E is the finite trigger-edge list row, recording the accepted hyperedges and their coordinate supports.*
3. *R is the reliability-budget row, carrying the finite acceptance budget against which trigger-edge reads are evaluated.*
4. *L is the local tag ledger for present, absent, covered, uncovered, triggering, nontriggering, accepted, and rejected edge reads.*
5. *W is the cellular window-trace row assigning trigger-edge reads to the visible window route.*
6. *D is the dyadic-tolerance row used to compare reliability budgets without importing real-valued probability or host polynomial equality.*
7. *A is the algebra transport row through the window-coverage trigger algebra and the trigger-hypergraph source vision.*
8. *H records componentwise* hsame *transport for boundary tiles, trigger-edge lists, reliability budgets, local tags, window traces, dyadic tolerances, algebra transport, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from each accepted trigger-edge read through B, E, R, L, W, D, A, H.*

10. *P is the* Pkg *provenance over* $\mathsf{TriggerHypergraphReliability}^{\uparrow}$*, the six-boundary-tile coverage route, the window-coverage trigger algebra, the cellular window trace, the dyadic tolerance ladder, the trigger-hypergraph source vision,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TriggerHypergraphReliability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, E, R, L, W, D, A, H, C, P, N$. It has no coordinate for host probability spaces, ambient polynomial equality, quotient codon equality, infinite trigger search, stochastic evolutionary dynamics, or a hidden reliability oracle.

Lean4 (statement) `BEDC.Derived.TriggerHypergraphReliabilityUp`

Theorem 3657.2 (TriggerHypergraphReliability NameCert obligations)**.** *For every accepted* TriggerHypergraphRel *carrier $T = (B, E, R, L, W, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TriggerHypergraphReliability}^{\uparrow}}$ *surface consists exactly of boundary-coverage admission, trigger-edge list exposure, reliability-budget exposure, finite tag accounting, window-trace assignment, dyadic-tolerance comparison, algebra transport, componentwise transport, displayed replay, provenance, and local naming.*

The reliability row R is accepted only when its read is paired with one finite trigger-edge list E and one finite budget row over the displayed B, L, W, D, A route. Any consumer that reads reliability without those rows, or replaces them by host probability spaces, ambient polynomial equality, quotient codon semantics, stochastic dynamics, infinite search, or a hidden reliability oracle, leaves the accepted packet surface.

Proof. Project the carrier of Definition 3657.1. The rows B, E, R, L, W, D, A expose the boundary coverage, finite edge list, reliability budget, finite tag ledger, window trace, dyadic tolerance row, and algebra transport.

The reliability-budget row is finite. It is read only together with the trigger-edge list E, while L, W, D record finite tags, cellular placement, and dyadic comparison data before any reliability decision is accepted.

Finally H, C, P, N preserve the same displayed route. Since no host probability space, polynomial equality, quotient codon equality, stochastic model, infinite search, or hidden reliability oracle is a carrier coordinate, the local NameCert obligations are exactly the listed finite rows. □

Theorem 3657.3 (TriggerHypergraphReliability factorization)**.** *Every accepted reliability read for* $\mathsf{TriggerHypergraphReliability}^{\uparrow}$ *factors through one finite trigger-edge list and one reliability-budget row:*

$$B \longmapsto E \longmapsto R \longmapsto L, W, D, A \longmapsto H, C, P, N.$$

Thus accepted reliability is a finite NameCert route through boundary coverage, trigger-edge exposure, budget accounting, window tracing, dyadic tolerance comparison, algebra transport, replay, provenance, and local naming.

Proof. Start from an accepted reliability read and project the carrier rows. The boundary row B supplies the only visible coverage data, and the trigger-edge list E supplies the only finite hypergraph edge surface.

Read the budget row R next. The row is paired with E, so reliability is not evaluated against an ambient probability space or an unbounded family of triggers.

The rows L, W, D, A then assign finite tags, cellular window placement, dyadic budget comparison, and algebra transport. The structural rows H, C, P, N preserve exactly this route, so the factorization has no coordinate outside the finite packet. □

Lean4 ✓ `BEDC.Derived.TriggerHypergraphReliabilityUp.TriggerHypergraphReliabilityFactorization`

Theorem 3657.4 (TriggerHypergraphReliability nonescape)**.** *Every public reliability read exported by an accepted* $\mathsf{TriggerHypergraphReliability}^{\uparrow}$ *packet is exhausted by* $B, E, R, L, W, D, A, H, C, P, N$*. In particular, a consumer cannot replace the trigger-edge list by the six-boundary-tile coverage route alone, the reliability budget by the cellular window trace alone, the dyadic comparison by a host real-probability model, or the algebra transport by polynomial-ring equality.*

Proof. Project the provenance row P. It names the six-boundary-tile coverage route, the window-coverage trigger algebra, the cellular window trace, the dyadic tolerance ladder, and the source trigger-hypergraph vision.

Apply Definition 3657.2. Each dependency is assigned to one displayed carrier row, so no sibling route alone contains the trigger-edge list, reliability budget, tag ledger, window trace, dyadic comparison, algebra transport, replay, provenance, and local name.

Apply Definition 3657.3. The reliability read is ordered through the finite edge list and budget row before any downstream tag, trace, tolerance, or algebra transport is consumed. Therefore the packet cannot export host probability spaces, polynomial equality, quotient codon equality, stochastic dynamics, infinite trigger search, or a hidden reliability oracle. □

Falsifiable prediction: Every accepted reliability read factors through one finite trigger-edge list and one reliability-budget row.

Independence witness: six-boundary-tile-coverage, window-coverage-trigger-algebra, cellular-window-trace, dyadic-tolerance-ladder, trigger-hypergraph vision source: none is bijective with $\mathsf{TriggerHypergraphReliability}^{\uparrow}$ because the packet jointly carries boundary coverage, trigger-edge lists, reliability budgets, finite tag accounting, cellular windows, dyadic tolerance comparison, algebra transport, replay, provenance, and local naming.

The Lean follow-up `BEDC.Derived.TriggerHypergraphReliabilityUp.TasteGate` supplies explicit $\mathsf{Nontrivial}\ \mathsf{TriggerHypergraphReliability}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{TriggerHypergraphReliability}^{\uparrow}$ instances preserving $B, E, R, L, W, D, A, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{TriggerHypergraphReliability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TriggerHypergraphReliability}^{\uparrow}$ packet is generated from boundary-coverage rows, trigger-edge list rows, reliability-budget rows, finite tag ledgers, cellular window traces, dyadic tolerance rows, algebra transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TriggerHypergraphReliability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3657.1, Definition 3657.2, Definition 3657.3, and Definition 3657.4 seed the finite trigger-edge reliability NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TriggerHypergraphReliability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host probability spaces, ambient polynomial equality, quotient codon equality, stochastic biological dynamics, infinite trigger search, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trigger-edge exposure, reliability-budget exposure, finite tag accounting, window-trace assignment, dyadic-tolerance comparison, algebra transport, Nontrivial TriggerHypergraphReliabilityUp, and FieldFaithful TriggerHypergraphReliabilityUp for BEDC.Derived.TriggerHypergraphReliabilityUp.

Chapter 3658

A Concrete Naming Certificate for $\mathsf{LocatedCompleteInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCompleteInterval}^{\uparrow}$ packet records a located complete closed interval as finite BEDC NameCert data. It refines the closed bounded interval carrier of chapter 1591, the located real interval surface of chapter 1709, and the nested interval Cauchy route of chapter 3599. Its completion-facing reads pass through the regular rational sequence packet of chapter 301, the terminal real seal of chapter 38, and the dyadic tolerance substrate of chapter 291. The packet names finite interval completeness evidence; it is not a host completeness axiom, quotient construction, trichotomy oracle, selected limit, or choice principle.

3658.1 Located Complete Interval Carrier

Definition 3658.1 (Located complete interval carrier)**.** *A* $\mathsf{LocatedCompleteInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, L, N, Q, D, S, R, E, K, H, C, P, M)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing lower and upper endpoint reads, endpoint order, rational containment, dyadic containment, finite windows, regular readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row that answers finite membership, containment, separation, and refinement requests through endpoint-radius locatedness data.*
3. *N is the* $\mathsf{NestedIntervalCauchy}^{\uparrow}$ *row carrying a descending bracket family, diameter budget, and finite Cauchy extraction route.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational centers and endpoint witnesses inspected by the bracket family.*
5. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to measure bracket diameter, endpoint slack, and refinement depth.*
6. *S is the finite observation schedule for bracket requests and Cauchy reads.*
7. *R is the completion-read row that sends each nested bracket request to a sealed* $\mathsf{Real}^{\uparrow}$ *output through B, L, N, Q, D, S.*

8. *E records the interval-membership evidence for the sealed output, again read only through the closed bounded and located interval rows.*
9. *K is the Cauchy-bracket induction ledger, recording the base bracket, successor refinement, diameter decrease, and endpoint containment rows for the displayed finite family.*
10. *H records componentwise* hsame *transport for all rows above.*
11. *C records displayed* Cont *replay from bracket refinement requests to the same completion-read and membership rows.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedCompleteInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{NestedIntervalCauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *M is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompleteInterval}^{\uparrow}}$ *row binding the packet.*

The carrier contains no host closed interval object, no quotient equality of real names, no selected representative stream, no trichotomy row, no countable choice schedule, and no ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LocatedCompleteIntervalUp.LocatedCompleteIntervalTasteGate single carrier alignment`

Theorem 3658.2 (Located complete interval NameCert obligations)**.** *For the carrier of Definition 3658.1, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompleteInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for $I = (B, L, N, Q, D, S, R, E, K, H, C, P, M)$ as one* BHist *packet;*
2. *source-interval exactness, requiring endpoint, containment, and Real-seal reads to pass through the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row B;*
3. *located-boundary exactness, requiring membership and separation reads to pass through the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row L;*
4. *nested-bracket exactness, requiring each Cauchy bracket read to pass through the* $\mathsf{NestedIntervalCauchy}^{\uparrow}$ *row N and the induction ledger K;*
5. *rational and dyadic budget exactness, requiring all centers, endpoint witnesses, diameters, and tolerances to be read through Q and D;*
6. *completion-read confinement, requiring the sealed* $\mathsf{Real}^{\uparrow}$ *output and its interval-membership evidence to be exported only through R and E;*
7. *transport and replay stability through H, C, P, M.*

These obligations name located interval completeness as a finite certificate surface. They do not assert host completeness, quotient construction, trichotomy, selected limits, countable choice, compactness beyond the displayed bracket route, or a public standard bridge.

Proof. Project the carrier of Definition 3658.1. The projection exposes exactly the closed bounded source row, located interval row, nested Cauchy bracket row, regular rational readback, dyadic tolerance ledger, schedule, completion read, membership evidence, induction ledger, and structural rows.

Source-interval and located-boundary exactness are immediate from the rows B and L. Every endpoint, containment, membership, separation, and refinement read is already routed through those two interval surfaces before a completion-facing consumer can inspect R or E.

Nested-bracket exactness is supplied by N and K. The bracket family, diameter decrease, and endpoint containment facts are displayed as finite rows, and the rational and dyadic budgets used by those rows are exactly Q and D.

Finally the structural rows close the obligation surface. The hsame transports, Cont replay routes, provenance, and local naming row preserve the listed packet without adding a host completeness coordinate, quotient, trichotomy decision, selected limit, or choice schedule. □

Theorem 3658.3 (Located complete interval Cauchy bracket induction)**.** *Let $I = (B, L, N, Q, D, S, R, E, K, H, C,$ be an accepted* $\mathsf{LocatedCompleteInterval}^{\uparrow}$ *carrier. Every nested-bracket Cauchy read exported by I is obtained by induction over the displayed bracket ledger K: the base step reads the source interval through B and L; the successor step refines the current bracket through N, Q, D, and S; and the terminal read exports a sealed* $\mathsf{Real}^{\uparrow}$ *row through R together with interval-membership evidence through E. The induction is finite-window BEDC data, not an appeal to ambient completeness or choice.*

Proof. Begin with the base bracket. The closed bounded source row B supplies the endpoint and containment packet, while the located interval row L supplies the finite membership and separation service for the same endpoints.

For the successor step, read the nested interval row N. Each refinement consumes a rational center or endpoint witness from Q, a positive dyadic tolerance from D, and an observation window from S. The ledger K records that the next bracket remains inside the previous bracket and has the displayed smaller diameter budget.

Iterating this finite ledger yields the Cauchy route named by the packet. The completion-read row R seals the resulting read as a $\mathsf{Real}^{\uparrow}$ output only after the bracket data have passed through B, L, N, Q, D, S, K.

The membership row E then reads the sealed output back into the same interval carrier. Since the construction has used only the displayed bracket induction rows and the structural transports H, C, P, M, no host completeness principle, quotient equality, selected representative, trichotomy, or choice schedule enters the export. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompleteInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompleteInterval}^{\uparrow}$ packet is generated from a closed bounded interval source row, a located real interval row, a nested interval Cauchy row, regular rational readback, dyadic tolerance data, finite schedules, completion-read and membership rows, a bracket induction ledger, componentwise transport, replay, provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompleteInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3658.1, Definition 3658.2, and Definition 3658.3 name the seed carrier, finite NameCert obligation surface, and nested-bracket induction route for located complete closed intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompleteInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host completeness, quotient construction, trichotomy, selected limits, countable choice, compactness beyond the displayed nested-bracket route, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-interval exactness, located-boundary exactness, nested-bracket exactness, rational and dyadic budget exactness, completion-read confinement, and bracket induction for the same finite packet.

Chapter 3659

A Concrete Naming Certificate for $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$ packet records the closed-interval Cauchy completeness route as finite BEDC NameCert data. It reads the endpoint and containment rows of chapter 1591, the regular rational sequence route of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the located interval boundary of chapter 3658. The packet names the interval-contained Cauchy readback surface; it does not assert open-cover compactness, selected subsequences, quotient equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

3659.1 Interval Cauchy Completeness Carrier

Definition 3659.1 (Interval Cauchy completeness carrier)**.** *An* $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *interval row, exposing lower and upper endpoint reads, endpoint order, rational containment, dyadic containment, and the local closed-interval NameCert surface.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy row for the inspected rational approximants, including the finite modulus windows used by the interval read.*
3. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare successive approximants, endpoint slack, and interval containment at the displayed scale.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row selecting exactly the stream observations consumed by the regular-Cauchy and interval-containment checks.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, Q, D, W have been replayed.*
6. *E records that the sealed read remains inside the same closed interval source row B through the located complete interval boundary.*
7. *H records componentwise* hsame *transport for endpoint rows, regular-Cauchy windows, dyadic tolerances, StreamName windows, the Real seal, interval-membership evidence, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite Cauchy-read request through W, Q, D, B and only then to R and E.*
9. *P is the* Pkg *provenance over* $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCompleteInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalCauchyCompleteness}^{\uparrow}}$ *row.*

The accepted carrier contains no open-cover compactness coordinate, no selected subsequence, no quotient equality of real names, no trichotomy row, no countable-choice schedule, and no ambient completeness field for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.IntervalCauchyCompletenessUp.IntervalCauchyCompletenessTasteGate single carrier alignment`

Theorem 3659.2 (Interval Cauchy completeness NameCert obligations)**.** *For every accepted* $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$ *carrier $I = (B, Q, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IntervalCauchyCompleteness}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint-row exactness, regular-Cauchy window consumption, dyadic tolerance exactness, StreamName window confinement, Real seal handoff, interval-membership readback, componentwise transport, continuation replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 3659.1. The projection exposes the closed interval row B, the regular rational row Q, the dyadic ledger D, the finite stream window row W, the Real seal R, the interval-membership evidence E, and the structural rows H, C, P, N.

Endpoint-row exactness is supplied by B. Every endpoint, order, rational containment, and dyadic containment read is already a row of the closed bounded interval packet before the Cauchy consumer can inspect Q, D, W, R, or E.

Regular-Cauchy and tolerance exactness are supplied by Q, D, W. The finite stream window names the observations, the regular rational row names the Cauchy approximants and modulus windows, and the dyadic ledger names the positive tolerances used in the endpoint and successor comparisons.

Finally R and E close the seal route, while H, C, P, N preserve and name only the displayed packet. Since no row stores open-cover compactness, a selected subsequence, quotient equality, trichotomy, countable choice, or ambient Real completeness, none of those objects can enter the local NameCert surface. □

Theorem 3659.3 (Interval Cauchy completeness regular seal)**.** *Let $I = (B, Q, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by I first consumes the finite route*

$$B, W, Q, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the sealed real output is visible only after the closed-interval endpoint rows, StreamName observation windows, regular-Cauchy readback, and dyadic tolerance ledger have all been displayed.

Proof. Begin with a Real-facing consumer of I. Carrier admission exposes R, but only as the seal row downstream of B, W, Q, D.

Replay the continuation row C. The request first reads the closed interval row B, then the StreamName window W, the regular rational Cauchy row Q, and the dyadic tolerance ledger D.

Only after this finite replay can R be read as a $\mathsf{Real}^{\uparrow}$ seal. The interval-membership row E then reads the same sealed output back through the source interval, and the structural rows H, P, N transport, package, and name that route without adding any separate completeness principle. □

Theorem 3659.4 (Interval Cauchy completeness no open-cover route)**.** *Every consumer of an* $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$ *packet receives a finite regular-Cauchy interval route through* $B, Q, D, W, R, E, H, C, P$ *The packet has no row from which an open-cover compactness proof, a selected subsequence, quotient equality for real names, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness can be recovered.*

Proof. Inspect the carrier of Definition 3659.1. Its non-structural rows are exactly the closed interval source, regular rational Cauchy readback, dyadic tolerance ledger, StreamName window, Real seal, and interval-membership readback.

Open-cover compactness and selected subsequences would require separate rows for cover indices, finite subcover choice, or subsequence selection. Quotient equality, trichotomy, countable choice, and ambient Real completeness would likewise require decision, selection, or host-completeness coordinates not present in the packet.

The only exported route is therefore the displayed finite Cauchy interval route. Componentwise transport, continuation replay, provenance, and local NameCert evidence preserve that route; they do not create any of the excluded coordinates. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalCauchyCompleteness}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IntervalCauchyCompleteness}^{\uparrow}$ packet is generated from a closed bounded interval row, a RegSeqRat regular-Cauchy row, a DyadicRatCore tolerance ledger, StreamName finite windows, a RealUp seal, interval-membership readback through the located complete interval boundary, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalCauchyCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3659.1, Definition 3659.2, Definition 3659.3, and Definition 3659.4 name the seed carrier, finite NameCert obligation surface, regular-Cauchy seal route, and excluded compactness route for closed-interval Cauchy completeness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalCauchyCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subsequences, quotient equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-row exactness, regular-Cauchy window consumption, dyadic tolerance exactness, StreamName window confinement, Real seal handoff, interval-membership readback, and structural stability for the same finite packet.

Chapter 3660

A Concrete Naming Certificate for $\mathsf{LimitPointCompact}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LimitPointCompact}^{\uparrow}$ packet records the sequence-facing compactness boundary: an infinite sequence in a displayed compactly bounded carrier has a named cluster-point route through a subsequence and a real-valued convergence witness. The packet sits beside the $\mathsf{SequentialCompact}^{\uparrow}$ chapter of chapter 2372, the $\mathsf{BolzanoWeierstrass}^{\uparrow}$ chapter of chapter 1254, the $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ chapter of chapter 1580, and the $\mathsf{Real}^{\uparrow}$ chapter of chapter 38. It deliberately names a limit-point route for sequences, not open-cover compactness, arbitrary choice, or ambient real-completeness.

Definition 3660.1 (LimitPointCompact carrier)**.** *A* $\mathsf{LimitPointCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, S, B, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compactly bounded carrier row whose points are read by the sequence packet;*
2. *S is the input sequence row, displaying a finite code for the sequence-facing object under consideration;*
3. *B is the boundedness and membership ledger, keeping every visible sequence value inside the carrier row K;*
4. *W is the* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *witness row that extracts a subsequence candidate from the bounded sequence data;*
5. *Q is the* $\mathsf{SequentialCompact}^{\uparrow}$ *subsequence route row, naming the selected subsequence only through displayed finite evidence;*
6. *E is the* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *endpoint row, reading the subsequence as converging to a real cluster point through* $\mathsf{Real}^{\uparrow}$ *data;*
7. *H records componentwise* hsame *transport for K, S, B, W, Q, E and the structural rows;*
8. *C records displayed* Cont *replay from the sequence row through boundedness, subsequence extraction, endpoint reading, and local naming;*
9. *P is the* Pkg *provenance over the displayed compactness, subsequence, cluster-point, real, transport, replay, and naming rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LimitPointCompact}^\uparrow}$ *row.*

The classifier accepts exactly packets whose visible coordinates are $K, S, B, W, Q, E, H, C, P, N$. It contains no open-cover subcover coordinate, no countable-choice selector, no ambient $\mathsf{Real}^\uparrow$ *completeness theorem, and no host-level selection of cluster points.*

Lean4 ✓ `BEDC.Derived.LimitPointCompactUp.LimitPointCompactTasteGate single carrier alignment`

Theorem 3660.2 (LimitPointCompact NameCert obligations)**.** *For the carrier of Definition 3660.1, the local* $\mathsf{NameCert}_{\mathsf{LimitPointCompact}^\uparrow}$ *surface consists exactly of five finite obligations:*

1. *carrier admission: every accepted object exposes the displayed packet $L = (K, S, B, W, Q, E, H, C, P, N)$;*
2. *bounded sequence exposure: every sequence value consumed by the packet is read through S and certified inside K by the ledger row B;*
3. *subsequence extraction: every cluster-point route passes through the* $\mathsf{BolzanoWeierstrass}^\uparrow$ *witness row W and the* $\mathsf{SequentialCompact}^\uparrow$ *subsequence row Q;*
4. *endpoint exactness: the cluster endpoint is read only through the* $\mathsf{RealSequenceClusterPoint}^\uparrow$ *row E and its* $\mathsf{Real}^\uparrow$ *coordinate data;*
5. *ledger exhaustion: H, C, P, N preserve, replay, source, and name the displayed route without adding open-cover compactness, countable choice, a selected representative, or ambient real completeness.*

Consequently the certificate names the sequence-facing limit-point compactness route and no stronger compactness principle.

Proof. Carrier admission is projection from the displayed tuple $L = (K, S, B, W, Q, E, H, C, P, N)$. The only point carrier is K, the only input sequence row is S, and the only boundedness ledger is B.

The subsequence part is forced by the witness inventory. The row W is the Bolzano–Weierstrass extraction witness and Q is the sequential-compactness subsequence route; a consumer reaches endpoint data only after those rows have been read.

The endpoint part is then supplied by E. It is the cluster-point row and reads the relevant real-valued convergence data through the $\mathsf{Real}^\uparrow$ packet, so no separate ambient completeness theorem is imported.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no open-cover, choice, selected-representative, or ambient-completeness coordinate, those principles cannot be exported by the local certificate. □

Theorem 3660.3 (LimitPointCompact Bolzano–Weierstrass factorization)**.** *Every accepted* $\mathsf{LimitPointCompact}^\uparrow$ *limit-point consumer factors through*

$$K, S \longmapsto B \longmapsto W \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Here W is read from the $\mathsf{BolzanoWeierstrass}^\uparrow$ *surface of chapter 1254, Q is read from the* $\mathsf{SequentialCompact}^\uparrow$ *surface of chapter 2372, and E is read from the* $\mathsf{RealSequenceClusterPoint}^\uparrow$ *and* $\mathsf{Real}^\uparrow$ *surfaces of chapter 1580 and chapter 38. The factorization exports no open-cover compactness, no countable choice, no selected representative, and no ambient real-completeness claim.*

Proof. Start with Definition 3660.2. Its bounded sequence exposure clause places every sequence-facing read behind K, S, B.

Next read the extraction rows. The Bolzano–Weierstrass chapter supplies the finite witness row W, and the sequential compactness chapter supplies the subsequence route Q; neither row carries an open-cover subcover object or an unrestricted choice function.

The endpoint is then read through the real sequence cluster-point packet and the real packet. This is exactly the row E, so the conclusion is a displayed sequence endpoint rather than ambient completeness for all real Cauchy data.

The structural rows H, C, P, N preserve and name the same route. Because the carrier inventory contains no stronger compactness coordinate, every consumer remains inside the stated factorization. □

Closure status for $\mathsf{NameCert}_{\mathsf{LimitPointCompact}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LimitPointCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3660.1, Definition 3660.2, and Definition 3660.3 seed the sequence-facing compactness route through bounded sequence data, Bolzano–Weierstrass extraction, sequential compactness, real cluster endpoints, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LimitPointCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, arbitrary choice, selected cluster-point representatives, quotient completion equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, bounded sequence exposure, Bolzano–Weierstrass factorization, sequential-subsequence exactness, real cluster-point endpoint exactness, nonescape ledgers, classifier transport, and provenance/name exhaustion for BEDC.Derived.LimitPointCompactUp.

Constructive story: A $\mathsf{LimitPointCompact}^{\uparrow}$ packet is generated from a compactly bounded carrier row, an input sequence row, a boundedness ledger, a Bolzano–Weierstrass witness row, a sequential-compactness subsequence row, a real sequence cluster-point endpoint row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3661

A Concrete Naming Certificate for $\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}$

The $\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}$ packet follows the proof-theoretic normal-form consistency tradition for typed calculi: a closed term displayed at the internal false encoding cannot simultaneously be a beta-strong normal endpoint. In BEDC form, this is not a full closed-consistency claim. It is a finite witness package for the exact closed-normal boundary of chapter 9376, sitting beside the closed-normal canonicity packet of chapter 799, the endpoint ledger of chapter 837, and the Z-normal predicate packet of chapter 936.

Definition 3661.1 (ClosedNormalConsistencyWitness carrier)**.** *A* $\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, F, L, B, E, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC term row, displaying the closed proof candidate under audit;*
2. *F is the internal false-encoding row, naming the target type at which the term is displayed;*
3. *L is the empty-context typing ledger for the judgement that T has type F;*
4. *B is the beta-strong endpoint row, recording that the displayed term is already at the normal-form boundary;*
5. *E is the closedness row, recording that the term has no external context dependency;*
6. *R is the false-exclusion witness row read from the closed-normal consistency theorem;*
7. *H records componentwise* hsame *transport for T, F, L, B, E, R and the structural rows;*
8. *C records displayed* Cont *replay from typing and closedness through beta-strong endpoint evidence to false exclusion;*
9. *P is the* Pkg *provenance over MetaCIC typing, closedness, beta-strong endpoint, false encoding, transport, replay, and naming rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible coordinates are $T, F, L, B, E, R, H, C, P, N$. It contains no subject-reduction transport, no full closed-consistency theorem, no Church–Rosser quotient, no normalization theorem for all closed terms, and no host proof of arbitrary false exclusion.

Lean4 ✓ BEDC.Derived.ClosedNormalConsistencyWitnessUp.ClosedNormalConsistencyWitnessTasteGate
single carrier alignment

Theorem 3661.2 (ClosedNormalConsistencyWitness NameCert obligations)**.** *For the carrier of Definition 3661.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission: every accepted object exposes the displayed packet* $W = (T, F, L, B, E, R, H, C, P, N)$*;*
2. *false typing exposure: the typing ledger* L *displays the empty-context judgement that the term row* T *has the false-encoding type row* F*;*
3. *normal endpoint exposure: the rows* B *and* E *display beta-strong endpoint evidence and closedness before false exclusion is read;*
4. *false-exclusion exactness: the row* R *is available only after* T, F, L, B, E *have been displayed together;*
5. *ledger exhaustion:* H, C, P, N *preserve, replay, source, and name that route without adding full closed consistency, subject reduction, Church–Rosser transport, or global normalization.*

Consequently the certificate names the closed-normal false-exclusion witness and no stronger consistency principle.

Proof. Carrier admission is projection from the displayed tuple. The only term row is T, the only false-encoding row is F, and the only typing ledger is L.

The normal endpoint is part of the input, not a theorem extracted from arbitrary closed typing. Rows B and E display beta-strong normality and closedness before the false-exclusion witness can be read.

The false-exclusion row R is therefore exactly the closed-normal consistency route. It consumes the typing, closedness, and beta-strong evidence together, matching the boundary stated in chapter 9376.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the packet has no subject-reduction, Church–Rosser, global-normalization, or full-consistency coordinate, none of those stronger principles can be exported by the certificate. □

Theorem 3661.3 (ClosedNormalConsistencyWitness false-exclusion factorization)**.** *Every accepted* $\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}$ *consumer of false exclusion factors through*

$$T, F \longmapsto L \longmapsto E \longmapsto B \longmapsto R \longmapsto H, C, P, N.$$

The route reads the term and false-encoding rows, exposes empty-context typing, checks closedness, checks beta-strong endpoint evidence, and only then exports the false-exclusion witness. It does not infer full closed consistency, arbitrary subject-reduction transport, Church–Rosser conversion, quotient equality of proofs, or normalization for all closed terms.

Proof. Use Definition 3661.2. The false typing exposure clause places the term and false encoding behind T, F, L.

Next the normal endpoint exposure clause places the closedness and beta-strong rows before any contradiction is read. This mirrors the main-result boundary: closed and typed alone are not enough for the present packet.

The row R is then the only false-exclusion coordinate. It is reached after the typing, closedness, and beta-strong rows have all been displayed.

The structural rows H, C, P, N preserve and name this route. The missing stronger principles have no carrier coordinate, so the exported witness remains closed-normal rather than full closed consistency. □

Lean4 ✓ `BEDC.Derived.ClosedNormalConsistencyWitnessUp.ClosedNormalConsistencyWitnessFalseExclusionfactorization`

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3661.1, Definition 3661.2, and Definition 3661.3 seed the closed-normal false-exclusion route through MetaCIC term display, false typing, closedness, beta-strong endpoint evidence, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full closed consistency, subject reduction, Church–Rosser conversion, quotient equality of proofs, global normalization for all closed terms, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, false typing exposure, closedness and beta-strong endpoint exactness, false-exclusion factorization, nonescape ledgers, classifier transport, and provenance/name exhaustion for BEDC.Derived.ClosedNormalConsistencyWitnessUp.

Constructive story: A $\mathsf{ClosedNormalConsistencyWitness}^{\uparrow}$ packet is generated from a MetaCIC term row, an internal false-encoding row, an empty-context typing ledger, a closedness row, a beta-strong endpoint row, a false-exclusion witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3662

A Concrete Naming Certificate for $\mathsf{FiniteGroupRepresentation}^{\uparrow}$

Following Frobenius on finite-group characters and the representation-theory treatments of Serre and Fulton–Harris, the $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ packet records a finite group action on a finite displayed vector-space row as NameCert data. It consumes the group source of chapter 41, the vector-space source of chapter 47, the linear-map and matrix rows of chapter 48 and chapter 49, and the downstream trace and ledger consumers of chapter 245, chapter 246, and chapter 3574. The packet names only the displayed finite action, transport, and consumer boundary rows; it does not assert Maschke semisimplicity, Schur orthogonality, complete reducibility, irreducible decomposition, or a host category of representations.

Definition 3662.1 (FiniteGroupRepresentation carrier)**.** *A* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, V, L, M, A, U, C, H, P, N)$$

with the following displayed rows:

1. *G is the consumed finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *source row, including the multiplication, unit, inverse, and finite support rows needed to index the action.*
2. *V is the consumed* $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ *row for the represented vector-space endpoint.*
3. *L is the consumed* $\mathsf{NameCert}_{\mathsf{LinMap}^{\uparrow}}$ *row naming the linear endomorphism surface over V.*
4. *M is the consumed* $\mathsf{NameCert}_{\mathsf{Mat}^{\uparrow}}$ *row used only when the finite action is displayed by matrix rows over a chosen presentation already recorded in the packet.*
5. *A is the finite action ledger assigning to each displayed group row a displayed linear endomorphism row and recording the multiplication and unit compatibility rows.*
6. *U is the finite action-unit row, recording that the unit row of G acts by the identity linear-map row on V.*
7. *C is the downstream consumer ledger, exposing only the rows read by* $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *and* $\mathsf{CharacterTable}^{\uparrow}$ *consumers.*
8. *H is the componentwise* hsame *transport for G, V, L, M, A, U, C.*
9. *P is the* Pkg *provenance over* $\mathsf{Group}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}$ *row.*

No carrier coordinate stores a host representation category, a quotient representation, an irreducible decomposition, a character table, a Maschke complement, or a Schur orthogonality relation.

Lean4 (definition) `BEDC.Derived.FiniteGroupRepresentationUp.FiniteGroupRepresentationUp`

Theorem 3662.2 (FiniteGroupRepresentation NameCert bridge)**.** *For every accepted* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *carrier*

$$R = (G, V, L, M, A, U, C, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier admission exposes the displayed group row G, vector-space row V, linear-map row L, optional matrix presentation row M, action ledger A, unit row U, consumer ledger C, transport row H, provenance row P, and local naming row N;*
2. *action exactness requires each action entry in A to be sourced by a group row of G and to land in a linear endomorphism row read through L over the represented vector-space row V;*
3. *unit and multiplication stability require the unit row U and the product rows of G to replay through finite* Cont *rows inside A and remain preserved by the componentwise* hsame *transport H;*
4. *matrix presentation compatibility allows M to display action entries only as rows already tied to L and V, so matrix reads cannot create an additional carrier outside the packet;*
