5. *consumer boundary requires every* $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTable}^{\uparrow}$ *read to pass through C after the action ledger has been displayed, and it excludes Maschke semisimplicity, Schur orthogonality, irreducible decomposition, quotient representation carriers, and host representation categories.*

These five obligations give the finite NameCert bridge from the consumed group and vector-space certificates to the downstream character and representation-ring consumers.

Proof. Project the carrier rows of Definition 3662.1. Carrier admission is exactly the displayed tuple $G, V, L, M, A, U, C, H, P, N$, so no additional source row is available.

For action exactness, read each entry of A as a finite row from the group source G into the endomorphism surface supplied by L over V. The unit row U and the product rows of G are then replayed through the same finite continuation ledger.

Matrix presentation compatibility is only a display route. Any matrix row in M must already be tied to the linear-map and vector-space rows L and V, so it cannot supply a second representation carrier.

Finally expose the consumer ledger C. Character-theory, representation-ring, and character-table consumers read only after the displayed action rows have been named, while Maschke semisimplicity and Schur orthogonality remain in their own chapters. Repacking the projected rows with H, P, and N gives the stated local NameCert surface. □

Lean4 ✓ `BEDC.Derived.FiniteGroupRepresentationUp.FiniteGroupRepresentationNameCertBridge`

Theorem 3662.3 (FiniteGroupRepresentation Schur consumer boundary)**.** *Any* $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{CharacterTable}^{\uparrow}$, *or* $\mathsf{SchurOrthogonality}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *packet*

$$R = (G, V, L, M, A, U, C, H, P, N)$$

must first expose the action ledger A, linear-map row L, vector-space row V, optional matrix row M, and consumer ledger C. A $\mathsf{SchurOrthogonality}^{\uparrow}$ *read may inspect finite character-pairing rows only through those displayed rows and cannot import a host representation category, quotient carrier, irreducible decomposition, or complete character table.*

Proof. Project the accepted carrier tuple of Definition 3662.1. The action ledger A, vector-space row V, linear-map row L, optional matrix row M, and consumer ledger C are the only rows through which downstream character-facing consumers can see the finite representation packet.

Route a Schur-facing request through C. The request may read character-pairing information only after the displayed action entries in A have landed in the endomorphism surface supplied by L over V, with any matrix presentation in M already tied to the same rows.

The exclusions follow from the carrier boundary. Since R contains no host representation category, quotient carrier, irreducible decomposition, or complete character-table coordinate, a $\mathsf{SchurOrthogonality}^{\uparrow}$ consumer cannot obtain any of those endpoints from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3662.1, Definition 3662.2, and Definition 3662.3 seed the finite action carrier, its NameCert obligation bridge, and the Schur-facing consumer boundary over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{CharacterTable}^{\uparrow}$, and $\mathsf{SchurOrthogonality}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Maschke semisimplicity, Schur orthogonality, irreducible decomposition, complete reducibility, character-table computation, quotient representation carriers, host representation categories, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, action exactness, unit and multiplication stability, matrix presentation compatibility, and downstream consumer boundary for the same finite packet.

Constructive story: A $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ packet is generated from a displayed finite group source, represented vector-space source, linear-map and matrix presentation rows, a finite action ledger, unit and multiplication replay rows, componentwise transport, package provenance, and local NameCert evidence.

Chapter 3663

A Concrete Naming Certificate for $\mathsf{KSpace}^{\uparrow}$

Following Kelley's compactly generated spaces, the $\mathsf{KSpace}^{\uparrow}$ packet records the topology whose public open rows are tested by compact probes. It sits after the topology carrier of chapter 88, the compact-space certificate surface, and the compact-open function-space consumer of chapter 2221. The packet names compact-test topology rows for downstream continuity and mapping-space consumers; it does not import arbitrary open-cover choice, a host category of spaces, quotient equality of opens, or an ambient set-theoretic coreflection.

Definition 3663.1 (K-space carrier)**.** *A* $\mathsf{KSpace}^{\uparrow}$ *carrier is a finite* BHist *tuple*

$$K = (X, T, Q, A, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying point-name carrier whose observations are read only through* BHist *rows.*
2. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row listing the candidate open-name classifier.*
3. *Q is the compact-probe ledger: each accepted row records a compact source certificate, a probe map into X, and its compact-domain provenance.*
4. *A is the compact-test topology ledger, saying that an open-name row U is admitted precisely when every compact probe in Q pulls U back to an open row on its compact source.*
5. *E records exactness between T and A for the displayed open names, so the packet exports the compactly generated topology rather than a second unrelated topology.*
6. *H records componentwise* hsame *transport for X, T, Q, A, E, C, P, N.*
7. *C records displayed* Cont *replay from topology requests and compact-probe requests through the same rows.*
8. *P is the* Pkg *provenance over* $\mathsf{KSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*, compact probes,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KSpace}^{\uparrow}}$ *row.*

The carrier exposes compact-test topology data only through $X, T, Q, A, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.KSpaceUp.KSpaceTasteGate single carrier alignment`

Definition 3663.2 (K-space classifier)**.** *The* $\mathsf{KSpace}^{\uparrow}$ *classifier accepts two carrier rows as the same public packet exactly when their point carrier, ambient topology row, compact-probe ledger, compact-test topology ledger, exactness row, transport row, replay row, provenance row, and local naming row are componentwise related by the displayed* hsame *evidence. It has no coordinate for selected subcovers, host open families, quotient-open representatives, choice of compact probes outside* Q*, or an external coreflection functor.*

Theorem 3663.3 (K-space NameCert obligations)**.** *For every accepted* $\mathsf{KSpace}^{\uparrow}$ *carrier* $K = (X, T, Q, A, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KSpace}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed point carrier, topology row, compact-probe ledger, compact-test topology ledger, exactness row, transport, replay, provenance, and local naming rows;*
2. *compact-probe accountability, requiring every probe inspected by* A *to be named by the compact-probe ledger* Q*;*
3. *compact-test exactness, requiring the admitted open rows to be exactly those whose pullbacks along all displayed compact probes are open on their compact sources;*
4. *componentwise transport and replay stability under* H *and* C *for the same displayed rows;*
5. *ledger refusal, stating that arbitrary open-cover choice, host compact-object selection, quotient equality of opens, and ambient set-theoretic coreflection are not carrier coordinates.*

No local obligation is stored outside these five rows.

Proof. Project the accepted carrier. The only mathematical rows are X, T, Q, A, E, and the structural rows are H, C, P, N.

The compact-probe accountability row is read through Q. Each pullback test used by A must name its compact source and probe map before the topology request can inspect it.

The exactness row E binds the topology row T to the compact-test ledger A. Hence the packet exports the compactly generated topology determined by the displayed probes, not a freely chosen open-family classifier.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since the excluded objects are absent from $X, T, Q, A, E, H, C, P, N$, no accepted packet can export them. □

Theorem 3663.4 (Compact-test continuity handoff)**.** *A downstream continuity or compact-open function-space consumer of an accepted* $\mathsf{KSpace}^{\uparrow}$ *carrier can inspect openness only through*

$$\mathsf{Topology}^{\uparrow}, \quad \mathsf{KSpace}^{\uparrow}, \quad Q, \quad A.$$

Thus a continuity check against a $\mathsf{KSpace}^{\uparrow}$ *source is routed through displayed compact probes and compact-test topology rows, while open-cover choice, external compact-object selection, and host coreflection data remain outside the packet.*

Proof. Read the topology request through T and the compact-test row through A. The row A can certify an open-name request only after all displayed compact probes in Q have supplied the corresponding pullback-open rows.

The exactness row E then identifies the exported open-name classifier with that compact-test ledger. A compact-open function-space consumer therefore receives the same probe route rather than a host-space construction.

Rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. No extra coordinate is available for open-cover choice, selected compact probes outside Q, or an ambient coreflection principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{KSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{KSpace}^{\uparrow}$ packet is generated from a point-name carrier, a TopologyUp row, compact-probe rows, compact-test topology rows, exactness between displayed opens and compact tests, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3663.1, Definition 3663.2, Definition 3663.3, and Definition 3663.4 seed the compactly generated topology packet for topology and compact-open consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.KSpaceUp.KSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected compact probes outside the displayed ledger, quotient equality of opens, host coreflections, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-probe accountability, compact-test exactness, transport and replay stability, and local NameCert registration for BEDC.Derived.KSpaceUp.

Chapter 3664

A Concrete Naming Certificate for $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$

Following Heine–Cantor and Lebesgue finite-cover analysis, the $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$ packet records the finite selector route used by compact-uniform-continuity proofs. It consumes the compact finite-net source of chapter 3606, the pointwise modulus rows of the continuous-function carrier, the rational lower-bound fold, and the uniform-modulus handoff. The packet names the finite cover selector as BEDC data; it is not an appeal to countable choice, a global modulus oracle, an open-cover compactness theorem, or an ambient minimum over a host set of radii.

Definition 3664.1 (Compact-uniform finite-cover selector carrier)**.** *A* $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$ *carrier is a finite* BHist *tuple*

$$S = (K, F, E, M, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric or compact finite-net source row that supplies a finite* ProbeBundle *cover for the requested tolerance.*
2. *F is the continuous-function row whose graph and pointwise modulus are being uniformized.*
3. *E is the finite cover selector ledger, listing the selected compact centers, half-radius coverage rows, and probe provenance.*
4. *M is the pointwise modulus ledger at the selected centers.*
5. *R is the rational lower-bound fold over the displayed positive radius rows.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exported after E, M, R have been read in order.*
7. *H records componentwise* hsame *transport for $K, F, E, M, R, U, C, P, N$.*
8. *C records displayed* Cont *replay from compact-uniform requests through the same rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$*, compact finite covers, continuous-function pointwise moduli, rational lower-bound folds,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}}$ *row.*

The carrier exposes only the finite cover selector, pointwise modulus, rational fold, and uniform-modulus handoff rows displayed above.

Lean4 ✓ `BEDC.Derived.CompactUniformFiniteCoverSelectorUp.CompactUniformFiniteCoverSelectorTasteGate`
`single carrier alignment`

Definition 3664.2 (Compact-uniform selector classifier)**.** *The* $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$ *classifier compares accepted packets componentwise through* $K, F, E, M, R, U, H, C, P, N$*. Two packets are classifier-equal exactly when the same compact source, continuous graph, finite cover selector, pointwise modulus rows, rational lower-bound fold, uniform-modulus handoff, transport, replay, provenance, and local naming rows are related by the displayed* hsame *evidence. It has no coordinate for an external selector, a host finite minimum, countable choice, a global modulus oracle, or open-cover compactness outside the displayed compact row.*

Theorem 3664.3 (Compact-uniform finite-cover selector obligations)**.** *For every accepted* CompactUniformFiniteCo *carrier* $S = (K, F, E, M, R, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the compact source, continuous-function row, finite cover selector, pointwise modulus ledger, rational lower-bound fold, uniform handoff, transport, replay, provenance, and local naming rows;*
2. *finite-cover accountability, requiring the selected centers and half-radius coverage rows in* E *to be read from the displayed compact source* K*;*
3. *pointwise-modulus compatibility, requiring every selected center in* E *to carry the matching pointwise modulus row in* M *for the same continuous-function row* F*;*
4. *rational-fold exactness and uniform handoff, requiring* R *to be a certified lower bound for the displayed radii before* U *exports the tolerance-only precision row;*
5. *ledger refusal, stating that countable choice, external finite minima, global modulus oracles, host open-cover compactness, and ambient completeness are not carrier coordinates.*

No accepted selector packet carries any additional NameCert obligation.

Proof. Project the accepted carrier. The compact source, continuous-function row, finite cover selector, pointwise modulus ledger, rational fold, and uniform handoff are precisely K, F, E, M, R, U.

The finite-cover accountability row is read first. Row E may list only centers and half-radius coverage witnesses supplied by the compact source row K.

The pointwise modulus row is then checked at those centers. Compatibility requires the ledger M to use the same continuous-function row F and the same selected centers exposed by E.

The rational fold R is read before the uniform handoff U. It certifies one positive precision history below the displayed half-radii, so U exports a tolerance-only uniform-modulus row without selecting a radius outside the finite ledger.

Rows H, C, P, N transport, replay, source, and name this route. Since no further coordinate occurs in S, the refused external principles cannot be exported by the local NameCert surface. □

Theorem 3664.4 (Finite selector to uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$ *carrier reaches its precision history only through the finite route*

$$\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}, \quad E, \quad M, \quad R, \quad U.$$

The consumer sees a displayed compact finite-net selector, pointwise modulus rows at its centers, a certified rational lower-bound fold, and the uniform-modulus handoff; it receives no countable-choice selector, host minimum, or open-cover compactness datum.

Proof. Start with the compact finite-net selector E. It exposes a finite ProbeBundle of centers and half-radius coverage rows already tied to the compact source K.

At each displayed center, read the pointwise modulus row in M for the same continuous-function row F. The row order prevents a modulus from being imported for a different graph or an unlisted center.

Fold the positive radius rows through R. The fold certificate supplies one lower-bound precision history, and only then can U export the uniform-modulus handoff.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. Therefore the consumer-facing datum is the finite BEDC selector route, not an external choice or host minimum. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverSelector}\uparrow}$.

Constructive story: A $\mathsf{CompactUniformFiniteCoverSelector}^{\uparrow}$ packet is generated from a compact source row, a continuous-function row, compact finite-net selector rows, pointwise modulus rows, rational lower-bound fold rows, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverSelector}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3664.1, Definition 3664.2, Definition 3664.3, and Definition 3664.4 seed the finite cover selector packet for compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverSelector}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, external finite minima, global modulus oracles, host open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover accountability, pointwise-modulus compatibility, rational-fold exactness, uniform handoff, transport and replay stability, and local NameCert registration for BEDC.Derived.CompactUniformFiniteCoverSelectorUp.

Chapter 3665

A Concrete Naming Certificate for $\mathsf{BishopRealCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRealCompletion}^{\uparrow}$ packet records real completion by regular rational names with located finite observation data. It sits on the dyadic arithmetic substrate of chapter 291, the finite stream-window surface of chapter 126, the regular rational sequence packet of chapter 301, the terminal real-name seal of chapter 38, and the located completion route of chapter 3488.

Definition 3665.1 (Bishop real completion carrier)**.** *A* $\mathsf{BishopRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, Q, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger whose positive dyadic rows name the tolerances inspected by the completion route;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming the finite rational observations read from the candidate Cauchy name;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the regular rational values visible on the windows in S;*
4. *L is the* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *located-completion row, recording the located brackets available for the same dyadic precision ledger and stream windows;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached from D, S, Q, L;*
6. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readbacks, located-completion row, Real-seal row, replay row, provenance row, and local naming row;*
7. *C records displayed* Cont *replay from dyadic precision queries through stream readback, located completion, and Real sealing;*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealCompletion}^{\uparrow}}$ *evidence.*

The carrier contains no quotient real object, no selected limiting representative, no countable-choice schedule, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopRealCompletionUp.TasteGate.BishopRealCompletionTasteGate single carrier alignment`

Theorem 3665.2 (Bishop real completion NameCert obligations)**.** *For every accepted carrier* $R = (D, S, Q, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRealCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; dyadic precision exactness through* D*; finite stream-window readback through* S*; regular rational Cauchy readback through* Q*; located completion handoff through* L*; Real-seal exposure through* E*; componentwise* hsame *stability through* H*; displayed* Cont *replay through* C*;* Pkg *provenance through* P*; and local naming through* N*.*

Proof. Carrier admission is coordinate projection from Definition 3665.1. The packet displays the dyadic precision ledger, finite stream windows, regular rational readbacks, located-completion row, Real-seal row, transport, replay, provenance, and local name as one BHist surface.

The dyadic and stream obligations are read before the located-completion row. Thus every precision request uses a positive row of D, every rational observation enters through the finite window ledger S, and every rational value is exposed by the regular readback row Q.

The located-completion and Real-seal obligations are then forced through L and E. Since H and C are the only transport and replay rows, any classified mate of the packet preserves the same finite route.

Finally P and N record provenance and local naming for exactly these rows. The carrier inventory has no quotient real, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, so the listed obligations exhaust the certificate surface. □

Theorem 3665.3 (Bishop real completion Real-seal route)**.** *Every Real-facing consumer of an accepted* $\mathsf{BishopRealCompletion}^{\uparrow}$ *packet reaches* $\mathsf{Real}^{\uparrow}$ *only through the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{BishopLocatedRealCompletion}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

displayed by $D, S, Q, L, E, H, C, P, N$*. The route supplies finite precision, window, readback, located-completion, and seal rows, and it supplies no quotient real equality, no selected limit, no countable-choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier $R = (D, S, Q, L, E, H, C, P, N)$. The only Real-facing row is E, and the only rows feeding it are the dyadic ledger D, stream windows S, regular rational readbacks Q, and located-completion row L.

Use the NameCert obligations of Definition 3665.2. They force precision queries, observations, regular readbacks, located completion, and Real sealing to pass through the same displayed carrier rows.

Transport and replay do not add a second route. The rows H and C preserve and replay the displayed path componentwise, while P and N record its provenance and local name.

The carrier excludes quotient real equality, selected limits, countable-choice schedules, and ambient completeness. Hence every Real-facing consumer receives exactly the finite Real-seal route stated above. □

Theorem 3665.4 (Bishop real completion local NameCert exhaustion)**.** *For any accepted* $\mathsf{BishopRealCompletion}^{\uparrow}$ *carrier*

$$R = (D, S, Q, L, E, H, C, P, N),$$

every local $\mathsf{NameCert}_{\mathsf{BishopRealCompletion}^{\uparrow}}$ *consumer factors through exactly the five dependency rows*

$$D, S, Q, L, E$$

followed by the structural rows H, C, P, N*. The first five rows are respectively the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger,* $\mathsf{StreamName}^{\uparrow}$ *window ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{BishopLocatedRealCompletion}^{\uparrow}$ *located-completion row, and* $\mathsf{Real}^{\uparrow}$ *seal; no consumer-visible branch is supplied by quotient real equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier using Definition 3665.1. The displayed dependency coordinates are exactly D, S, Q, L, E, and the only structural coordinates are H, C, P, N.

Split over the finite row inventory. Precision requests land in D, finite observations in S, regular rational values in Q, located completion data in L, and Real-facing seals in E.

Apply Definition 3665.2. Its obligation list identifies the same dependency rows and then the same transport, replay, provenance, and local naming rows as the full local certificate surface.

Finally use Definition 3665.3 for consumer-visible reads that reach $\mathsf{Real}^{\uparrow}$. That route ends at E after D, S, Q, L, and the remaining rows H, C, P, N preserve and name it without adding a second branch. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopRealCompletion}^{\uparrow}$ packet is generated from a dyadic precision ledger, finite StreamName windows, RegSeqRat readbacks, a BishopLocatedRealCompletion row, a Real seal row, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3665.1, Definition 3665.2, and Definition 3665.3 name the seed carrier, finite NameCert obligation surface, and Real-seal route for Bishop real completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not assert quotient reals, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic precision exactness, finite stream-window readback, regular rational readback, located-completion handoff, Real-seal exposure, transport stability, replay, provenance, and local naming for the displayed Bishop real completion packet.

Chapter 3666

A Concrete Naming Certificate for UniformCompletionUniversalProperty$^{\uparrow}$

Following Bishop and Bridges constructive completion and Kelley uniform-space terminology, the UniformCompletionUniversalProperty$^{\uparrow}$ packet records the uniform analogue of the L10 completion universal property. It sits after the uniform-completion carrier of chapter 1473, the generic completion surface of chapter 397, and the regular-rational readbacks of chapter 126, chapter 301, and chapter 38. The packet names extension and uniqueness only through finite uniform rows, not through quotient completions, selected limits, ambient complete spaces, or choice.

Definition 3666.1 (Uniform completion universal-property carrier)**.** *A* UniformCompletionUniversalProperty$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, D, T, E, L, M, W, H, C, P, N)$$

with the following displayed rows:

1. *U is the uniform source row, exposing only the displayed* UniformSpace$^{\uparrow}$ *entourages and their finite source windows.*
2. *D is the dense unit row from the source into the completion carrier, aligned with the* UniformCompletion$^{\uparrow}$ *unit surface.*
3. *T is the uniformly continuous target row, naming the complete separated target interface through finite entourage/modulus data.*
4. *E is the extension row for uniformly continuous source consumers, read only after U, D, T have been displayed.*
5. *L is the uniqueness row, comparing two displayed extensions by* hsame *over the dense unit and the same target row.*
6. *M is the entourage/modulus ledger for source entourages, target entourages, and the finite modulus witnesses used by E and L.*
7. *W is the readback row for* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *observations downstream of the same uniform route.*
8. *H stores componentwise* hsame *transport for the source, dense unit, target, extension, uniqueness, modulus, readback, continuation, provenance, and naming rows.*

9. *C stores displayed* Cont *replay from source windows through the dense unit, target modulus, extension row, uniqueness row, and readback row.*

10. *P is the* Pkg *provenance over* UniformCompletionUniversalProperty$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CompletionUniversalPro UniformSpace$^{\uparrow}$, UniformModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

11. *N is the local* NameCert$_{\text{UniformCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, D, T, E, L, M, W, H, C, P, N$. It has no coordinate for quotient completion points, selected representatives, ambient target completeness, host function extensionality, or countable choice.

Theorem 3666.2 (Uniform completion universal-property NameCert obligations)**.** *For every accepted* UniformCompletionUniversalProperty$^{\uparrow}$ *carrier $K = (U, D, T, E, L, M, W, H, C, P, N)$, the local* NameCert$_{\text{UniformCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, uniform-source exposure through U, dense-unit exposure through D, complete separated target exposure through T, extension existence through E, uniqueness through L, entourage/modulus accounting through M,* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *readbacks through W, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.UniformCompletionUniversalPropertyUp.UniformCompletionUniversalPropertyTasteGate`
`single carrier alignment`

Proof. Project the carrier of Definition 3666.1. The source, dense unit, target, extension, uniqueness, modulus ledger, readback row, transport, replay, provenance, and local name are exactly the displayed coordinates of one finite BHist packet.

The extension row E is available only after the source row U, dense unit row D, target row T, and entourage/modulus ledger M have been displayed. The uniqueness row L compares extensions over the same rows by the recorded hsame ledger.

The readback row W is downstream of that uniform route. Since the classifier has no remaining coordinate for selected limits, quotient completions, host function equality, countable choice, or ambient target completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3666.3 (Uniform completion universal-property extension uniqueness)**.** *Let $K = (U, D, T, E, L, M, W, H$ be an accepted* UniformCompletionUniversalProperty$^{\uparrow}$ *carrier. Every extension-and-uniqueness consumer factors through*

$$U, D, T, M \longmapsto E \longmapsto L \longmapsto W$$

together with H, C, P, N. Thus extension existence, uniqueness over the dense unit, and any StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *or* Real$^{\uparrow}$ *readback are all read from the same finite uniform packet, and no consumer obtains a quotient completion, selected extension, ambient complete target theorem, or choice principle.*

Proof. Read the carrier definition. The extension coordinate is E, and its stated inputs are the uniform source U, dense unit D, uniformly continuous target T, and entourage/modulus ledger M.

The uniqueness row L is not an independent equality principle. It compares displayed extensions only along the same dense unit and target row, using the componentwise hsame route recorded by H and replayed by C.

Finally inspect the downstream rows. The readback coordinate W is attached to the same route, while P and N record provenance and local naming. Row exhaustion excludes every omitted host object, so the extension-and-uniqueness surface is exactly the finite route displayed above. □

Falsifiable prediction: Every accepted $\mathsf{UniformCompletionUniversalProperty}^{\uparrow}$ consumer that exports extension existence or uniqueness while omitting the uniform source, dense unit, uniformly continuous target, extension row, uniqueness row, entourage/modulus ledger, readback row, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: uniformcompletion, completionuniversalproperty, uniformspace, uniformmodulus, streamname, regseqrat, real: $\mathsf{UniformCompletionUniversalProperty}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries uniform source, dense unit, target continuity, extension, uniqueness, modulus ledger, readbacks, transport, replay, provenance, and local NameCert rows in one universal-property packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionUniversalProperty}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionUniversalProperty}^{\uparrow}$ packet is generated from a uniform source row, dense unit row, uniformly continuous target row, extension row, uniqueness row, entourage/modulus ledger, StreamName/RegSeqRat/Real readbacks, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionUniversalProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3666.1, Definition 3666.2, and Definition 3666.3 seed the finite uniform universal-property certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionUniversalProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected extensions, ambient complete target theorems, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, extension existence, uniqueness, readback nonescape, transport replay, provenance, and TasteGate field faithfulness for BEDC.Derived.UniformCompletionUniversalPropertyUp.

Chapter 3667

A Concrete Naming Certificate for CauchyCompletionStableReflection$^{\uparrow}$

Following Bishop and Bridges on constructive completion, the CauchyCompletionStableReflection$^{\uparrow}$ packet records the stable reflection surface by which a displayed completion functor, its universal property, separatedness, regular rational sequence data, and terminal real-name rows remain attached to one finite NameCert route. It sits after the completion functor of chapter 423, the universal handoff of chapter 397, the separated limit classifier of chapter 1411, the regular rational sequence rows of chapter 301, and the Real seal of chapter 38. The packet names a stable reflection certificate for the displayed route; it does not assert quotient completion construction, selected limits, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 3667.1 (Cauchy completion stable reflection carrier)**.** *A* CauchyCompletionStableReflection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, U, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* CauchyCompletionFunctor$^{\uparrow}$ *row, containing the named source metric, target completion surface, and functorial map route.*
2. *U is the* CompletionUniversalProperty$^{\uparrow}$ *row, storing the extension and uniqueness handoff for maps out of the displayed dense source.*
3. *S is the* SeparatedMetric$^{\uparrow}$ *row, recording the zero-distance classifier used for completion-limit uniqueness.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *row, carrying the regular rational sequence schedules and finite tolerance windows read by the completion route.*
5. *E is the* Real$^{\uparrow}$ *seal row reached from the regular sequence and zero-distance data.*
6. *H records componentwise* hsame *transport for functor, universal-property, separatedness, regular-sequence, Real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from F, Q through U, S, E and back to the local naming row.*
8. *P is the* Pkg *provenance over* CauchyCompletionStableReflection$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionStableReflection}^{\uparrow}}$ *row.*
The carrier contains no quotient completion object, no chosen representative of a limit, no external completeness theorem for $\mathsf{Real}^{\uparrow}$*, and no route outside the displayed BEDC rows.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionStableReflectionUp.CauchyCompletionStableReflectionTasteGate`
`single carrier alignment`

Theorem 3667.2 (Cauchy completion stable reflection NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionStableReflection}^{\uparrow}$ *carrier* $R = (F, U, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionStableRefl}}$ *surface consists exactly of carrier admission for* $F, U, S, Q, E, H, C, P, N$*; functor stability through* F*; extension uniqueness through* U*; separated zero-distance classification through* S*; regular rational window control through* Q*; Real seal confinement through* E*; componentwise* hsame *transport through* H*; displayed* Cont *replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Carrier admission is projection from Definition 3667.1. The accepted packet displays exactly the completion functor row, the universal-property row, the separatedness row, the regular rational sequence row, the Real seal, and the structural rows.

Functor stability and extension uniqueness are read in that order. The row F supplies the completion-facing map route, while U allows an extension consumer to compare two displayed routes only after they share the same source, completion surface, and regular sequence data.

Separatedness and Real sealing are likewise internal to the packet. The row S turns zero-distance evidence into classifier equivalence, the row Q supplies the finite regular rational windows that feed the completion comparison, and E seals the resulting value inside the displayed $\mathsf{Real}^{\uparrow}$ boundary.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since the carrier has no quotient object, selected limit, countable-choice schedule, trichotomy row, or ambient Real-completeness coordinate, every local NameCert obligation is confined to the listed rows. □

Theorem 3667.3 (Cauchy completion stable reflection extension route)**.** *Every extension-facing consumer of an accepted* $\mathsf{CauchyCompletionStableReflection}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}^{\uparrow} \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, the consumer receives the rows $F, U, S, Q, E, H, C, P, N$ *and no quotient completion carrier, selected representative, hidden completion theorem, countable-choice schedule, trichotomy row, or off-packet certificate.*

Proof. Begin with the functor row F. It is the only coordinate that exposes the completion-facing map route and the source-to-completion handoff.

Next use the universal-property row U. It compares extension candidates only after the route through F is fixed, so extension uniqueness cannot be read as a host equality or as a selected representative of a completed object.

The separatedness and regular-sequence rows then bind the uniqueness read to finite BEDC data. The row S supplies the zero-distance classifier, Q supplies the regular rational windows that make the completion comparison visible, and E confines the resulting value to the Real seal.

Finally H, C, P, N transport, replay, source, and name that same route. Coordinate exhaustion rules out any hidden quotient completion, ambient Real-completeness theorem, choice schedule, trichotomy row, or off-packet certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionStableReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionStableReflection}^{\uparrow}$ packet is generated from a CauchyCompletionFunctor row, a CompletionUniversalProperty row, a SeparatedMetric row, a RegSeqRat row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStableReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3667.1, Definition 3667.2, and Definition 3667.3 seed the finite stable-reflection certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStableReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion construction, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, functor stability, extension uniqueness, separated zero-distance classification, regular rational window control, Real seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionStableReflectionUp.

Chapter 3668

A Concrete Naming Certificate for $\mathsf{SetLike}^{\uparrow}$

Following Russell and Bourbaki-style set-membership grounding, the $\mathsf{SetLike}^{\uparrow}$ packet records the finite BEDC carrier by which membership, subset implication, restricted comprehension, and extensional boundary reads are exposed without importing an ambient powerset, host quotient, or impredicative universe. It sits before the displayed family discipline of chapter 3600, the syntactic carrier of chapter 197, and the satisfaction carrier of chapter 198. The packet names only finite membership source, classifier, implication, bounded comprehension, extensionality boundary, transport, replay, provenance, and local naming rows.

Definition 3668.1 (SetLike carrier)**.** *A* $\mathsf{SetLike}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, Q, I, R, E, H, C, P, N)$$

with the following rows:

1. *M is the membership-source row, naming the finite source from which element and set-read markers are admitted;*
2. *Q is the classifier row for displayed membership decisions and membership-compatible reads;*
3. *I is the subset-implication row, recording finite implications from one membership classifier to another;*
4. *R is the restricted-comprehension row, admitting only classifiers already routed through M, Q, I;*
5. *E is the extensionality-boundary ledger, recording when two displayed set rows may be compared by the carried membership classifier;*
6. *H records componentwise* hsame *transport for M, Q, I, R, E together with the structural rows;*
7. *C records* Cont *replay through which a consumer reads membership source, classifier, subset implication, restricted comprehension, and extensionality boundary data;*
8. *P is the* Pkg *provenance over* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*,* $\mathsf{ModelTheory}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient powerset, unrestricted separation, quotient equality of sets, selected representatives, global choice of elements, or a host universe of all sets.

Lean4 ✓ BEDC.Derived.SetlikeUp.SetlikeTasteGate single carrier alignment

Definition 3668.2 (SetLike membership carrier)**.** *For an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier*

$$S = (M, Q, I, R, E, H, C, P, N),$$

the membership carrier is the finite BHist *surface*

$$S_{\in} = (M, Q, H, C, P, N).$$

Here M is the membership-source row, Q is the classifier-based membership row, H is the componentwise hsame *transport for the displayed rows, C is the* Cont *replay route, P is the* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row. The membership carrier has no coordinate for host elementhood, powersets, quotient equality of sets, unrestricted comprehension, or an external universe of sets.*

Lean4 (definition) BEDC.Derived.SetlikeUp.SetlikeMembershipCarrier

Theorem 3668.3 (SetLike membership stability)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier $S = (M, Q, I, R, E, H, C, P,$ every classifier-based membership read through the membership carrier $S_{\in} = (M, Q, H, C, P, N)$ remains the same finite* BHist *read after componentwise* hsame *transport and* Cont *replay. In particular, transport may expose only the membership source M, classifier row Q, structural route H, C, provenance P, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row N.*

Lean4 ✓ BEDC.Derived.SetlikeUp.SetlikeMembershipStability

Proof. Project the membership carrier of Definition 3668.2. Its only membership data are the source row M and the classifier row Q.

Transport is componentwise through H, and replay is displayed through C. These rows preserve and expose the same classifier-based membership surface rather than creating a second element relation.

The rows P and N source and name the same finite packet. Hence a transported membership read remains a BHist read through M, Q, H, C, P, N and cannot become host elementhood, a powerset coordinate, quotient equality, or unrestricted comprehension. □

Theorem 3668.4 (SetLike membership classifier public boundary)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier $S = (M, Q, I, R, E, H, C, P, N)$, every* $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{ModelTheory}^{\uparrow}$, *or root consumer must read membership through M, Q, H, C, P, N, subset and restricted-comprehension data through I, R, and the extensional boundary through E. The public boundary exports no host membership relation, powerset, unrestricted separation rule, quotient set equality, selected representative, or external satisfaction predicate.*

Proof. Project Definition 3668.1 and Definition 3668.2. The membership carrier exposes only the source row M, classifier row Q, transport row H, replay row C, provenance row P, and local naming row N.

Apply Definition 3668.3. A membership read transported through the public boundary remains the same finite classifier read, so a downstream root or typed consumer cannot replace it by host elementhood or an external satisfaction predicate.

For subset and comprehension consumers, use Definition 3668.5 and Definition 3668.6. These place subset implication and restricted comprehension behind I, R over the displayed membership classifier.

Finally read the extensional boundary through E and close by the existing consumer-boundary rows. Since no coordinate of S stores a powerset, unrestricted separation rule, quotient set equality, selected representative, or external satisfaction predicate, the public boundary exports exactly the displayed rows. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipClassifierPublicBoundary`

Theorem 3668.5 (SetLike subset ledger exactness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the subset ledger is exact: every accepted subset read is the implication row* I *over the classifier-based membership carrier* $S_{\in}$*, together with the restricted-comprehension row* R *only as a bounded consumer of* M, Q, I*. No subset consumer receives host-set extensionality, a global inclusion predicate, quotient equality of sets, or a powerset row outside* M, Q, I, R, H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetLedger exactness`

Proof. Start with the membership carrier $S_{\in}$ and the subset row I. The classifier Q is the only membership classifier available to the implication row, and M is the only membership source.

The restricted-comprehension row R is bounded by the same displayed route. It can consume M, Q, I but does not provide an ambient subset object.

Transport and replay through H, C preserve the same ledger, while P, N record provenance and local naming. Since no extra coordinate exists, the subset ledger is exactly the finite route M, Q, I, R, H, C, P, N. □

Theorem 3668.6 (SetLike comprehension scope)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P,$ *restricted comprehension through* R *is scoped by classifier-based membership over* M, Q *and subset implication through* I*. The resulting read remains a finite* BHist *row transported by* H*, replayed by* C*, sourced by* P*, and named by* N*; it does not assert unrestricted separation, host-set extensionality, quotient equality, or a universe of all subsets.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeComprehensionScope`

Proof. Read R from the carrier of Definition 3668.1. The row is restricted comprehension, not a powerset constructor.

The scope is supplied by the membership carrier of Definition 3668.2 and the implication row I. Thus a comprehension read is accepted only when its classifier is already routed through M, Q, I.

Finally apply the structural rows. Componentwise hsame transport, displayed Cont replay, provenance, and local naming keep the same finite row visible, so the comprehension scope does not become unrestricted separation, host-set extensionality, quotient equality, or a universe of all subsets. □

Theorem 3668.7 (SetLike bounded-comprehension induction)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every accepted restricted-comprehension read through* R *is generated by finite induction over the displayed membership-source row* M *and subset-implication row* I*. The generated row is transported through* H *and replayed through* C *before provenance* P *and local naming* N *are consumed, and the route cannot introduce unrestricted separation, powerset data, quotient set equality, selected representatives, or an external universe of sets.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionInduction`

Proof. Project the carrier of Definition 3668.1. The only rows available before restricted comprehension is read are the membership-source row M, the classifier row Q, and the subset-implication row I.

Apply Definition 3668.6. It fixes R as a bounded consumer of M, Q, I, so the induction has no case for a host powerset, unrestricted separator, quotient equality witness, or external universe.

Induct over the displayed BHist packet. The base case reads the empty or initial membership-source row and carries no unrestricted subset data. In the finite step case, a new displayed membership row from M may be admitted only when the implication row I keeps it inside the already displayed classifier route.

Transport through H and replay through C preserve the same generated route, while P and N only source and name the finite packet. Thus every accepted restricted-comprehension read is produced by the finite row induction and cannot export any refused comprehension principle. □

Theorem 3668.8 (SetLike finite membership induction)**.** *Every accepted finite* $\mathsf{SetLike}^{\uparrow}$ *membership ledger whose rows are generated from displayed* BHist *membership observations and transported by* hsame *can be consumed by induction over the displayed ledger rows. The induction exports only the carrier row, membership row, classifier row, transport row,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row; it exports no host powerset membership, quotient-set equality, unrestricted comprehension, selected representatives, or ambient extensional equality.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFiniteMembershipInduction`

Proof. Start from the membership carrier of Definition 3668.2. Its displayed ledger exposes only M, Q, H, C, P, N, so the base case is the empty or initial membership observation together with the same carrier, replay, provenance, and naming rows.

For the finite step case, append one displayed BHist membership observation. The row is admitted only through the classifier row Q and then transported componentwise by hsame through H.

Finally read the structural rows. The Cont replay C, provenance P, and local $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ row N repack the same finite ledger for downstream consumers, while Definition 3668.3 blocks replacement by host powerset membership or ambient extensional equality. □

Theorem 3668.9 (SetLike membership-family BHist induction)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, any finite membership-family consumer generated from* $M, Q, I, R, E, H, C, P, N$ *is obtained by induction on the displayed* BHist *membership source of Definition 3668.2. The step case first routes a displayed membership request through the classifier row* Q*, then through the subset-implication row* I*, and only then may the restricted-comprehension row* R *consume it. The induction has no branch for powersets, unrestricted separation, quotient set equality, host universe rows, selected representatives, or ambient elementhood.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipFamilyBHistInduction`

Proof. Start with Definition 3668.1 and Definition 3668.2. The displayed membership-family source is $S_{\in} = (M, Q, H, C, P, N)$, so the base case exposes only the membership source, classifier, transport, replay, provenance, and local naming rows.

For the finite step case, read the classifier row Q before any subset or comprehension consumer is allowed. The implication row I records the displayed subset route over that classifier, and Definition 3668.7 then permits R to consume only the already routed M, Q, I data.

The extensional boundary remains separate. By Definition 3668.82, E is a displayed comparison boundary and not a quotient set equality row. Hence the induction never opens powerset data,

unrestricted separation, quotient equality, host universe rows, selected representatives, or ambient elementhood. □

Theorem 3668.10 (SetLike NameCert obligations)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier*

$$S = (M, Q, I, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *surface consists exactly of carrier admission for* S*, membership-source admission through* M*, classifier exposure through* Q*, subset-implication exposure through* I*, restricted-comprehension exposure through* R*, extensionality-boundary exposure through* E*, componentwise* hsame *stability through* H*,* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeNameCertObligations`

Proof. Project the accepted carrier of Definition 3668.1. The membership source M and classifier Q provide the only entry points for element-in-set reads.

The subset row I records implication between displayed classifiers, while the restricted-comprehension row R may bind only predicates already exposed through the same membership source and classifier route. The extensionality row E records the comparison boundary for displayed set rows; it does not identify host sets outside the packet.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate is present, the NameCert obligations cannot require unrestricted separation, ambient powersets, quotient equality of sets, selected representatives, global element choice, or a universe of all sets. □

Theorem 3668.11 (SetLike membership source admission)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every membership read must expose the membership-source row* M*, displayed classifier row* Q*, componentwise transport row* H*, continuation replay row* C*, package provenance row* P*, and local naming row* N *before the read is accepted. In particular, a membership consumer cannot replace* M, Q, H, C, P, N *by an ambient element relation, a host powerset, selected representatives, or an external universe of sets.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipSourceAdmission`

Proof. Project the carrier of Definition 3668.1. The only rows that open an element-in-set assertion are the membership source M and displayed classifier Q.

Use the obligation surface of Definition 3668.10. It requires membership-source admission, classifier exposure, componentwise hsame stability, Cont replay, provenance, and local naming as visible NameCert rows.

The existing route theorem Definition 3668.27 then blocks every bypass. Since no carrier coordinate stores an ambient element relation, powerset, representative selector, or host universe, every accepted membership read must expose M, Q, H, C, P, N. □

Theorem 3668.12 (SetLike classifier transport route)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, classifier transport for subset implication, restricted comprehension, and extensional boundary rows stays inside the finite route*

$$Q, I, R, E \longmapsto H, C, P, N.$$

The transported classifier remains the displayed membership classifier over M *and cannot be reinterpreted as proof-irrelevant host truth, unrestricted separation, quotient equality of sets, or an external inclusion relation.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeClassifierTransportRoute`

Proof. Start from the classifier row Q in Definition 3668.1. The subset implication row I, restricted-comprehension row R, and extensionality-boundary ledger E are all defined as displayed rows that consume the same membership classifier.

Apply Definition 3668.58, Definition 3668.59, and Definition 3668.60. These obligations keep subset, comprehension, and extensional comparison reads attached to M, Q and to the structural rows H, C, P, N.

Finally use Definition 3668.68. Transport and replay preserve the displayed classifier route rather than replacing it by host truth, unrestricted separation, quotient equality, or external inclusion. □

Theorem 3668.13 (SetLike membership carrier admission)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, any membership-facing consumer must first admit the membership carrier*

$$S_{\in} = (M, Q, H, C, P, N)$$

from Definition 3668.2. The admissible read exposes M, Q, H, C, P, N *as source, classifier, transport, replay, provenance, and local naming rows, and it cannot inspect host elementhood, a powerset coordinate, unrestricted comprehension, quotient equality, selected representatives, or an ambient universe before those rows are visible.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipCarrierAdmission`

Proof. Project the carrier of Definition 3668.1 and the membership carrier of Definition 3668.2. The only membership rows available at this stage are the source row M and classifier row Q.

Use Definition 3668.10. The NameCert surface requires componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N for the same displayed rows.

Finally apply Definition 3668.12. Classifier transport keeps the read inside the displayed route, so no consumer can replace M, Q, H, C, P, N by host elementhood, powerset data, unrestricted comprehension, quotient equality, selected representatives, or an ambient universe. □

Theorem 3668.14 (SetLike membership kernel obligations)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every consumer that reads membership or subset data from* S *must first expose the membership source* M*, displayed classifier* Q*, subset implication* I*, restricted comprehension* R*, extensional boundary* E*, componentwise* hsame *row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row* N*. The admissible read is therefore the concrete kernel route*

$$M, Q, I, R, E \longmapsto H, C, P, N,$$

and it cannot be replaced by an ambient powerset, unrestricted separation, quotient equality of sets, selected representatives, or a host universe.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipKernel obligations`

Proof. Project the carrier of Definition 3668.1. Its membership-facing coordinates are exactly the source row M and the classifier row Q, while subset and bounded family reads are carried only by I and R.

Use Definition 3668.13. A membership-facing consumer must admit $S_{\in} = (M, Q, H, C, P, N)$ before it can inspect element-in-set data, so the source and classifier are visible before the structural rows are replayed.

Next apply Definition 3668.12. The subset implication, restricted comprehension, and extensional boundary rows stay attached to the displayed classifier route Q, I, R, E under H, C, P, N.

It remains to exclude host-level replacements. The membership route theorem Definition 3668.27 and the bounded-comprehension and extensional-boundary obligations keep every membership, subset, comprehension, and comparison read inside $M, Q, I, R, E, H, C, P, N$. Since Definition 3668.1 has no powerset, unrestricted-separation, quotient-equality, representative-selection, or host-universe coordinate, every accepted consumer must expose the displayed kernel route before reading membership or subset data. □

Theorem 3668.15 (SetLike subset classifier exactness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, subset implication and restricted comprehension are exact over the classifier route*

$$Q, I, R, E \longmapsto H, C, P, N.$$

The implication row I *and restricted-comprehension row* R *may use only the displayed classifier* Q *and extensional-boundary ledger* E *before transport, replay, provenance, and local naming are read. They export no powerset row, host-universe coordinate, unrestricted separation rule, quotient set equality, or external inclusion predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetClassifierExactness`

Proof. Start from Definition 3668.1. The rows I and R are displayed subset-implication and restricted-comprehension rows over the classifier row Q, while E records the comparison boundary.

Apply Definition 3668.10. Its obligation surface keeps subset, comprehension, and boundary reads attached to the accepted packet before structural replay.

Use Definition 3668.12. Since classifier transport stays inside Q, I, R, E, H, C, P, N, exactness is a property of the displayed rows rather than an ambient powerset, host universe, unrestricted separation rule, quotient equality, or external inclusion relation. □

Theorem 3668.16 (SetLike TypeLike and model-theory handoff)**.** *Every* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{ModelTheory}^{\uparrow}$ *consumer that reads family, satisfaction, or model data from an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet must first pass through the membership carrier* M, Q, H, C, P, N *and the classifier route* Q, I, R, E, H, C, P, N*. Satisfaction-facing and family-facing reads therefore remain downstream of the SetLike membership and classifier surface, not of an ambient set-theoretic assumption.*

Proof. Begin with the accepted carrier of Definition 3668.1. The membership source, classifier, subset implication, restricted comprehension, and extensional boundary rows are M, Q, I, R, E.

Use Definition 3668.2 and Definition 3668.10. These fix the membership carrier and require the structural rows H, C, P, N before a sibling consumer receives any membership data.

Apply Definition 3668.12. The classifier route remains displayed through Q, I, R, E, H, C, P, N, so $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, and $\mathsf{ModelTheory}^{\uparrow}$ consumers may build family, syntax, and satisfaction reads only after that SetLike surface is visible.

Thus no downstream consumer obtains satisfaction, family membership, or model-theory data from an ambient powerset, host universe, external satisfaction relation, quotient set equality, or unrestricted comprehension principle. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypelikeModeltheoryHandoff`

Theorem 3668.17 (SetLike membership classifier transport)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, membership transport is accepted only as the displayed classifier route*

$$M, Q \longmapsto H, C, P, N.$$

Here M *is the finite* BHist *membership source,* Q *is the membership classifier,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay, and* N *is the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row. The transported read cannot become host elementhood, an ambient powerset, quotient equality of sets, unrestricted comprehension, or an external satisfaction relation.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipClassifierTransport`

Proof. Project the accepted carrier and its membership subcarrier. The only element-facing rows before the structural tail are M and Q.

Apply the SetLike membership route and classifier transport route. These force every transported membership read to remain a classifier-bounded BHist read before H and C replay it.

Finally use the local NameCert obligations. The rows P and N source and name the same displayed route, so no host elementhood, powerset, quotient equality, unrestricted comprehension, or external satisfaction coordinate is available. □

Theorem 3668.18 (SetLike NameCert ledger nonescape)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *ledger records membership, subset implication, restricted comprehension, and extensional-boundary obligations only through*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

The ledger is a finite BHist *route stable under* hsame *and* Cont*; it cannot export an ambient powerset, unrestricted separation, quotient equality of sets, selected representatives, or a host universe outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeNameCertLedgerNonescape`

Proof. Read the NameCert obligations of Definition 3668.10. They expose exactly the carrier rows $M, Q, I, R, E, H, C, P, N$.

Use subset classifier exactness, restricted-comprehension membership factorization, and extensional-subset transport. These keep subset, comprehension, and extensional comparison on the same membership classifier before structural replay.

The structural tail is exhausted by hsame transport, Cont replay, provenance, and local naming. Therefore the ledger cannot escape into powersets, unrestricted separation, quotient equality, selected representatives, or a host universe. □

Theorem 3668.19 (SetLike type-model satisfaction boundary)**.** *Every* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must first expose* $M, Q, I, R, E, H, C, P, N$ *as a finite* BHist *route with componentwise* hsame*, displayed* Cont*, provenance, and local* NameCert *rows. Type, syntax, and satisfaction reads remain downstream of this displayed SetLike route and cannot replace it by host membership, quotient equality of sets, unrestricted comprehension, an ambient universe, or an external satisfaction predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypeModelSatisfactionBoundary`

Proof. Start with the SetLike TypeLike and model-theory handoff. It already requires family, syntax, and satisfaction consumers to pass through the membership carrier and classifier route.

Apply membership classifier transport and NameCert ledger nonescape. Together they expose $M, Q, I, R, E, H, C, P, N$ and block any replacement by host membership or a powerset-style carrier.

Finally use the FirstOrder signature and ModelTheory satisfaction root-unblock theorems. A typed or model-theoretic consumer that stays on the displayed route receives only the finite BEDC packet, while a consumer that leaves it lacks the required SetLike source. □

Theorem 3668.20 (SetLike family handoff obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every* $\mathsf{TypeLike}^{\uparrow}$ *family consumer that reads indexed fibers from* S *must expose the membership source* M*, classifier row* Q*, subset implication row* I*, restricted-comprehension row* R*, extensional boundary row* E*, componentwise transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N*. The family handoff cannot replace these rows by an ambient powerset, unrestricted separation principle, host element relation, quotient equality of sets, or external universe.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFamilyHandoffObligation`

Proof. Project the accepted carrier of Definition 3668.1. The family consumer sees only the displayed rows $M, Q, I, R, E, H, C, P, N$ before it can build a TypeLike fiber read.

Use Definition 3668.16. It forces sibling family reads through the membership carrier and the classifier route, so M, Q and Q, I, R, E remain visible before the consumer proceeds.

Finally apply Definition 3668.26 and Definition 3668.52. These keep the restricted family row bounded and the comparison row tied to the displayed classifier; hence no ambient powerset, unrestricted separation, quotient set equality, host element relation, or external universe is exported. □

Theorem 3668.21 (SetLike satisfaction handoff obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every* $\mathsf{FirstOrder}^{\uparrow}$ *or* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction consumer must obtain its membership and comprehension base through the concrete route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

The satisfaction handoff exports no host satisfaction predicate, ambient powerset, unrestricted separation rule, quotient equality of sets, selected representative, or external universe outside those nine rows.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSatisfactionHandoffObligation`

Proof. Start with Definition 3668.16. Satisfaction-facing reads are downstream of the SetLike membership and classifier surface, not independent model-theoretic coordinates.

Apply Definition 3668.54. First-order syntax may consume membership, subset implication, restricted comprehension, and extensional comparison only after the carrier route has been displayed.

Then use Definition 3668.89. The ModelTheory satisfaction consumer inherits the same classifier-bounded envelope through FirstOrder syntax, so host satisfaction, ambient powersets, unrestricted separation, quotient equality, selected representatives, and external universes remain outside the route. □

Theorem 3668.22 (SetLike family fiber obligations)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a* $\mathsf{TypeLike}^{\uparrow}$ *family-fiber consumer accepted from* S *must expose the membership source* M*, classifier row* Q*, subset implication row* I*, restricted-comprehension row* R*, extensional boundary row* E*, componentwise transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N *before any* $\mathsf{FirstOrder}^{\uparrow}$ *or* $\mathsf{ModelTheory}^{\uparrow}$ *consumer reads satisfaction or family membership. The fiber route cannot replace those rows by a host powerset, unrestricted separation principle, quotient equality of sets, selected representative, external satisfaction predicate, or ambient universe.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFamilyFiberObligations`

Proof. Project the accepted carrier of Definition 3668.1. The family-fiber consumer has access only to $M, Q, I, R, E, H, C, P, N$ before it can form a typed fiber read.

Use the SetLike family handoff obligation. It forces indexed fibers through the membership source, classifier, subset implication, restricted-comprehension row, extensional boundary, transport, replay, provenance, and local naming rows.

Finally compose with the satisfaction handoff obligation and the type-model satisfaction boundary. FirstOrder and ModelTheory consumers inherit the same visible rows from the TypeLike fiber route, so satisfaction and family membership cannot be read from an external powerset, host element relation, quotient set equality, selected representative, unrestricted separation rule, or ambient universe. □

Theorem 3668.23 (SetLike family-fiber model-satisfaction route)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, any* $\mathsf{TypeLike}^{\uparrow}$ *family-fiber consumer that feeds a* $\mathsf{FirstOrder}^{\uparrow}$ *or* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction read must expose the rows* $M, Q, I, R, E, H, C, P, N$ *before satisfaction or family membership is inspected. The route cannot be replaced by host membership, quotient equality of sets, unrestricted comprehension, selected representatives, or an external satisfaction predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFamilyFiberModelSatisfactionRoute`

Proof. Start with the family handoff obligation. It opens the membership source, classifier, subset implication, restricted-comprehension row, extensional boundary, transport, replay, provenance, and local naming rows before a TypeLike family fiber is available.

Next compose with the satisfaction handoff obligation and the type-model satisfaction boundary. These force FirstOrder and ModelTheory satisfaction reads to inherit the same displayed SetLike route rather than introducing a separate model-theoretic carrier.

Finally apply the family-fiber obligations above. Since the fiber route already blocks host powersets, unrestricted separation, quotient equality, selected representatives, and external universes, the satisfaction-facing consumer has no coordinate from which host membership or an external satisfaction predicate can be read. □

Theorem 3668.24 (SetLike family-fiber FirstOrder ModelTheory lock)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every* $\mathsf{TypeLike}^{\uparrow}$ *family-fiber consumer that feeds a* $\mathsf{FirstOrder}^{\uparrow}$ *syntax read or a* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction read must expose exactly the rows* $M, Q, I, R, E, H, C, P, N$ *from the accepted packet. The lock cannot replace those rows by host membership, unrestricted comprehension, quotient set equality, selected representatives, external satisfaction, or ambient universe data.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFamilyFiberFirstorderModeltheoryLock`

Proof. Start with Definition 3668.23. It already routes every family-fiber satisfaction read through the displayed SetLike packet before any FirstOrder or ModelTheory consumer inspects membership or satisfaction.

Apply Definition 3668.20. A TypeLike family-fiber consumer receives the membership source, classifier, subset implication, restricted-comprehension row, extensional boundary, transport, replay, provenance, and local naming rows from S, not from a host membership relation or ambient family carrier.

Next apply Definition 3668.21. FirstOrder syntax and ModelTheory satisfaction inherit the same route, so no external satisfaction predicate, unrestricted comprehension rule, quotient set equality, selected representative, or universe datum is available as a replacement.

Finally use Definition 3668.18. The local ledger names only $M, Q, I, R, E, H, C, P, N$ and exports no coordinate outside the accepted packet, so the cross-consumer route is locked to those nine rows. □

Theorem 3668.25 (SetLike extensionality refusal obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the extensional row* E *is a classifier-boundary row over the displayed membership route* M, Q, I, R *and the structural route* H, C, P, N*. A downstream TypeLike, FirstOrder, or ModelTheory consumer may cite* E *only as that boundary row, not as host set extensionality, quotient equality, a powerset equality principle, unrestricted separation, or an external universe equality.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalityRefusalObligation`

Proof. Project the row E from Definition 3668.1. It is the carrier's extensionality-boundary coordinate, not a host equality object.

Use Definition 3668.62 and Definition 3668.71. Together they route every extensional read through $M, Q, I, R, E, H, C, P, N$ and rule out quotient equality, powersets, unrestricted separation, host set equality, and external inclusion predicates.

Finally apply Definition 3668.16. Since TypeLike, FirstOrder, and ModelTheory consumers must receive SetLike data through the same membership and classifier surface, they cannot reinterpret E as ambient extensionality or as an equality principle outside the concrete carrier rows. □

Theorem 3668.26 (SetLike bounded comprehension nonescape)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a restricted-comprehension read through* R *cannot export a powerset, unrestricted separation principle, host subset object, or universe of all subsets. It remains a bounded finite* BHist *row over* M, Q, I *and is accepted only together with* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionNonescape`

Proof. Project the restricted-comprehension coordinate R from Definition 3668.1. The carrier describes R as a row admitting only classifiers already routed through M, Q, I.

Use Definition 3668.59 and Definition 3668.66. Both results keep the comprehension read inside the shared membership classifier and the subset implication route.

The structural rows H, C, P, N preserve and name that finite row. Since the packet has no coordinate for a powerset, unrestricted separation rule, host subset object, or universe of all subsets, restricted comprehension cannot export any of them. □

Theorem 3668.27 (SetLike membership route)**.** *Every downstream consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet that reads membership, subset implication, restricted comprehension, or extensional comparison must factor through the finite route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Consequently sibling reads by $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{ModelTheory}^{\uparrow}$ *may use* $\mathsf{SetLike}^{\uparrow}$ *only through the carried membership route, and cannot replace it by an ambient powerset, unrestricted comprehension principle, host quotient of sets, or external satisfaction relation.*

Proof. Begin with an accepted carrier $S = (M, Q, I, R, E, H, C, P, N)$. A membership consumer can reach an element-in-set assertion only by reading the source row M and the classifier row Q.

Subset and comprehension reads then remain inside the same boundary. The row I supplies finite implication between displayed membership classifiers, and R admits restricted comprehension only when the classifier has already passed through M, Q, I.

Extensional reads are likewise bounded. The row E permits comparison only through the displayed membership classifier, so it does not introduce quotient equality or an ambient host set identity.

Finally replay the structural rows. The rows H, C, P, N preserve, replay, source, and name the same finite route, while $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, and $\mathsf{ModelTheory}^{\uparrow}$ can cite the packet only through P and C. No sibling read therefore bypasses M, Q, I, R, E. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipRoute`

Theorem 3668.28 (SetLike kernel membership obligation)**.** *Every root consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *that reads membership must expose* M *as the* BHist *membership source and* Q *as the displayed membership classifier before any TypeLike, FirstOrder, or ModelTheory row is consumed. The read remains valid only through componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeKernelMembershipObligation`

Proof. Project the carrier and the membership carrier. Their membership-facing coordinates are exactly M, Q, H, C, P, N.

Apply the membership route theorem. It forces every downstream membership read through the displayed BHist source and classifier before sibling consumers can use the packet.

The structural tail is then read by projection. The rows H, C, P, N transport, replay, source, and locally name the same membership surface, so no host element relation, powerset row, or unrecorded classifier is introduced. □

Definition 3668.29 (SetLike root membership carrier)**.** *The root membership carrier of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet* $S = (M, Q, I, R, E, H, C, P, N)$ *is the finite* BHist *route*

$$M \longrightarrow Q \longrightarrow I \longrightarrow R \longrightarrow E,$$
$$H \longrightarrow C \longrightarrow P \longrightarrow N.$$

Here M *is the displayed membership source,* Q *is the classifier-based membership row,* I *records subset as implication of membership over* Q*,* R *records restricted comprehension only after* M, Q, I *are visible,* E *records the extensional boundary for the restricted result,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row.*

Lean4 (definition) `BEDC.Derived.SetlikeUp.SetlikeRootMembershipCarrier`
Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipCarrier route readback`

Theorem 3668.30 (SetLike root membership transport)**.** *Every root membership read of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet transports only the classifier-based membership surface of Definition 3668.29. A consumer that moves the read along* hsame *must replay* M, Q, I, R, E *through the displayed* Cont *row, preserve the* Pkg *provenance, and expose the same local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *rows before any TypeLike, FirstOrder, ModelTheory, or root-unblock consumer may use the membership judgment.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipTransport`

Proof. Project the carrier of Definition 3668.29. The only membership row is Q over the displayed BHist source M, while subset and comprehension rows are downstream of that classifier.

Use the existing membership, subset, and comprehension obligations in this surface. They keep membership reads on M, Q, subset reads on the implication row I, and restricted-comprehension reads on R, E.

The structural rows then provide the transport discipline. Componentwise hsame transport, Cont replay, Pkg provenance, and the local NameCert row preserve the same route, so no host powerset, quotient set equality, unrestricted separation principle, or carrier-equivalence replacement is introduced. □

Theorem 3668.31 (SetLike root subset ledger non-escape)**.** *For an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet, every subset ledger exported to a root consumer is the implication-of-membership row* I *from Definition 3668.29. The export must display classifier-based membership* M, Q*, restricted-comprehension boundary rows* R, E *when comprehension is read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *rows; it cannot escape to host inclusion, powerset equality, quotient set equality, or an unrestricted subset object.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootSubsetLedgerNonescape`

Proof. Read the subset coordinate I. Its source and target are classifier memberships over M, Q, so the ledger records implication of membership rather than an ambient inclusion relation.

When a comprehension consumer is present, read R only through the same M, Q, I route and then attach E as the displayed extensional boundary. This keeps restricted comprehension subordinate to the classifier ledger.

Finally project H, C, P, N. These rows transport, replay, source, and locally name the finite subset route, leaving no carrier coordinate for host inclusion, powerset equality, quotient equality, or unrestricted separation. □

Theorem 3668.32 (SetLike root comprehension scope)**.** *Every root comprehension consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet must treat comprehension as the restricted row* R *scoped by classifier-based membership* M, Q *and subset implication* I*. The consumer may read the extensional boundary* E*,* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row* N*, but it receives no unbounded predicate former, no host powerset, no quotient equality of sets, and no carrier-equivalence transport outside the displayed root route.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootComprehensionScope`

Proof. Start with the restricted-comprehension obligation already present in the child surface. It places R after the membership source, classifier, and subset implication rows.

Attach the extensional boundary E. The boundary describes the displayed restricted result only, and it remains tied to the same classifier-based membership route.

The structural tail H, C, P, N is then read without adding a new classifier or carrier. Thus the comprehension scope is exactly the finite SetLike root route and not an unrestricted separation, host powerset, quotient-set equality, or external subset object. □

Theorem 3668.33 (SetLike subset classifier obligation)**.** *Every accepted subset-classifier read of a* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must expose the* BHist *membership source* M*, membership classifier* Q*, subset implication row* I*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row* N*. It cannot replace the implication row by host inclusion, carrier-equivalence transport, quotient equality of sets, or an ambient powerset predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetClassifierObligation`

Proof. Start with the subset row I in the carrier. It is an implication over the displayed classifier Q and membership source M, not an external inclusion relation.

Use subset ledger exactness and classifier transport. These keep subset reads on the same M, Q, I route while H and C replay the displayed classifier rather than transporting across a different carrier.

Finally read P and N. Provenance and local naming expose the same finite packet to downstream consumers, so the subset classifier has no coordinate for powersets, quotient equality, host inclusion, or carrier-equivalence replacement. □

Theorem 3668.34 (SetLike comprehension ledger obligation)**.** *Every restricted-comprehension ledger read of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must expose* $M, Q, I, R, E, H, C, P, N$ *as one finite* BHist *route. The row* R *is admitted only after the membership source, classifier, and subset implication rows are visible; the row* E *records the resulting extensional boundary;* H, C, P, N *preserve, replay, source, and locally name that ledger.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeComprehensionLedgerObligation`

Proof. Project the carrier to the comprehension row R. By the restricted-comprehension factorization theorem, R is bounded by M, Q, I before the structural rows are read.

Attach the extensional boundary row E. The extensional-boundary route keeps comparison of the displayed comprehension result inside the same classifier ledger.

The final projection reads H, C, P, N. Componentwise transport, continuation replay, provenance, and local NameCert expose the ledger as one finite packet, with no powerset, unrestricted separation principle, host subset object, quotient set equality, or carrier-equivalence transport. □

Theorem 3668.35 (SetLike root extensional boundary)**.** *Every extensionality read exported by the* $\mathsf{SetLike}^{\uparrow}$ *root route is bounded by the displayed membership source* M*, classifier* Q*, subset row* I*, restricted-comprehension row* R*, extensional boundary* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row* N*. The export gives no host powerset equality, quotient set equality, unrestricted separation, carrier-equivalence replacement, or ambient equality of set-like carriers.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootExtensionalBoundary`

Proof. Project the root membership carrier of Definition 3668.29. Its extensional-facing row is E, and E is available only after the membership source, classifier, subset implication, and restricted-comprehension rows have been displayed.

Use the subset and comprehension obligations. The subset ledger keeps comparison on I over M, Q, while the comprehension ledger places R behind the same membership route and then attaches E as the boundary for the displayed restricted result.

Finally read H, C, P, N. These rows transport, replay, source, and locally name the same finite route, so the exported extensionality is the bounded root boundary rather than host powerset equality, quotient equality, unrestricted separation, carrier-equivalence replacement, or ambient equality of carriers. □

Theorem 3668.36 (SetLike root finite route package)**.** *Every FirstOrder, ModelTheory, TypeLike, or root logic consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet must read*

$$M, Q, I, R, E, H, C, P, N$$

as one finite BHist *route. The package exposes classifier-based membership, subset-as-implication, restricted comprehension, and the extensional boundary only through the displayed carrier of Definition 3668.29; it gives no host powerset, quotient set equality, unrestricted separation, carrier-equivalence replacement, or ambient equality of set-like carriers.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootFiniteRoutePackage`

Proof. Start with Definition 3668.30. It places every root membership read on M, Q and keeps downstream consumers inside the displayed transport, replay, provenance, and local naming rows.

Next apply Definition 3668.31 and Definition 3668.32. The subset ledger is the implication row I over the classifier membership surface, and the comprehension row R is available only after M, Q, I have been displayed.

Finally apply Definition 3668.35. The extensional row E remains tied to the same restricted-comprehension route, while H, C, P, N preserve the finite packet for logic consumers. Since the existing root obligations already exclude host powersets, quotient set equality, unrestricted separation, carrier-equivalence replacement, and ambient carrier equality, the packaged consumer boundary excludes them as well. □

Theorem 3668.37 (SetLike root type-model membership factorization)**.** *Every TypeLike, FirstOrder, and ModelTheory consumer of the* $\mathsf{SetLike}^{\uparrow}$ *root route factors membership through* M, Q*, subset through* I*, restricted comprehension through* R, E*, and structural preservation through* H, C, P, N *before any logic-facing judgment is exported. The factorization gives no host powerset, quotient set equality, unrestricted separation, carrier-equivalence replacement, or ambient equality of set-like carriers.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootTypeModelMembershipFactorization`

Proof. Start with the membership transport theorem. It forces each membership read to expose the displayed source M and classifier Q before a TypeLike, FirstOrder, or ModelTheory consumer can use the judgment.

Next apply subset non-escape and comprehension scope. The subset read is the implication row I over classifier membership, while restricted comprehension is admitted only through R together with the extensional boundary E.

Use the root extensional boundary and finite-route package. They keep the resulting logic-facing judgment inside M, Q, I, R, E and preserve it only through componentwise hsame transport, displayed Cont replay, provenance, and local naming rows H, C, P, N.

The excluded host powerset, quotient equality, unrestricted separation, carrier-equivalence replacement, and ambient carrier equality are not coordinates of this route. Hence no logic or model-theory consumer can export them from the root packet. □

Theorem 3668.38 (SetLike membership classifier non-escape)**.** *Every TypeLike, FirstOrder, and ModelTheory consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *root packet must keep membership on the displayed source and classifier rows* M, Q *and must preserve the structural rows* H, C, P, N *before exporting any logic-facing judgment. The consumer cannot replace classifier membership by host elementhood, powerset membership, quotient equality, carrier-equivalence transport, or an ambient set equality outside the root route.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipClassifierNonescape`

Proof. First apply the root membership transport theorem. It keeps every membership read on the displayed BHist source M and classifier row Q before any logic consumer may use the judgment.

Next use subset ledger non-escape and comprehension scope. The subset row remains the implication ledger I over classifier membership, while restricted comprehension is admitted only through R, E after the same M, Q, I route has been displayed.

Finally apply the type-model membership factorization theorem. It packages TypeLike, FirstOrder, and ModelTheory reads through $M, Q, I, R, E, H, C, P, N$, so the structural rows preserve the classifier route rather than transporting it to host elementhood, powerset membership, quotient equality, carrier-equivalence replacement, or ambient set equality. □

Theorem 3668.39 (SetLike membership classifier transport boundary)**.** *Every TypeLike, FirstOrder, or ModelTheory consumer that transports membership from an accepted* $\mathsf{SetLike}^{\uparrow}$ *root packet* $S = (M, Q, I, R, E, H, C, P, N)$ *must preserve the displayed route*

$$M, Q, I, R, E, H, C, P, N.$$

The transported read cannot replace Q *by host elementhood, powerset membership, quotient set equality, carrier-equivalence transport, or ambient set equality.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipClassifierTransportBoundary`

Proof. Start with the membership transport and membership classifier non-escape theorems. They keep the membership source on the displayed BHist row M and the classifier on Q before any TypeLike, FirstOrder, or ModelTheory consumer can read the judgment.

Next apply subset non-escape and restricted comprehension scope. The subset row is still the displayed implication row I, and the comprehension route remains confined to R, E over the same M, Q, I prefix.

Finally use the root extensional boundary and type-model membership factorization theorem. These force transport to proceed through H, C, P, N after the displayed classifier route has been exposed, so none of the excluded host elementhood, powerset, quotient, carrier-equivalence, or ambient set-equality routes is available as a replacement for Q. □

Theorem 3668.40 (SetLike root membership obligation)**.** *Every root consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet that attempts to read membership must display the route*

$$M, Q, H, C, P, N$$

before the membership judgment is available. The source row M supplies the carried membership surface, Q supplies the displayed membership classifier, and H, C, P, N transport, replay, source, and name the same route. The read exports no ambient powerset, unrestricted subset object, host equality of sets, quotient set equality, or universe-level membership relation.

Proof. Project the accepted carrier of Definition 3668.1. The only membership-facing source row is M, and the only classifier row attached to that source is Q.

Use Definition 3668.27. Any downstream membership read must factor through the displayed finite route before sibling consumers may cite the packet.

Finally read the structural rows. The rows H, C, P, N preserve, replay, source, and locally name the same membership surface, so the root consumer cannot replace it by a host powerset, quotient set equality, or universe-level membership relation. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipObligation`

Theorem 3668.41 (SetLike bounded comprehension family handoff)**.** *Every restricted-comprehension consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet reads a bounded family only through*

$$M, Q, I, R.$$

The membership source M, displayed classifier Q, implication ledger I, and restricted-comprehension row R together provide the bounded family handoff. The handoff does not supply unrestricted separation, a powerset carrier, quotient equality of subsets, selected representatives, or an external comprehension principle.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionFamilyHandoff`

Proof. Start from the restricted-comprehension row R in Definition 3668.1. It is a displayed packet coordinate and not a host comprehension operator.

Apply Definition 3668.53. The bounded family consumed by R is visible only after the membership source, classifier, and implication rows M, Q, I have been read.

The structural preservation clauses then keep the same bounded route under transport and replay. Since no row stores unrestricted separation, powersets, quotient subset equality, selected representatives, or an external comprehension principle, the consumer receives only the bounded family handoff. □

Theorem 3668.42 (SetLike TypeLike family nonescape)**.** *A* $\mathsf{TypeLike}^{\uparrow}$ *family consumer that cites a* $\mathsf{SetLike}^{\uparrow}$ *packet may use only the displayed rows*

$$M, Q, I, R, E, H, C, P, N$$

and cannot reinterpret the SetLike membership or family rows as a host universe, an ambient type of all subsets, quotient set equality, or external equality of family fibers.

Proof. Begin with the sibling read through the package row P. The $\mathsf{TypeLike}^{\uparrow}$ consumer receives a cited $\mathsf{SetLike}^{\uparrow}$ packet, not a replacement carrier for the host universe.

Apply Definition 3668.27 and Definition 3668.53. Membership, implication, bounded comprehension, and extensional comparison all remain inside M, Q, I, R, E before the structural rows are replayed.

Finally use H, C, P, N to transport, replay, source, and name that same route. These rows do not add a universe classifier, a powerset object, quotient set equality, or external equality of family fibers, so the TypeLike family read cannot escape the SetLike certificate surface. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypeLikeFamilyNonescape`

Theorem 3668.43 (SetLike root membership family exhaustion)**.** *Every root consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet that combines membership reads, bounded-comprehension family reads, and* $\mathsf{TypeLike}^{\uparrow}$ *family reads is exhausted by the displayed rows*

$$M, Q, I, R, E, H, C, P, N.$$

The combined route supplies membership, the bounded implication and comprehension handoff, extensional comparison, componentwise transport, continuation replay, package provenance, and local naming. It supplies no powerset, unrestricted separation, host universe, quotient set equality, selected representatives, or external family equality.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipFamilyExhaustion`

Proof. First apply Definition 3668.40. A root membership consumer must expose M, Q, H, C, P, N before it can read membership, and that route has no ambient powerset or host equality field.

Next apply Definition 3668.41. A restricted-comprehension consumer may add only the implication and bounded-comprehension rows I, R to the same displayed membership route.

Finally apply Definition 3668.42. A $\mathsf{TypeLike}^{\uparrow}$ family read may cite the SetLike packet only through $M, Q, I, R, E, H, C, P, N$ and cannot reinterpret those rows as a host universe, quotient set equality, selected representatives, or external equality of family fibers.

The three consumer routes therefore share the same finite row inventory. Their union is exactly $M, Q, I, R, E, H, C, P, N$, so no further family or set-forming coordinate is available to the root consumer. □

Definition 3668.44 (SetLike root carrier membership)**.** *For an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet* $S = (M, Q, I, R, E, H, C, P, N)$*, the root carrier membership read is the certified family route*

$$\begin{gathered} M \longrightarrow Q \longrightarrow I \longrightarrow R \longrightarrow E, \\ H \longrightarrow C \longrightarrow P \longrightarrow N. \end{gathered}$$

The row M is the finite BHist *membership source, Q is the classifier row over that source, I is subset implication between certified membership rows, R is bounded comprehension after the membership and subset rows are visible, E is the displayed extensional boundary, and H, C, P, N transport, replay, source, and locally name the same certified family packet.*

Lean4 (definition) `BEDC.Derived.SetlikeUp.SetlikeRootCarrierMembership`
Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootCarrierMembership route closed`

Theorem 3668.45 (SetLike root classifier transport)**.** *Every* hsame *or* Cont *transport of the root carrier membership read of Definition 3668.44 preserves the displayed membership classifier. A TypeLike, FirstOrder, ModelTheory, or root consumer that reads the transported packet receives* $M, Q, I, R, E, H, C, P, N$ *as one certified family route, and receives no host membership relation, ambient powerset, quotient equality of sets, selected representative, or external classifier.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootClassifierTransport`

Proof. Project the route of Definition 3668.44. The membership read is based on M and Q, while I, R, E are downstream ledger rows over the same classifier.

Use componentwise hsame transport and displayed Cont replay. These rows move the finite packet without replacing Q by a host relation or by a classifier over a different source.

Finally read P and N. Provenance and local naming expose the same certified family packet to downstream consumers, so TypeLike, FirstOrder, ModelTheory, and root consumers see only the transported SetLike route. □

Theorem 3668.46 (SetLike root NameCert obligations)**.** *The root* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *obligations for membership consumers are exactly carrier admission for Definition 3668.44, classifier transport for* M, Q*, bounded-comprehension ledger exposure for* I, R, E*, componentwise* hsame *and* Cont *preservation through* H, C*, provenance and local naming through* P, N*, and the boundary excluding host extensionality. Any root consumer that imports host set equality, ambient powersets, unrestricted separation, selected representatives, or an external membership classifier is outside the accepted packet.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootNameCertObligations`

Proof. Start with carrier admission. The definition presents the only membership carrier available to a root consumer: the finite route $M, Q, I, R, E, H, C, P, N$.

Apply classifier transport. It keeps membership reads on M, Q and makes H, C preserve the displayed classifier rather than a host membership relation.

Use the bounded-comprehension ledger rows. The subset and comprehension coordinates I, R, E are read only after the membership classifier is visible, so comprehension remains a finite BEDC ledger.

Finally attach provenance and local naming. Since P, N name only the displayed route, the accepted NameCert surface has no coordinate for host extensionality, powersets, unrestricted separation, selected representatives, or external classifiers. □

Theorem 3668.47 (SetLike membership classifier root unblock)**.** *Every downstream membership read of an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet exposes the membership source* M*, the classifier row* Q*, the transport row* H*, the replay row* C*, the provenance row* P*, and the local naming row* N *before the read may be consumed by a root dependency. The read therefore reaches TypeLike, FirstOrder, ModelTheory, or another root consumer only as the displayed finite membership classifier route, not as host membership, ambient powerset inclusion, unrestricted separation, quotient equality, or an external satisfaction relation.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipClassifierRootUnblock`

Proof. Project Definition 3668.44. The membership source and classifier are exactly M and Q, and no other row supplies a membership predicate.

Apply Definition 3668.27 and Definition 3668.45. They force every membership-facing read through the displayed carrier route and preserve the classifier under hsame transport and Cont replay.

Finally read the structural rows H, C, P, N. Provenance and local naming expose the same finite route to downstream consumers, so the root dependency cannot replace it by host membership, powersets, unrestricted separation, quotient equality, or external satisfaction. □

Theorem 3668.48 (SetLike subset comprehension root unblock)**.** *Every root read of subset implication or restricted comprehension for an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet must pass through the finite route* M, Q, I, R, H, C, P, N*:* M, Q *expose the displayed membership classifier,* I *exposes subset implication between those classified rows,* R *exposes restricted comprehension only after* M, Q, I *are visible, and* H, C, P, N *transport, replay, source, and locally name the same packet. The route exports no ambient powerset, unrestricted comprehension principle, host subset relation, selected representative, or quotient equality of sets.*

Proof. Start with the membership route of Definition 3668.27. Any subset or comprehension read is downstream of the displayed membership classifier M, Q.

Use the rows I and R from Definition 3668.44. The implication row compares certified membership rows, and the restricted-comprehension row is available only after that comparison has been displayed.

Finally apply Definition 3668.46. The structural rows H, C, P, N keep the same finite route available to root consumers and leave no coordinate for ambient powersets, unrestricted comprehension, host subset relations, selected representatives, or quotient equality. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetComprehensionRootUnblock`

Theorem 3668.49 (SetLike extensionality root unblock)**.** *Every extensional comparison exported by an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet is only the displayed classifier boundary* E *over the membership rows* M, Q *with support from* H, C, P, N*. A downstream root consumer may read that boundary as the packet's extensional comparison route, but it may not identify it with host set equality, quotient equality of sets, selected representatives, an ambient inclusion predicate, or an external extensionality principle.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalityRootUnblock`

Proof. Project the extensional boundary of Definition 3668.44. The row E is the only comparison coordinate, and it is tied to the same displayed membership source M and classifier Q.

Use the SetLike membership route and the root NameCert obligations. They make E available only after the carrier rows have exposed the membership classifier and the structural preservation rows.

Thus a root consumer receives an extensional boundary for the accepted packet, not host set equality. The rows H, C, P, N preserve and name that boundary without adding quotient equality, selected representatives, ambient inclusion, or external extensionality. □

Theorem 3668.50 (SetLike root membership provenance exhaustion)**.** *Every TypeLike, FirstOrder, ModelTheory, or root consumer of accepted* $\mathsf{SetLike}^{\uparrow}$ *membership must exhaust the finite route* $M, Q, I, R, E, H, C, P, N$ *before exporting membership, subset, comprehension, or extensionality rows. In particular, the provenance row* P *and the local naming row* N *are required before any of the displayed membership classifier, subset implication, restricted-comprehension, or extensional boundary rows may leave the root packet.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipProvenanceExhaustion`

Proof. Project Definition 3668.44. The only accepted membership carrier is the displayed route $M, Q, I, R, E, H, C, P, N$, with P and N attached to the same packet as the membership and comparison rows.

Apply Definition 3668.45 and Definition 3668.46. These results keep the membership classifier on M, Q under hsame transport and Cont replay, while requiring provenance and local naming before downstream reads can treat the route as a NameCert surface.

Use Definition 3668.47, Definition 3668.48, and Definition 3668.49. The membership, subset, comprehension, and extensionality exports are exactly the rows M, Q, I, R, E supported by H, C, P, N.

Thus any consumer that omits P or N has not exhausted the root route. The omitted coordinate would be precisely where host membership, powersets, unrestricted separation, selected representatives, quotient set equality, or external satisfaction could enter, so the accepted packet refuses that export. □

Theorem 3668.51 (SetLike root membership nonescape ledger)**.** *Every TypeLike, FirstOrder, ModelTheory, or root consumer that has exhausted the accepted* $\mathsf{SetLike}^{\uparrow}$ *route* $M, Q, I, R, E, H, C, P, N$ *can export only the membership, subset, restricted-comprehension, and extensional-boundary rows already displayed in the SetLike packet. Such a consumer cannot introduce host membership, ambient powersets, unrestricted separation, quotient equality, selected representatives, or external satisfaction.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipNonescapeLedger`

Proof. Start from Definition 3668.44. The carrier route exposes exactly the membership source M, classifier Q, subset row I, restricted-comprehension row R, extensional boundary E, transport H, replay C, provenance P, and local naming N.

Apply the root classifier and NameCert rows, Definition 3668.45 and Definition 3668.46. They keep the membership classifier on M, Q and confine the accepted NameCert surface to the displayed finite route.

Use the three root-unblock exports: Definition 3668.47, Definition 3668.48, and Definition 3668.49. These are exactly the membership, subset, restricted-comprehension, and extensional-boundary rows available to downstream root consumers.

Finally use provenance exhaustion from Definition 3668.50. Once P, N have been read, no remaining carrier coordinate can supply host membership, ambient powersets, unrestricted separation, quotient equality, selected representatives, or external satisfaction. Hence the ledger is exhausted by the displayed SetLike packet. □

Theorem 3668.52 (SetLike extensional boundary classifier lock)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, an extensional comparison read must expose the membership source* M*, the displayed classifier* Q*, the extensionality-boundary ledger* E*, and the structural rows* H, C, P, N *before any downstream consumer treats the comparison as available. The read is locked to the displayed classifier and cannot be replaced by host set equality, quotient equality, selected representatives, or an external inclusion predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalBoundaryClassifierLock`

Proof. Project the carrier of Definition 3668.1. The extensional read is the row E, and its only membership data are the source row M and classifier row Q.

Use Definition 3668.27. The route forces any membership-facing consumer to expose M, Q, I, R, E before the structural rows are replayed.

Finally apply the local carrier rows H, C, P, N. Transport, replay, provenance, and naming keep E attached to the same displayed classifier, so the comparison is not host set equality, quotient equality, selected representatives, or external inclusion. □

Theorem 3668.53 (SetLike bounded comprehension transport)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, restricted-comprehension transport remains inside the finite route*

$$M, Q, I, R, H, C, P, N.$$

It may read a bounded family only after the membership source, classifier, and subset implication rows are visible, and componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *naming preserve that bounded route without importing powersets, unrestricted separation, quotient equality, or an external comprehension principle.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionTransport`

Proof. Project the restricted-comprehension row R from Definition 3668.1. The row is part of the accepted finite packet and is not an ambient comprehension operator.

Apply Definition 3668.27. The bounded family consumed by R must already pass through M, Q, I before comprehension data are visible.

Transport is then componentwise. The rows H, C, P, N preserve, replay, source, and name the same bounded route, so the transported comprehension remains inside M, Q, I, R, H, C, P, N and cannot introduce the excluded host-level surfaces. □

Theorem 3668.54 (SetLike first-order membership handoff)**.** *Every* $\mathsf{FirstOrder}^{\uparrow}$ *consumer that receives membership data from an accepted* $\mathsf{SetLike}^{\uparrow}$ *packet receives it only through the displayed finite route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Thus first-order syntax may consume SetLike membership, subset implication, restricted comprehension, and extensional comparison only after the carrier route has been displayed, and it cannot import an ambient powerset, unrestricted comprehension principle, quotient equality of sets, selected representatives, or external satisfaction relation.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFirstOrderMembershipHandoff`

Proof. Start with Definition 3668.27. It states the exact finite route available to downstream $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, and $\mathsf{ModelTheory}^{\uparrow}$ consumers.

Project the carrier of Definition 3668.1. The rows M, Q, I, R, E are the only membership, subset, comprehension, and extensional comparison rows available before structural replay.

Finally replay H, C, P, N. These rows transport, replay, source, and name the same finite membership route for the $\mathsf{FirstOrder}^{\uparrow}$ consumer, so first-order syntax receives no independent powerset, unrestricted comprehension, quotient equality, selected representative, or external satisfaction surface. □

Theorem 3668.55 (SetLike finite-family membership route)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a finite family of membership reads accepted by* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{ModelTheory}^{\uparrow}$ *consumers is routed componentwise through the same displayed packet*

$$M, Q, I, R, E, H, C, P, N.$$

Each family member first reads the BHist *membership source M and classifier Q, then consumes subset implication I, bounded comprehension R, and the extensional boundary E before the shared transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^\uparrow}$ *rows may be used. The family route exports no ambient powerset, unrestricted separation, quotient equality of sets, selected representative, host elementhood relation, or external satisfaction predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFiniteFamilyMembershipRoute`

Proof. Project the accepted carrier and read the family one displayed member at a time. Carrier admission supplies the same finite rows $M, Q, I, R, E, H, C, P, N$ for every member, with no additional row indexed by the family.

Apply the membership route and the bounded-comprehension transport theorem. They force every member read to enter through M, Q and to use I, R only as bounded rows over that same classifier.

Finally use the extensional boundary classifier lock. The row E compares only displayed SetLike data, while H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no powerset, unrestricted separation, quotient-set equality, selector, host elementhood, or satisfaction row, a finite family cannot export one. □

Theorem 3668.56 (SetLike TypeLike consumer handoff)**.** *For every accepted* $\mathsf{SetLike}^\uparrow$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a* $\mathsf{TypeLike}^\uparrow$ *consumer receives SetLike membership as the classifier-bounded route M, Q together with the bounded-comprehension rows I, R, E and the structural tail H, C, P, N. The handoff preserves both the displayed membership classifier and the bounded-comprehension ledger; it cannot replace them by a host type predicate, an ambient powerset, unrestricted separation, quotient equality of sets, selected representatives, or a global elementhood oracle.*

Proof. Start with the membership route for downstream TypeLike, FirstOrder, and ModelTheory consumers. It gives the TypeLike consumer access to SetLike data only after the membership source, classifier, subset, comprehension, extensional, transport, replay, provenance, and local naming rows have been displayed.

Use the extensional boundary classifier lock to keep Q attached to the same source row M. Then use bounded-comprehension transport to keep I, R, E attached to that classifier route rather than an ambient type predicate or powerset.

The structural rows H, C, P, N complete the handoff by transporting, replaying, sourcing, and naming the same finite packet. Because no host type predicate, powerset, unrestricted separation, quotient equality, selector, or global elementhood coordinate occurs in the accepted carrier, the TypeLike consumer receives only the preserved SetLike route. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypeLikeConsumerHandoff`

Theorem 3668.57 (SetLike ModelTheory satisfaction boundary)**.** *For every accepted* $\mathsf{SetLike}^\uparrow$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a* $\mathsf{ModelTheory}^\uparrow$ *satisfaction consumer may read SetLike data only through the FirstOrder-facing finite route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

The boundary supplies displayed membership, classifier-bounded subset and comprehension rows, extensional comparison, componentwise transport, continuation replay, provenance, and local naming. It refuses external satisfaction predicates, powerset semantics, unrestricted separation, quotient equality of sets, selected representatives, host universes, and completed model-theoretic semantics.

Proof. First route the consumer through the FirstOrder membership handoff. The syntax-facing read exposes $M, Q, I, R, E, H, C, P, N$ before satisfaction-facing data can be consumed.

Next apply the root unblock for ModelTheory satisfaction. It keeps satisfaction downstream of the FirstOrder syntactic carrier and therefore downstream of the displayed SetLike membership classifier and bounded-comprehension ledger.

Finally use the finite-family route for any displayed family of satisfaction reads. Each member still reads the same rows, and the carrier has no external satisfaction predicate, powerset semantics, unrestricted separation, quotient equality, selector, host universe, or completed semantic closure coordinate. The ModelTheory boundary is therefore the finite BEDC packet itself. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeModelTheorySatisfactionBoundary`

Theorem 3668.58 (SetLike subset implication obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, an accepted subset read is an implication row* I *over the displayed membership classifier* Q *and the membership-source row* M*. The read is admitted as finite* BHist *data only when the componentwise* hsame *row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row* N *all keep the same implication surface visible; it cannot import host subset equality or a global inclusion relation outside those rows.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetImplicationObligation`

Proof. Project the carrier and isolate the subset row I. The only membership facts available to I are the source row M and the displayed classifier row Q.

Route the implication through the existing membership classifier. A consumer may read that an accepted membership assertion under one displayed row implies an accepted membership assertion under another, but the route is still the finite M, Q, I ledger.

The structural rows close the boundary. Transport by H, replay by C, provenance by P, and local naming by N preserve the same finite implication row, so no host subset equality or external inclusion predicate enters the packet. □

Theorem 3668.59 (SetLike bounded comprehension obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a comprehension read is admitted only through the restricted-comprehension row* R *bounded by a displayed certified family over* M, Q, I*. The resulting* BHist *row remains tied to componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *naming* N*, and therefore does not create a powerset or unrestricted separation principle.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionObligation`

Proof. Begin with the restricted-comprehension coordinate R. By Definition 3668.1, R is not an ambient class former; it is one row of the accepted finite packet.

The bound is supplied by the existing membership route. The source row M, classifier row Q, and implication row I determine which displayed family may be read before R is exposed.

Finally replay the structural rows. The rows H, C, P, N transport, replay, source, and name the same bounded family row, so the comprehension read remains finite BEDC data and never becomes a powerset, unrestricted separation rule, or host universe of subsets. □

Theorem 3668.60 (SetLike extensional boundary obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, extensional comparison is a boundary ledger* E *over displayed membership rows rather than quotient equality of sets. The comparison is accepted as* BHist *data*

only when its membership evidence is routed through M, Q, I, R and its stability is preserved by componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalBoundaryObligation`

Proof. Project the extensionality row E. It is a boundary ledger inside the carrier, not a quotient constructor and not a host equality of sets.

Use the existing membership classifier to supply the comparison evidence. A displayed extensional read compares membership rows already exposed through M, Q and routed through the subset and bounded-comprehension rows I, R.

The structural rows keep the boundary exact. Componentwise transport H, replay C, provenance P, and local naming N preserve the same displayed membership ledger, so no quotient equality, representative selection, or ambient set identity is exported. □

Definition 3668.61 (SetLike membership boundary subcarrier)**.** *For an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier*

$$S = (M, Q, I, R, E, H, C, P, N),$$

the membership-boundary subcarrier is the finite prefix

$$S_{\partial} = (M, Q, I, R, E).$$

It cuts out the membership source, classifier, subset implication, restricted-comprehension row, and extensionality-boundary ledger before transport, replay, provenance, and local naming are consumed. The subcarrier has no coordinate for powersets, unrestricted separation, quotient equality of sets, selected representatives, or host universe membership.

Lean4 (definition) `BEDC.Derived.SetlikeUp.SetlikeMembershipBoundarySubcarrier`

Theorem 3668.62 (SetLike extensional boundary route)**.** *Every extensional read of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier $S = (M, Q, I, R, E, H, C, P, N)$ must first factor through the membership-boundary subcarrier $S_{\partial} = (M, Q, I, R, E)$ and then through H, C, P, N. Thus an extensional consumer may compare displayed set rows only after the membership source, classifier, subset implication, restricted-comprehension boundary, extensionality ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row have all remained visible.*

Proof. Project the membership-boundary subcarrier of Definition 3668.61. It exposes exactly M, Q, I, R, E before any structural replay is used.

The extensional comparison is the row E. By Definition 3668.60, the comparison evidence must already be routed through the membership source, classifier, subset implication, and restricted-comprehension rows.

Finally replay the structural rows H, C, P, N. They transport, replay, source, and name the same finite boundary, so an extensional consumer cannot bypass M, Q, I, R, E or replace the displayed boundary by host set equality. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalBoundaryRoute`

Theorem 3668.63 (SetLike subset implication witness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier $S = (M, Q, I, R, E, H, C, P, N)$, the implication row I is the only subset witness available over the displayed membership classifier Q and membership source M. Any accepted subset read must keep I attached to M, Q, H, C, P, N and cannot replace it by powersets, unrestricted separation, quotient equality of sets, host subset equality, selected representatives, or an external inclusion predicate.*

Proof. Project the carrier of Definition 3668.1. The subset coordinate is exactly the row I, and the only membership data available to it are the source row M and displayed classifier row Q.

Use the membership route and subset obligation, Definition 3668.27 and Definition 3668.58. These force every subset consumer to read implication as finite carrier data over M, Q, I before the structural rows are replayed.

Finally replay through H, C, P, N. Since the carrier has no powerset, unrestricted separation, quotient-equality, selected-representative, host-subset, or external-inclusion coordinate, I is the only subset witness exposed by the packet. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetImplicationWitness`

Theorem 3668.64 (SetLike bounded comprehension witness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the restricted-comprehension row* R *is bounded by the displayed membership source* M*, classifier* Q*, and subset-implication row* I*. The row* R *witnesses only bounded comprehension inside that carrier route and cannot export powersets, unrestricted separation, quotient equality of sets, selected representatives, host subset objects, or an external comprehension principle.*

Proof. Project the carrier of Definition 3668.1. The comprehension coordinate is the row R, and its definition admits only classifiers already routed through M, Q, I.

Apply bounded-comprehension obligation and restricted-comprehension factorization, Definition 3668.59 and Definition 3668.75. They identify M, Q, I as the required bound before R may be read.

The structural rows H, C, P, N preserve and name that same bounded route. Because no other carrier row stores powersets, unrestricted separation, quotient equality, selected representatives, host subset objects, or external comprehension, R remains only the displayed bounded-comprehension witness. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionWitness`

Theorem 3668.65 (SetLike extensional boundary witness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the extensionality row* E *is only a classifier boundary over the displayed membership route* M, Q, I, R*. It may witness that two displayed set rows have the same carried classifier behavior, but it does not export host set equality, powersets, unrestricted separation, quotient equality of sets, selected representatives, or an equality oracle outside* $M, Q, I, R, E, H, C, P, N$*.*

Proof. Project the carrier of Definition 3668.1. The row E is an extensionality-boundary ledger, not a quotient constructor or host equality coordinate.

Use the extensional boundary obligation and route, Definition 3668.60 and Definition 3668.62. They force every extensional read through the membership source, classifier, subset implication, and restricted-comprehension rows before H, C, P, N are replayed.

Finally cite classifier extensional nonescape, Definition 3668.71. The displayed classifier boundary remains inside $M, Q, I, R, E, H, C, P, N$, so the refused powerset, unrestricted-separation, quotient-equality, selected-representative, host-equality, and equality-oracle readings cannot be exported. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalBoundaryWitness`

Theorem 3668.66 (SetLike subset-comprehension stability)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, subset implication through* I *and restricted comprehension through* R *share the same membership classifier* Q *over the membership source* M*. Any consumer that reads both rows must keep the common classifier visible through* H, C, P, N*, and the read cannot introduce a powerset row, unrestricted separation row, host subset equality, or an external comprehension principle.*

Proof. Start from the accepted carrier and its subcarrier $S_{\partial} = (M, Q, I, R, E)$. The rows I and R both sit inside the same finite boundary and have access only to the membership source M and classifier Q.

The subset implication row I reads implication between displayed membership classifiers. The restricted-comprehension row R may bind only a classifier already routed through M, Q, I; it therefore cannot choose a second classifier outside the packet.

The structural rows close the stability claim. Componentwise transport H, replay C, provenance P, and local naming N preserve the same classifier route for both I and R, so the combined read remains finite BHist data and does not become a powerset or unrestricted separation surface. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetComprehensionStability`

Theorem 3668.67 (SetLike membership carrier stability)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a membership read remains on the same finite carrier when transported by the componentwise* hsame *row* H *and replayed by* Cont *row* C*. More precisely, if a consumer reads membership through* M, Q *before transport, then every transported read is again a membership-source and classifier read through* M, Q, H, C, P, N*, not a new host element relation, powerset coordinate, or external equality predicate.*

Proof. Project the carrier of Definition 3668.1. The membership source M and classifier Q are the only rows from which an element-in-set read can be opened.

Apply the componentwise transport row H. Since H is recorded for M, Q, I, R, E together with the structural rows, it preserves the displayed membership source and classifier rather than replacing them by an ambient relation.

Finally replay through C and name the route through P, N. The continuation can expose only the transported M, Q rows, so the transported consumer remains inside the same finite BHist carrier and no host powerset or external equality predicate enters. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipCarrierStability`

Theorem 3668.68 (SetLike classifier transport exactness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, classifier transport is exact on the displayed membership surface: subset implication through* I*, restricted comprehension through* R*, and extensional comparison through* E *may use only the classifier* Q *transported by* H *and replayed by* C*. The transported classifier cannot be weakened to a proof-irrelevant host proposition or strengthened to an unrestricted comprehension classifier.*

Proof. Start with the classifier row Q. The subset, comprehension, and extensionality rows I, R, E are all described in Definition 3668.1 as rows over the same membership source and classifier.

Transport by H is componentwise. It therefore moves Q together with I, R, E and leaves no independent classifier coordinate from which a consumer could read a stronger or weaker predicate.

Replay by C exposes the same classifier route to downstream packets. Because P, N source and name only this finite packet, the transported classifier is exact: it remains the displayed membership classifier and does not become proof irrelevance, unrestricted separation, or a host proposition. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeClassifierTransportExactness`

Theorem 3668.69 (SetLike ledger scope closure)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the visible ledger scope for membership, subset implication, restricted comprehension, and extensional boundary reads is exactly the finite route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Every $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *consumer that leaves this route lacks the carrier rows needed for an accepted read, and every consumer that stays on the route has the full ledger scope required by the chapter.*

Proof. The forward direction is carrier projection. The rows M, Q, I, R, E are the complete membership-boundary prefix, and the rows H, C, P, N are the complete transport, replay, provenance, and local naming tail.

For nonescape, suppose a consumer leaves this route. It then omits either the membership source, the classifier, one of the subset/comprehension/extensional boundary rows, or one of the structural rows that preserves and names them. By Definition 3668.10, such a consumer lacks a required local obligation.

For closure inside the route, keep all nine rows visible. The earlier membership route, subset implication, bounded comprehension, extensional boundary, and subset ledger theorems each consume only these rows, so the displayed $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ ledger scope is exhausted by the route and no additional host coordinate is required. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeLedgerScopeClosure`

Falsifiable prediction: A consumer that claims a $\mathsf{SetLike}^{\uparrow}$ membership, subset, restricted-comprehension, or extensionality read while omitting the membership source, classifier, subset implication, restricted comprehension, extensionality boundary, hsame, Cont, Pkg, or local NameCert rows refutes the carrier of Definition 3668.1.

Independence witness: typelike, firstorder, modeltheory: $\mathsf{SetLike}^{\uparrow}$ is not bijective to any listed sibling because it carries membership source, classifier, subset implication, restricted comprehension, extensionality boundary, componentwise transport, continuation replay, provenance, and local NameCert rows. TypeLikeUp adds displayed indexed fibers beyond membership; FirstOrderUp adds syntax and deduction rows without membership-source extensionality; ModelTheoryUp adds satisfaction over FirstOrderUp without a general finite membership carrier.

Theorem 3668.70 (SetLike subset ledger obligation)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the subset ledger exposed to downstream consumers consists exactly of membership-carrier rows* M, Q*, subset-as-membership-implication rows* I*, restricted-comprehension provenance rows* R*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*, and the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *rows named through* P, N*. The ledger exports no host set extensionality, unrestricted comprehension, powerset row, quotient equality of sets, or external inclusion predicate.*

Proof. Project the accepted carrier in Definition 3668.1. The membership source M and displayed classifier Q are the only rows from which membership facts can be read.

Use the subset obligation of Definition 3668.58. The subset row I is an implication between displayed membership classifiers over M, Q, not a host inclusion relation.

Add the restricted-comprehension and extensional boundary controls from Definition 3668.59 and Definition 3668.60. The row R records only bounded comprehension provenance, while E remains a boundary ledger and does not export host set extensionality.

Finally replay Definition 3668.27. The structural rows H, C, P, N preserve and name the same finite route, so the subset ledger seen by downstream TypeLike, FirstOrder, and ModelTheory consumers contains no powerset, unrestricted comprehension, quotient equality, or external inclusion coordinate. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeSubsetLedgerObligation`

Theorem 3668.71 (SetLike classifier extensional nonescape)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the extensional row* E *can compare only displayed membership rows over* M, Q, I, R*. It cannot export quotient equality of sets, powersets, unrestricted separation, host set equality, or an external inclusion predicate; any accepted extensional read must keep* E *inside the structural route* H, C, P, N*.*

Proof. Project E from the carrier of Definition 3668.1. The carrier assigns E to the extensionality-boundary ledger, not to a quotient or host equality coordinate.

Use the extensional boundary route of Definition 3668.62. That theorem forces every extensional read through the membership-boundary subcarrier $S_{\partial} = (M, Q, I, R, E)$ before the structural rows are replayed.

Finally apply Definition 3668.68 and Definition 3668.70. Classifier transport stays on the displayed Q surface, and the downstream ledger exposes no powerset, unrestricted comprehension, quotient equality, or host inclusion coordinate. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeClassifierExtensionalNonescape`

Definition 3668.72 (SetLike extensional-subset carrier)**.** *For an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier*

$$S = (M, Q, I, R, E, H, C, P, N),$$

the extensional-subset subcarrier is the finite displayed comparison packet

$$S_{\subseteq\partial} = (M, Q, I, E, H, C, P, N).$$

Here M, Q *expose the membership source and classifier,* I *records subset-as-classifier implication,* E *records the extensional comparison boundary, and* H, C, P, N *transport, replay, source, and locally name the same displayed comparison. The subcarrier has no coordinate for host set equality, powersets, unrestricted separation, quotient equality of sets, or an external inclusion predicate.*

Lean4 (definition) `BEDC.Derived.SetlikeUp.SetlikeExtensionalSubsetCarrier`

Theorem 3668.73 (SetLike extensional-subset NameCert obligations)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, an accepted extensional-subset read through* $S_{\subseteq\partial}$ *requires exactly membership-source admission through* M*, classifier exposure through* Q*, subset implication through* I*, extensional-boundary exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *naming through* N*. It cannot require or export host set equality, powersets, unrestricted separation, quotient equality of sets, or an external inclusion predicate.*

Proof. Project the subcarrier of Definition 3668.72. The only comparison rows available before the structural tail are the membership source, classifier, subset implication, and extensional boundary.

Use the membership route and subset ledger obligation, Definition 3668.27 and Definition 3668.70. These force subset reads to remain implications over the displayed classifier rather than external inclusion predicates.

Apply classifier extensional nonescape and ledger scope closure, Definition 3668.71 and Definition 3668.69. The row E stays a boundary ledger over displayed membership rows, while H, C, P, N preserve and name the same route. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalSubsetNameCertObligations`

Theorem 3668.74 (SetLike extensional-subset transport)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, componentwise* hsame *transport and displayed* Cont *replay preserve the extensional-subset route*

$$M, Q, I, E \longmapsto H, C, P, N.$$

Thus a transported extensional-subset read remains the same classifier route and cannot become host set equality, a powerset read, unrestricted separation, quotient equality of sets, or an external inclusion predicate.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalSubsetTransport`

Proof. Start with the extensional-subset subcarrier of Definition 3668.72. It keeps only M, Q, I, E before structural replay, so the displayed classifier and implication rows determine the comparison.

Apply classifier transport exactness. The row H transports the displayed classifier surface componentwise, and C replays the same subset and extensional-boundary route rather than introducing a second inclusion relation.

Finally use the extensional-subset obligations of Definition 3668.73. Provenance and local naming through P, N keep the transported read inside the finite BHist packet, excluding host equality, powersets, unrestricted separation, quotient equality, and external inclusion. □

Theorem 3668.75 (SetLike restricted comprehension membership factorization)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, every restricted-comprehension read through* R *first factors through the membership source* M*, displayed classifier* Q*, and subset implication row* I*. Only after this factorization may the read use* H, C, P, N *for transport, replay, provenance, and local naming; it cannot create a powerset row, unrestricted separation principle, host subset object, or external comprehension predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRestrictedComprehensionMembershipFactorization`

Proof. Start with Definition 3668.59. It admits R only as a restricted-comprehension row bounded by a displayed certified family over M, Q, I.

The common classifier is fixed by Definition 3668.66. Subset implication through I and restricted comprehension through R share the membership classifier Q over the source M, so a comprehension read cannot skip the membership route.

Apply bounded comprehension nonescape and ledger scope closure, Definition 3668.26 and Definition 3668.69. The structural rows H, C, P, N preserve the displayed factorization and add no powerset, unrestricted separation, host subset object, or external comprehension coordinate. □

Theorem 3668.76 (SetLike TypeLike FirstOrder ModelTheory consumer boundary)**.** *Every* $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, *or* $\mathsf{ModelTheory}^{\uparrow}$ *consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must cite the SetLike route through*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Such a consumer cannot replace the route by external satisfaction, host membership, quotient equality of sets, a powerset row, unrestricted comprehension, or a host universe of sets.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypeLikeFirstOrderModelTheoryConsumerBoundary`

Proof. Use the membership route theorem Definition 3668.27. It already states that TypeLike, FirstOrder, and ModelTheory sibling reads may use $\mathsf{SetLike}^{\uparrow}$ only through the carried membership route.

Next apply the subset ledger obligation and classifier extensional nonescape, Definition 3668.70 and Definition 3668.71. These results keep subset, comprehension, and extensionality reads on M, Q, I, R, E before H, C, P, N are used.

Finally invoke Definition 3668.69. A consumer leaving the displayed route lacks the required carrier rows, while a consumer staying on it receives the complete local ledger. Therefore external satisfaction, host membership, quotient equality, powersets, unrestricted comprehension, and host universes are outside the accepted SetLike consumer boundary. □

Theorem 3668.77 (SetLike root unblock for FirstOrder signatures)**.** *Every* $\mathsf{FirstOrder}^{\uparrow}$ *signature consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must factor membership, subset, restricted-comprehension, and extensional-boundary reads through the displayed route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

The signature consumer may use this route as the SetLike membership base for syntactic symbols, arities, relation slots, and bounded classifier reads, but it cannot replace the route by host set membership, an ambient universe of sets, a powerset row, unrestricted comprehension, or quotient equality of sets.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootUnblockFirstOrderSignature`

Proof. Project the accepted carrier of Definition 3668.1. The only SetLike data available to a signature consumer are the membership source, classifier, subset implication, restricted comprehension, extensional boundary, transport, replay, provenance, and local naming rows.

Use the membership route theorem Definition 3668.27. It forces FirstOrder sibling reads through the carried membership route before syntax can consume SetLike membership, subset, comprehension, or extensional comparison data.

Apply classifier transport and extensional boundary routing, Definition 3668.12 and Definition 3668.62. The syntactic consumer receives transported displayed classifiers and displayed boundary ledgers, not host elementhood, ambient universes, powersets, unrestricted comprehension, or quotient equality. □

Theorem 3668.78 (SetLike root unblock for ModelTheory satisfaction)**.** *Every* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *may read SetLike data only through the classifier-based membership route and the* $\mathsf{FirstOrder}^{\uparrow}$ *syntactic carrier that consumes that route. The satisfaction-facing read must keep* $M, Q, I, R, E, H, C, P, N$ *visible, and cannot import an external satisfaction relation, quotient equality of sets, host powerset, unrestricted comprehension, or ambient host universe.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootUnblockModelTheorySatisfaction`

Proof. Start from Definition 3668.1. The carrier has no satisfaction row of its own; it exposes only the SetLike membership source, classifier, subset, restricted-comprehension, extensional-boundary, transport, replay, provenance, and local-name rows.

Use Definition 3668.27. A ModelTheory consumer can cite SetLike only through the same classifier-based route already available to TypeLike and FirstOrder siblings, so satisfaction cannot read an independent element relation.

Now apply Definition 3668.12 and Definition 3668.62. Transport preserves the displayed classifier route, and extensional reads remain boundary ledgers over M, Q, I, R, E before H, C, P, N are replayed. The satisfaction consumer therefore obtains SetLike data only through the FirstOrder syntactic carrier built on that route, with no external satisfaction relation, quotient equality, host powerset, unrestricted comprehension, or ambient universe. □

Theorem 3668.79 (SetLike kernel membership source totality)**.** *Every accepted* $\mathsf{SetLike}^{\uparrow}$ *membership consumer must expose the full kernel membership source before any TypeLike, FirstOrder, or ModelTheory read is available. Concretely, the consumer must display M as the finite* BHist *membership source, Q as the membership classifier row, H as the componentwise* hsame *transport ledger, C as the displayed* Cont *replay, P as the* Pkg *provenance row, and N as the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row.*

Proof. Start with the carrier of Definition 3668.1. The carrier lists $M, Q, I, R, E, H, C, P, N$, so any accepted membership read has M, Q, H, C, P, N available as displayed rows.

Use the membership route theorem Definition 3668.27. It forces TypeLike, FirstOrder, and ModelTheory consumers through the carried membership route before they may read typed, syntactic, or satisfaction-facing data.

Finally apply the consumer boundary of Definition 3668.76. A consumer lacking M, Q, H, C, P, N has left the displayed route, while a consumer staying inside the route exposes exactly the kernel membership source and structural rows. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeKernelMembershipSourceTotality`

Theorem 3668.80 (SetLike restricted comprehension kernel scope)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier $S = (M, Q, I, R, E, H, C, P, N)$, the restricted-comprehension row R is admitted only over the displayed membership source M, classifier Q, and subset implication row I. The row R cannot export a powerset, unrestricted separation, a host subset family, or an external comprehension predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRestrictedComprehensionKernelScope`

Proof. Apply the restricted-comprehension membership factorization theorem Definition 3668.75. It already factors every R read through M, Q, I before structural replay.

Use bounded comprehension nonescape from Definition 3668.26. This blocks powerset, unrestricted separation, host subset objects, and external comprehension predicates from the comprehension row.

The ledger scope closure theorem Definition 3668.69 then repacks the result through H, C, P, N. Thus R remains a kernel-scoped row over M, Q, I and not an escaping separation principle. □

Theorem 3668.81 (SetLike extensional ledger kernel nonescape)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier $S = (M, Q, I, R, E, H, C, P, N)$, extensional comparison through E is a visible ledger over*

the membership, classifier, subset, and restricted-comprehension rows. It is not quotient equality of sets, host extensionality, selected representatives, or an equality oracle outside $M, Q, I, R, E, H, C, P, N$.

Proof. Begin with the extensional boundary route Definition 3668.62. It routes extensional reads through the membership-boundary subcarrier before structural replay.

Apply classifier extensional nonescape from Definition 3668.71. The extensional comparison remains attached to the displayed classifier and cannot become quotient equality or host extensionality.

Finally use the TypeLike FirstOrder ModelTheory consumer boundary Definition 3668.76. Downstream consumers receive the visible ledger $M, Q, I, R, E, H, C, P, N$ and no equality oracle outside it. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalLedgerKernelNonescape`

Theorem 3668.82 (SetLike extensional-boundary consumer exactness)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, any* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{ModelTheory}^{\uparrow}$ *consumer of a SetLike extensional comparison must read exactly*

$$M, Q, I, R, E, H, C, P, N.$$

The row E *remains the displayed extensional-boundary ledger over the membership, classifier, subset, and restricted-comprehension route. It cannot be replaced by host set equality, quotient equality, powerset equality, unrestricted separation, or any equality oracle outside the accepted packet.*

Proof. Begin with the extensional boundary route Definition 3668.62. It makes E a boundary row over M, Q, I, R before the structural tail H, C, P, N is replayed.

Use the classifier transport route Definition 3668.12. Transport by H preserves the displayed classifier route and does not substitute a host equality predicate, quotient equality, powerset equality, or unrestricted separation row for E.

Apply ledger scope closure Definition 3668.69. The membership, classifier, subset, comprehension, and extensional rows are repacked with H, C, P, N as one finite BEDC ledger.

Finally use the TypeLike FirstOrder ModelTheory consumer boundary Definition 3668.76. A downstream consumer that reads the extensional comparison therefore receives exactly $M, Q, I, R, E, H, C, P, N$, while any attempted replacement for E leaves the accepted $\mathsf{SetLike}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeExtensionalBoundaryConsumerExactness`

Theorem 3668.83 (SetLike membership carrier root surface)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the membership-facing root surface seen by* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, and* $\mathsf{ModelTheory}^{\uparrow}$ *is exactly the finite* BHist *carrier*

$$S_{\in} = (M, Q, H, C, P, N).$$

Here M *is the displayed membership source,* Q *is the membership classifier,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ *row. The surface exports no powerset, host elementhood, quotient equality of sets, unrestricted comprehension, selected representatives, or external satisfaction predicate.*

Proof. Project the accepted carrier and the membership carrier of Definition 3668.2. The only rows retained in $S_\in$ are M, Q, H, C, P, N.

Use the membership route theorem Definition 3668.27. It forces TypeLike, FirstOrder, and ModelTheory consumers to enter through the carried membership source and classifier before any sibling read is available.

Finally apply membership carrier stability and the consumer boundary, Definition 3668.67 and Definition 3668.76. Componentwise transport and continuation replay keep the read inside the same BHist route, while provenance and local naming certify that no host element relation, powerset, quotient equality, unrestricted comprehension, selected representative, or external satisfaction row has been inserted. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipCarrierRootSurface`

Theorem 3668.84 (SetLike membership classifier stability)**.** *For every accepted* $\mathsf{SetLike}^\uparrow$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the membership classifier* Q *remains stable under the complete displayed route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Subset implication through I*, bounded comprehension through* R*, and extensional comparison through* E *may consume* Q *only as the same classifier over the same* BHist *source* M*. A* $\mathsf{FirstOrder}^\uparrow$*,* $\mathsf{TypeLike}^\uparrow$*, or* $\mathsf{ModelTheory}^\uparrow$ *consumer therefore receives a stable SetLike classifier, not a proof-irrelevant host predicate, ambient powerset classifier, unrestricted separation rule, or external satisfaction relation.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeMembershipClassifierStability`

Proof. Start with classifier transport exactness, Definition 3668.68. It states that I, R, E consume the displayed membership classifier Q and that transport by H does not replace it with a second predicate.

Next use subset-comprehension stability and extensional ledger nonescape, Definition 3668.66 and Definition 3668.81. These keep the subset, comprehension, and comparison rows attached to the same M, Q route.

The structural tail is supplied by C, P, N. By the TypeLike, FirstOrder, and ModelTheory consumer boundary, any downstream read that omits this tail is not an accepted SetLike read, and any downstream read that keeps it receives only the stable displayed classifier. □

Theorem 3668.85 (SetLike bounded comprehension ledger)**.** *For every accepted* $\mathsf{SetLike}^\uparrow$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the bounded-comprehension ledger is the finite route*

$$M, Q, I, R \longmapsto E, H, C, P, N.$$

The row R *records only comprehension over classifiers already exposed by the membership source* M*, membership classifier* Q*, and subset-implication row* I*; the extensional ledger* E *can compare only the displayed result. Thus FirstOrder syntax, TypeLike family data, and ModelTheory satisfaction may consume the ledger only through* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, with no powerset, unrestricted separation, host subset object, quotient set equality, or external comprehension predicate.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeBoundedComprehensionLedger`

Proof. Apply restricted-comprehension membership factorization, Definition 3668.75. It factors every R read through M, Q, I before the structural rows are available.

Use bounded comprehension nonescape and the extensional boundary route, Definition 3668.26 and Definition 3668.62. The first keeps R from becoming a powerset or unrestricted separation principle; the second keeps any comparison of the displayed result inside E over the same classifier route.

Finally replay ledger scope closure and the sibling consumer boundary, Definition 3668.69 and Definition 3668.76. The FirstOrder, TypeLike, and ModelTheory consumers therefore receive only the finite BEDC ledger $M, Q, I, R, E, H, C, P, N$ and no host comprehension or quotient-set coordinate. □

Theorem 3668.86 (SetLike TypeLike signature scope)**.** *Let $S = (M, Q, I, R, E, H, C, P, N)$ be an accepted $\mathsf{SetLike}^{\uparrow}$ packet. Any TypeLike, FirstOrder, or ModelTheory consumer that reads S as a set-like signature must first read the membership source row M, membership classifier row Q, subset implication row I, restricted-comprehension row R, extensional boundary row E, componentwise transport row H, continuation row C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$ row N. The signature read exports no ambient powerset, unrestricted separation, quotient equality of sets, selected representative, or host equality oracle outside $M, Q, I, R, E, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypelikeSignatureScope`

Proof. Start with the membership route of Definition 3668.27. It makes M and Q the visible source of every membership read before a typed, syntactic, or satisfaction-facing consumer can inspect the packet.

Next apply restricted comprehension factorization from Definition 3668.75 and the kernel scope theorem Definition 3668.80. These force R to remain a row over M, Q, I rather than a powerset or unrestricted separation principle.

Finally use the consumer boundary of Definition 3668.76 together with the extensional ledger nonescape theorem Definition 3668.81. The downstream TypeLike, FirstOrder, and ModelTheory reads receive exactly $M, Q, I, R, E, H, C, P, N$, and no external set-equality or comprehension coordinate is available. □

Theorem 3668.87 (SetLike typed-comprehension kernel envelope)**.** *For every accepted $\mathsf{SetLike}^{\uparrow}$ carrier $S = (M, Q, I, R, E, H, C, P, N)$, a typed-comprehension read is accepted only as the finite BEDC envelope*

$$M, Q, I, R \longmapsto H, C, P, N.$$

Here M is the BHist membership source, Q is the classifier-bounded membership row, I is subset implication over that classifier, and R is restricted comprehension over the same displayed rows. The envelope cannot be read as an ambient powerset, a host universe, unrestricted separation, quotient equality of sets, or an external comprehension predicate.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypedComprehensionKernelEnvelope`

Proof. Project the carrier. The rows M, Q, I, R are the only membership, classifier, subset, and restricted-comprehension data before the structural tail.

Use restricted-comprehension membership factorization and restricted-comprehension kernel scope. These results force R to remain bounded by M, Q, I rather than becoming an unrestricted separation or powerset row.

Finally replay the structural route through H, C, P, N. Since no carrier coordinate stores an ambient powerset, host universe, quotient equality, or external comprehension predicate, the accepted typed-comprehension read is exactly the finite BEDC envelope. □

Theorem 3668.88 (SetLike FirstOrder membership substitution boundary)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a* $\mathsf{FirstOrder}^{\uparrow}$ *substitution consumer may substitute membership only through the displayed classifier route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

The substitution boundary is classifier-bounded over BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and it cannot import host membership, an ambient universe of sets, unrestricted comprehension, quotient equality, or an external satisfaction relation.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeFirstOrderMembershipSubstitutionBoundary`

Proof. Start with SetLike TypeLike signature scope. It exposes $M, Q, I, R, E, H, C, P, N$ before any syntactic consumer may read the packet as a signature.

Apply the typed-comprehension kernel envelope. The comprehension side of the substitution remains bounded by M, Q, I, R, and the extensional row E stays a boundary ledger over the same classifier route.

Use the FirstOrder signature root unblock theorem. A substitution consumer that leaves $M, Q, I, R, E, H, C, P, N$ lacks the displayed SetLike base, so host membership, ambient universes, unrestricted comprehension, quotient equality, and external satisfaction remain outside the accepted boundary. □

Theorem 3668.89 (SetLike ModelTheory satisfaction envelope)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, a* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction consumer may read SetLike data only after the* $\mathsf{FirstOrder}^{\uparrow}$ *syntax has consumed the classifier-bounded membership and typed-comprehension route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Thus satisfaction sees a BEDC envelope over displayed membership, restricted comprehension, extensional boundary, transport, replay, provenance, and local naming rows, not an ambient powerset, host universe, quotient set equality, unrestricted separation, or external satisfaction predicate.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeModelTheorySatisfactionEnvelope`

Proof. Read the ModelTheory satisfaction root unblock theorem. It already routes satisfaction-facing use through the classifier-based membership route and the FirstOrder syntactic carrier.

Next use FirstOrder membership substitution boundary. The syntactic carrier receives only $M, Q, I, R, E, H, C, P, N$, so the satisfaction consumer inherits the same classifier-bounded envelope.

Finally apply typed-comprehension kernel envelope and extensional ledger kernel nonescape. The comprehension and extensional rows remain finite BEDC ledgers, and no ambient powerset, host universe, quotient set equality, unrestricted separation, or external satisfaction predicate is available. □

Theorem 3668.90 (SetLike root-unblock kernel membership envelope)**.** *Every* $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{ModelTheory}^{\uparrow}$, *or* $\mathsf{TypeLike}^{\uparrow}$ *consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *reads membership only through the finite kernel envelope*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

Here M *is the displayed* BHist *membership carrier,* Q *is the classifier-bounded membership row,* I *is the subset-implication ledger,* R *is the bounded-comprehension row,* E *is the extensional-boundary row, and* H, C, P, N *provide componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. The envelope does not expose host set extensionality, quotient membership, unbounded comprehension, or an ambient universe of sets.*

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootUnblockKernelMembershipEnvelope`

Proof. Start with the SetLike root-unblock theorem and the TypeLike signature scope. These routes expose the membership carrier M, classifier row Q, subset implication ledger I, bounded-comprehension row R, extensional-boundary row E, and the structural tail H, C, P, N before any typed consumer can read the packet.

For FirstOrder consumers, apply the FirstOrder membership substitution boundary. For ModelTheory consumers, apply the ModelTheory satisfaction envelope. Both routes pass through the same classifier-bounded membership and typed-comprehension rows before syntax or satisfaction can use SetLike data.

Finally use typed-comprehension kernel envelope and extensional ledger kernel nonescape. The bounded-comprehension and extensional-boundary rows remain displayed BEDC rows, while H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores host set extensionality, quotient membership, unbounded comprehension, or an ambient universe of sets, every listed consumer receives exactly the finite kernel membership envelope. □

Theorem 3668.91 (SetLike root membership triple unblock)**.** *Every* $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{ModelTheory}^{\uparrow}$, *and* $\mathsf{TypeLike}^{\uparrow}$ *consumer that reads membership from an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must enter through the shared BEDC membership source* M *and classifier row* Q *before it can consume syntax, satisfaction, or carrier-transport data. The common read is the finite route*

$$M, Q \longmapsto I, R, E, H, C, P, N.$$

It cannot be replaced by host elementhood, an ambient powerset, unrestricted separation, quotient equality, an external satisfaction predicate, or a selected element.

Proof. Start with the membership carrier root surface and classifier stability. They make M, Q the only membership source and classifier available to the three downstream consumers.

For syntactic use, apply the FirstOrder membership substitution boundary. For satisfaction use, apply the ModelTheory satisfaction envelope. For carrier transport, apply the TypeLike signature scope.

Finally use the root-unblock kernel membership envelope. All three reads are repacked through the same $M, Q, I, R, E, H, C, P, N$ ledger, so none of them has a coordinate for host elementhood, powersets, unrestricted separation, quotient equality, external satisfaction, or selected elements. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipTripleUnblock`

Theorem 3668.92 (SetLike root membership source triple)**.** *For an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, the row* M *is the single source-admission row for* $\mathsf{FirstOrder}^{\uparrow}$ *formulas,* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction rows, and* $\mathsf{TypeLike}^{\uparrow}$ *carrier transport. Each consumer may read* M *only together with the classifier* Q *and the structural rows* H, C, P, N*, and no consumer may import a second membership source, host universe, quotient-set source, unrestricted separation domain, or selected representative.*

Proof. Project the membership carrier $S_{\in} = (M, Q, H, C, P, N)$ from Definition 3668.83. It exposes one source row M and one classifier row Q.

Use classifier stability and the TypeLike signature scope. They force typed transport and syntactic reads to keep the same source while H, C, P, N replay and name the packet.

Apply the ModelTheory satisfaction envelope for satisfaction-facing reads. Since satisfaction is downstream of the FirstOrder syntax carrier, it inherits the same M, Q, H, C, P, N source admission and cannot add a host universe, quotient source, unrestricted domain, or selected representative. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootMembershipSourceTriple`

Theorem 3668.93 (SetLike root comprehension ledger triple)**.** *For every accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$*, bounded comprehension remains a ledger-filtered membership route for* $\mathsf{FirstOrder}^{\uparrow}$*,* $\mathsf{ModelTheory}^{\uparrow}$*, and* $\mathsf{TypeLike}^{\uparrow}$ *consumers:*

$$M, Q, I, R \longmapsto E, H, C, P, N.$$

The row R *may be read only after* M, Q, I *are visible, and its result may be compared only through* E *before transport, replay, provenance, and local naming. The route exports no ambient powerset, unrestricted separation, quotient equality, host subset object, external comprehension predicate, or choice of elements.*

Proof. Begin with the bounded-comprehension ledger and the typed-comprehension kernel envelope. They place R after the membership source, membership classifier, and subset-implication rows.

Next apply the FirstOrder membership substitution boundary and ModelTheory satisfaction envelope. Syntax and satisfaction can consume comprehension only through the same classifier-bounded ledger.

Finally use TypeLike signature scope and the root-unblock kernel membership envelope. Typed carrier transport receives the same $M, Q, I, R, E, H, C, P, N$ route, while powersets, unrestricted separation, quotient equality, host subset objects, external comprehension predicates, and element choices remain outside the accepted packet. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeRootComprehensionLedgerTriple`

Theorem 3668.94 (SetLike type-model membership envelope)**.** *Every* $\mathsf{TypeLike}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, and* $\mathsf{ModelTheory}^{\uparrow}$ *consumer of an accepted* $\mathsf{SetLike}^{\uparrow}$ *carrier* $S = (M, Q, I, R, E, H, C, P, N)$ *must read membership, bounded comprehension, extensional boundary, transport, replay, provenance, and local naming as the single finite route*

$$M, Q, I, R, E \longmapsto H, C, P, N.$$

No such consumer may replace this route by host membership, an ambient powerset, unrestricted separation, quotient equality, or external satisfaction.

Proof. Begin with the root membership triple and the root comprehension ledger triple, Definition 3668.91 and Definition 3668.93. They expose M, Q, I, R, E before any typed, syntactic, or satisfaction-facing consumer can read the packet.

For syntactic consumers, apply the FirstOrder membership substitution boundary, Definition 3668.88. For satisfaction consumers, apply the ModelTheory satisfaction envelope, Definition 3668.89. For typed-family consumers, use TypeLike signature scope, Definition 3668.86.

The three routes share the same structural tail H, C, P, N. Since the accepted carrier stores no coordinate for host membership, powersets, unrestricted separation, quotient equality, or external satisfaction, the displayed route is the only membership envelope available to all three consumers. □

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikeTypeModelMembershipEnvelope`

Theorem 3668.95 (SetLike public NameCert export)**.** *The public* $\mathsf{SetLike}^{\uparrow}$ *export is exactly the finite route*

$$M, Q, I, R, E, H, C, P, N.$$

Membership reads expose M, Q, subset reads expose I, restricted-comprehension reads expose R, extensional-boundary reads expose E, and all public consumers pass through the structural rows H, C, P, N. The export contains no powerset coordinate, unrestricted separation principle, host quotient equality of sets, selected representative row, global choice coordinate, or external universe of all sets.

Lean4 ✓ `BEDC.Derived.SetlikeUp.SetlikePublicNameCertExport`

Proof. Start from the carrier of Definition 3668.1. Its displayed rows are precisely $M, Q, I, R, E, H, C, P, N$, so every public read must be assembled from those rows before any downstream consumer can name a $\mathsf{SetLike}^{\uparrow}$ packet.

The membership route theorem Definition 3668.27 supplies the public read for M, Q, H, C, P, N. The subset ledger obligation Definition 3668.70 and the bounded comprehension obligation Definition 3668.59 add I and R without adding a powerset or unrestricted separation coordinate.

Finally, the extensional-boundary consumer exactness theorem Definition 3668.82 fixes E as a displayed boundary row rather than host quotient equality. The TypeLike, FirstOrder, and ModelTheory consumer boundary keeps sibling consumers on the same nine-row route, so the public export is exactly $M, Q, I, R, E, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SetLike}^{\uparrow}$ packet is generated from a finite membership source, classifier row, subset implication row, restricted-comprehension row, extensionality-boundary ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 3668.1, Definition 3668.10, the membership, subset, bounded-comprehension, extensional-boundary, TypeLike, FirstOrder, and ModelTheory consumer-boundary rows, and Definition 3668.95 bind the mature paper surface from the finite SetLike membership carrier to its public consumer export.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SetLike}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: This chapter does not claim an ambient powerset, unrestricted separation, quotient equality of sets, selected representatives, global choice of elements, Lean verification, bridge checking, or a host universe of all sets.

Upgrade path: Bridge checking requires Lean verification of the same carrier, consumer-boundary rows, and public export for BEDC.Derived.SetLikeUp.

Chapter 3669

A Concrete Naming Certificate for $\mathsf{SchauderBasis}^{\uparrow}$

Following Schauder and the Banach-space basis tradition, the $\mathsf{SchauderBasis}^{\uparrow}$ packet records a sequence of named basis vectors together with finite coordinate projections and partial-sum controls. It sits over the linear carrier of chapter 47, the norm row of chapter 89, the Banach-space completion surface of chapter 90, the finite-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives basis expansions a finite NameCert surface before any coordinate functional or projection budget is consumed.

Definition 3669.1 (Schauder basis carrier)**.** *A* $\mathsf{SchauderBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, Nrm, B, C, S, E, R, H, T, P, L)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row naming the vector-space carrier, addition, scalar action, zero vector, and finite linear-combination syntax.*
2. *Nrm is the* $\mathsf{Norm}^{\uparrow}$ *row naming the norm, triangle budget, scalar-compatibility budget, and zero-detection surface.*
3. *B is the basis-vector stream row, a* $\mathsf{StreamName}^{\uparrow}$ *finite-window record whose inspected entries name the vectors $b_0, b_1, \ldots$ available to the packet.*
4. *C is the coordinate-readback row, recording finite coordinate requests and their* $\mathsf{RegSeqRat}^{\uparrow}$ *rational names.*
5. *S is the partial-sum row, recording finite sums $\sum_{i<n} c_i b_i$ together with the requested truncation index.*
6. *E is the error-control row, a* $\mathsf{Real}^{\uparrow}$*-facing norm estimate for the tail between the named vector and the displayed partial sum.*
7. *R is the reconstruction row, recording that each accepted vector read is recovered through the displayed partial sums and tail estimates.*
8. *H records componentwise* hsame *transport for the vector, norm, basis stream, coordinate, partial-sum, error, reconstruction, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from a coordinate request through B, C, S, E, R.*

10. *P records* Pkg *provenance over* $\mathsf{SchauderBasis}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{SchauderBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, Nrm, B, C, S, E, R, H, T, P, L$. It has no coordinate for a Hamel basis choice, an arbitrary linear functional, a detached coefficient oracle, ambient compactness, countable choice, or a global unconditional-basis assertion.

Lean4 ✓ `BEDC.Derived.SchauderBasisUp.SchauderBasisTasteGate single carrier alignment`

Theorem 3669.2 (Schauder basis NameCert obligations)**.** *For every accepted* $\mathsf{SchauderBasis}^{\uparrow}$ *carrier $K = (V, Nrm, B, C, S, E, R, H, T, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{SchauderBasis}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, vector-space exposure through V, norm exposure through Nrm, basis-stream exposure through B, coordinate readback through C, partial-sum exposure through S, tail-error control through E, reconstruction through R, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through L.*

Proof. Carrier admission is coordinate projection from Definition 3669.1. The accepted packet exposes the vector-space carrier, norm row, basis-vector stream, coordinate readback, partial sums, tail-error estimates, reconstruction row, transport, replay, provenance, and local naming.

The analytic route is fixed by V, Nrm, B, C, S, E, R. The vector row supplies the finite linear-combination syntax, the norm row supplies the tail metric, the basis stream supplies inspected vectors, the coordinate row supplies rational names, the partial-sum row supplies the finite approximants, the error row supplies the Real-facing tail estimate, and the reconstruction row binds those finite approximants to the named vector.

The structural rows H, T, P, L preserve that same route under transport, replay, provenance, and naming. Since the carrier has no coordinate for a Hamel basis choice, detached coefficient oracle, arbitrary functional, compactness substitute, countable-choice schedule, or unconditional-basis assertion, those objects cannot belong to the local NameCert surface. □

Theorem 3669.3 (Schauder basis coordinate-projection handoff)**.** *Every coordinate-projection consumer of an accepted* $\mathsf{SchauderBasis}^{\uparrow}$ *packet must read the projection through the basis stream B, coordinate row C, partial-sum row S, tail-error row E, reconstruction row R, replay row T, provenance row P, and local name L. The handoff exports finite coordinate projections and norm-controlled partial sums, but it exports no standalone bounded linear functional, no choice of representatives outside the displayed stream, and no unconditional convergence claim.*

Proof. Start with a coordinate-projection request. The carrier definition places the visible projection data in B, C, S, E, R: the basis vectors are inspected through the stream row, coordinates are read through regular rational names, partial sums are formed in the vector-space row, and the tail is measured by the norm and Real-facing estimate.

Next use the replay and provenance rows. The replay row T requires the consumer to traverse the displayed coordinate and partial-sum route, while P records that the route belongs to the $\mathsf{SchauderBasis}^{\uparrow}$ packet and its Banach-space dependencies.

Finally the local name L certifies only that displayed route. Because the packet has no coordinate for arbitrary functionals, detached coefficient selection, ambient compactness, or unconditional convergence, a coordinate-projection consumer receives only the finite projection handoff governed by B, C, S, E, R, T, P, L. □

Falsifiable prediction: Every accepted $\mathsf{SchauderBasis}^{\uparrow}$ coordinate-projection export factors through a VecSpace carrier row, Norm row, StreamName basis-vector window, RegSeqRat coordinate readback, finite partial-sum row, Real tail estimate, reconstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: banach, vecspace, norm, streamname, regseqrat, real: no listed sibling supplies the whole packet $K = (V, Nrm, B, C, S, E, R, H, T, P, L)$, because the Schauder basis carrier binds linear syntax, norm control, basis windows, rational coordinate readback, finite partial sums, tail estimates, reconstruction, transport, replay, provenance, and local naming in one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderBasis}^{\uparrow}$ packet is generated from a vector-space row, norm row, basis-vector StreamName window, RegSeqRat coordinate readback, finite partial-sum row, Real tail estimate, reconstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchauderBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3669.1, Definition 3669.2, and Definition 3669.3 seed the Schauder basis route from Banach-space carrier data to finite coordinate projections and norm-controlled partial sums.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchauderBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Hamel bases, arbitrary linear functionals, detached coefficient oracles, ambient compactness, countable choice, unconditional convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, basis-window exposure, coordinate-readback exactness, partial-sum control, tail-error control, reconstruction, projection handoff, and non-escape rows for the displayed Schauder basis packet.

Chapter 3670

A Concrete Naming Certificate for $\mathsf{RationalCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalCauchyCompletion}^{\uparrow}$ packet records the rational Cauchy completion route as finite regular-name data rather than as a quotient of rational sequences or a selected ambient limit. It sits between the rational source of chapter 37, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet gives the L10 completion route a concrete carrier before later formalization reads it as a derived Lean surface.

Definition 3670.1 (Rational Cauchy completion carrier)**.** *A* $\mathsf{RationalCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, D, S, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row, recording the rational endpoints and rational difference witnesses supplied to the completion route.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording finite dyadic radii, slack comparisons, and tolerance budgets.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording inspected requests and omitted-tail boundaries for the source rational stream.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational name produced by the displayed windows and tolerances.*
5. *M is the explicit Cauchy-modulus row, a finite schedule assigning every requested tolerance a displayed tail threshold.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, D, S, R, M have been displayed.*
7. *H records componentwise* hsame *transport for the rational source, dyadic tolerance, stream window, regular readback, modulus, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through Q, D, S, R, M, E.*
9. *P records* Pkg *provenance over* $\mathsf{RationalCauchyCompletion}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, S, R, M, E, H, C, P, N$. It has no coordinate for quotient sequence equality, selected representatives, countable choice, detached limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RationalCauchyCompletionUp.RationalCauchyCompletionTasteGate single carrier alignment`

Theorem 3670.2 (Rational Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{RationalCauchyComplet}$ *carrier $K = (Q, D, S, R, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalCauchyCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, rational-source exposure through Q, dyadic tolerance exposure through D, finite-window exposure through S, regular readback through R, explicit Cauchy-modulus control through M, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is coordinate projection from Definition 3670.1. The accepted packet exposes the rational source, dyadic tolerance ledger, finite stream window, regular rational readback, explicit modulus, terminal Real seal, transport, replay, provenance, and local naming rows.

The analytic route is fixed by Q, D, S, R, M, E. The source row Q supplies rational endpoints, D supplies dyadic tolerance comparisons, S exposes only finite observations, R records the regular rational readback, M binds each requested tolerance to a displayed tail threshold, and E seals the resulting Real-facing read.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and naming. Since the carrier has no coordinate for quotient sequence equality, selected representatives, countable choice, detached limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those objects cannot belong to the local NameCert surface. □

Theorem 3670.3 (Rational Cauchy completion diagonal seal handoff)**.** *Every diagonal completion read from a* $\mathsf{RationalCauchyCompletion}^{\uparrow}$ *packet to a* $\mathsf{Real}^{\uparrow}$ *consumer factors through the same finite route*

$$\mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The explicit modulus row M is the only row that may choose tail thresholds for the diagonal, and the terminal seal E exports only the regular rational readback named by R.

Proof. Start with a Real-facing diagonal read. The carrier definition places the terminal seal in coordinate E, and E is downstream of the source, tolerance, stream, readback, and modulus rows.

Trace the read backward. A diagonal tolerance request is served by M, interpreted through the dyadic row D, inspected through the finite-window row S, and returned as the regular rational readback R from the rational source Q.

Finally H, C, P, N transport, replay, package, and name the same displayed route. There is no separate coordinate for a selected limit, quotient stream equality, countable choice schedule, or host real equality, so every accepted diagonal handoff reaches $\mathsf{Real}^{\uparrow}$ only through Q, D, S, R, M, E. □

Falsifiable prediction: Every accepted $\mathsf{RationalCauchyCompletion}^{\uparrow}$ Real-facing read factors through a Rat source row, DyadicRatCore tolerance row, StreamName finite-window row, RegSeqRat readback row, explicit Cauchy-modulus row, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the whole packet $K = (Q, D, S, R, M, E, H, C, P, N)$, because the completion carrier binds

source rationals, dyadic tolerances, finite windows, regular readback, explicit modulus, terminal sealing, transport, replay, provenance, and local naming in one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCauchyCompletion}\uparrow}$.

Constructive story: A $\mathsf{RationalCauchyCompletion}^{\uparrow}$ packet is generated from a Rat source row, DyadicRatCore tolerance row, StreamName finite-window row, RegSeqRat readback row, explicit Cauchy modulus, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalCauchyCompletion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3670.1, Definition 3670.2, and Definition 3670.3 seed the rational Cauchy completion route from rational source data to the Real seal through finite tolerance, window, readback, modulus, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalCauchyCompletion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient sequence equality, selected representatives, countable choice, detached limits, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic tolerance exposure, finite-window exposure, regular readback, explicit modulus control, Real-seal handoff, and non-escape rows for the displayed rational Cauchy completion packet.

Chapter 3671

A Concrete Naming Certificate for $\mathsf{CompactMetricClosedBall}^{\uparrow}$

Following Bishop and Bridges constructive compact metric practice, the $\mathsf{CompactMetricClosedBall}^{\uparrow}$ packet consumes chapter 3464, chapter 129, chapter 57, chapter 127, chapter 128, and chapter 38. It names the finite-net surface of a closed ball inside a displayed compact metric carrier; it does not turn the ball into a host subset, choose a finite subcover, quotient points, or import ambient real completeness.

Definition 3671.1 (Compact metric closed ball carrier)**.** *A* $\mathsf{CompactMetricClosedBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, c, r, M, F, T, C, H, P, N)$$

with the following visible rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the shared metric carrier, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net family, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *complete-limit family over one point classifier.*
2. *c is the displayed center row carried by the same metric source.*
3. *r is the* $\mathsf{Real}^{\uparrow}$ *radius row together with its nonnegative-radius ledger.*
4. *M is the* $\mathsf{ClosedMetricBall}^{\uparrow}$ *membership row, recording the comparison $d(c, x) \leq r$ for each displayed point row x that enters the ball surface.*
5. *F is the finite-net row obtained by restricting a* $\mathsf{TotallyBounded}^{\uparrow}$ *ProbeBundle-net request to centers whose coverage route remains inside the closed-ball membership row M.*
6. *T is the total-bounded handoff row that records the tolerance request, bundled centers, membership constructors, coverage distances, and rational comparison ledgers inherited from the compact metric source.*
7. *C is the complete-limit inheritance row: every carried Cauchy name whose observations remain inside M is routed through the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit witness of X and returns a limit row still admitted by M.*
8. *H records componentwise* hsame *transport for the compact metric source, center, radius, closed-ball membership, finite-net row, total-bounded handoff, complete-limit inheritance, and structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricClosedBall}^{\uparrow}$, $\mathsf{ClosedMetricBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricClosedBall}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected finite subcover, quotient balls, host subsets, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactMetricClosedBallUp.CompactMetricClosedBallTasteGate single carrier alignment`

Theorem 3671.2 (Compact metric closed ball finite-net obligations)**.** *For an accepted* $\mathsf{CompactMetricClosedBall}^{\uparrow}$ *carrier* $K = (X, c, r, M, F, T, C, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactMetricClosedBall}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the compact metric source X, center c, radius r, closed-ball membership row M, finite-net row F, total-bounded handoff T, complete-limit inheritance row C, transport row H, provenance row P, and local naming row N;*
2. *closed-ball membership stability, requiring the comparison $d(c, x) \leq r$ to transport through the metric classifier, the* $\mathsf{Real}^{\uparrow}$ *radius ledger, and the* $\mathsf{ClosedMetricBall}^{\uparrow}$ *row M;*
3. *finite-net extraction inside the closed ball, requiring each displayed tolerance request to read bundled centers, membership constructors, coverage distances, and rational comparison rows through F and T without leaving M;*
4. *completion inheritance for carried Cauchy names, requiring every Cauchy thread whose observations are admitted by M to use the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness family of X and return a limit row still admitted by the same closed-ball comparison;*
5. *ledger nonescape, stating that no open-cover compactness theorem, selected subcover, quotient ball, host subset, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row is exported by the packet.*

Proof. Project the carrier of Definition 3671.1. The tuple lists exactly the compact metric source, center, radius, closed-ball membership row, finite-net row, total-bounded handoff, complete-limit inheritance, transport, provenance, and local naming row.

Membership stability is inherited from the displayed metric and closed-ball surfaces. The row M supplies the center-radius comparison, X supplies the metric classifier and distance rows, and the radius row r supplies the $\mathsf{Real}^{\uparrow}$ comparison ledger. Transport through H preserves the same comparison rather than replacing it by a host subset predicate.

For a positive tolerance request, read the $\mathsf{TotallyBounded}^{\uparrow}$ family inside X and then restrict the resulting ProbeBundle route through F. The handoff row T records the bundled centers, membership constructors, coverage distances, and rational comparison ledgers that remain inside the closed-ball membership row M.

For a carried Cauchy name, use only the complete-limit family already present in X. The inheritance row C states that observations admitted by M are handed to the complete-metric limit witness and that the returned limit row is checked again by the same center-radius comparison.

The remaining structural rows H, P, N transport, source, and name this finite route. Since the carrier inventory contains no open-cover object, subcover selector, quotient-ball constructor, host subset, countable-choice row, or ambient real-completeness row, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricClosedBall}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactMetricClosedBall}^{\uparrow}$ packet is generated from a $\mathsf{CompactMetric}^{\uparrow}$ source row, center row, $\mathsf{Real}^{\uparrow}$ radius row, $\mathsf{ClosedMetricBall}^{\uparrow}$ membership row, restricted finite-net row, total-bounded handoff, complete-limit inheritance, componentwise hsame transport, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompactMetricClosedBall}^{\uparrow}}$, seed)

Scope closed: Definition 3671.1 and Definition 3671.2 seed the finite closed-ball compact-metric NameCert surface for displayed center-radius packets.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactMetricClosedBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice of subcover, quotient balls, host subsets, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, membership stability, finite-net extraction inside the closed ball, completion inheritance for carried Cauchy names, and ledger nonescape.

Chapter 3672

A Concrete Naming Certificate for RegularCauchyProductCriterion$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the RegularCauchyProductCriterion$^{\uparrow}$ packet isolates the finite sufficiency criterion by which two regular rational Cauchy source rows produce a product read suitable for the CauchyProductCriterion$^{\uparrow}$ surface. It sits between the pointwise regular product carrier of chapter 461 and the synchronized product criterion of chapter 1586. The chapter records the L10 Real and Completion handoff as finite NameCert data, not as host multiplication of completed reals, quotient equality of streams, a selected product limit, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 3672.1 (Regular Cauchy product criterion carrier)**.** *A* RegularCauchyProductCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, W_A, W_B, D, P, K, R, E, H, C, L, N)$$

with the following displayed rows:

1. *A and B are the two* RegSeqRat$^{\uparrow}$ *source rows whose scheduled rational observations supply the regular Cauchy inputs.*
2. *W_A and W_B are synchronized* StreamName$^{\uparrow}$ *window rows for the same precision request and product observation index.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *product-budget row, recording input tolerances, visible endpoint magnitude bounds, cross-error terms, and the output tolerance assigned to the product read.*
4. *P is the* RegularCauchyProduct$^{\uparrow}$ *route row, read only after A, B, W_A, W_B, D have been displayed.*
5. *K is the* CauchyProductCriterion$^{\uparrow}$ *sufficiency row, certifying that the displayed product route is adequate for the downstream criterion.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row produced by the route P under the budget D and criterion row K.*
7. *E is the* Real$^{\uparrow}$ *seal row, consumed only after the regular-rational readback R has been displayed.*
8. *H records componentwise* hsame *transport for $A, B, W_A, W_B, D, P, K, R, E, C, L, N$ and the local packet shape.*
9. *C records displayed* Cont *replay from the two source rows through the synchronized windows, dyadic product budget, regular product route, criterion row, readback row, and real seal.*

10. *L is the* Pkg *provenance over* $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{CauchyProductCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W_A, W_B, D, P, K, R, E, H, C, L, N$. It has no coordinate for host multiplication of completed reals, quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyProductCriterionUp.RegularCauchyProductCriterionTasteGate single carrier alignment`

Theorem 3672.2 (Regular Cauchy product criterion NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ *carrier $Q = (A, B, W_A, W_B, D, P, K, R, E, H, C, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductCriterion}^{\uparrow}}$ *obligations are exactly carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic product-budget exactness, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route, the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *sufficiency row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, component-wise transport through H, displayed continuation replay through C, provenance through L, and local naming through N.*

Proof. Carrier admission is projection from Definition 3672.1. The displayed packet lists the two source rows, synchronized windows, dyadic budget, product route, criterion row, readback row, real seal, and structural rows.

The source and window obligations are read from A, B, W_A, W_B. These rows display the regular rational inputs and the shared product window before any product observation reaches the criterion.

The dyadic product-budget obligation is the row D. It records finite tolerance and magnitude data, so the route P is a budgeted regular Cauchy product route rather than host multiplication of completed real names.

The rows K, R, E are the downstream sufficiency, regular-rational, and real-seal boundaries. Transport through H, replay through C, provenance through L, and local naming through N preserve the same route and introduce no additional coordinate.

Thus the listed rows exhaust the local certificate surface. □

Theorem 3672.3 (Regular Cauchy product criterion window-budget exactness)**.** *For an accepted* $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ *carrier, the synchronized source windows W_A, W_B and the dyadic row D determine the product-budget data consumed by the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route P and the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *row K. Every downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of the product factors through*

$$A, B \longmapsto W_A, W_B \longmapsto D \longmapsto P \longmapsto K \longmapsto R.$$

No additional budget rule is read from a quotient stream, a selected product limit, countable choice, trichotomy, host real multiplication, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyProductCriterionUp.RegularCauchyProductCriterionCarrier window budget exactness`

Proof. Read the two regular rational source rows through the synchronized windows. The rows W_A and W_B expose the finite observations used by the product request at the same displayed precision.

The row D is the only dyadic product-budget row in the packet. It supplies the tolerance and endpoint-bound data consumed by the regular product route P.

The sufficiency row K then certifies that the displayed route is acceptable for the Cauchy product criterion. Since the readback row R occurs only after P and K, every regular-rational product read factors through the displayed chain.

The carrier has no coordinate for any excluded budget source, so the budget exactness is internal to the finite packet. □

Theorem 3672.4 (Regular Cauchy product criterion Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ *carrier factors through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route, the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *sufficiency row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the displayed* hsame *transports,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductCriterion}^{\uparrow}}$ *row. Hence the terminal seal is a finite product-sufficiency object, not host multiplication, quotient stream equality, a selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The real-facing consumer can read only E as the terminal $\mathsf{Real}^{\uparrow}$ seal row. In the carrier, E is downstream of R, and R is downstream of the criterion route through P and K.

Apply the window-budget exactness theorem. It places the readback route on the finite chain from the two source rows through the synchronized windows, dyadic product budget, product route, criterion row, and regular-rational readback.

The structural rows H, C, L, N preserve that same chain under transport, replay, provenance, and local naming. They do not add a second source for the real seal.

Therefore every terminal read remains inside the displayed finite criterion, and the excluded host, quotient, selector, choice, order, and completeness routes cannot be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyProductCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ packet is generated from two RegSeqRat source rows, synchronized StreamName windows, a DyadicRatCore product budget, a RegularCauchyProduct route, a CauchyProductCriterion sufficiency row, a RegSeqRat readback row, a RealUp seal row, componentwise transport, displayed continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3672.1, Definition 3672.2, Definition 3672.3, and Definition 3672.4 seed the finite L10 product-sufficiency object between RegularCauchyProduct and CauchyProductCriterion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host multiplication of completed reals, quotient streams, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window admission, dyadic product-budget exactness, RegularCauchyProduct routing, CauchyProductCriterion sufficiency, RegSeqRat readback, Real seal handoff, transport stability, continuation replay, and provenance non-escape for BEDC.Derived.RegularCauchyProductCriterionUp.

Chapter 3673

A Concrete Naming Certificate for $\mathsf{BishopMetricSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopMetricSpace}^{\uparrow}$ packet names a metric presentation whose distances are read through displayed regular rational approximations, finite stream windows, and real-name seals. It sits between the abstract metric certificate of chapter 57, the positive-separation interface of chapter 3505, the finite observation surface of chapter 126, the regular rational route of chapter 301, and the sealed real-name consumer of chapter 38. The packet is a constructive metric object for Real and completion-facing consumers; it is not a host metric-space structure, quotient completion, choice-selected limit, or ambient classical distance oracle.

Definition 3673.1 (Bishop metric-space carrier)**.** *A* $\mathsf{BishopMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, D, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the displayed point-name row and local carrier admission surface.*
2. *D is the metric-distance row, read as a* $\mathsf{Real}^{\uparrow}$ *name rather than as a host real-valued function.*
3. *S stores the* $\mathsf{StreamName}^{\uparrow}$ *finite windows used to observe the distance name.*
4. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback of each displayed distance.*
5. *A is the* $\mathsf{MetricApartness}^{\uparrow}$ *handoff row, present when a positive distance window exports apartness.*
6. *H stores componentwise* hsame *transport for point names, distance rows, stream windows, regular rational readbacks, apartness handoff, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from point-name reads through the distance, stream, regular rational, apartness, and Real-seal rows.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricApartness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, D, S, R, A, H, C, P, N$. It has no coordinate for host equality of points, host-valued distance functions, quotient completion, choice-selected limits, total boundedness, compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.BishopMetricSpaceUp.BishopMetricSpaceTasteGate single carrier alignment`

Theorem 3673.2 (Bishop metric-space NameCert obligations)**.** *For every accepted* $\mathsf{BishopMetricSpace}^{\uparrow}$ *carrier*

$$M = (X, D, S, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed point names, Real-valued distance rows, finite stream windows, regular rational readbacks, optional positive-distance apartness handoff, componentwise transport, displayed replay, package provenance, and local naming row.*

Proof. Project the carrier of Definition 3673.1. The projection exposes point-name rows X, distance rows D, stream windows S, regular readbacks R, and the apartness handoff A.

The distance row is Real-facing because every inspected distance is routed through S and R before it reaches the $\mathsf{Real}^{\uparrow}$ seal. Thus no consumer can replace the displayed constructive distance with a host-valued function.

The apartness handoff is confined to A. It can be exported only when the displayed distance window supplies positive separation, and the transport rows H, C replay that same finite route.

Finally P and N record provenance and local naming for exactly these rows. Since the carrier has no coordinate for host point equality, quotient completion, selected limits, compactness, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 3673.3 (Bishop metric-space located Cauchy route)**.** *Every completion-facing read of an accepted* $\mathsf{BishopMetricSpace}^{\uparrow}$ *packet factors through*

$$X, D \longmapsto S, R \longmapsto A, H, C, P, N.$$

Thus a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer may inspect a Cauchy or locatedness claim only through displayed distance windows, regular rational readbacks, optional apartness handoff, transport, replay, provenance, and local naming.*

Proof. Begin with the point-name and distance rows X, D. They name the metric input but do not by themselves expose a Real-valued oracle.

The stream and regular rational rows S, R provide the finite observation route for the distance name. Any located Cauchy read must therefore pass through those rows before it reaches a Real-facing consumer.

The rows A, H, C, P, N preserve the same route under apartness handoff, componentwise transport, replay, provenance, and local naming. A claim using quotient completion, selected limits, host equality of points, compactness, total boundedness, or ambient completeness has no carrier coordinate and leaves the packet. □

Theorem 3673.4 (Bishop metric-space distance-window exactness)**.** *Let* $M = (X, D, S, R, A, H, C, P, N)$ *be an accepted* $\mathsf{BishopMetricSpace}^{\uparrow}$ *packet. Every accepted read of a distance row factors through the displayed route*

$$D \longmapsto S \longmapsto R \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the distance consumed by a $\mathsf{Real}^{\uparrow}$*-facing or completion-facing reader is the finite StreamName window and RegSeqRat readback of* D*, not a host-valued metric function or an ambient distance oracle.*

Proof. Project the carrier of Definition 3673.1. The row D is present only as the displayed metric-distance row, while S and R are the StreamName and RegSeqRat rows attached to that distance.

Apply Definition 3673.2. Its local certificate surface lists distance rows, finite stream windows, regular rational readbacks, transport, replay, provenance, and local naming as the exact obligations for accepted packets.

Finally use Definition 3673.3. Any Real-facing or completion-facing read must pass through the same S, R windows before it reaches a Real consumer, so no host-valued metric function can replace the displayed route. □

Theorem 3673.5 (Bishop metric-space apartness handoff)**.** *Let $M = (X, D, S, R, A, H, C, P, N)$ be an accepted* $\mathsf{BishopMetricSpace}^{\uparrow}$ *packet. Apartness can be exported from M only through the displayed positive-distance row A, and only after the same distance-window route*

$$D \longmapsto S \longmapsto R$$

has supplied the positive separation read. The handoff cannot be replaced by host inequality of points or by an apartness predicate detached from the displayed distance data.

Proof. Read the carrier in Definition 3673.1. The row A is the only MetricApartness handoff coordinate, and the carrier contains no separate host point-equality or host inequality field.

Apply Definition 3673.2. The certificate surface makes the apartness row optional and ties it to positive-distance evidence transported with the same componentwise rows H and C.

Use Definition 3673.3 to identify the upstream read. Since every completion-facing distance claim goes through D, S, R before the structural rows, the exported apartness handoff is exactly the displayed row A downstream of those windows. □

Theorem 3673.6 (Bishop metric-space Real-seal nonescape)**.** *Let $M = (X, D, S, R, A, H, C, P, N)$ be an accepted* $\mathsf{BishopMetricSpace}^{\uparrow}$ *packet. Every Real-facing consumer of a distance row receives only the finite route*

$$D \longmapsto S \longmapsto R \longmapsto \mathsf{Real}^{\uparrow}$$

together with the structural rows A, H, C, P, N when they are displayed. The packet exports no quotient completion, selected limit, host point equality, total boundedness, compactness, or ambient completeness principle.

Proof. Start from Definition 3673.1. The accepted packet exposes point names, a distance row, finite windows, regular readbacks, optional apartness, transport, replay, provenance, and local naming, and it has no coordinate for the excluded objects.

Apply Definition 3673.2. The local NameCert admits exactly those displayed rows and refuses host-valued distance functions, quotient completion data, selected limits, compactness, total boundedness, and ambient completeness.

Apply Definition 3673.3. The Real-facing read stays on the finite StreamName and RegSeqRat path before it reaches the seal, so the consumer cannot escape into any object outside the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopMetricSpace}^{\uparrow}$ packet is generated from displayed point names, Real-valued distance rows, StreamName finite windows, RegSeqRat regular rational readbacks, optional MetricApartness handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3673.1, Definition 3673.2, and Definition 3673.3 seed the constructive metric carrier, finite NameCert obligations, and located Cauchy route for Real and completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{BishopMetricSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, compactness, total boundedness, host equality of points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distance-window exactness, regular rational readback, apartness handoff, located Cauchy routing, and TasteGate field faithfulness for BEDC.Derived.BishopMetricSpaceUp.

Chapter 3674

A Concrete Naming Certificate for $\mathsf{BishopSpace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, a Bishop space is read through finite observation windows, explicit metric evidence, and constructive continuity data rather than through a host set with ambient point equality. The $\mathsf{BishopSpace}^{\uparrow}$ packet records that interface as a NameCert surface on the L10 Phase Real and Completion route: it starts from the metric witness of chapter 57, hands distance reads to the located metric-space route of chapter 3685, and keeps the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows visible before any completion-facing consumer reads the packet.

Definition 3674.1 (Bishop-space carrier)**.** *A* $\mathsf{BishopSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, M, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the local point-observation row. It contains only finite observation windows and the classifier used by the packet; it is not a host equality relation on an ambient set.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, recording the metric witness consumed by each accepted observation pair.*
3. *L is the* $\mathsf{LocatedMetricSpace}^{\uparrow}$ *handoff row. It routes each metric read through located-distance evidence before the read can be used by a completion-facing consumer.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the located metric read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the displayed stream-name windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the regular readback.*
7. *H records componentwise* hsame *transport for X, M, L, W, R, E and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from point observations to metric witnesses, then through located reads, stream windows, regular readbacks, and real seals.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopSpace}^\uparrow}$ *row.*
The carrier has no coordinate for host point equality, quotient completion, selected limits, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopSpaceUp.BishopSpaceTasteGate single carrier alignment`

Theorem 3674.2 (Bishop-space NameCert obligations)**.** *For every accepted* $\mathsf{BishopSpace}^\uparrow$ *carrier*

$$B = (X, M, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSpace}^\uparrow}$ *surface consists exactly of carrier admission for the displayed observation row, metric-source readback through M, located metric-space handoff through L, finite stream-window exposure through W, regular rational readback through R, real-seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 3674.1. The point-observation row X supplies the finite observation windows and the local classifier, while the metric source row M supplies the distance witness inspected by each accepted observation pair.

The located handoff is the role of L. It forces each distance read onto the $\mathsf{LocatedMetricSpace}^\uparrow$ route before the read can open completion-facing data.

The L10 readback obligations are then W, R, E. Row W displays the finite $\mathsf{StreamName}^\uparrow$ windows, row R packages those windows as $\mathsf{RegSeqRat}^\uparrow$ data, and row E exposes the $\mathsf{Real}^\uparrow$ seal only after the regular readback has been displayed.

Finally, H, C, P, N transport, replay, source, and name exactly the same rows. Since the carrier contains no host point equality, quotient completion, selected limit, choice, or ambient real-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 3674.3 (Bishop-space located-metric handoff)**.** *Every L10 completion consumer that reads an accepted* $\mathsf{BishopSpace}^\uparrow$ *packet factors through*

$$X \longmapsto M \longmapsto L \longmapsto W \longmapsto R \longmapsto E$$

together with H, C, P, N. Thus the consumer reads the $\mathsf{Met}^\uparrow$ *source, then the* $\mathsf{LocatedMetricSpace}^\uparrow$ *handoff, then the* $\mathsf{StreamName}^\uparrow$ *finite windows,* $\mathsf{RegSeqRat}^\uparrow$ *readback, and* $\mathsf{Real}^\uparrow$ *seal before any completion-facing endpoint is exposed.*

Proof. Begin with a completion-facing request against the accepted packet. The observation row X contains only finite point windows, so the request must use the metric source row M to obtain a displayed distance witness.

Next use the located handoff row L. This is where the metric read becomes a located metric-space read, so the route cannot jump from M directly to a real or completion endpoint.

The readback then passes through W, R, E. The finite windows in W are read as stream-name data, the regular rational row R packages those windows, and the real seal E is visible only after that regular readback.

Rows H, C, P, N preserve the same route under transport, continuation replay, provenance, and local naming. Because the packet has no coordinate for host equality, quotient completion, selected limits, countable choice, or ambient $\mathsf{Real}^\uparrow$ completeness, every completion-facing read remains on the displayed L10 route. □

Falsifiable prediction: Every L10 completion-facing read from a $\mathsf{BishopSpace}^{\uparrow}$ packet factors through the displayed MetricUp source, LocatedMetricSpaceUp handoff, StreamName finite windows, RegSeqRat readback, RealUp seal, componentwise transport, continuation replay, provenance, and local naming row before completion data is consumed.

Independence witness: metric, locatedmetricspace, streamname, regseqrat, real: $\mathsf{BishopSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries point-observation windows, a MetricUp source, a LocatedMetricSpaceUp handoff, StreamName windows, RegSeqRat readback, RealUp seal, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopSpace}^{\uparrow}$ packet is generated from finite point observations, a MetricUp source, a LocatedMetricSpaceUp handoff, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3674.1, Definition 3674.2, and Definition 3674.3 seed the Bishop-space carrier and its L10 real-and-completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host point equality, quotient completion, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric source readback, located metric-space handoff, stream-window exposure, RegSeqRat readback, RealUp seal handoff, transport replay, and ledger refusal for BEDC.Derived.BishopSpaceUp.

Chapter 3675

A Concrete Naming Certificate for $\mathsf{RealClosure}^{\uparrow}$

Following Kelley and Bourbaki topology, the $\mathsf{RealClosure}^{\uparrow}$ packet names a closure operation by displayed finite sequential data rather than by ambient completeness of a host real line. It sits over the terminal real-name seal of chapter 38, the finite window surface of chapter 126, the regular rational readback route of chapter 301, the topological carrier of chapter 88, and the sequential closure packet of chapter 1571. The chapter uses these rows to expose an L10 closure object for Real-facing and completion-facing consumers without asserting quotient reals, host equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3675.1 (Real closure carrier)**.** *A* $\mathsf{RealClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, T, S, Q, A, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Real}^{\uparrow}$ *point-name row whose accepted entries are inspected only through terminal real-name seals.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood row for the displayed Real-facing carrier.*
3. *S stores the* $\mathsf{StreamName}^{\uparrow}$ *finite windows used to observe candidate closure witnesses.*
4. *Q stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback of the same windows.*
5. *A is the* $\mathsf{SequentialClosure}^{\uparrow}$ *approach row, displaying a sequence or net-free sequential route from the named source rows toward the closure point.*
6. *E is the exactness and refusal row stating that the closure verdict is read from X, T, S, Q, A and not from quotient representatives, host real equality, choice-selected subsequences, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*
7. *H stores componentwise* hsame *transport for Real names, topological neighbourhood rows, stream windows, regular rational readbacks, sequential approach rows, exactness rows, replay rows, provenance rows, and local naming rows.*
8. *C stores displayed* Cont *replay from finite Real-name observations through topology, stream, regular rational, sequential closure, and refusal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RealClosure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SequentialClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RealClosure}^\uparrow}$ *row.*
The classifier compares accepted packets only through $X, T, S, Q, A, E, H, C, P, N$. It has no coordinate for completed subsets of a host real line, quotient real equality, selected limits, countable-choice schedules, trichotomy, open-cover compactness, or ambient Real completeness.

Theorem 3675.2 (Real closure NameCert obligations)**.** *For every accepted* $\mathsf{RealClosure}^\uparrow$ *carrier*

$$R = (X, T, S, Q, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealClosure}^\uparrow}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{Real}^\uparrow$ *point names,* $\mathsf{Topology}^\uparrow$ *neighbourhood rows,* $\mathsf{StreamName}^\uparrow$ *windows,* $\mathsf{RegSeqRat}^\uparrow$ *readbacks,* $\mathsf{SequentialClosure}^\uparrow$ *approach row, exactness and refusal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.RealClosureUp.TasteGate.RealClosureTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3675.1. The projection exposes Real names X, neighbourhood rows T, stream windows S, regular rational readbacks Q, and the sequential approach row A.

The closure verdict is then forced through E. That row records exactness of the displayed sequential route and refuses any replacement by quotient real representatives, host equality, countable-choice selection, trichotomy, open-cover compactness, or an ambient completeness theorem.

Finally transport and replay are only the componentwise rows H and C, while P and N record provenance and local naming for the same finite surface. Since no other coordinate is present, the listed rows exhaust the NameCert obligations. □

Theorem 3675.3 (Real closure stream-regular handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{RealClosure}^\uparrow$ *packet reaches the closure verdict only through the ordered handoff*

$$\mathsf{Real}^\uparrow \longrightarrow \mathsf{StreamName}^\uparrow \longrightarrow \mathsf{RegSeqRat}^\uparrow \longrightarrow \mathsf{Topology}^\uparrow \longrightarrow \mathsf{SequentialClosure}^\uparrow$$

displayed by $X, S, Q, T, A, E, H, C, P, N$. The handoff supplies finite observation windows, regular rational readback, neighbourhood membership, sequential approach evidence, transport, replay, provenance, and local naming; it supplies no quotient real, host equality, countable-choice schedule, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^\uparrow$ *completeness principle.*

Proof. Begin with an accepted carrier $R = (X, T, S, Q, A, E, H, C, P, N)$. A consumer may inspect a Real name only through X, and every finite observation of that name is recorded by the stream-window and regular-rational rows S, Q.

The topological and sequential closure rows then consume the same readback. The neighbourhood row T records the local closure test, while A records the displayed sequential route that meets the test.

Use the exactness row E and the transport-replay rows H, C. They preserve the ordered handoff under classifier comparison and prevent a consumer from replacing the finite route by quotient equality, selected representatives, countable choice, trichotomy, compactness, or ambient completeness.

The provenance and local name rows P, N package exactly this route. Hence every downstream closure read receives the stated L10 handoff and nothing stronger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{RealClosure}^{\uparrow}$ packet is generated from Real point names, topology neighbourhood rows, finite StreamName windows, RegSeqRat readbacks, a SequentialClosure approach row, exactness refusal, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3675.1, Definition 3675.2, and Definition 3675.3 seed the constructive L10 closure carrier, finite NameCert obligation surface, and stream-to-regular-rational handoff for Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient reals, host real equality, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology-neighbourhood exactness, finite stream-window readback, regular rational readback, sequential closure handoff, refusal, transport stability, replay, provenance, and local naming for BEDC.Derived.RealClosureUp.

Chapter 3676

A Concrete Naming Certificate for $\mathsf{IntermediateValueTheorem}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{IntermediateValueTheorem}^{\uparrow}$ packet records the constructive intermediate-value theorem as a finite theorem-object certificate rather than as host real analysis. It reads the real-name seal of chapter 38 for $\mathsf{Real}^{\uparrow}$, the regular rational readback route of chapter 301 for $\mathsf{RegSeqRat}^{\uparrow}$, the finite observation windows of chapter 126 for $\mathsf{StreamName}^{\uparrow}$, the endpoint interval packet of chapter 394 for $\mathsf{LocatedInterval}^{\uparrow}$, the graph-and-modulus surface of chapter 130 for $\mathsf{ContinuousMap}^{\uparrow}$, and the closed interval carrier of chapter 1591 for $\mathsf{ClosedBoundedInterval}^{\uparrow}$. The chapter packages the theorem route as BEDC rows: it does not decide classical trichotomy, use Heine–Borel or open-cover compactness, select a zero, identify quotient real names, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3676.1 (Intermediate value theorem carrier)**.** *An* $\mathsf{IntermediateValueTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, J, F, A, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source interval row, exposing lower and upper endpoint reads, endpoint order, containment ledgers, and interval windows.*
2. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint-location row used by the sign route, carrying the same endpoint surface as displayed interval data.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-and-modulus row for the displayed map on the interval.*
4. *A and B are the endpoint sign rows, recording the inspected negative-side and positive-side evidence as finite real-name reads rather than as a trichotomy decision.*
5. *S stores the* $\mathsf{StreamName}^{\uparrow}$ *windows used to inspect endpoint, midpoint, and branch values along the theorem route.*
6. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readbacks attached to those windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the located sign-transition output, reached only after I, J, F, A, B, S, R have been displayed.*
8. *H stores componentwise* hsame *transport for the interval, location, map, sign, window, readback, seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from an intermediate-value request through I, J, F, A, B, S, R, E.*
10. *P is the* Pkg *provenance over* $\mathsf{IntermediateValueTheorem}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IntermediateValueTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, J, F, A, B, S, R, E, H, C, P, N$. It has no coordinate for classical trichotomy, Heine–Borel compactness, open-cover compactness, a selected zero, quotient real equality, host semantic continuity, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntermediateValueTheoremUp.IntermediateValueTheoremTasteGate single carrier alignment`

Theorem 3676.2 (Intermediate value theorem NameCert obligations)**.** *For every accepted* IntermediateValueTheore *carrier*

$$T = (I, J, F, A, B, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntermediateValueTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed interval and endpoint-location rows, continuous-map admission through F, endpoint sign exposure through A and B, finite-window exposure through S, regular rational readback through R, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.IntermediateValueTheoremUp.IntermediateValueTheoremCarrier namecert obligations`

Proof. Project the carrier of Definition 3676.1. The accepted packet exposes the closed bounded interval row I, the located endpoint row J, the continuous-map row F, the sign rows A, B, the finite windows S, the regular readbacks R, and the terminal seal row E.

The theorem route is constructive because every sign and value read is a displayed window-readback pair. The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite observations, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational readback, and the $\mathsf{Real}^{\uparrow}$ row receives only the sealed sign-transition output.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. Since the carrier has no coordinate for classical trichotomy, Heine–Borel or open-cover compactness, a selected zero, quotient real equality, host semantic continuity, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those objects cannot belong to the local NameCert surface. □

Theorem 3676.3 (Intermediate value theorem finite sign-route handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{IntermediateValueTheorem}^{\uparrow}$ *packet factors through*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longrightarrow \mathsf{LocatedInterval}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff exports only the displayed interval row, endpoint-location row, continuous-map row, endpoint sign rows, finite windows, regular readbacks, Real seal, componentwise transport, replay, provenance, and local naming.

Proof. Start with a Real-facing theorem read. The carrier definition places the terminal seal in row E, and E is downstream of the interval, location, map, sign, window, and readback rows.

Trace the read backward through the finite route. The closed interval row I and located endpoint row J supply the domain surface, the continuous-map row F supplies the displayed modulus and graph data, and the endpoint sign rows A, B are inspected only through S and R before the seal is reached.

Finally H, C, P, N transport, replay, package, and name the same displayed route. There is no second coordinate for a selected zero, quotient real equality, classical trichotomy, Heine–Borel compactness, open-cover compactness, host semantic continuity, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so every accepted handoff reaches $\mathsf{Real}^{\uparrow}$ only through the displayed rows. □

Falsifiable prediction: Every accepted $\mathsf{IntermediateValueTheorem}^{\uparrow}$ Real-facing read factors through a ClosedBoundedInterval source row, a LocatedInterval endpoint-location row, a ContinuousMap graph-and-modulus row, endpoint sign rows, StreamName finite windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: closedboundedinterval, locatedinterval, continuousmap, streamname, regseqrat, real: $\mathsf{IntermediateValueTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the theorem-level interval source, endpoint-location surface, continuous-map row, endpoint sign ledger, finite window route, regular rational readback, terminal seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{IntermediateValueTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{IntermediateValueTheorem}^{\uparrow}$ packet is generated from a $\mathsf{ClosedBoundedInterval}^{\uparrow}$ source row, a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint-location row, a $\mathsf{ContinuousMap}^{\uparrow}$ graph-and-modulus row, endpoint sign rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntermediateValueTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3676.1, Definition 3676.2, and Definition 3676.3 seed the constructive intermediate-value theorem route as a finite NameCert packet over interval, map, sign, window, readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntermediateValueTheorem}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.IntermediateValueTheoremUp.IntermediateValueTheoremTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close classical trichotomy, Heine–Borel compactness, open-cover compactness, selected zeros, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint sign visibility, continuous-map routing, finite-window readback, Real-seal handoff, transport and replay stability, and provenance exhaustion for BEDC.Derived.IntermediateValueTheor

Chapter 3677

A Concrete Naming Certificate for $\mathsf{FirstExitChannel}^{\uparrow}$

The $\mathsf{FirstExitChannel}^{\uparrow}$ packet realizes the first-exit channel geometry of Definition 9462.1480 as finite BEDC NameCert data. It reads a killed bit-flip walk state through origin state, flipped bit, outside target, target class, transition ledger, transport, replay, provenance, and local naming before any first-exit geometry claim is exported. The packet is a finite science-facing certificate; it is not a bijection with the six-boundary-tile coverage, not a host biological law, not an optimizer for unseen codon tables, and not an unrestricted stochastic-process oracle.

The transition ledger is consumed beside chapter 3470, chapter 3478, chapter 3463, and chapter 3625 because those chapters supply the codon-window partition, trigger activation, cube adjacency, and post-median shell consumer rows.

Falsifiable prediction: Every accepted $\mathsf{FirstExitChannel}^{\uparrow}$ read must display origin state, flipped bit, outside target, target class, transition ledger, transport, replay, provenance, and local naming before any first-exit geometry claim is exported.

Independence witness: six-boundary-tile-coverage, window-coverage-trigger-algebra, post-median-gate-shell, punctured-cube-skeleton: six-boundary-tile coverage names the codon-window partition, window-coverage trigger algebra names gate activation, post-median gate shell names the downstream shell consumer, and the punctured-cube skeleton names cube adjacency. None is bijective to $\mathsf{FirstExitChannel}^{\uparrow}$ because this packet binds origin row, flipped-bit row, outside-target row, target-class row, transition ledger, transport, replay, provenance, and local naming as one accepted first-exit surface.

Definition 3677.1 (First-exit channel carrier)**.** *A* $\mathsf{FirstExitChannel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, B, T, K, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the origin-state row inside the killed median-closure domain.*
2. *B is the flipped-bit row naming the bit coordinate through which the walk exits.*
3. *T is the outside-target row naming the codon reached after the bit flip.*
4. *K is the target-class row recording the standard genetic-code class of T.*
5. *L is the transition ledger binding O, B, T, and K to the displayed killed-walk boundary half-edge.*

6. *H stores componentwise* hsame *transport for origin, bit, outside target, target class, transition ledger, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from the first-exit request through O, B, T, K, L, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FirstExitChannel}^{\uparrow}$*, the six-boundary-tile coverage, the window-coverage trigger algebra, the post-median gate shell, the punctured-cube skeleton,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FirstExitChannel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, B, T, K, L, H, C, P, N$. It has no coordinate for global codon-table optimality, unseen-window extrapolation, host biochemical causality, an unrestricted Markov-chain oracle, or bridge checking.

Lean4 (definition) `BEDC.Derived.FirstExitChannelUp.FirstExitChannelUp`

Lean4 ✓ `BEDC.Derived.FirstExitChannelUp.FirstExitChannelTasteGate single carrier alignment`

Theorem 3677.2 (First-exit channel NameCert obligations)**.** *For every accepted* $\mathsf{FirstExitChannel}^{\uparrow}$ *carrier*

$$F = (O, B, T, K, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FirstExitChannel}^{\uparrow}}$ *surface consists exactly of carrier admission for the origin-state row O, flipped-bit row B, outside-target row T, target-class row K, transition ledger L, componentwise transport H, continuation replay C, package provenance P, and local naming row N.*

Lean4 ✓ `BEDC.Derived.FirstExitChannelUp.FirstExitChannelNamecertObligations`

Proof. Project the carrier of Definition 3677.1. The projection exposes origin, bit, outside target, target class, and transition rows before it exposes the structural rows.

The transition ledger L is the only row that binds the four observational rows into a first-exit boundary half-edge. Thus a consumer cannot replace the displayed exit by an unrelated codon adjacency or by an unrestricted stochastic-process read.

The rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for global codon-table optimality, unseen-window extrapolation, or host biochemical causality, the displayed rows exhaust the NameCert obligations. □

Theorem 3677.3 (First-exit channel geometry readback)**.** *Every accepted first-exit geometry read through* $\mathsf{FirstExitChannel}^{\uparrow}$ *factors through*

$$O, B, T, K \longmapsto L \longmapsto H, C, P, N.$$

Consequently the read may export origin-state distribution rows, flipped-bit rows, outside-target rows, and target-class rows only after the transition ledger and structural NameCert rows are displayed.

Proof. Start with the four observational rows O, B, T, K. They name the origin state, flipped bit, outside target, and target class, but they do not by themselves assert first-exit geometry.

The transition ledger L binds those rows to the killed-walk boundary half-edge. This is the point where the packet distinguishes a first exit from an arbitrary bit flip or a free codon-class lookup.

Finally H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Any geometry claim that bypasses one of these rows, or that asserts an unseen-window optimizer or host biochemical cause, is outside the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FirstExitChannel}^{\uparrow}}$.

Constructive story: A $\mathsf{FirstExitChannel}^{\uparrow}$ packet is generated from origin-state rows, flipped-bit rows, outside-target rows, target-class rows, a transition ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FirstExitChannel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3677.1, Definition 3677.2, and Definition 3677.3 seed the finite first-exit channel carrier, NameCert obligations, and geometry readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FirstExitChannel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global codon-table optimality, unseen-window extrapolation, host biochemical causality, unrestricted Markov-chain semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, origin-bit-target-class ledger exactness, transition replay, provenance, local naming, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.FirstExitChannelUp.TasteGate.

Chapter 3678

A Concrete Naming Certificate for $\mathsf{BoundaryShadowTrigger}^{\uparrow}$

Following finite Markov-chain first-exit arguments and the stopped-walk boundary convention, the $\mathsf{BoundaryShadowTrigger}^{\uparrow}$ packet records the narrow trigger surface by which a killed bit-flip walk exposes a boundary half-edge before any first-exit conclusion is read. It sits below the first-exit channel packet of chapter 3677, reads the first-exit channel geometry of Definition 9462.1480, and consumes the six-boundary-tile coverage of chapter 3470, the punctured-cube skeleton of chapter 3463, and the window-coverage trigger algebra of chapter 3478. The packet names only the finite origin row, exit bit, outside target, target class, boundary-shadow row, trigger ledger, transport, replay, provenance, and local naming rows; it does not assert a global stochastic-process oracle, codon-table optimality, unseen-window extrapolation, host biochemical causality, or bridge checking.

Definition 3678.1 (BoundaryShadowTrigger carrier)**.** *A* $\mathsf{BoundaryShadowTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, B, X, K, W, L, H, C, P, N),$$

with the following displayed rows:

1. *O is the origin-state row inside the killed median-closure domain.*
2. *B is the exit-bit row naming the coordinate through which the stopped walk leaves the displayed window.*
3. *X is the outside-target row reached by the boundary half-edge.*
4. *K is the target-class row read from the standard genetic-code class of X.*
5. *W is the boundary-shadow row recording that O, B, X, K are inspected only through the displayed half-edge.*
6. *L is the trigger ledger binding O, B, X, K, W into a first-exit trigger event.*
7. *H stores componentwise* hsame *transport for the observational, shadow, ledger, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from the boundary-shadow trigger request through $O, B, X, K, W, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundaryShadowTrigger}^{\uparrow}$, $\mathsf{FirstExitChannel}^{\uparrow}$, *the six-boundary-tile coverage, the punctured-cube skeleton, the window-coverage trigger algebra,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundaryShadowTrigger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $O, B, X, K, W, L, H, C, P, N$. It has no coordinate for a free codon-class lookup, unrestricted Markov-chain semantics, global codon-table optimality, unseen-window extrapolation, host biochemical causality, or bridge checking.

Theorem 3678.2 (BoundaryShadowTrigger NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryShadowTrigger}^{\uparrow}$ *carrier*

$$T = (O, B, X, K, W, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundaryShadowTrigger}^{\uparrow}}$ *surface consists exactly of carrier admission for the origin-state row O, exit-bit row B, outside-target row X, target-class row K, boundary-shadow row W, trigger ledger L, componentwise transport H, continuation replay C, package provenance P, and local naming row N.*

Every first-exit-channel consumer must read W and L before using O, B, X, K as a boundary trigger. No consumer receives a free codon-class lookup, unrestricted Markov-chain semantics, global codon-table optimality, unseen-window extrapolation, host biochemical causality, or bridge checking.

Proof. Project the carrier of Definition 3678.1. The rows expose the origin, exit bit, outside target, target class, boundary shadow, trigger ledger, transport, replay, provenance, and local naming data in the order available to the classifier.

The boundary-shadow row W is the only row that marks the observational tuple O, B, X, K as a half-edge read rather than as a free lookup. The trigger ledger L then binds that half-edge to the stopped-walk first-exit event before any downstream first-exit-channel consumer can inspect it.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for unrestricted Markov-chain semantics, global codon-table optimality, unseen-window extrapolation, host biochemical causality, or bridge checking, the local NameCert obligations are exhausted by the stated finite rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowTrigger}^{\uparrow}$ packet is generated from origin-state rows, exit-bit rows, outside-target rows, target-class rows, boundary-shadow rows, trigger ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundaryShadowTrigger}^{\uparrow}}$, seed)

Scope closed: Definition 3678.1 and Definition 3678.2 seed the finite boundary-shadow trigger carrier and NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundaryShadowTrigger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted Markov-chain semantics, global codon-table optimality, unseen-window extrapolation, host biochemical causality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, origin-bit-target-class shadow exactness, trigger-ledger replay, provenance, local naming, and TasteGate instances for BEDC.Derived.BoundaryShadowTriggerUp.

Chapter 3679

A Concrete Naming Certificate for $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$

Following Whitney's finite-jet extension theorem and the constructive finite-row presentation of differentiability data, the $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ packet records a finite jet family over a closed carrier together with the compatibility estimates needed by extension consumers. It sits over the real and order-facing rows of chapter 38 and chapter 766, the metric and ball rows of chapter 57 and chapter 1450, the derivative-facing surface of chapter 122, and the Sobolev trace boundary of chapter 3647. The packet is a finite NameCert carrier for jet compatibility and consumer routing; it is not a global smooth extension operator, a selected extension function, host compactness, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3679.1 (Whitney finite-jet extension carrier)**.** *A* $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (X, F, J, A, E, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *or Euclidean metric carrier whose distance rows supply the only spatial comparisons used by the packet.*
2. *F is the closed-set classifier row naming the finite observation domain on which jets are read.*
3. *J is the finite jet table, containing the displayed value and derivative rows indexed by the admitted multiindex budget.*
4. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison ledger for the Whitney difference quotients, radius bounds, and finite error budgets.*
5. *E is the local extension-admissibility ledger, recording that every requested jet comparison is routed through F, J, A and the displayed metric-ball scales.*
6. *R is the readback row for derivative-facing and Sobolev-trace-facing consumers.*
7. *H records componentwise* hsame *transport for the carrier, closed-set classifier, jet table, order ledger, extension-admissibility ledger, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite jet request through $X, F, J, A, E, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{SobolevTrace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, F, J, A, E, R, H, C, P, N$. It has no coordinate for a host smooth function, a selected extension, compactness, arbitrary choice, quotient equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3679.2 (Whitney finite-jet NameCert obligations)**.** *For every accepted* $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ *carrier $W = (X, F, J, A, E, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}}$ *surface consists exactly of the finite rows named in Definition 3679.1: carrier admission for $X, F, J, A, E, R, H, C, P, N$, closed-set classifier stability, finite jet-table stability, order-ledger comparison for the Whitney estimates, extension-admissibility replay through metric-ball scales, derivative and Sobolev trace readback, transport, provenance, and local naming. No obligation row stores a host extension function, a global smoothness theorem, a selected representative, compactness, choice, quotient equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.WhitneyExtensionFiniteJetUp.TasteGate.WhitneyExtensionFiniteJetTasteGate`
`single carrier alignment`

Proof. Project the accepted carrier of Definition 3679.1. The only geometric data are X and F, and the only analytic data are the finite jet table J, the comparison ledger A, the extension-admissibility row E, and the readback row R.

The NameCert obligations are therefore rowwise. A finite jet request first names the metric carrier and closed-set classifier, then opens the jet table and the order-facing comparison ledger before any admissibility claim is available.

The admissibility row E is the only coordinate that relates two jet reads at a displayed scale. It forces every difference-quotient and remainder comparison through F, J, A and the relevant metric-ball radius rather than through a host extension function.

Finally, H, C, P, N transport, replay, package, and name exactly the same route. Since the carrier contains no coordinate for a selected smooth extension, compactness, arbitrary choice, quotient equality, trichotomy, or ambient Real completeness, none of those objects can become a local obligation. □

Theorem 3679.3 (Whitney finite-jet consumer boundary)**.** *Every* $\mathsf{Derivative}^{\uparrow}$, $\mathsf{SobolevTrace}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, *or* $\mathsf{RealAlgOrder}^{\uparrow}$ *consumer reading an accepted* $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ *carrier must factor through the displayed route*

$$X, F \longmapsto J, A \longmapsto E, R \longmapsto H, C, P, N.$$

The consumer receives finite jet compatibility, order-facing estimates, and derivative or trace readback only along this route. It receives no global extension operator, no selected smooth function, no host compactness theorem, no arbitrary choice principle, no quotient equality, no trichotomy, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer read. By Definition 3679.1, the read can inspect only the metric carrier X, the closed-set classifier F, the jet table J, the comparison ledger A, and the admissibility row E before it reaches derivative-facing or trace-facing output.

The row R supplies the public readback boundary. It exposes the finite derivative and trace-facing records already justified by E, but it does not introduce a host smooth function or select an extension outside the displayed rows.

The structural rows preserve the same route. Componentwise transport and continuation replay move the packet through H and C, while P and N record provenance and local naming. Thus every downstream consumer remains inside the finite Whitney jet surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3679.1, Definition 3679.2, and Definition 3679.3 seed the finite Whitney jet packet over metric carriers, closed-set classifier rows, jet tables, order-facing estimates, and derivative or Sobolev trace readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the classical global Whitney theorem, a selected smooth extension operator, compactness, arbitrary choice, quotient equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, jet-table stability, order-ledger comparison, extension-admissibility replay, derivative or trace readback, transport, provenance, and local naming for BEDC.Derived.WhitneyExtensionFinite.

Constructive story: A $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ packet is generated from a MetricUp carrier, a closed-set classifier row, a finite jet table, a RealAlgOrderUp comparison ledger, a local extension-admissibility row, derivative or Sobolev trace readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3680

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionKernel}^{\uparrow}$

Following Hausdorff and Bourbaki-style completion language, the $\mathsf{HausdorffCompletionKernel}^{\uparrow}$ packet records the separated Cauchy-completion boundary as finite BEDC data. It sits between the separated metric classifier of chapter 1411, the complete metric service of chapter 128, the Cauchy-filter completion route of chapter 1569, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Hausdorff completion boundary of chapter 402. The packet names the zero-distance kernel that separates completion reads before any quotient representative, host equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem may be consumed.

Definition 3680.1 (Hausdorff completion kernel carrier)**.** *A* $\mathsf{HausdorffCompletionKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, Z, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the Cauchy-completion thread row, recording the inspected Cauchy filter, Cauchy sequence, or regular Cauchy name requests that enter the completion boundary.*
2. *Z is the separated zero-distance row supplied by* $\mathsf{SeparatedMetric}^{\uparrow}$*, recording when two displayed completion reads have zero carried distance.*
3. *F is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff row, keeping filter-completion requests tied to the same finite Cauchy thread.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing only regular rational windows read from Q and F.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, Z, F, R have been displayed.*
6. *H records componentwise* hsame *transport for the Cauchy thread, zero-distance row, filter-completion handoff, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a separated completion request through Q, Z, F, R, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{HausdorffCompletionKernel}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{HausdorffCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionKernel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, Z, F, R, E, H, C, P, N$. It has no coordinate for quotient representatives, host completion equality, selected limits, countable choice, detached Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionKernelUp.HausdorffCompletionKernelTasteGate single carrier alignment`

Theorem 3680.2 (Hausdorff completion kernel NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffCompletionKe}$ *carrier $K = (Q, Z, F, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionKernel}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, Cauchy-completion thread exposure through Q, separated zero-distance exposure through Z, Cauchy-filter completion handoff through F, regular rational readback through R, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionKernelUp.TasteGate.HausdorffCompletionKernelTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 3680.1. The accepted packet exposes the Cauchy thread, separated zero-distance boundary, filter-completion handoff, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows.

The separated completion route is fixed by Q, Z, F, R, E. The Cauchy thread Q supplies the inspected completion source, Z supplies the zero-distance classifier, F binds Cauchy-filter completion reads to that source, R gives the regular rational readback, and E seals the resulting Real-facing boundary.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. Since the carrier has no coordinate for quotient representatives, host completion equality, selected limits, countable choice, detached Real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those objects cannot belong to the local NameCert surface. □

Theorem 3680.3 (Hausdorff completion kernel nonescape)**.** *Every separated completion consumer of an accepted* $\mathsf{HausdorffCompletionKernel}^{\uparrow}$ *packet factors through*

$$\mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchyFilterCompletion}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{HausdorffCompletion}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hs}$$

In particular, equality of completed reads is exposed only by the displayed zero-distance row Z and its transported replay through H, C, P, N.

Proof. Start with a consumer that requests equality or reuse of a completed read. The carrier exposes no equality coordinate before the Cauchy thread Q and the separated zero-distance row Z have been read.

Next read the completion and real-facing rows. The handoff F ties the request to the Cauchy-filter completion route, R gives the regular rational readback used by the real-name boundary, and E is downstream of those rows.

Finally replay the structural data. The rows H, C, P, N preserve and name the same finite route, while the $\mathsf{HausdorffCompletion}^{\uparrow}$ provenance identifies the separated completion boundary. No quotient representative, host equality, selected limit, countable-choice schedule, detached Real equality, or ambient completeness coordinate is available to the consumer. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffCompletionKernel}^{\uparrow}$ separated completion read factors through a Cauchy-completion thread row, a separated zero-distance row, a CauchyFilterCompletion handoff, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: separatedmetric, completemetric, cauchyfiltercompletion, regseqrat, real, hausdorffcompletion: $\mathsf{HausdorffCompletionKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Cauchy thread, zero-distance kernel, filter-completion handoff, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffCompletionKernel}^{\uparrow}$ packet is generated from a Cauchy-completion thread row, a separated zero-distance row, a CauchyFilterCompletion handoff, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3680.1, Definition 3680.2, and Definition 3680.3 seed the separated Cauchy-completion kernel over displayed completion, zero-distance, regular-readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, host completion equality, selected limits, countable choice, detached Real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated zero-distance exactness, Cauchy-filter handoff, regular readback, Real-seal nonescape, and TasteGate field faithfulness for BEDC.Derived.HausdorffCompletionKernelUp.

Chapter 3681

A Concrete Naming Certificate for RadialWobbleSpectrum$^{\uparrow}$

The RadialWobbleSpectrum$^{\uparrow}$ packet realizes the radial spectral surface of Definition 9462.1448 as finite BEDC NameCert data. It consumes the boundary-tile coverage packet of chapter 3470, the support-closure algebra of chapter 3478, the hyperbolic metric reading of chapter 3474, and the substrate trace invariant of chapter 2360. The packet names radial-shell, spectral-hinge, wobble-edge, and trigger-ledger rows; it is not a biological code table, stochastic evolutionary model, quotient codon semantics, or hidden spectral oracle.

Definition 3681.1 (Radial wobble spectrum carrier)**.** *A* RadialWobbleSpectrum$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, S, H, W, L, M, A, Q, P, N)$$

with the following displayed rows:

1. *T is the* SixBoundaryTileCoverage$^{\uparrow}$ *boundary-tile coverage row, exposing the finite trigger support read by the radial packet.*
2. *S is the radial-shell row, recording the six displayed states $X_3, X_2, X_1, X_0, Y_R, Y_Y$ and their finite adjacency counts.*
3. *H is the spectral-hinge row, recording the cubic hinge $r^3 - 12r^2 + 26r - 9$ and the Perron read attached to the radial matrix.*
4. *W is the wobble-edge row, recording the f_3 self-loop contribution and its normalized contribution to the killed bit-flip spectrum.*
5. *L is the* WindowCoverageTriggerAlgebra$^{\uparrow}$ *trigger ledger, binding support closure, residue accounting, blocker rows, and coverage thresholds to the same radial read.*
6. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row used only as a boundary geometry witness for the radial shells.*
7. *A is the* SubstrateTraceInvariant$^{\uparrow}$ *substrate trace row, preserving the source trace across shell, hinge, wobble, and trigger reads.*
8. *Q records componentwise* hsame *transport and displayed* Cont *replay for T, S, H, W, L, M, A.*
9. *P records* Pkg *provenance over* RadialWobbleSpectrum$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgeb HyperbolicMetric$^{\uparrow}$, SubstrateTraceInvariant$^{\uparrow}$, *the source vision of Definition 9462.1448,* BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RadialWobbleSpectrum}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, S, H, W, L, M, A, Q, P, N$. It has no coordinate for hidden biological semantics, stochastic transition laws, quotient codon equality, infinite spectral computation, or a detached Perron oracle.

Lean4 ✓ `BEDC.Derived.RadialWobbleSpectrumUp.RadialWobbleSpectrumTasteGate single carrier alignment`

Theorem 3681.2 (Radial wobble spectrum NameCert obligations)**.** *For every accepted* $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ *carrier $R = (T, S, H, W, L, M, A, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RadialWobbleSpectrum}^{\uparrow}}$ *surface consists exactly of boundary-tile coverage admission through T, radial-shell exposure through S, spectral-hinge exactness through H, wobble-edge accounting through W, trigger-ledger exposure through L, hyperbolic metric boundary reading through M, substrate trace preservation through A, componentwise transport and replay through Q, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 3681.1. The accepted packet exposes only the boundary-tile coverage, radial-shell, spectral-hinge, wobble-edge, trigger-ledger, metric, substrate-trace, transport, replay, provenance, and naming rows.

The radial spectrum is carried by S, H, W. The shell row records the six states and adjacency counts, the hinge row records the cubic spectral constraint, and the wobble row records the f_3 contribution before any spectral read may be exported.

The support and geometry rows are T, L, M, A. Boundary-tile coverage and trigger algebra bind the finite support surface, while the hyperbolic metric and substrate trace rows preserve the geometric and trace witnesses without adding a hidden spectral oracle.

Finally Q, P, N transport, replay, source, and name the same finite route. Since no coordinate records biological semantics, stochastic transition laws, quotient codon equality, infinite spectral computation, or detached Perron data, none of those objects belongs to the local NameCert surface. □

Theorem 3681.3 (Radial wobble spectrum trigger nonescape)**.** *Every concrete radial wobble stability read of an accepted* $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ *packet factors through*

$$\mathsf{SixBoundaryTileCoverage}^{\uparrow} \longrightarrow \mathsf{WindowCoverageTriggerAlgebra}^{\uparrow} \longrightarrow \mathsf{HyperbolicMetric}^{\uparrow} \longrightarrow \mathsf{SubstrateTraceInvariant}^{\uparrow}$$

The radial-shell row S, spectral-hinge row H, wobble-edge row W, and trigger ledger L must be displayed before the packet may claim radial wobble stability.

Proof. Start with the boundary-tile support. The row T supplies finite trigger coverage, and L records the support closure and residue ledger from the trigger algebra.

Next read the radial spectral data. The shell row S gives the six-state adjacency surface, the hinge row H gives the spectral cubic, and W records the wobble self-loop contribution. Removing any one of these rows leaves no carrier coordinate for the claimed radial wobble stability.

Finally read the boundary geometry and trace rows. The hyperbolic metric row M and substrate trace row A preserve the geometric and source-trace witnesses, while Q, P, N transport, replay, source, and name the same route. Thus the packet cannot export a hidden biological table, stochastic transition law, quotient codon equality, infinite spectral computation, or detached Perron oracle. □

Falsifiable prediction: The packet fails if the spectral-hinge row is removed while the same carrier still claims radial wobble stability.

Independence witness: `six_boundary_tile_coverage`, `window_coverage_trigger_algebra`, `hyperbolic_metric`, `substrate_trace_invariant`: the carrier has a radial spectral row and trigger ledger not bijective to any single sibling packet.

The later Lean route for `BEDC.Derived.RadialWobbleSpectrumUp` must provide explicit Nontrivial RadialWobbl and FieldFaithful $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ instances preserving $T, S, H, W, L, M, A, Q, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{RadialWobbleSpectrum}^{\uparrow}}$.

Constructive story: A $\mathsf{RadialWobbleSpectrum}^{\uparrow}$ packet is generated from boundary-tile coverage, radial-shell, spectral-hinge, wobble-edge, trigger-ledger, hyperbolic metric, substrate trace, componentwise transport, displayed replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RadialWobbleSpectrum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3681.1, Definition 3681.2, and Definition 3681.3 seed the finite radial wobble spectrum packet over boundary-tile, radial-shell, spectral-hinge, wobble-edge, trigger-ledger, geometry, and trace rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RadialWobbleSpectrum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological table identity, stochastic evolutionary modeling, quotient codon equality, infinite spectral computation, detached Perron oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radial-shell exactness, spectral-hinge preservation, wobble-edge accounting, trigger-ledger nonescape, Nontrivial RadialWobbleSpectrumUp, and FieldFaithful RadialWobbleSpectrumUp for BEDC.Derived.RadialWobbleSpectrumUp.

Chapter 3682

A Concrete Naming Certificate for $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$

Following Schwarz–Pick and Ahlfors' hyperbolic metric reading of holomorphic disk maps, the $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ packet names disk-map contraction as finite BEDC data. It is grounded in the unit disk carrier of chapter 377, the Poincare disk transport route of chapter 3455, the hyperbolic metric certificate of chapter 3474, the boundary-dynamics route of chapter 3575, and the observer-expansion vision of chapter 9463. The packet certifies finite disk-map, metric comparison, boundary refusal, transport, provenance, and NameCert rows; it is not an ambient theorem about all analytic self-maps of a completed complex disk.

Definition 3682.1 (Schwarz-Pick disk-contraction carrier)**.** *A* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, F, M, K, B, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate row for displayed source and target disk points.*
2. *F is the finite disk-map row, recording how the displayed points are transported by the named map.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *readout row for source and target point pairs.*
4. *K is the contraction-comparison row stating that the target hyperbolic readout is no larger than the source readout on the displayed pair.*
5. *B is the boundary-refusal row, separating interior disk-map comparison from Denjoy–Wolff or far-end boundary dynamics.*
6. *R is the route row linking finite disk coordinates, map transport, metric readout, comparison, and boundary refusal.*
7. *H stores componentwise* hsame *transport for disk coordinates, map rows, metric readouts, comparison rows, boundary refusals, route rows, replay rows, provenance rows, and local naming rows.*
8. *C stores displayed* Cont *replay of the same disk-map and metric-comparison route.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwarzPickDiskContraction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, F, M, K, B, R, H, C, P, N$. It has no coordinate for a host holomorphic function space, completed complex disk equality, boundary fixed-point selection, open-cover compactness, or unlogged analytic continuation.

Lean4 ✓ `BEDC.Derived.SchwarzPickDiskContractionUp.SchwarzPickDiskContractionTasteGate single carrier alignment`

Theorem 3682.2 (Schwarz-Pick disk-contraction NameCert obligations)**.** *For every accepted* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ *carrier*

$$S = (D, F, M, K, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwarzPickDiskContraction}^{\uparrow}}$ *surface consists exactly of carrier admission for displayed disk coordinates, finite disk-map rows, hyperbolic metric readouts, contraction-comparison rows, boundary-refusal rows, route rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3682.1. The projection exposes disk coordinates D, the finite map row F, hyperbolic metric readouts M, the contraction comparison K, and the boundary-refusal row B.

The comparison is read only through R. Thus a consumer first displays the source and target disk coordinates, applies the named finite disk-map row, reads the hyperbolic metric on both displayed pairs, and then consumes the no-expansion comparison.

Transport and replay are confined to H and C. The provenance and local naming rows P, N record exactly the same route, and the carrier has no coordinate for host analytic function spaces, completed disk equality, boundary fixed-point selection, compactness, or unlogged continuation. These rows therefore exhaust the NameCert obligations. □

Theorem 3682.3 (Schwarz-Pick hyperbolic-metric handoff)**.** *Every hyperbolic-metric consumer of an accepted* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ *packet reaches the contraction verdict only through the ordered handoff*

$$\mathsf{UnitDisk}^{\uparrow} \longrightarrow \mathsf{PoincareDiskPhaseTransport}^{\uparrow} \longrightarrow \mathsf{HyperbolicMetric}^{\uparrow} \longrightarrow \mathsf{SchwarzPickDiskContraction}^{\uparrow}$$

displayed by $D, F, M, K, B, R, H, C, P, N$. The handoff supplies finite disk-map transport, source and target metric readouts, contraction comparison, boundary refusal, provenance, and NameCert data, and it supplies no ambient analytic self-map theorem or boundary fixed-point conclusion.

Proof. Start with the disk-coordinate row D and the finite map row F. These rows display the only source and target points available to the contraction comparison.

The hyperbolic-metric row M then reads the source and target distances on those displayed pairs. The comparison row K consumes those two readouts, while B keeps Denjoy–Wolff boundary dynamics and far-end fixedness outside the interior disk-contraction verdict.

Use the route, transport, and replay rows R, H, C to preserve the same handoff under classifier comparison. The provenance and local naming rows P, N package the finite route, so no host analytic function space, completed disk equality, selected boundary point, compactness argument, or unlogged continuation can enter the metric handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchwarzPickDiskContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ packet is generated from UnitDisk coordinates, a finite disk-map row, HyperbolicMetric readouts, a contraction-comparison row, boundary refusal, a route row, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwarzPickDiskContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3682.1, Definition 3682.2, and Definition 3682.3 seed the finite disk-contraction carrier, NameCert obligations, and hyperbolic-metric handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwarzPickDiskContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not assert a host holomorphic-function theorem, completed disk equality, selected boundary fixed point, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk-map exactness, hyperbolic metric readback, contraction comparison, boundary refusal, route preservation, transport stability, replay, provenance, and local naming for BEDC.Derived.SchwarzPickDiskContractionUp.

Chapter 3683

A Concrete Naming Certificate for $\mathsf{PoincareTriangleDefect}^{\uparrow}$

The $\mathsf{PoincareTriangleDefect}^{\uparrow}$ packet realizes the Poincare disk representation of chapter 9463 as finite NameCert data. It reads disk-point rows, geodesic-side rows, hyperbolic metric rows, cross-ratio comparison rows, and terminal $\mathsf{Real}^{\uparrow}$ seals through the existing Poincare disk phase-transport, hyperbolic metric, geodesic boundary, hyperbolic cross-ratio, and real-name certificates. The packet names a finite triangle-defect surface, not a host model of the hyperbolic plane, an ambient angle measure, a selected ideal boundary representative, a global field instance, or a completed real-geometric quotient.

Definition 3683.1 (Poincare triangle defect carrier)**.** *A* $\mathsf{PoincareTriangleDefect}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, G, M, X, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk-point row, displaying three accepted Poincare disk readouts and the local incidence data needed to form a triangle.*
2. *G is the geodesic-side row, read through the boundary-geodesic route and recording the three displayed side carriers.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row used to read side and angle-facing metric comparisons.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the finite cross-ratio comparison data used to orient the defect reading.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed defect value or defect-bound read.*
6. *H records componentwise* hsame *transport for D, G, M, X, R, C, P, N and the local triangle-defect packet shape.*
7. *C records displayed* Cont *replay from disk-point admission through geodesic-side admission, metric reading, cross-ratio reading, and the real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{PoincareTriangleDefect}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareTriangleDefect}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, M, X, R, H, C, P, N$. It has no coordinate for a host hyperbolic plane, global angle measure, selected boundary representative, field-completion quotient, Lean TasteGate instance, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.PoincareTriangleDefectUp.PoincareTriangleDefectTasteGate single carrier alignment`

Theorem 3683.2 (Poincare triangle defect NameCert obligations)**.** *For an accepted* $\mathsf{PoincareTriangleDefect}^{\uparrow}$ *carrier* $T = (D, G, M, X, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PoincareTriangleDefect}^{\uparrow}}$ *obligations are exactly disk-point carrier admission, geodesic-side admission, hyperbolic-metric readout, cross-ratio comparison admission,* $\mathsf{Real}^{\uparrow}$ *defect sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3683.1. The tuple displays disk points, geodesic sides, metric rows, cross-ratio rows, a real seal, and the structural rows.

The disk and geodesic rows determine the finite triangle surface. The metric and cross-ratio rows provide the only comparison data from which the defect read can be formed.

The real seal R is downstream of those displayed geometric rows. The transport, replay, provenance, and local name preserve the same packet and introduce no ambient model.

Thus the listed rows exhaust the local certificate obligations. □

Theorem 3683.3 (Poincare triangle defect transport stability)**.** *Let* $T = (D, G, M, X, R, H, C, P, N)$ *be an accepted* $\mathsf{PoincareTriangleDefect}^{\uparrow}$ *carrier. Replacing disk-point rows, geodesic-side rows, hyperbolic-metric rows, cross-ratio rows, and the* $\mathsf{Real}^{\uparrow}$ *seal by displayed componentwise* hsame *rows, and replaying the replacement through* C*, preserves the admissible triangle-defect route*

$$D \longmapsto G \longmapsto M \longmapsto X \longmapsto R.$$

The transported packet exports no host hyperbolic plane, ambient angle measure, selected boundary representative, global field quotient, or unrecorded geometric equality.

Proof. The accepted carrier has a single real-facing route: disk points are displayed first, geodesic sides are read from those points, the metric and cross-ratio rows compare the displayed sides, and the real seal records the defect read.

The row H transports each displayed coordinate componentwise. The row C then replays the same continuation from the transported disk and side rows through the transported metric, cross-ratio, and real-seal rows.

The provenance row P and local name N only source and name this route. Since the carrier contains no coordinate for an ambient model or selected boundary representative, the transported defect remains the same finite BEDC packet. □

Theorem 3683.4 (Poincare triangle defect sibling route)**.** *Every accepted* $\mathsf{PoincareTriangleDefect}^{\uparrow}$ *carrier reads disk rows through the Poincare disk phase-transport surface of chapter 3455, side rows through the hyperbolic geodesic boundary surface of chapter 3491, comparison rows through the hyperbolic metric surface of chapter 3474 and the hyperbolic cross-ratio surface of chapter 3948, and terminal value rows through the real-name seal of chapter 38. The local packet exports the resulting route only through* $D, G, M, X, R, H, C, P, N$ *and exports no host hyperbolic plane, ambient angle measure, selected boundary representative, or unrecorded quotient geometry.*

Proof. Project the carrier of Definition 3683.1. The disk row D is the only row from which point data may be read, so it is routed through the Poincare disk phase-transport sibling before any side or comparison consumer sees the packet.

Next read the side and comparison rows. The side row G is routed through the hyperbolic geodesic boundary sibling, while M and X are routed through the hyperbolic metric and hyperbolic cross-ratio siblings. These four sibling surfaces provide the displayed geometric input rows; none adds a host hyperbolic plane or ambient angle measure.

Finally read R, H, C, P, N. The terminal value is sealed through the RealUp sibling, and the transport, replay, provenance, and local name rows keep the same sibling route attached to the finite triangle-defect packet. Since no accepted coordinate names a selected boundary representative or quotient geometry, those objects cannot be exported by the sibling route. □

Falsifiable prediction: A candidate implementation of $\mathsf{PoincareTriangleDefect}^{\uparrow}$ that omits any one of the disk-point, geodesic-side, hyperbolic-metric, cross-ratio, or $\mathsf{Real}^{\uparrow}$ seal rows will fail to export a stable defect read under componentwise hsame transport.

Independence witness: The packet depends on the visible rows named poincare-disk-phase-transport, hyperbolic-metric, hyperbolic-geodesic-boundary, hyperbolic-cross-ratio, and real; it does not depend on a host hyperbolic plane, ambient angle measure, selected boundary representative, or global quotient geometry. Lean TasteGate support will require explicit Nontrivial and FieldFaithful instances before the geometric rows can be checked as a typed finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareTriangleDefect}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareTriangleDefect}^{\uparrow}$ packet is generated from disk-point rows, geodesic-side rows, HyperbolicMetric rows, HyperbolicCrossRatio rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareTriangleDefect}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3683.1, Definition 3683.2, Definition 3683.3, and Definition 3683.4 seed the finite Poincare disk triangle-defect packet and its sibling dependency route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareTriangleDefect}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host hyperbolic plane, ambient angle measure, selected ideal boundary representative, global field quotient, Lean TasteGate instances, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-point admission, geodesic-side admission, hyperbolic-metric readout, cross-ratio comparison, Real seal handoff, transport stability, continuation replay, and provenance non-escape for BEDC.Derived.PoincareTriangleDefectUp.

Chapter 3684

A Concrete Naming Certificate for $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed regular Cauchy source carries a boundedness ledger before it is sealed as a Real-completion object. It sits beside the regular rational name surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the bounded regular Cauchy route of chapter 1697, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet supplies an L10 completion-facing boundedness criterion; it is not a quotient stream, not a selected limit, not countable choice, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3684.1 (Cauchy boundedness criterion carrier)**.** *A* $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the Cauchy source row, naming the regular rational sequence whose finite observations are admitted by the packet.*
2. *B is the boundedness ledger, recording the displayed initial bound, tail bound, and comparison rows that make the source a* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *object.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source at the requested precision and tail threshold.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite window and boundedness ledger.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the precision budget, bound comparison, and tail estimate consumed by the readback.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, B, W, R, D have been displayed.*
7. *H stores componentwise* hsame *transport for the Cauchy source, boundedness ledger, window row, readback row, dyadic tolerance row, Real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a bounded Cauchy request through $S, B, W, R, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$, $\mathsf{BoundedRegularCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyBoundednessCriterion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, B, W, R, D, E, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected Real limit, countable choice, trichotomy, a host supremum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyBoundednessCriterionUp.CauchyBoundednessCriterionTasteGate single carrier alignment`

Theorem 3684.2 (Cauchy boundedness criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$ *carrier*

$$K = (S, B, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyBoundednessCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row S, boundedness ledger B,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{Real}^{\uparrow}$ *seal row E, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3684.1. The analytic rows are the source S, boundedness ledger B, window row W, readback row R, dyadic tolerance row D, and Real seal E.

The boundedness obligation is read only from B together with the dyadic row D. The ledger records the displayed bound comparisons and tail estimates, while D records the precision budget consumed by those comparisons.

The regular readback is downstream of the same finite window. Thus R is a $\mathsf{RegSeqRat}^{\uparrow}$ row obtained through W, B, D, not a host sequence, quotient stream, selected limit, or completeness argument.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for countable choice, trichotomy, host suprema, quotient-stream equality, selected Real limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Theorem 3684.3 (Cauchy boundedness criterion Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing completion read exported by an accepted* $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$ *packet factors through*

$$S \longmapsto B \longmapsto W, D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently a completion consumer may use the displayed Cauchy source, boundedness ledger, finite $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and local structural rows, but it receives no quotient-stream equality, selected limit, countable choice, trichotomy, host supremum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the displayed source S. The source is admissible for the packet only as a Cauchy row whose boundedness information is supplied by the ledger B.

The finite observation then passes through W and D. The row W exposes the inspected stream window, while D supplies the dyadic tolerance and bound-comparison budget for the same request.

Only after those rows have been displayed does the packet expose R and then E. The row R is the regular rational readback, and E is the terminal Real seal served by that readback.

The structural rows H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming. Since none of the excluded objects occurs in the carrier, no completion-facing read can bypass the bounded finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBoundednessCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyBoundednessCriterion}^{\uparrow}$ packet is generated from a Cauchy source row, a boundedness ledger, a StreamName finite-window row, a RegSeqRat readback row, a DyadicRatCore tolerance row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyBoundednessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3684.1, Definition 3684.2, and Definition 3684.3 seed the finite boundedness criterion for regular Cauchy sources and Real-completion handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyBoundednessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-stream equality, selected Real limits, countable choice, trichotomy, host suprema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundedness-ledger exactness, StreamName window admission, DyadicRatCore tolerance readback, RegSeqRat handoff, Real seal confinement, transport stability, continuation replay, and provenance non-escape for BEDC.Derived.CauchyBoundednessCriterionUp.

Chapter 3685

A Concrete Naming Certificate for $\mathsf{LocatedMetricSpace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedMetricSpace}^{\uparrow}$ packet records a constructive metric space whose distance reads are located before they are consumed by the L10 Phase Real and Completion route. It refines the metric source of chapter 57 by forcing every distance observation through the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet supplies a finite NameCert surface for completion-facing consumers without importing host equality of points, quotient completion, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3685.1 (Located metric-space carrier)**.** *A* $\mathsf{LocatedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric-source carrier row, including the local point classifier and the finite point-observation windows on which distance requests are opened.*
2. *M is the metric source row inherited from chapter 57; it displays the distance witness inspected by each accepted pair of point observations.*
3. *D is the located-distance witness and dyadic tolerance ledger. For each displayed distance request and positive tolerance, it records the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison data that locates the requested distance at that scale.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It packages the dyadic comparison windows in D as regular rational distance names before any real-facing consumer can read them.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *readback and seal boundary reached only after the metric source, located-distance witness, dyadic tolerance ledger, and regular rational readback have all been displayed.*
6. *H stores componentwise* hsame *transport for point observations, metric source rows, located-distance witnesses, dyadic tolerance ledgers, regular rational readbacks, real seals, replay rows, provenance rows, and local naming rows.*
7. *C stores displayed* Cont *replay from point observations to metric witnesses, from metric witnesses to located dyadic comparisons, from those comparisons to* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and from the readbacks to the* $\mathsf{Real}^{\uparrow}$ *seal.*

8. *P is the* Pkg *provenance over* $\mathsf{LocatedMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted located metric-space packets only through $X, M, D, R, E, H, C, P, N$. It has no coordinate for host equality of points, quotient real equality, quotient completion, selected limits, total trichotomy of distances, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedMetricSpaceUp.LocatedMetricSpaceTasteGate single carrier alignment`

Theorem 3685.2 (Located metric-space NameCert obligations)**.** *For every accepted* $\mathsf{LocatedMetricSpace}^{\uparrow}$ *carrier*

$$L = (X, M, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, distance-witness readback through M, located-distance and dyadic tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 3685.1. The point observations and their local classifier are read from X, and every distance request is forced through the metric source row M before locatedness data can be inspected.

The located-distance obligation is the role of D. A positive tolerance request reads the dyadic comparison window stored in the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, so the packet gives a finite locatedness witness rather than a semantic real-order decision.

The readback obligation then passes through R and E. Row R packages the same dyadic windows as regular rational distance names, and row E exposes the real seal only after that regular readback has been displayed.

Finally, H, C, P, N transport, replay, source, and name exactly the same rows. Since the carrier contains no coordinate for host point equality, quotient equality, quotient completion, selected limits, trichotomy, choice, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3685.3 (L10 located metric-space completion route)**.** *Every L10 Phase Real and Completion consumer that reads an accepted* $\mathsf{LocatedMetricSpace}^{\uparrow}$ *packet factors through*

$$X \longmapsto M \longmapsto D \longmapsto R \longmapsto E$$

together with H, C, P, N. Thus completion-facing distance reads pass through the metric source, located-distance witness, dyadic tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal before any completion data is consumed.*

Proof. Begin with a completion-facing distance request. The source row X supplies only displayed point observations, so the request must use the metric source row M to obtain the finite distance witness certified by the metric sibling.

Locatedness is supplied by D. The dyadic tolerance ledger binds the requested radius to the same metric witness, and it exposes only finite $\mathsf{DyadicRatCore}^{\uparrow}$ comparison data at the requested scale.

The L10 real-facing route is then determined by R and E. The regular rational readback packages the dyadic windows as distance-name data, and the real seal is reached only after that package is visible.

Rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Because no excluded quotient, selection, host equality, choice, trichotomy, or ambient-completeness coordinate appears in the carrier, every completion-facing read remains on the displayed L10 route. □

Falsifiable prediction: Every L10 completion-facing read from a $\mathsf{LocatedMetricSpace}^{\uparrow}$ packet factors through the displayed metric source, located-distance witness, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise transport, continuation replay, provenance, and local naming row before completion data is consumed.

Independence witness: metric, dyadicratcore, regseqrat, real: $\mathsf{LocatedMetricSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source, located-distance witness, dyadic tolerance ledger, RegSeqRat readback, RealUp seal, componentwise transport, continuation replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedMetricSpace}^{\uparrow}$ packet is generated from a metric source, located-distance witness, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3685.1, Definition 3685.2, and Definition 3685.3 seed the located metric-space carrier and its L10 real-and-completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host equality of points, quotient real equality, quotient completion, selected limits, total trichotomy of distances, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-distance witness exactness, dyadic tolerance ledger accounting, RegSeqRat readback, RealUp seal handoff, transport replay, and ledger refusal for BEDC.Derived.LocatedMetricSpaceU

Chapter 3686

A Concrete Naming Certificate for $\mathsf{ProperMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{ProperMetricSpace}^{\uparrow}$ packet records the constructive metric-space interface in which displayed closed metric balls carry compactness-style readback for completion consumers. It sits after the metric carrier of chapter 57, the open-ball boundary of chapter 1450, the closed-ball containment surface of chapter 3464, the compact-metric certificate of chapter 129, the bounded-family completion route of chapter 1896, and the terminal real-name seal of chapter 38. The packet is a finite closed-ball compactness ledger, not an open-cover compactness theorem, a selected finite subcover, quotient point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3686.1 (Proper metric space carrier)**.** *A* $\mathsf{ProperMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P_{\mathrm{pms}} = (X, B, R, K, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *row carrying the point classifier, distance witnesses, and metric transport surface.*
2. *B is the displayed family of* $\mathsf{ClosedMetricBall}^{\uparrow}$ *rows indexed by the accepted center-radius windows of X.*
3. *R is the radius ledger, recording nonnegative radius rows, strict-boundary handoffs to* $\mathsf{MetricBall}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *comparison readback.*
4. *K assigns compactness-style* $\mathsf{CompactMetric}^{\uparrow}$ *readback to each displayed closed ball in B.*
5. *O records compatibility between the closed-ball family and the* $\mathsf{CauchyBornology}^{\uparrow}$ *bounded-family route consumed by completion-facing readers.*
6. *H records componentwise* hsame *transport for the metric row, closed-ball family, radius ledger, compactness readback, bornology compatibility, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a proper-metric request through X, B, R, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ProperMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{ClosedMetricBall}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{CauchyBornology}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProperMetricSpace}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows and exposes no host subset of points, open-cover compactness object, selected compactness witness outside the displayed closed ball, quotient metric equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.ProperMetricSpaceUp.TasteGate.ProperMetricSpaceTasteGate single carrier alignment`

Theorem 3686.2 (Proper metric space NameCert obligations)**.** *For every accepted* $\mathsf{ProperMetricSpace}^{\uparrow}$ *carrier*

$$P_{\mathrm{pms}} = (X, B, R, K, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProperMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric row* X*, closed-ball family row* B*, radius ledger* R*, compactness readback* K*, bornology compatibility row* O*, componentwise transport* H*, displayed replay* C*, package provenance* P*, and local naming* N*; center-radius compatibility between* X, B, R*; compact readback exactness for each displayed ball through* K*; completion-facing bounded-family compatibility through* O*; and non-escape for host subsets, open-cover compactness, selected subcovers, quotient point equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3686.1. The metric row, closed-ball family, radius ledger, compact readback, bornology compatibility, and structural rows are all displayed before a consumer reads the local naming row.

Center-radius compatibility is forced by the order of the rows. The row X supplies the metric source, B supplies only closed balls over that source, and R supplies the radius comparisons and strict-boundary handoffs used by $\mathsf{MetricBall}^{\uparrow}$ consumers.

Compactness readback is attached ball by ball. The row K is indexed by the displayed closed-ball family B, so a consumer cannot replace it by an open-cover compactness proof or by a compactness witness for an undisplayed ball.

Finally O, H, C, P, N preserve the same route for completion-facing and bounded-family consumers. Since the carrier has no coordinate for the excluded host principles, the listed rows exhaust the NameCert obligations. □

Theorem 3686.3 (Proper metric space closed-ball compactness readback)**.** *Every compactness-style read of a displayed closed ball in an accepted* $\mathsf{ProperMetricSpace}^{\uparrow}$ *packet factors through*

$$\mathsf{Met}^{\uparrow},\quad \mathsf{ClosedMetricBall}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The $\mathsf{ClosedMetricBall}^{\uparrow}$ *row supplies the center-radius containment, the radius ledger supplies the ordered-real comparison, and the* $\mathsf{CompactMetric}^{\uparrow}$ *row supplies the compactness readback attached to that same displayed ball. The readback exports no open-cover compactness theorem, selected finite subcover, quotient point equality, host closed subset, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the closed-ball family row B of Definition 3686.1. Each accepted ball read is indexed by a center-radius window over the metric row X and by a radius comparison in R.

Read the compactness row K only after that ball is fixed. Its index is the displayed closed-ball row, so compactness-style data are attached to the same metric source, center, radius, and containment comparison.

The structural rows H, C, P, N transport, replay, source, and name this finite route. No row names an open cover, a chosen subcover, a quotient point equality, or an ambient completeness theorem. □

Theorem 3686.4 (Proper metric space ball-bornology boundary)**.** *Every completion-facing consumer of an accepted* $\mathsf{ProperMetricSpace}^{\uparrow}$ *packet reads bounded-family data through the displayed boundary*

$$\mathsf{MetricBall}^{\uparrow},\quad \mathsf{ClosedMetricBall}^{\uparrow},\quad \mathsf{CauchyBornology}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{Real}^{\uparrow}.$$

Open-ball handoffs use the strict-radius side of R, closed-ball handoffs use B, bounded-family requests use O, and compactness-style requests use K. Thus the consumer receives a finite ball and bornology boundary rather than a host bounded set, selected bound, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the radius ledger R. Its strict-radius entries are the only route to $\mathsf{MetricBall}^{\uparrow}$ consumers, while its non-strict entries are the radius comparisons used by the $\mathsf{ClosedMetricBall}^{\uparrow}$ family B.

The bornology compatibility row O is downstream of those ball rows. A completion-facing consumer therefore reads bounded-family data only after the metric row, radius ledger, and ball family have been displayed.

Compactness-style information remains attached through K. The same transport, replay, provenance, and local naming rows preserve the boundary, so the route cannot turn into a host bounded set, selected bound, open-cover compactness proof, or ambient Real-completeness datum. □

Theorem 3686.5 (Proper metric space compact-ball route)**.** *Every completion-facing proper-metric consumer must expose the metric row X, the displayed* $\mathsf{ClosedMetricBall}^{\uparrow}$ *family B, the* $\mathsf{Real}^{\uparrow}$ *radius ledger R, the* $\mathsf{CompactMetric}^{\uparrow}$ *readback row K, the* $\mathsf{CauchyBornology}^{\uparrow}$ *bounded-family route O, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N before reading compact-ball data.*

The compact-ball route is therefore the displayed finite packet

$$X, B, R, K, O, H, C, P, N$$

read in the order forced by Definition 3686.1. It refuses open-cover compactness, selected finite subcovers, quotient point equality, host bounded sets, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3686.1. The only available completion-facing rows are the metric source, closed-ball family, radius ledger, compact readback, bornology route, transport, replay, provenance, and local naming rows.

Use the closed-ball compactness readback theorem, Definition 3686.3, to attach compactness-style information to a displayed closed ball over X, B, R. Then compose the ball-bornology boundary of Definition 3686.4, which routes bounded-family consumers through O while keeping the compact readback attached through K.

The structural rows H, C, P, N preserve the same finite route. Since no carrier coordinate names open covers, selected finite subcovers, quotient point equality, host bounded sets, or ambient Real completeness, a compact-ball consumer cannot read any of those principles from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProperMetricSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProperMetricSpace}^{\uparrow}$ packet is generated from a MetricUp row, a displayed ClosedMetricBallUp family, a RealUp radius ledger, CompactMetricUp readback for each displayed closed ball, CauchyBornologyUp compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProperMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3686.1, Definition 3686.2, Definition 3686.3, Definition 3686.4, and Definition 3686.5 seed the constructive closed-ball compactness ledger for completion-facing proper metric space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProperMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, open-cover compactness, selected subcovers, quotient metric equality, host bounded sets, arbitrary compactness outside displayed closed balls, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, center-radius compatibility, compact readback exactness, ball-bornology boundary routing, transport, replay, provenance, and local NameCert exactness for BEDC.Derived.ProperMetricSpace

Chapter 3687

A Concrete Naming Certificate for $\mathsf{CompleteMetricSpace}^{\uparrow}$

Following Bishop and Bridges constructive metric completion, the $\mathsf{CompleteMetricSpace}^{\uparrow}$ packet records a metric carrier together with finite Cauchy-limit service data visible to BEDC consumers. It sits beside the constructive metric surface of chapter 3673, the separated metric route of chapter 2355, the regular Cauchy completion unit of chapter 3646, and the Real-facing finite-window route of chapter 38. The packet supplies an L10 completion-facing neighbour for separated metric, Baire, and completion chapters; it is not a quotient completion, not a selected-limit principle, not countable choice, not host equality, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3687.1 (Complete metric-space carrier)**.** *A* $\mathsf{CompleteMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, C, E, L, U, H, T, P, N)$$

with the following displayed rows:

1. *M is the underlying* $\mathsf{Met}^{\uparrow}$ *row, exposing only the point-name and distance-read surfaces consumed by the packet.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, recording that accepted Cauchy requests are answered through displayed limit rows.*
3. *E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *boundary row, used only to identify regular Cauchy names that have the same displayed tail behaviour.*
4. *L is the limit-row ledger. It names the proposed limit point, the convergence-distance rows, and the precision requests consumed by the limit service.*
5. *U is the uniform Cauchy-service route through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*; it exposes finite windows, regular rational readbacks, and the terminal Real seal in that order.*
6. *H stores componentwise* hsame *transport for the metric row, completeness row, Cauchy-equivalence boundary, limit ledger, uniform service route, replay, provenance, and local naming rows.*
7. *T stores displayed* Cont *replay from Cauchy-request inspection through M, C, E, L, U, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, C, E, L, U, H, T, P, N$. It has no coordinate for quotient completions, selected limits, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompleteMetricSpaceUp.CompleteMetricSpaceTasteGate single carrier alignment`

Theorem 3687.2 (Complete metric-space NameCert obligations)**.** *For every accepted* $\mathsf{CompleteMetricSpace}^{\uparrow}$ *carrier*

$$K = (M, C, E, L, U, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric row M, the complete-metric service row C, the Cauchy-sequence equivalence boundary E, the limit-row ledger L, the uniform Cauchy-service route U, componentwise transport H, displayed replay T, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3687.1. The projection exposes exactly the metric surface M, completeness service C, Cauchy-equivalence boundary E, limit ledger L, uniform service route U, and structural rows H, T, P, N.

The completeness service is read only through C and L. A consumer receives a displayed limit row and convergence-distance ledger, not a quotient completion object or an externally selected representative.

The Cauchy boundary is confined to E, while the finite observation route is confined to U. Thus tail comparison passes through $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any limit read is exported.

Finally H, T, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for countable choice, host equality, trichotomy, selected limits, quotient completions, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Theorem 3687.3 (Complete metric-space Cauchy-limit route)**.** *Every Cauchy-limit read exported by an accepted* $\mathsf{CompleteMetricSpace}^{\uparrow}$ *packet factors through*

$$M \longmapsto E \longmapsto U \longmapsto C, L \longmapsto H, T, P, N.$$

Consequently separated metric, Baire, and completion-facing consumers may use only the displayed metric row, Cauchy-equivalence boundary, finite-window regular readback route, complete-metric service row, limit ledger, transport, replay, provenance, and local naming.

Proof. Begin with the metric row M. It supplies the point-name and distance-read surface, but it does not by itself export a limit object.

The Cauchy request then passes through E and U. The row E fixes the tail-equivalence boundary for the displayed Cauchy name, while U exposes the finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and terminal $\mathsf{Real}^{\uparrow}$ seal needed for the convergence-distance route.

Only after those rows are displayed may the packet read C and L. The row C supplies the complete-metric service, and L records the proposed limit point and convergence ledger for the same request.

The rows H, T, P, N preserve that route under transport, replay, provenance, and local naming. Any route that appeals to quotient completions, selected limits, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness has no displayed coordinate in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteMetricSpace}^{\uparrow}$ packet is generated from a Metric row, a CompleteMetric service row, a CauchySequenceEquivalence boundary, a limit ledger, a RegSeqRat–StreamName–Real uniform service route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3687.1, Definition 3687.2, and Definition 3687.3 seed the finite complete metric-space carrier, NameCert obligation surface, and Cauchy-limit route for separated metric, Baire, and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-equivalence exactness, finite-window regular readback, complete-metric service confinement, limit-ledger exactness, and non-escape for BEDC.Derived.CompleteMetricSpaceUp.

The $\mathsf{Cauchy}^{\uparrow}$ hub routes finite completion reads through the sibling lattice of chapter 126, chapter 301, chapter 38, chapter 3794, and chapter 1569 before any completed-object consumer is reached.

Chapter 3688

A Concrete Naming Certificate for $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ packet records the constructive complete ordered-field interface by finite regular-Cauchy and order-algebra rows rather than by an ambient completed real line. It sits beside the terminal Real naming seal of chapter 38, the regular rational sequence packet of chapter 301, the finite stream-window surface of chapter 126, the dyadic arithmetic substrate of chapter 291, the constructive algebraic order packet of chapter 766, and the Bishop real completion route of chapter 3665. The chapter exposes the common interface downstream completion and metric chapters can cite when they need Real scalars, regular Cauchy limit rows, and ordered-field compatibility in one NameCert packet.

Definition 3688.1 (Cauchy-complete ordered-field carrier)**.** *A* $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, D, S, Q, B, A, L, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar row, read only through terminal Real name seals.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-precision ledger used by the regular Cauchy and order rows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row for rational windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row.*
5. *B is the* $\mathsf{BishopRealCompletion}^{\uparrow}$ *completion route from D, S, Q into the Real seal R.*
6. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *algebra-order row, recording addition, multiplication, zero, one, positivity, and order compatibility only as displayed finite ledger entries.*
7. *L is the regular-Cauchy limit ledger naming accepted Cauchy requests, precision windows, candidate limit rows, and convergence readbacks through D, S, Q, B, R.*
8. *O is the order-algebra compatibility ledger, recording that limit rows preserve the displayed ordered-field operations through A and not through host equality.*
9. *H records componentwise* hsame *transport for scalar, dyadic, stream, regular-Cauchy, completion, algebra-order, limit, compatibility, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from precision requests through regular Cauchy readback, Bishop completion, Real sealing, algebra-order compatibility, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedField}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, D, S, Q, B, A, L, O, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of real names, trichotomy, open-cover compactness, selected representatives, or choice.*

Theorem 3688.2 (Cauchy-complete ordered-field NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ *carrier*

$$K = (R, D, S, Q, B, A, L, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedField}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Real scalar row R, dyadic precision ledger D, stream-window row S, regular rational sequence row Q, Bishop completion route B, algebra-order row A, regular-Cauchy limit ledger L, order-algebra compatibility ledger O, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3688.1. The projection exposes exactly the Real scalar, dyadic precision, stream-window, regular rational, Bishop completion, algebra-order, limit, compatibility, transport, replay, provenance, and naming rows.

The completion-facing rows are read only through D, S, Q, B, R, L. A consumer receives finite precision requests, finite rational windows, regular readbacks, the Bishop completion route, the terminal Real seal, and a displayed limit ledger.

The ordered-field rows are read only through A and O. They record operation and order compatibility for the same displayed limit rows, without adding host equality, quotient representatives, trichotomy, open-cover compactness, selected limits, or choice.

Finally H, C, P, N transport, replay, source, and name that finite surface. Since the carrier has no further coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 3688.3 (Regular-Cauchy limit route)**.** *Every limit read exported by an accepted* CauchyCompleteOrderedF *packet factors through the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{BishopRealCompletion}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

and then through the displayed limit ledger L and structural rows H, C, P, N. Thus downstream completion and metric consumers may cite one finite interface for regular-Cauchy limit service, but they receive no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient equality, selected representative, trichotomy, open-cover compactness, or choice principle.*

Proof. Begin with the precision ledger D. It supplies only the positive dyadic rows inspected by the regular-Cauchy request.

The request then passes through S and Q. The row S names the finite rational windows, and Q supplies the regular rational readback for those windows.

Only after that readback may the packet use B and R. The Bishop completion row B routes the same data to the terminal Real seal R, while L records the candidate limit and convergence readbacks for the accepted request.

The rows H, C, P, N preserve, replay, source, and name the route. No excluded ambient completeness or choice coordinate appears in the carrier, so every exported limit read is confined to the stated finite path. □

Theorem 3688.4 (Order-algebra compatibility route)**.** *Every algebraic or order read exported by an accepted* $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ *packet factors through the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row A together with the regular-Cauchy limit ledger L and the compatibility ledger O. Addition, multiplication, zero, one, positivity, and order comparison are available only as displayed rows compatible with the route through D, S, Q, B, R, and not as ambient host-field operations.*

Proof. Read the algebra-order row A. It is the only coordinate naming field operations and order comparison, so a consumer cannot obtain algebraic structure from the host Real carrier.

Next read the limit ledger L. The ledger ties the operation and order requests to the same regular-Cauchy route through D, S, Q, B, R used for limit service.

Use the compatibility ledger O to bind the two surfaces. It records preservation of addition, multiplication, zero, one, positivity, and order comparison for the displayed limit rows.

Transport and replay are again confined to H and C, with P and N supplying provenance and local naming. Thus the compatibility surface remains finite and supplies no quotient equality, trichotomy, open-cover compactness, selected representative, ambient completeness, or choice. □

Theorem 3688.5 (Cauchy-complete ordered-field regular-Cauchy existence)**.** *For every accepted* $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ *carrier*

$$K = (R, D, S, Q, B, A, L, O, H, C, P, N),$$

every regular-Cauchy limit request admitted by K is presented only by a finite route through

$$D \longrightarrow S \longrightarrow Q \longrightarrow B \longrightarrow R$$

and by the limit ledger L. The existence surface therefore names limit service as displayed precision, stream-window, regular-sequence, Bishop-completion, Real-seal, and ledger rows, with no quotient equality, selected representative, choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with an admitted limit request. The carrier projection gives the dyadic precision row D, stream-window row S, regular rational sequence row Q, Bishop completion route B, Real seal R, and limit ledger L as the only completion-facing coordinates.

The request is first read against D, then against the finite observation row S, then against the regular-sequence row Q. The route can enter the Real naming surface only through B and then R.

The ledger L records the accepted request, the precision windows, the candidate limit row, and the convergence readbacks for that same route. Since the carrier has no quotient, representative-selection, choice, trichotomy, or ambient-completeness coordinate, the displayed rows are the whole existence surface. □

Theorem 3688.6 (Cauchy-complete ordered-field order-limit transport)**.** *For every accepted* $\mathsf{CauchyCompleteOrder}$ *carrier*

$$K = (R, D, S, Q, B, A, L, O, H, C, P, N),$$

every algebraic and order read on a limit row of L factors through the algebra-order row A and the compatibility ledger O. The transport rows H, replay rows C, provenance row P, and local naming row N preserve that same finite route through D, S, Q, B, R, L, A, O and add no host equality, selected representative, choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read a limit row from L. Its completion data has already been confined to the route through D, S, Q, B, R.

Algebraic and order observations can then use only A and O. The row A names addition, multiplication, zero, one, positivity, and comparison, while O records that those reads are compatible with the same displayed limit rows.

The structural rows do not create a second route. The transport row H preserves the componentwise names, C replays the displayed dependencies, P records provenance, and N supplies the local certificate name. Hence order-limit transport stays on the finite rows and does not expose host-field equality, representatives, choice, trichotomy, or ambient completeness. □

Theorem 3688.7 (CauchyCompleteOrderedField scoped kernel route)**.** *For every accepted* CauchyCompleteOrdere *carrier*

$$K = (R, D, S, Q, B, A, L, O, H, C, P, N),$$

the consumer-visible kernel route consists exactly of Real scalar exposure through R, dyadic precision through D, finite $\mathsf{StreamName}^{\uparrow}$ *windows through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, Bishop completion handoff through B,* $\mathsf{RealAlgOrder}^{\uparrow}$ *operations through A, regular-Cauchy limit ledger reads through L, order-algebra compatibility through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedField}^{\uparrow}}$ *row N. No accepted carrier exports ambient Real completeness, quotient streams, host field operations, trichotomy, or selected limits beyond those displayed rows.*

Proof. Project the carrier of Definition 3688.1. The projection exposes precisely the rows $R, D, S, Q, B, A, L, O, H, C$ so any consumer route must begin inside the displayed finite packet.

Apply the NameCert obligations of Definition 3688.2. They identify the Real scalar, dyadic precision, stream-window, regular-rational, Bishop completion, algebra-order, limit, compatibility, transport, replay, provenance, and local naming rows as the full obligation surface.

The completion side is then fixed by Definition 3688.3. The route to a Real-facing limit read passes through D, S, Q, B, R, L and the structural rows, with no quotient stream or selected-limit coordinate.

The algebra and order side is fixed by Definition 3688.4. Operations and order comparisons are read only through A and O against the same displayed limit ledger.

Since no carrier coordinate remains after H, C, P, N, the route refuses ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, host field operations, trichotomy, and selected limits. The scoped dependency surface is exactly the finite row list stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedField}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ packet is generated from Real scalar seals, dyadic precision rows, StreamName windows, RegSeqRat readbacks, a BishopRealCompletion route, RealAlgOrder operation and order rows, regular-Cauchy limit ledgers, compatibility ledgers, componentwise transport, replay, provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedField}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 3688.1, Definition 3688.2, Definition 3688.3, Definition 3688.4, Definition 3688.5, Definition 3688.6, and Definition 3688.7 close the explicit finite scoped surface for Real, regular-Cauchy existence, order-limit transport, completion, and metric consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedField}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of real names, trichotomy, open-cover compactness, selected representatives, choice, Lean verification, or bridge checking.

Upgrade path: Public closure requires checked consumer exports and downstream bridge rows for BEDC.Derived.CauchyCompleteOrdered

The $\mathsf{Cauchy}^{\uparrow}$ hub exposes a displayed Real and Completion route only after finite stream windows and regular rational readback rows have been made visible. This child route records the dependency on chapter 126, chapter 301, and chapter 38 without adding substantive prose to the hub.

Theorem 3688.8 (Cauchy displayed RegSeqRat route)**.** *Any* $\mathsf{Cauchy}^{\uparrow}$ *route used by the L10* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *surface must pass through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows before a* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The route carries only displayed* BHist*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows, and it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyDisplayedRegseqratRoute`

Proof. Begin with a Real- or Completion-facing Cauchy read. The finite window surface of chapter 126 is the first visible observation boundary, so the consumer cannot treat the Cauchy source as an uninspected host sequence.

Read those windows through chapter 301. The regular rational readback row supplies the displayed tail data required before any terminal seal can be used.

Finally consume the terminal row of chapter 38. The structural rows transport, replay, source, and name the same finite route, so the Cauchy handoff reaches the L10 Real and Completion surface only after StreamName windows and RegSeqRat readback have been displayed. □

Theorem 3688.9 (Cauchy L10 child dependency route)**.** *Every finite-window read exported by the* $\mathsf{Cauchy}^{\uparrow}$ *hub is consumed by sibling L10 chapters only after it passes through the child routes displayed in this chapter. The regular-rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-facing route of chapter 1569 read the* $\mathsf{Cauchy}^{\uparrow}$ *packet through finite stream windows, dyadic tolerance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. No child route exports quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the hub through its child files. The core carrier in chapter 3413 displays the stream-window, dyadic tolerance, regular readback, transport, replay, provenance, and naming rows before any downstream consumer can inspect a Cauchy object.

The sibling dependency spine then sends those rows to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The cited regular-rational and Real chapters consume only the displayed finite route; they do not receive a quotient stream, selected limit, choice schedule, trichotomy oracle, host equality coordinate, or ambient completeness proof.

The completion-facing consumer follows the same rows through the Cauchy-filter completion surface. Because the hub contains only child inputs and each child route exposes finite BHist and NameCert data, the L10 dependency path is connected through sibling chapters rather than through an unstated top-level object. □

Theorem 3688.10 (Cauchy RegSeqRat and completion forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *finite-window packet consumed by* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *factors through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The route exports no quotient streams, selected limits, choice schedules, host equality, or ambient completeness.*

Proof. Start with the child dependency route above. It already displays the finite stream-window, dyadic tolerance, regular readback, Real-seal, transport, replay, provenance, and naming rows before any L10 consumer reads a Cauchy packet.

The regular rational and Real consumers are the first forward users. The chapters chapter 301 and chapter 38 read only the displayed finite windows, readback rows, tolerance rows, and terminal seal.

The completion consumer reads the same route through chapter 1506. A metric-completion request can inspect Cauchy data only after the finite windows, tolerances, readbacks, Real seal, transport, replay, provenance, and local naming rows have been displayed.

The excluded objects have no row in this finite route. Thus quotient streams, selected limits, choice schedules, host equality, and ambient completeness cannot be exported by the forward handoff. □

The L10 route consumes $\mathsf{Cauchy}^{\uparrow}$ through the finite-window surface of chapter 126, the regular readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal seal rows of chapter 38. These four child dependencies keep the Cauchy packet attached to finite stream windows, regular rational evidence, dyadic budgets, and the Real seal before any L10 consumer may read it.

Every $\mathsf{Cauchy}^{\uparrow}$ read used by Real and completion consumers factors through the same horizontal lattice: finite observation windows from chapter 126, regular-rational readback from chapter 301, dyadic tolerance rows from chapter 291, and the terminal seal of chapter 38. Downstream consumers therefore receive a displayed finite-window route before they may treat the packet as Real-facing Cauchy data.

Theorem 3688.11 (Cauchy regular-source completion dependency route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *read consumed by an L10 completion-facing packet is public only through the displayed dependency route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route first exposes the regular-rational tail budget of chapter 301, then the metric-distance comparison used by the $\mathsf{MetricCompletion}^{\uparrow}$ *boundary of chapter 1506, and only then the terminal real seal of chapter 38. It exports no quotient stream, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the $\mathsf{Cauchy}^{\uparrow}$ hub through its child carriers. The hub contributes only displayed finite rows, so a completion-facing consumer must first inspect the regular-rational tail budget that names the tail data and tolerance requests.

Next compare distances at the metric-completion boundary. The $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives the same displayed regular-source route and metric-distance comparison; it does not receive a quotient representative or a selected completed point.

Finally consume the terminal $\mathsf{Real}^{\uparrow}$ seal. Since the seal is reached only after the regular tail budget and the metric-completion comparison have been displayed, the public route is a dependency edge through sibling chapters rather than an ambient completeness principle. □

Theorem 3688.12 (Cauchy filter-base net-convergence route)**.** *Every completion-facing consumer of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet that reads Cauchy finite-window evidence through filter or net interfaces must first pass through the displayed routes of chapter 1601, chapter 1915, and chapter 1667. The route exposes the same finite windows, tolerance ledger, tail comparisons, componentwise transport, replay, provenance, and local naming rows before any filter-base or net-convergence*

completion consumer inspects the packet. It exports no selected limit, quotient completion equality, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or detached net convergence theorem.*

Proof. Project the accepted $\mathsf{Cauchy}^{\uparrow}$ packet to its finite-window and tolerance rows. These are the only rows available to a downstream filter or net consumer.

The filter-base read is routed through the finite basis surface named by chapter 1601 and the Cauchy-specific basis of chapter 1915. The net read then passes through chapter 1667, which consumes the same displayed rows rather than a separate completion theorem.

Since the route never adds a coordinate for selected limits, quotient completion equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or detached convergence, those objects remain outside the exported Cauchy packet. □

Theorem 3688.13 (Cauchy RegSeqRat–Real completion lattice)**.** *Every completion-facing* $\mathsf{Cauchy}^{\uparrow}$ *read factors through the displayed sibling lattice*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before any completion consumer may read a limit row. The StreamName windows are the observation boundary of chapter 126; the regular rational tails are the readback boundary of chapter 301; the metric-completion request is the comparison boundary of chapter 1506; and the terminal seal is the Real boundary of chapter 38. The route exports no quotient stream, selected representative, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRegSeqRatRealCompletionLattice`

Proof. Read the hub through its displayed child routes. The finite-window dependency of Definition 3688.8 and the RegSeqRat–StreamName dependency lattice already force every Real-facing Cauchy read to expose $\mathsf{StreamName}^{\uparrow}$ windows before it consumes regular rational readback rows.

Next apply the regular-source completion route of Definition 3688.11. The $\mathsf{MetricCompletion}^{\uparrow}$ boundary receives the same displayed $\mathsf{RegSeqRat}^{\uparrow}$ tail budget, so a completion consumer cannot jump directly from a Cauchy name to a limit row.

Finally use the metric-completion forward lattice. It places the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the metric-completion comparison, with no quotient stream, selected representative, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate. Thus the public completion read is exactly the four-surface lattice displayed in the statement. □

Every completion-facing $\mathsf{Cauchy}^{\uparrow}$ read first exposes the regular rational row of chapter 301, then passes the same finite-window and tolerance data to the $\mathsf{MetricCompletion}^{\uparrow}$ boundary of chapter 1506, and only afterward reaches the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Thus the visible dependency route is $\mathsf{Cauchy}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{MetricCompletion}^{\uparrow} \to \mathsf{Real}^{\uparrow}$, not a self-contained hub read, quotient stream, selected limit, or ambient completeness principle.

Theorem 3688.14 (Cauchy regular-fusion forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *completion-facing read that uses a fused regular-Cauchy tail passes through the sibling* $\mathsf{RegularCauchyFusion}^{\uparrow}$ *packet before the Cauchy hub exports the route. The displayed route consumes the* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *evidence,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows before any completion consumer may inspect the fused tail.*

Proof. Read the fused tail as a sibling packet rather than as a hidden coordinate of the Cauchy hub. The $\mathsf{RegularCauchyFusion}^{\uparrow}$ row supplies the displayed fusion boundary, while $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ expose the finite observation windows, regular-rational readback, and dyadic tolerance rows used by the tail.

The completion-facing consumer then reaches the $\mathsf{Real}^{\uparrow}$ seal only after the finite route has been replayed through BHist, hsame, Cont, Pkg, and NameCert. Thus the Cauchy hub exports a sibling dependency route for fused regular-Cauchy tails, not a quotient stream, selected limit, choice schedule, trichotomy oracle, or ambient completeness row. □

The $\mathsf{Cauchy}^{\uparrow}$ carrier reads regular rational tails through chapter 301 and finite observation schedules through chapter 126. The tolerance rows supplied by chapter 291 and the terminal sealing of chapter 38 remain downstream of that lattice, so the hub exposes the RegSeqRat and StreamName dependencies before completion-facing consumers inspect the Real boundary.

Theorem 3688.15 (Cauchy RegSeqRat and Real sibling lattice repair)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *route used by this hub depends on the* $\mathsf{RegSeqRat}^{\uparrow}$ *sibling for regular rational windows and on the* $\mathsf{Real}^{\uparrow}$ *sibling for the terminal seal boundary. Thus every completion-facing consumer first reads the regular rational dependency of chapter 301 and then the Real seal of chapter 38; the hub exports no quotient stream, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row of its own.*

Proof. Use the displayed RegSeqRat dependency files already routed through the hub. They force the Cauchy read through regular rational windows before any completion-facing row can be interpreted.

Then apply the terminal Real sibling route named by chapter 38. The seal boundary is therefore read as a sibling obligation after RegSeqRat evidence, not as hidden content of the top-level hub. □

The $\mathsf{Cauchy}^{\uparrow}$ hub also exposes the forward lattice used by regular-real consumers: the displayed Cauchy source is first read as $\mathsf{RegSeqRat}^{\uparrow}$ data and then handed to the $\mathsf{RegularCauchyReal}^{\uparrow}$ packet before any terminal real-facing consumer treats it as a completed object.

Theorem 3688.16 (Cauchy RegSeqRat to RegularCauchyReal sibling route)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *route consumed by a regular-real boundary must pass through the regular rational readback of chapter 301 before it reaches the* $\mathsf{RegularCauchyReal}^{\uparrow}$ *carrier of chapter 3546. The route exports a displayed L10 handoff through finite windows, regular readback, transport, replay, provenance, and local naming; it exports no detached Cauchy representative, quotient stream equality, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the hub through its existing regular-source children. Those children expose the Cauchy data as finite observation windows and regular rational rows before any real-facing seal can be consumed.

The $\mathsf{RegSeqRat}^{\uparrow}$ row is then the source read by the $\mathsf{RegularCauchyReal}^{\uparrow}$ carrier. Its sibling chapter adds the StreamName, dyadic tolerance, convergence handoff, Real seal, transport, replay, provenance, and local naming rows around the same regular readback.

Since neither route contains a detached representative, quotient stream equality, selected limit, countable-choice schedule, or ambient completeness coordinate, the handoff is exactly the displayed finite L10 lattice. □

The public $\mathsf{Cauchy}^{\uparrow}$ route consumed by completion and real-readback arguments is routed through the same finite lattice: $\mathsf{StreamName}^{\uparrow}$ windows from chapter 126, $\mathsf{RegSeqRat}^{\uparrow}$ rational

readback from chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the net-facing completion surface of chapter 3794, and the filter-facing completion surface of chapter 1569. The hub exports this dependency route only as finite BHist, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ data; it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.

Theorem 3688.17 (Cauchy RegSeqRat Real dependency top link)**.** *Every completion-facing* $\mathsf{Cauchy}^{\uparrow}$ *consumer must expose the regular-source row of chapter 301, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before it can read a completion endpoint. The route remains inside componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row.*

Proof. Read the top-level $\mathsf{Cauchy}^{\uparrow}$ hub through its displayed children. The hub exports only ordered sibling routes, so a completion-facing consumer first encounters finite observation windows and dyadic tolerance data rather than a hidden completion endpoint.

The regular-source handoff is then forced through the $\mathsf{RegSeqRat}^{\uparrow}$ row named by chapter 301. Only after that handoff is visible can the consumer read the terminal $\mathsf{Real}^{\uparrow}$ seal named by chapter 38.

The structural rows preserve the same path. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row keep the completion read inside the finite packet, with no quotient stream, selected limit, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 3688.18 (Cauchy forward RegSeqRat and Real route)**.** *Every completion-facing read of an accepted* $\mathsf{Cauchy}^{\uparrow}$ *packet must pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301 and then the terminal* $\mathsf{Real}^{\uparrow}$ *seal row of chapter 38 before any completion consumer may use it. The route carries only the finite stream-window, dyadic tolerance, regular-rational readback, real-seal,* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows exposed by the Cauchy sibling files; it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Begin with the carrier of Definition 3413.1. Its public readback is organized by finite stream windows, dyadic tolerances, regular-rational readback, terminal real-name sealing, componentwise transport, replay, provenance, and local naming.

Apply Definition 3688.8 and Definition 3413.4. These routes place every Real-facing or completion-facing Cauchy read behind displayed finite windows and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row before any terminal seal is consumed.

Finally apply Definition 3413.9 together with Definition 5888.13. The Real seal is reached only after the regular-rational row has been displayed, and the completion-facing consumer receives the same finite route. Since the cited sibling routes provide no coordinate for quotient equality, selected limits, choice, host equality, trichotomy, or ambient completeness, none can enter the forward route. □

Theorem 3688.19 (Cauchy StreamName–RegSeqRat forward route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *completion-facing read that is later consumed by* $\mathsf{RegSeqRat}^{\uparrow}$ *must pass through* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* BHist*-indexed observations, regular rational readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. The route is the displayed L10 handoff through chapter 126 and chapter 301; it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.*

Proof. Begin with the displayed RegSeqRat route of Definition 3688.8. It already places every Real- or Completion-facing Cauchy read behind finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback before the terminal seal can be consumed.

Next use the dependency lattice of the Cauchy hub. The lattice records the sibling order in which the $\mathsf{RegSeqRat}^{\uparrow}$ tail rows and $\mathsf{StreamName}^{\uparrow}$ observation schedules are read, so the consumer cannot bypass the finite windows by appealing to a host Cauchy sequence.

Finally apply the regular-fusion route of Definition 3688.14. Its fused-tail handoff preserves the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, so the Cauchy hub reaches any later $\mathsf{RegSeqRat}^{\uparrow}$ consumer only through the finite StreamName and regular rational surface. □

The $\mathsf{Cauchy}^{\uparrow}$ hub routes completion-facing consumers through the regular rational source of chapter 301, the complete-metric boundary of chapter 128, and the Cauchy-completion functor surface of chapter 423. Thus a completion read remains a displayed finite dependency route before any regular-name, metric-completion, or functorial completion sibling is consumed.

Chapter 3689

A Concrete Naming Certificate for $\mathsf{CauchyTailDominance}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailDominance}^{\uparrow}$ packet records the finite tail-dominance surface for Cauchy names at a displayed tolerance. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the index cofinality discipline of chapter 1594. The packet gives completion-facing Real arguments a named route from tolerance requests to tail windows; it does not select a limit, choose a subsequence, identify quotient real names, or import ambient completeness.

Definition 3689.1 (Cauchy tail-dominance carrier)**.** *A* $\mathsf{CauchyTailDominance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, I, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected Cauchy-name segment.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from that window.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that records the requested radius, slack budget, and comparison cell used for the tail test.*
4. *I is the* $\mathsf{CofinalSequence}^{\uparrow}$ *index row witnessing that the displayed tail index dominates the requested tolerance window.*
5. *W is the tail-window ledger, pairing the tolerance row D with the cofinal index row I and the inspected stream segment S.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D, I, W have been displayed.*
7. *H records componentwise* hsame *transport for the stream window, regular readback, tolerance row, cofinal index row, tail ledger, Real seal, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from a tolerance request through $D, I, S, R, W, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailDominance}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CofinalSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailDominance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a chosen limit, quotient stream equality, selected subsequence, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3689.2 (Cauchy tail-dominance NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailDominance}^{\uparrow}$ *carrier*

$$T = (S, R, D, I, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailDominance}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite stream window* S*, regular rational readback* R*, dyadic tolerance row* D*, cofinal index row* I*, tail-window ledger* W*, terminal Real seal* E*, componentwise transport* H*, displayed continuation replay* C*, package provenance* P*, and local naming row* N*.*

Proof. Project the carrier of Definition 3689.1. The projection exposes exactly $S, R, D, I, W, E, H, C, P, N$.

The tolerance request is first read through D. The cofinal row I then supplies the displayed index dominance needed to open the tail window, while S and R supply only the finite stream segment and regular rational readback attached to that request.

The ledger W binds D, I, S, R before the terminal seal E is visible. Thus the Real-facing consumer receives a tolerance-directed tail route rather than a chosen limit or a quotient equality of completed names.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no row for selected subsequences, countable choice, trichotomy, quotient equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3689.3 (Cauchy tail-dominance RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{CauchyTailDominance}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{CofinalSequence}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The consumer therefore reads tail dominance only as a displayed tolerance request, cofinal index witness, finite stream window, regular rational readback, and terminal Real seal. It receives no chosen Cauchy limit, selected subsequence, quotient stream equality, countable choice, trichotomy, or ambient completeness row.

Proof. Start with an admitted consumer read. By Definition 3689.1, the only analytic rows available before the Real seal are the tolerance row D, cofinal index row I, stream window S, regular readback R, and tail-window ledger W.

Read the requested precision through D. The row I then certifies the displayed dominance of the chosen tail index over that request, and W records that the same request controls the window opened in S.

The regular rational handoff is exactly R. It is downstream of D, I, S, W and upstream of the terminal seal E, so the Real-facing boundary cannot bypass the finite tail route.

The structural rows H, C, P, N replay and name this route without adding analytic coordinates. Hence every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read factors through the displayed tail-dominance packet and exports none of the excluded limit, subsequence, quotient, choice, trichotomy, or completeness data. □

Theorem 3689.4 (Cauchy tail-dominance Real seal consumption)**.** *Every* $\mathsf{Real}^{\uparrow}$ *completion-facing consumer of an accepted* $\mathsf{CauchyTailDominance}^{\uparrow}$ *packet must read the tolerance row, cofinal index*

witness, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and tail-window ledger before the Real seal is visible. Thus the completion boundary consumes the finite tail route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CofinalSequence}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ W \longrightarrow \mathsf{Real}^{\uparrow}$$

and cannot introduce selected limits, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier of Definition 3689.1. The terminal Real row E is downstream of the tolerance row D, cofinal index row I, stream window S, regular rational readback R, and tail-window ledger W.

Apply Definition 3689.2. It makes those rows part of the local certificate surface, so a completion-facing consumer cannot read E before it has exposed the same displayed tolerance request, dominance witness, finite window, readback, and ledger.

Now use the handoff of Definition 3689.3. It identifies the route from $\mathsf{DyadicRatCore}^{\uparrow}$ through $\mathsf{CofinalSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ to the terminal Real seal.

The structural rows H, C, P, N preserve and name that route without adding analytic coordinates. Since the accepted carrier has no selected-limit row, no quotient stream equality row, no countable-choice row, no trichotomy row, and no ambient completeness row, the Real seal can only be consumed through the displayed finite tail boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailDominance}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailDominance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3689.1, Definition 3689.2, Definition 3689.3, and Definition 3689.4 seed the finite tolerance-directed Cauchy tail-dominance route through StreamName, RegSeqRat, DyadicRatCore, CofinalSequence, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailDominance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, selected subsequences, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-row exactness, cofinal-index dominance, tail-window confinement, RegSeqRat handoff, and RealUp seal non-escape for BEDC.Derived.CauchyTailDominanceUp.

Constructive story: A $\mathsf{CauchyTailDominance}^{\uparrow}$ packet is generated from a StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance row, CofinalSequence index row, tail-window ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{Cauchy}^{\uparrow}$ completion-facing tail arguments consume chapter 3689 as the finite route that opens the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{CofinalSequence}^{\uparrow}$ index witness, and terminal $\mathsf{Real}^{\uparrow}$ seal before any Cauchy boundary is visible. This sibling route records that the Cauchy lattice reaches tail dominance through displayed L10 rows rather than through selected limits, quotient stream equality, countable choice, trichotomy, or ambient completeness.

Theorem 3689.5 (Cauchy metastability-filter sibling route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *completion-facing read that uses finite tail control factors through* $\mathsf{CauchyMetastability}^{\uparrow}$ *and* $\mathsf{CauchyFilter}^{\uparrow}$ *before reaching* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. Concretely, the consumer first reads the finite-tail stability packet of chapter 2093 and the finite-filterbase carrier of chapter 333; only then may it inspect stream windows, regular rational readback, dyadic tolerance ledgers, terminal real seals,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Proof. Start with the Cauchy hub dependency surface. Its completion-facing children already route through finite stream windows and regular rational readback before the terminal real seal is visible.

For finite tail control, use chapter 2093. The metastability packet exposes the precision request, control row, finite tail-window answer, dyadic ledger, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local name.

For filter-facing Cauchy data, use chapter 333. The CauchyFilter packet exposes the finite filterbase carrier, directed refinement row, Cauchy modulus row, stream schedules, regular observations, dyadic neighbourhood witnesses, transport, replay, provenance, and local name.

Combining the two sibling packets gives the stated route. No completion-facing $\mathsf{Cauchy}^{\uparrow}$ read can reach the StreamName, RegSeqRat, DyadicRatCore, or RealUp rows by bypassing both finite-tail stability and finite-filterbase data. □

Theorem 3689.6 (Cauchy top-level sibling route)**.** *The top-level* $\mathsf{Cauchy}^{\uparrow}$ *hub routes ordinary Cauchy evidence,* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *sequence-surface data, completion algebra, and tail-dominance readback through its sibling chapters before any Real or Completion consumer reads a terminal seal. The route consumes the finite observation surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Bishop regular completion consumer of chapter 1639. It thereby keeps Cauchy, sequence-space, completion-algebra, and tail-dominance surfaces on sibling NameCert routes rather than on a hidden hub coordinate.*

Proof. Read the hub as an ordered sibling route. Its ordinary Cauchy and tail-dominance files supply local Cauchy evidence, while the displayed RegSeqRat and metric-completion dependency files point outward to the Real and Completion lattice.

The finite-window side is supplied by chapter 126 and chapter 291. Those siblings provide observation windows and tolerance rows before a regular rational or real-seal consumer can inspect the Cauchy surface.

The completion-facing side then passes through chapter 301, chapter 38, and chapter 1639. Thus the Cauchy hub exports only a horizontal dependency route among displayed sibling chapters, with no quotient stream, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness row. □

Theorem 3689.7 (Cauchy Real-completion forward route)**.** *Every Real-completion consumer of the top-level* $\mathsf{Cauchy}^{\uparrow}$ *hub first passes through the sibling route displayed in Definition 3689.6: finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the Bishop regular completion handoff. No hub coordinate supplies quotient streams, selected limits, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness for such a consumer.*

Proof. Apply Definition 3689.6 to read the hub as an ordered dependency route rather than as a terminal completion object. Its first two displayed siblings provide the finite-window and dyadic-tolerance data that a completion-facing consumer must expose before any rational or real readback can be inspected.

The remaining siblings then force the read through RegSeqRat, the terminal $\mathsf{Real}^{\uparrow}$ seal, and the Bishop regular completion handoff. Since the route already accounts for every completion-facing coordinate named by the hub, there is no remaining coordinate from which a quotient stream, selected limit, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle could be exported. □

Theorem 3689.8 (Cauchy top-level completion lattice route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer of the top-level hub factors through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before it can use any completion*

boundary. The route is read through chapter 126, chapter 291, chapter 301, chapter 38, and the Bishop regular completion surface of chapter 1639; it exports no quotient stream, selected limit, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with a completion-facing read of the hub. The hub is only an ordered list of child routes, so the consumer first meets the finite StreamName window rows and the DyadicRatCore tolerance rows named by the displayed siblings, not a hidden completion object.

The regular rational readback is then routed through $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is visible. Structural replay through hsame, Cont, Pkg, and NameCert preserves the same ordered rows rather than adding a quotient stream or selected endpoint.

Finally the Bishop regular completion surface may consume the already displayed route. Since every completion-facing coordinate has passed through the sibling lattice, no remaining hub coordinate can supply choice, host equality, or an ambient completeness theorem. □

Chapter 3690

A Concrete Naming Certificate for MonotoneCauchySubsequence$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the MonotoneCauchySubsequence$^{\uparrow}$ packet records the finite surface by which a monotone source sequence exposes a Cauchy subsequence route without exporting a selected limit or quotient stream. It sits after the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal Real$^{\uparrow}$ seal of chapter 38, the monotone bounded source packet of chapter 3407, and the subsequence-stability handoff of chapter 3515. The packet names the extraction surface available to Real and Completion consumers; it has no coordinate for a quotient stream, selected limit, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 3690.1 (MonotoneCauchySubsequence carrier)**.** *A* MonotoneCauchySubsequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, I, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source monotone sequence row, read through the* MonotoneBoundedSequence$^{\uparrow}$ *and* StreamName$^{\uparrow}$ *surfaces before any subsequence request is consumed.*
2. *I is the monotone index row. It records the finite increasing index schedule used to inspect subsequence windows.*
3. *M is the modulus and tail row. It records the finite tail threshold requested by a Cauchy read and the matching source windows opened by I.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *budget row carrying the dyadic tolerance and refinement data for the source and subsequence windows.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the selected windows after the index and dyadic budget rows have been displayed.*
6. *E is the* Real$^{\uparrow}$ *seal row reached only after S, I, M, D, R have been read.*
7. *H records componentwise* hsame *transport for the source sequence, index schedule, modulus and tail row, dyadic budget, readback, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a subsequence Cauchy request through $S, I, M, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* MonotoneCauchySubsequence$^{\uparrow}$*,* MonotoneBoundedSequence$^{\uparrow}$*,* RegularCauchySubseq StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MonotoneCauchySubsequence}^{\uparrow}}$ *row.*
The carrier exports only the finite subsequence extraction packet. It exports no quotient stream, selected limit, countable choice, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.MonotoneCauchySubsequenceUp.MonotoneCauchySubsequenceTasteGate single carrier alignment`

Definition 3690.2 (MonotoneCauchySubsequence classifier)**.** *Two accepted* $\mathsf{MonotoneCauchySubsequence}^{\uparrow}$ *carriers*

$$Q = (S, I, M, D, R, E, H, C, P, N)$$

and

$$Q' = (S', I', M', D', R', E', H', C', P', N')$$

are classified together exactly when the displayed hsame *rows transport S to S', I to I', M to M', D to D', R to R', and E to E', and the displayed* Cont *rows replay the same route from the monotone source through index schedule, tail modulus, dyadic budget, regular readback, and Real seal. The classifier has no coordinate for host sequence equality, quotient stream equality, a selected infinite subsequence, a selected limit, countable choice, trichotomy, or ambient completeness.*

Theorem 3690.3 (MonotoneCauchySubsequence NameCert obligations)**.** *For every accepted* MonotoneCauchySub *carrier*

$$Q = (S, I, M, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MonotoneCauchySubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the source monotone sequence row, monotone index row, modulus and tail row, dyadic budget row, regular rational readback, Real seal, componentwise transport, replay, provenance, and local naming. Every subsequence Cauchy read must display S, I, M, D, R before E is available, and H, C, P, N only preserve that route.*

Proof. Project the carrier of Definition 3690.1. The displayed analytic rows are S, I, M, D, R, E, and the structural rows are H, C, P, N.

The source row S is read through the monotone bounded sequence surface, while I records the increasing index schedule. A Cauchy request can therefore inspect a subsequence window only after the source schedule and the selected index row have both been displayed.

The modulus and budget rows come next. The row M supplies the finite tail threshold, and D supplies the dyadic tolerance and refinement budget for the same source and subsequence windows.

The readback and seal rows are downstream. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads the scheduled windows after the index and dyadic budget have been displayed, and the $\mathsf{Real}^{\uparrow}$ row E seals only that finite route. Transport, replay, provenance, and local naming preserve the same coordinates, so the listed rows exhaust the local NameCert obligations. □

Theorem 3690.4 (MonotoneCauchySubsequence RegSeqRat handoff)**.** *Every accepted* MonotoneCauchySubsequen *carrier $Q = (S, I, M, D, R, E, H, C, P, N)$ hands a subsequence Cauchy read to* $\mathsf{RegSeqRat}^{\uparrow}$ *only through the finite route*

$$S, I \longmapsto M, D \longmapsto R \longmapsto E, H, C, P, N.$$

The handoff composes the source monotone bounded sequence route with the stability surface of chapter 3515; it does not export a quotient stream, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier and classifier. They force every subsequence read to preserve the source sequence row, monotone index schedule, modulus and tail row, dyadic budget, readback, and seal by componentwise transport and displayed replay.

Apply Definition 3690.3. It places the $\mathsf{RegSeqRat}^{\uparrow}$ row R after S, I, M, D, so the regular rational readback cannot be detached from the selected source windows or the dyadic tolerance ledger.

Finally use the sibling stability route of chapter 3515. That route preserves regular Cauchy readback under monotone cofinal subsequence schedules. The present packet supplies the corresponding $S, I, M, D, R, E, H, C, P, N$ rows, and no excluded quotient, selector, choice, trichotomy, or completeness coordinate is available. □

Falsifiable prediction: Every accepted $\mathsf{MonotoneCauchySubsequence}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ must display the monotone source row, increasing index row, modulus and tail row, dyadic budget, regular readback, Real seal, transport, replay, provenance, and local NameCert row first.

Independence witness: monotoneboundedsequence, regularcauchysubsequencestability, regseqrat, streamname, dyadicratcore, real: $\mathsf{MonotoneCauchySubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source monotone sequence, increasing index schedule, modulus and tail row, dyadic budget, readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneCauchySubsequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3690.1, Definition 3690.2, Definition 3690.3, and Definition 3690.4 seed the finite extraction surface for monotone Cauchy subsequence reads over source sequence, index, modulus, dyadic budget, readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneCauchySubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, classifier preservation, monotone index exactness, dyadic budget transport, RegSeqRat handoff, Real seal nonescape, provenance, and local naming for BEDC.Derived.MonotoneCauchySubseque

Constructive story: A $\mathsf{MonotoneCauchySubsequence}^{\uparrow}$ packet is generated from a monotone source sequence row, increasing index row, modulus and tail row, dyadic budget, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3691

A Concrete Naming Certificate for $\mathsf{CauchySequenceCompletion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchySequenceCompletion}^{\uparrow}$ packet records Cauchy completion data by finite regular-sequence rows rather than by ambient quotient language. It sits after the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the completion handoff of chapter 1506 and chapter 128, the terminal real-name seal of chapter 38, and the separated uniqueness boundary of chapter 1411. The packet gives Real and Completion consumers one displayed route from finite Cauchy sequence observations to a named completion point.

Definition 3691.1 (CauchySequenceCompletion carrier)**.** *A* $\mathsf{CauchySequenceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, S, R, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric or regular-Cauchy source row whose distance observations are the only metric data available to the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the inspected indices and the request schedule used by the Cauchy read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row on exactly those windows, including the rational approximants and their displayed tail budgets.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row exposing the completion-facing carrier and entry discipline.*
5. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-service row reached only after S, R, M have been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the completed readback, paired with the* $\mathsf{SeparatedMetric}^{\uparrow}$ *uniqueness route when two completed names are compared.*
7. *H records componentwise* hsame *transport for the source, window, readback, completion handoff, limit-service, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through $X, S, R, M, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchySequenceCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, S, R, M, L, E, H, C, P, N$. It has no coordinate for quotient completion classes, selected representatives, countable choice, host equality of sequences, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceCompletionUp.CauchySequenceCompletionTasteGate single carrier alignment`

Theorem 3691.2 (CauchySequenceCompletion NameCert obligations)**.** *For every accepted* CauchySequenceCompl*carrier $K = (X, S, R, M, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the source metric row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff,* $\mathsf{CompleteMetric}^{\uparrow}$ *limit row,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{SeparatedMetric}^{\uparrow}$ *uniqueness route, componentwise transport, displayed replay, provenance, and local naming.*

Every completion-facing consumer must read these rows in the order

$$X, S \longmapsto R \longmapsto M, L \longmapsto E \longmapsto H, C, P, N.$$

No obligation is discharged by a quotient-completion equality, a selected limit, countable choice, host sequence equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3691.1. The only source observations are the metric row X, the finite windows S, and the regular rational readback R.

The completion data is downstream of those observations. The row M exposes the $\mathsf{MetricCompletion}^{\uparrow}$ handoff, while L records the $\mathsf{CompleteMetric}^{\uparrow}$ limit service and cannot be read before the displayed windows and readback have been accepted.

The terminal row E is the Real-facing seal. When two completed names are compared, the separated uniqueness boundary is reached through the same displayed rows before any classifier identification is exported.

Finally H, C, P, N transport, replay, source, and name the route. Since the carrier contains no quotient, selected representative, countable-choice schedule, host equality, trichotomy, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3691.3 (CauchySequenceCompletion finite-window route)**.** *Every public read of an accepted* $\mathsf{CauchySequenceCompletion}^{\uparrow}$ *packet that reaches* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *must first display the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback used by the Cauchy sequence. If a uniqueness consumer compares two completed reads, it must then pass through the* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance route before reading equality of the exposed completion names.*

Thus the route exports completion data only as a finite window-and-readback handoff:

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow}.$$

It exports no quotient completion class, selected representative, unrestricted limit selector, host sequence equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a completion-facing request. By Definition 3691.1, the request must open S and R before it can reach either completion row.

The $\mathsf{MetricCompletion}^{\uparrow}$ handoff M and $\mathsf{CompleteMetric}^{\uparrow}$ row L then carry the displayed Cauchy read into the completion surface. The Real seal E is downstream of the same handoff, so a Real-facing read cannot bypass finite windows or regular rational readback.

For uniqueness reads, apply the separated boundary recorded in the carrier. The comparison passes through the zero-distance route of $\mathsf{SeparatedMetric}^{\uparrow}$ before any completed-name identification is public.

The structural rows H, C, P, N preserve this dependency order under transport and replay. No excluded completion, choice, host-equality, trichotomy, or Real-completeness principle is present as a carrier row, so none can be exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3691.1, Definition 3691.2, and Definition 3691.3 seed the finite Cauchy sequence completion route over StreamName windows, RegSeqRat readback, MetricCompletion and CompleteMetric handoffs, Real seals, separated uniqueness, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host sequence equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window readback, completion handoff, limit-service exposure, Real seal nonescape, separated uniqueness, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequenceCompletionUp.

Constructive story: A $\mathsf{CauchySequenceCompletion}^{\uparrow}$ packet is generated from a source metric row, finite StreamName windows, RegSeqRat readback, MetricCompletion handoff, CompleteMetric limit service, Real seal, SeparatedMetric uniqueness route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3692

A Concrete Naming Certificate for $\mathsf{BoundedIntervalProjection}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{BoundedIntervalProjection}^{\uparrow}$ packet records the finite data needed to project a displayed real-name input into a displayed closed bounded interval. It sits after the real-name seal of chapter 38, the regular rational readback of chapter 301, the finite stream window surface of chapter 126, the dyadic tolerance core of chapter 291, the endpoint interval packet of chapter 3527, the clamp route of Definition 1810.4, and the located interval surface of chapter 1709. The packet gives bounded-subsequence, interval-trapping, and completion-facing consumers a named projection object; it is not host trichotomy, not quotient equality, not a selected limit, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3692.1 (Bounded interval projection carrier)**.** *A* $\mathsf{BoundedIntervalProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, L, U, D, W, R, I, C, H, T, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Real}^{\uparrow}$ *row whose projected value is being named.*
2. *L and U are the lower and upper endpoint* $\mathsf{Real}^{\uparrow}$ *rows of the closed bounded interval.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-order and tolerance ledger used to compare finite reads of X, L, U.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface for the source and endpoint names.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
6. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row tying the endpoint seals, dyadic order ledger, and locatedness data to the interval surface.*
7. *C is the* $\mathsf{RealClamping}^{\uparrow}$ *row naming the constructive clamp of X against the displayed interval.*
8. *H stores componentwise* hsame *transport for the source, endpoints, tolerance ledger, windows, readback, interval, clamp, replay, provenance, and naming rows.*
9. *T stores displayed* Cont *replay of the projection route through $X, L, U, D, W, R, I, C, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedIntervalProjection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealBoundedInterval}^{\uparrow}$, $\mathsf{RealClamping}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedIntervalProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, L, U, D, W, R, I, C, H, T, P, N$. It has no coordinate for host trichotomy, quotient equality of real names, selected limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3692.2 (Bounded interval projection NameCert obligations)**.** *For every accepted* BoundedIntervalProjecti *carrier*

$$B = (X, L, U, D, W, R, I, C, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedIntervalProjection}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *row X, endpoint rows L, U, dyadic endpoint-order and tolerance ledger D, finite stream windows W, regular rational readback R, located interval row I, constructive clamping row C, componentwise transport H, displayed replay T, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3692.1. The projection exposes exactly the source real row, endpoint rows, dyadic tolerance ledger, finite windows, regular readback, located interval row, clamp row, and structural rows.

The interval boundary is read through the $\mathsf{RealBoundedInterval}^{\uparrow}$ and $\mathsf{LocatedRealInterval}^{\uparrow}$ surfaces. Thus endpoint order, locatedness, and finite bracket information are visible before any projection output is named.

The projection value is read through C. By the $\mathsf{RealClamping}^{\uparrow}$ route cited above, the clamp consumes the same source, endpoints, dyadic tolerance ledger, stream windows, regular readback, and located interval row, so it introduces no host comparison oracle or hidden limit selector.

Finally H, T, P, N transport, replay, source, and name that same route. Since the carrier has no coordinate for host trichotomy, quotient equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Lean4 ✓ `BEDC.Derived.BoundedIntervalProjectionUp.BoundedIntervalProjectionTasteGate single carrier alignment`

Theorem 3692.3 (Bounded interval projection clamping stability)**.** *Let*

$$B = (X, L, U, D, W, R, I, C, H, T, P, N)$$

be an accepted $\mathsf{BoundedIntervalProjection}^{\uparrow}$ *carrier. Any componentwise* hsame *transport of the source row, endpoint rows, dyadic ledger, stream windows, regular readback, and located interval row transports the clamp row C to the same* $\mathsf{BoundedIntervalProjection}^{\uparrow}$ *output surface. Consequently bounded-subsequence and interval-trapping consumers read a stable closed-interval projection through the displayed rows, not through quotient equality, selected limits, host trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier and its finite interval boundary. The rows L, U, D, W, R, I display the endpoint seals, dyadic tolerance comparisons, finite windows, regular rational readback, and located interval data used by the clamp.

Apply the clamp stability route of Definition 1810.4. It states that the clamped value is stable under the displayed finite Cauchy readback and transport rows, so the projection output is determined by the same rows already present in B.

The transport row H and replay row T preserve that route for the local packet. Provenance and naming through P, N then repack the result as a $\mathsf{NameCert}_{\mathsf{BoundedIntervalProjection}^{\uparrow}}$ surface.

There is no further coordinate in Definition 3692.1 from which a host comparison, quotient real equality, selected limit, or ambient completeness principle could be read. Thus clamping stability is exactly stability of the displayed finite projection packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedIntervalProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedIntervalProjection}^{\uparrow}$ packet is generated from a source RealUp row, two endpoint RealUp rows, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a LocatedRealInterval row, a RealClamping row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedIntervalProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3692.1, Definition 3692.2, and Definition 3692.3 seed the finite closed-interval projection route over $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealBoundedInterval}^{\uparrow}$, $\mathsf{RealClamping}^{\uparrow}$, and $\mathsf{LocatedRealInterval}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedIntervalProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host trichotomy, quotient equality of real names, selected limits, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order evidence, finite-window readback, located interval handoff, clamping stability, transport, replay, provenance, and local naming for BEDC.Derived.BoundedIntervalProjection

Chapter 3693

A Concrete Naming Certificate for $\mathsf{MontelTheorem}^{\uparrow}$

Following Montel's theorem in the normal-family tradition, the $\mathsf{MontelTheorem}^{\uparrow}$ packet records only the BEDC finite-window content of constructive normal-family compactness. It binds compact-window rows, local boundedness and equicontinuity ledgers, uniform Cauchy extraction, and holomorphic readback rows over displayed finite charts. The chapter does not claim classical open-cover compactness, countable choice, quotient real or complex equality, selected subsequences, or full analytic compactness. Its sibling route passes through the finite-modulus Arzela–Ascoli surface of chapter 412, the compact metric and complete metric rows already available in the concrete-instance family, the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, and the holomorphic and complex surfaces when those rows are present.

Definition 3693.1 (Montel theorem carrier)**.** *A* $\mathsf{MontelTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, L, E, U, Q, G, R, D, Z, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-window row, naming the finite subwindow, metric inspection data, and compact-source certificate used by the family read.*
2. *L is the local boundedness ledger for the displayed family on the same compact window.*
3. *E is the equicontinuity ledger, expressed as finite modulus rows over the compact-window inspection schedule.*
4. *U is the uniform Cauchy extraction row, recording a finite tail window, a subsequence or subnet schedule when already displayed by the source packet, and a dyadic tolerance budget.*
5. *Q is the uniform-limit readback row over the same compact window.*
6. *G is the holomorphic or complex-read row, restricted to the displayed chart and consumed only after K, L, E, U, Q have been exposed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback family for the finite observation windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the local boundedness, equicontinuity, and uniform Cauchy rows.*
9. *Z is the terminal complex or real seal row read by the holomorphic surface when such a row is part of the source family.*

10. *H records componentwise* hsame *transport for all displayed rows.*
11. *C records displayed* Cont *replay from compact-window request through local boundedness, equicontinuity, uniform Cauchy extraction, uniform-limit readback, and holomorphic readback.*
12. *P is the* Pkg *provenance over* $\mathsf{MontelTheorem}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, *compact-window and complete-metric rows,* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *complex or holomorphic surfaces,* BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MontelTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their structural transport, replay, provenance, and local naming data.

Lean4 (definition) `BEDC.Derived.MontelTheoremUp.TasteGate.MontelTheoremUp`
Lean4 ✓ `BEDC.Derived.MontelTheoremUp.TasteGate.MontelTheoremTasteGate single carrier alignment`

Theorem 3693.2 (Montel theorem NameCert obligations)**.** *For every accepted* $\mathsf{MontelTheorem}^{\uparrow}$ *carrier* $M = (K, L, E, U, Q, G, R, D, Z, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{MontelTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *compact-window admission for K and agreement of every later row with the same displayed window;*
2. *local boundedness admission for L over the compact-window schedule;*
3. *equicontinuity admission for E with dyadic tolerances read from D;*
4. *uniform Cauchy extraction through U, with every late-tail comparison served by R and D;*
5. *uniform-limit readback through Q before any holomorphic or complex read in G is exposed;*
6. *holomorphic readback compatibility, requiring G and Z to consume only the displayed uniform Cauchy and uniform-limit rows;*
7. *transport, replay, provenance, and naming stability through H, C, P, N.*

No obligation introduces open-cover compactness, countable choice, quotient real equality, quotient complex equality, a selected analytic limit, or ambient analytic compactness.

Proof. Project the carrier in Definition 3693.1. The compact-window row K is the only source of domain inspection data, so every later read is scoped to the same finite compact window.

Local boundedness and equicontinuity are the finite normal-family inputs. The rows L and E expose pointwise bound and finite-modulus data over K, while D supplies the dyadic tolerance budget used by both ledgers.

The extraction step is the finite Arzela–Ascoli route. Apply the sibling surface chapter 412 through the displayed rows K, L, E, U, R, D to obtain a uniform Cauchy extraction over the compact window rather than a choice-selected analytic subsequence.

The readback step consumes Q and then G. The uniform-limit row is displayed before the holomorphic or complex-read row, so holomorphic readback can use only the finite uniform Cauchy and tolerance surface already named by the carrier.

Finally, H, C, P, N preserve the same row inventory under transport, continuation, provenance, and local naming. Since the carrier has no coordinate for open-cover compactness, countable choice, quotient equality, selected analytic limits, or ambient analytic compactness, the NameCert surface cannot export any such datum. □

Theorem 3693.3 (Montel theorem finite normal-family criterion)**.** *Let $M = (K, L, E, U, Q, G, R, D, Z, H, C, P, N)$ be an accepted* $\mathsf{MontelTheorem}^{\uparrow}$ *packet. Any consumer claiming a normal-family compactness read from M factors through the finite route*

$$\textit{compact window} \longmapsto \textit{local boundedness and equicontinuity} \longmapsto \textit{uniform Cauchy extraction} \longmapsto \textit{uniform-limit readl}$$

Thus the consumer receives compact-window, boundedness, equicontinuity, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *uniform Cauchy, uniform-limit, and holomorphic rows as finite BEDC data. It receives no classical open-cover compactness theorem, countable-choice selector, quotient real or complex equality, selected analytic limit, or full analytic compactness assertion.*

Proof. Start from the accepted carrier. The only admissible source route begins with K, so every compactness-facing consumer first reads the displayed compact-window packet.

Next consume L and E. These rows give local boundedness and equicontinuity over that window, with the tolerance budget synchronized by D and the regular readbacks synchronized by R.

Now replay C through U and Q. The route supplies uniform Cauchy extraction and uniform-limit readback on the same finite window, matching the ContinuousMap and UniformLimit style chapters without selecting an external analytic limit.

Finally consume G and Z only after the uniform-limit row is present. Componentwise transport through H and provenance through P, N preserve the same route, so no forbidden open-cover, choice, quotient-equality, selected-limit, or ambient-compactness coordinate can enter the public read. □

Closure status for $\mathsf{NameCert}_{\mathsf{MontelTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MontelTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3693.1, Definition 3693.2, and Definition 3693.3 seed the finite normal-family route through compact windows, local boundedness, equicontinuity, uniform Cauchy extraction, uniform-limit readback, and holomorphic readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MontelTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical open-cover compactness, countable choice, quotient real equality, quotient complex equality, selected analytic limits, full analytic compactness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-window exactness, local-boundedness and equicontinuity ledgers, uniform Cauchy extraction, holomorphic readback compatibility, and provenance exhaustion for BEDC.Derived.MontelTheoremUp.

Constructive story: A $\mathsf{MontelTheorem}^{\uparrow}$ packet is generated from compact-window rows, local boundedness and equicontinuity ledgers, uniform Cauchy extraction, uniform-limit readback, holomorphic or complex readback, RegSeqRat and DyadicRatCore tolerance rows, transport, replay, provenance, and local NameCert rows.

Chapter 3694

A Concrete Naming Certificate for $\mathsf{AntipodalTriggerLedger}^{\uparrow}$

The $\mathsf{AntipodalTriggerLedger}^{\uparrow}$ packet realizes the antipodal AGY trigger of Definition 9462.1506 as finite NameCert data. It records the median-closure source, the R-halfspace with its CUY anchor, the AGY antipode row, the trigger ledger, transport, replay, provenance, and local naming surface. The packet is adjacent to the six-boundary and trigger-algebra family of chapter 3470, chapter 3478, chapter 3651, and chapter 3681, but it is not bijective to any of them because it binds the one-pass antipodal median trigger as its own carrier row.

Definition 3694.1 (Antipodal trigger ledger carrier)**.** *An* $\mathsf{AntipodalTriggerLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, Y, G, T, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row for $M^{\star} = \mathrm{NNR} \cup \mathrm{CUY}$, including the saturated R halfspace and the* CUY *anchor row.*
2. *Y is the third-position Y halfspace shell ledger, displaying the shell decomposition H_0, H_1, H_2, H_3, H_4.*
3. *G is the antipodal* AGY *row, displaying either* AGU *or* AGC *as the single trigger.*
4. *T is the trigger ledger that pairs the* CUY *anchor, the* AGY *antipode, and the already present R-halfspace witness t_b for each target Y-side codon b.*
5. *M is the median-closure replay row, recording that the coordinatewise median of those three displayed witnesses reaches b and hence fills the whole codon cube in one pass.*
6. *H records componentwise* hsame *transport for the source, shell, antipode, trigger, median-closure, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from source presentation through the antipode trigger ledger into the median-closure row.*
8. *P is the* Pkg *provenance over* $\mathsf{AntipodalTriggerLedger}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{AnchorSubcubeTrigger}^{\uparrow}$, $\mathsf{RadialWobbleSpectrum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AntipodalTriggerLedger}^{\uparrow}}$ *row.*

The classifier admits only packets carrying these finite rows and future implementations must provide the corresponding Nontrivial *and* FieldFaithful *instances before a Lean-side field interpretation can be claimed.*

Lean4 (definition) `BEDC.Derived.AntipodalTriggerLedgerUp.AntipodalTriggerLedgerUp`

Falsifiable prediction: Removing the displayed AGY antipode row prevents an accepted $\mathsf{AntipodalTriggerLedger}^{\uparrow}$ packet from claiming one-pass full-cube median closure.

Independence witness: `six_boundary_tile_coverage`, `window_coverage_trigger_algebra`, `anchor_subcube_trigger`, and `radial_wobble_spectrum`: none is bijective to $\mathsf{AntipodalTriggerLedger}^{\uparrow}$ because the packet jointly stores the $M^{\star}$ source, the CUY anchor, the AGY antipode, the one-pass target witness ledger, median replay, transport, continuation, provenance, and local naming rows.

Theorem 3694.2 (Antipodal trigger ledger NameCert obligations)**.** *For every accepted* $\mathsf{AntipodalTriggerLedger}^{\uparrow}$ *carrier* $A = (S, Y, G, T, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AntipodalTriggerLedger}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *source admission for* $M^{\star} = \mathrm{NNR} \cup \mathrm{CUY}$ *and its median-closed halfspace anchor;*
2. *shell admission for the displayed* Y*-halfspace ledger and its antipodal* $H_4 = \mathrm{AGY}$ *row;*
3. *trigger exactness, requiring the same* CUY *anchor,* AGY *antipode, and* R*-halfspace witness row to feed the median calculation;*
4. *one-pass median replay, requiring the row* M *to expose every* Y*-side target before the full-cube claim is exported;*
5. *transport, replay, provenance, and naming stability through* H, C, P, N*;*
6. *field-read discipline, requiring future* Nontrivial *and* FieldFaithful *instances before any field-facing interpretation of the trigger ledger is exposed.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier in Definition 3694.1. The source row S supplies the R halfspace and the CUY anchor, while Y supplies the finite shell ledger.

The trigger row G is indispensable. Without a displayed AGY antipode, the packet contains no finite row pairing the anchor with the antipodal point required by Definition 9462.1506.

The ledger T then names the witness triple for each target Y-side codon b: the CUY anchor, the AGY antipode, and the already present R-halfspace point t_b. The replay row M records the coordinatewise median calculation and exposes the one-pass full-cube result.

Finally H, C, P, N preserve this route under transport, continuation, provenance, and local naming. The field-read clause is only a discipline on later interpretation: until Nontrivial and FieldFaithful instances are displayed, the packet exports a finite median-trigger ledger rather than a field theorem. □

Theorem 3694.3 (Antipodal trigger ledger median nonescape)**.** *Every accepted* $\mathsf{AntipodalTriggerLedger}^{\uparrow}$ *full-cube read factors through the finite route*

$$M^{\star} \longmapsto \mathrm{CUY}\ \textit{anchor} \longmapsto \mathrm{AGY}\ \textit{antipode} \longmapsto \textit{target witness ledger} \longmapsto \textit{one-pass median replay.}$$

Thus the one-pass median-closure claim is available only when $S, Y, G, T, M, H, C, P, N$ *are all displayed. A packet missing the* AGY *row, the target witness ledger, or the median replay row cannot export full-cube closure.*

Proof. Begin with an accepted carrier. The public full-cube read must first expose S, so the median source is exactly $M^\star$ with the CUY anchor and the already present R halfspace.

Next the read consumes Y and G. These rows place the AGY point in the antipodal shell H_4 and identify it as the single trigger rather than as an undifferentiated radial-shell element.

Now apply the trigger ledger T and median replay M. For each target Y-side codon, the route supplies the anchor, antipode, and matching R-halfspace witness, so the coordinatewise median calculation remains inside displayed finite data.

The structural rows H, C, P, N do not add another closure principle; they preserve the same finite route. Hence a consumer that omits the antipode, witness ledger, or median replay row cannot claim one-pass full-cube median closure from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AntipodalTriggerLedger}^\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AntipodalTriggerLedger}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 3694.1, Definition 3694.2, and Definition 3694.3 seed the finite median-trigger ledger from the $M^\star$ source through the AGY antipode into one-pass full-cube median replay.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AntipodalTriggerLedger}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, field-facing interpretation without Nontrivial and FieldFaithful instances, radial optimality, spectral optimality, or a public standard bridge.

Upgrade path: Obligation closure requires checked source admission, shell admission, antipode exactness, target-witness ledger replay, median nonescape, field-read discipline, and provenance exhaustion for BEDC.Derived.AntipodalTriggerLedgerUp.

Constructive story: An $\mathsf{AntipodalTriggerLedger}^\uparrow$ packet is generated from the $M^\star$ source row, Y-halfspace shell ledger, AGY antipode row, target witness ledger, one-pass median replay, transport, continuation, provenance, and local NameCert rows.

Chapter 3695

A Concrete Naming Certificate for $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ packet records the displayed criterion by which a Cauchy source, an effective precision schedule, and a finite tail-window readback become one completion-facing BEDC object. It sits after the criterion surface of chapter 392, the modulus schedule of chapter 292, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the effective modulus packet of chapter 3518, and the terminal real-name seal of chapter 38. The packet supplies a finite L10 criterion/modulus handoff; it does not construct quotient streams, select a host limit, import countable choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3695.1 (Effective Cauchy criterion carrier)**.** *An* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, M, S, T, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *source row naming the finite Cauchy request and its accepted comparison surface.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, refined through the* $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ *packet to a displayed precision-to-tail request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite source window opened by the criterion request.*
4. *T is the finite tail-window row selected by the effective modulus schedule for the same request.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the requested radius, tail comparison, and endpoint budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after Q, M, S, T, D have been displayed.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only to consumers that have already read the criterion, schedule, windows, tolerance ledger, and regular-rational readback.*
8. *H stores componentwise* hsame *transport for the criterion, modulus, windows, tolerance ledger, readback, seal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from an effective Cauchy request through $Q, M, S, T, D, R, L, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{EffectiveCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, S, T, D, R, L, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected limit, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EffectiveCauchyCriterionUp.TasteGate.EffectiveCauchyCriterionTasteGate single carrier alignment`

Theorem 3695.2 (Effective Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *carrier*

$$E = (Q, M, S, T, D, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the criterion row Q, effective modulus schedule M, source window S, tail window T, dyadic tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal L, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3695.1. The analytic rows are exactly the criterion request Q, the effective modulus schedule M, the source and tail windows S, T, the dyadic tolerance ledger D, the regular-rational readback R, and the terminal real seal L.

The schedule obligation is read through M and T. The modulus row turns a displayed precision request into a finite tail threshold, and the tail-window row records the finite observations permitted at that threshold.

The readback obligation is downstream of Q, M, S, T, D. The regular-rational row R is therefore a finite readback from the same criterion and tolerance ledger, not a quotient stream, selected limit, or ambient completeness argument.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded objects, the listed rows exhaust the local NameCert obligation surface. □

Theorem 3695.3 (Effective Cauchy criterion RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *packet factors through*

$$Q, M \longmapsto S, T, D \longmapsto R \longmapsto L \longmapsto H, C, P, N.$$

Consequently the consumer receives the displayed criterion request, effective modulus schedule, finite source and tail windows, dyadic tolerance ledger, regular-rational readback, terminal real seal, and local structural rows; it receives no quotient-stream equality, selected host limit, countable choice, host sequence equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the criterion and modulus rows. The row Q states the Cauchy comparison request, while M supplies the effective precision-to-tail schedule consumed by that request.

Next open the finite windows and tolerance ledger. The source window S and tail window T provide the only observations exposed to the request, and D records the dyadic budget against which those observations are compared.

Only after those rows are displayed does the packet expose R and then L. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback produced from the finite windows and tolerance ledger, and L is the terminal $\mathsf{Real}^{\uparrow}$ seal available to completion-facing consumers.

The structural rows H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming. Thus every consumer route factors through the displayed finite handoff and cannot bypass it through any excluded host object. □

Closure status for NameCert$_{EffectiveCauchyCriterionUp}$.

Constructive story: An EffectiveCauchyCriterion$^{\uparrow}$ packet is generated from a CauchyCriterion request row, a CauchyModulus effective schedule, StreamName source and tail windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{EffectiveCauchyCriterionUp}$, seed)

Scope closed: Definition 3695.1, Definition 3695.2, and Definition 3695.3 seed the finite effective Cauchy criterion handoff for RegSeqRat and Real-completion consumers.

Formal verification: FormalStatus(NameCert$_{EffectiveCauchyCriterionUp}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient-stream equality, selected limits, host sequence equality, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective schedule exactness, StreamName source and tail window admission, DyadicRatCore tolerance readback, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance non-escape for BEDC.Derived.EffectiveCauchyCriterionUp.

Chapter 3696

A Concrete Naming Certificate for $\mathsf{UniformlyCauchySequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the packet records a uniformly Cauchy sequence as displayed finite tail schedules rather than host convergence. It sits beside the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the displayed modulus interface of chapter 1438, and the terminal seal of chapter 38. The packet supplies an L10 completion-facing finite schedule object; it is not a quotient stream, not a selected limit, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3696.1 (Uniformly Cauchy sequence carrier)**.** *A* $\mathsf{UniformlyCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence source row, naming the displayed stream whose finite observations are admitted by the packet.*
2. *T is the uniform tail-threshold schedule. For each requested dyadic tolerance it records the single tail index after which all later source windows are compared.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source at the threshold and at later comparison windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the precision budget and dyadic comparison rows consumed by the uniform tail schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same source, window, tolerance, and tail-threshold data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, T, W, D, R have been displayed.*
7. *H stores componentwise* hsame *transport for the source, threshold schedule, window row, tolerance row, readback row, Real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a uniform Cauchy request through $S, T, W, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, W, D, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, hidden cofinal subsequences, countable choice, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformlyCauchySequenceUp.UniformlyCauchySequenceTasteGate single carrier alignment`

Theorem 3696.2 (Uniformly Cauchy sequence NameCert obligations)**.** *For every accepted* UniformlyCauchySequen *carrier*

$$K = (S, T, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformlyCauchySequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the sequence source S, uniform tail-threshold schedule T,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{Real}^{\uparrow}$ *seal row E, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3696.1. The analytic rows are the source S, threshold schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback R, and Real seal E.

The uniformity obligation is read only from T, W, D. For a requested tolerance, T gives one displayed threshold and W supplies the inspected windows beyond it, while D records the dyadic comparison budget used by those windows.

The regular readback is downstream of the same schedule. Thus R is a $\mathsf{RegSeqRat}^{\uparrow}$ row obtained through S, T, W, D, not a host sequence, quotient stream, selected limit, hidden cofinal family, or completeness argument.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for countable choice, host equality, quotient streams, selected limits, hidden cofinal subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Theorem 3696.3 (Uniformly Cauchy sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer exported by an accepted* $\mathsf{UniformlyCauchySequence}^{\uparrow}$ *packet factors through*

$$S \longmapsto T \longmapsto W, D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently completion and filter consumers may use the displayed source, uniform tail threshold, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and local structural rows, but they receive no quotient stream, selected limit, hidden cofinal tail, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the displayed source S. The source is admissible for the packet only as a sequence row whose uniform Cauchy information is supplied by the threshold schedule T.

The finite observation then passes through W and D. The row W exposes the inspected stream windows at and beyond the chosen tail threshold, while D supplies the dyadic tolerance and comparison budget for the same request.

Only after those rows have been displayed does the packet expose R and then E. The row R is the regular rational readback, and E is the terminal Real seal served by that readback.

The structural rows H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming. Since none of the excluded objects occurs in the carrier, no completion-facing or filter-facing consumer can bypass the finite uniform schedule. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyCauchySequence}^{\uparrow}$ packet is generated from a sequence source row, a uniform tail-threshold schedule, a StreamName finite-window row, a DyadicRatCore tolerance row, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3696.1, Definition 3696.2, and Definition 3696.3 seed the finite uniform Cauchy schedule object and its regular-rational handoff for completion and filter consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, hidden cofinal tails, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-threshold exactness, StreamName window coverage, DyadicRatCore tolerance readback, RegSeqRat handoff, Real seal confinement, transport stability, continuation replay, and provenance non-escape for BEDC.Derived.UniformlyCauchySequenceUp.

Chapter 3697

A Concrete Naming Certificate for DyadicMeshScaleNormalization$^{\uparrow}$

Following Bishop and Bridges constructive analysis and the interval-normalization practice of Moore–Kearfott–Cloud interval computation, the DyadicMeshScaleNormalization$^{\uparrow}$ packet records the common-scale conversion needed before finite nets, dyadic approximations, and real-name seal windows compare mesh cells. It sits after the finite mesh carrier of chapter 358, the dyadic arithmetic core of chapter 291, the precision-scale ledger of chapter 1768, and the real embedding boundary of chapter 1942. The packet exposes a displayed common scale and its readback route; it is not host real equality, quotient stream equality, countable choice, or an appeal to ambient completeness.

Definition 3697.1 (Dyadic mesh scale-normalization carrier)**.** *A* DyadicMeshScaleNormalization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, A, B, S, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* DyadicMesh$^{\uparrow}$ *mesh row whose cells are to be compared or consumed by a finite-net route.*
2. *A and B are the source mesh-scale rows exposed before normalization.*
3. *S is the common-scale row, recording one dyadic scale that refines both A and B for the requested comparison window.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *arithmetic ledger for rescaling endpoints, widths, and cell representatives from A and B into S.*
5. *T is the* DyadicToleranceScale$^{\uparrow}$ *precision row that binds the normalization scale to the requested tolerance.*
6. *W is the* StreamName$^{\uparrow}$ *finite-window row opened only after S, D, T have been displayed.*
7. *R is the* RegSeqRat$^{\uparrow}$ *handoff row obtained from the normalized dyadic windows.*
8. *E is the* RealDyadicEmbedding$^{\uparrow}$ *seal row reached after the normalized dyadic readback.*
9. *H records componentwise* hsame *transport for the mesh row, source scales, common scale, arithmetic ledger, tolerance row, window row, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a mesh comparison request through* $G, A, B, S, D, T, W, R, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{DyadicMeshScaleNormalization}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealDyadicEmbedding}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshScaleNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, A, B, S, D, T, W, R, E, H, C, P, N$. *It has no coordinate for host real equality, quotient streams, selected representatives, hidden cofinal refinements, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicMeshScaleNormalizationUp.DyadicMeshScaleNormalizationTasteGate`
`single carrier alignment`

Theorem 3697.2 (Dyadic mesh scale-normalization NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMeshScaleNormalization}^{\uparrow}$ *carrier*

$$M = (G, A, B, S, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicMeshScaleNormalization}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic mesh row G, source scale rows A, B, common-scale row S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *rescaling ledger D,* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *precision row T,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *seal row E, componentwise transport H, displayed continuation replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3697.1. The analytic rows are exactly the mesh row G, the two source scales A, B, the common scale S, the dyadic arithmetic ledger D, the tolerance-scale row T, the finite-window row W, the regular rational readback R, and the real-dyadic seal E.

The normalization obligation is read only from S, D, T. The row S names the common dyadic scale, D records the arithmetic that rewrites both source scales into that scale, and T binds the scale choice to the requested tolerance.

The stream and real-facing rows are downstream of the same normalization. Thus W opens only normalized finite windows, R reads the corresponding regular rational data, and E seals the route through $\mathsf{RealDyadicEmbedding}^{\uparrow}$ rather than through host equality of real numbers.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient streams, selected representatives, hidden cofinal refinements, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 3697.3 (Dyadic mesh common-scale exhaustion)**.** *Every finite-net, dyadic-approximation, or* $\mathsf{RealDyadicEmbedding}^{\uparrow}$ *consumer exported by an accepted* $\mathsf{DyadicMeshScaleNormalization}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{DyadicMesh}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{DyadicToleranceScale}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealDyadicEm}$$

Consequently such a consumer may read the original mesh, the two source scales, the common scale, the dyadic rescaling ledger, the tolerance row, normalized stream windows, regular rational readback, and real-dyadic seal, but it receives no host real equality, quotient stream, selected representative, hidden cofinal refinement, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with an admitted consumer read. By Definition 3697.1, the only mesh-facing data before readback are G, A, B, S, D, T, W.

The common scale is forced through S. The rows A and B expose the two source scales, while D supplies the dyadic rescaling ledger that rewrites both into S under the tolerance request recorded by T.

Only after that scale has been displayed may the packet expose W, R, and E. The finite windows are therefore normalized before regular-rational readback, and the real-facing seal is the $\mathsf{RealDyadicEmbedding}^{\uparrow}$ row downstream of that readback.

The structural rows H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming. Hence every exported finite-net, approximation, or real-dyadic consumer factors through the displayed common-scale route and cannot bypass it by using any excluded host, quotient, choice, or completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMeshScaleNormalization}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMeshScaleNormalization}^{\uparrow}$ packet is generated from a DyadicMesh row, two source scale rows, one displayed common scale, a DyadicRatCore rescaling ledger, a DyadicToleranceScale precision row, StreamName finite windows, a RegSeqRat readback row, a RealDyadicEmbedding seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMeshScaleNormalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3697.1, Definition 3697.2, and Definition 3697.3 seed the common-scale normalization packet used by finite nets, dyadic approximation, and real-dyadic seal windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMeshScaleNormalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient streams, selected representatives, hidden cofinal refinements, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-scale exactness, dyadic rescaling confinement, tolerance-scale binding, normalized StreamName coverage, RegSeqRat handoff, RealDyadicEmbedding seal non-escape, transport stability, continuation replay, and provenance confinement for BEDC.Derived.DyadicMeshScaleNormalizationUp.

Chapter 3698

A Concrete Naming Certificate for $\mathsf{CompactCompletionExtensionModulus}^{\uparrow}$

Following the Heine–Cantor and Bishop finite-net route, the $\mathsf{CompactCompletionExtensionModulus}^{\uparrow}$ packet records the compact-domain uniform modulus data that completion-extension consumers need before a completed map can be read. It refines the compact-uniform-continuity vision of chapter 9237 into concrete rows over the compact metric packet of chapter 129, the continuous-map surface of chapter 130, the uniform modulus consumer of chapter 369, the Cauchy lift route of chapter 2037, and the regular completion readback rows of chapter 301, chapter 126, chapter 291, and chapter 38. The packet names the finite modulus consumer; it does not choose a pointwise selector, quotient a completion, or import ambient compactness or completeness.

Definition 3698.1 (Compact completion extension modulus carrier)**.** *A* $\mathsf{CompactCompletionExtensionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, G, B, M, L, R, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the compact metric finite-net source row, carrying the finite net bundle, located radius rows, and coverage witnesses used by the uniform-modulus fold.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus and graph row, read at bundled centers of the compact net.*
3. *B is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, recording the finite rational radius comparison that produces a tolerance-only precision history.*
4. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row opened by Q, G, B.*
5. *L is the* $\mathsf{CauchyCompletionLift}^{\uparrow}$ *route row, exposing the modulus handoff before any completion-extension consumer reads lifted map data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular Cauchy approximants opened by the completion consumer.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to compare the compact-net source data with the completion readback.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying dyadic radii, error budgets, and transported comparison rows.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, visible only after Q, G, B, M, L, R, S, D have been displayed.*
10. *H records componentwise* hsame *transport for the compact source, graph, lower-bound fold, uniform modulus, lift route, readback, window, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay of the route*

$$Q, G, B \longmapsto M, L \longmapsto R, S, D \longmapsto E.$$

12. *P is the* Pkg *provenance over* $\mathsf{CompactCompletionExtensionModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CauchyCompletionLift}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCompletionExtensionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, G, B, M, L, R, S, D, E, H, C, P, N$. It has no coordinate for a global point selector, quotient completion equality, selected completed representatives, host function equality, open-cover compactness, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3698.2 (Compact modulus preservation for completion-extension consumers)**.** *Let*

$$K = (Q, G, B, M, L, R, S, D, E, H, C, P, N)$$

be an accepted $\mathsf{CompactCompletionExtensionModulus}^{\uparrow}$ *carrier. Any completion-extension consumer that reads the compact-domain map must preserve the uniform modulus row M produced from the finite-net source Q, pointwise graph row G, and rational lower-bound fold B before it can inspect the* $\mathsf{CauchyCompletionLift}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows.*

Lean4 ✓ `BEDC.Derived.CompactCompletionExtensionModulusUp.TasteGate.CompactCompletionExtensionModulus modulus preservation route`

Proof. Project the carrier. The compact finite-net source row Q, continuous graph row G, and rational lower-bound fold row B are displayed before the uniform modulus row M.

The completion-extension consumer then enters through L. Since L is downstream of M, the completion-facing map is read as data carrying the compactly produced uniform modulus rather than as a host function on completed representatives.

The readback rows R, S, D, E preserve this dependency order. Regular approximants, finite stream windows, dyadic tolerance budgets, and the terminal Real seal are all opened after the modulus handoff, so none can replace it with quotient completion equality or a selected limit.

The structural rows H, C, P, N only transport, replay, source, and name the same route. Therefore point selectors, host equality, open-cover compactness, choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the accepted consumer surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCompletionExtensionModulus}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCompletionExtensionModulus}^{\uparrow}}$, seed)

Scope closed: Definition 3698.1 and Definition 3698.2 seed the compact finite-net uniform-modulus route consumed by completion-extension packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactCompletionExtensionModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close point selector choice, quotient completion equality, selected completed representatives, host function equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net visibility, continuous-map pointwise modulus readback, rational lower-bound fold stability, uniform-modulus preservation, completion-lift routing, regular readback, finite-window stability, dyadic tolerance stability, Real seal non-escape, and ledger exhaustion for BEDC.Derived.CompactCompletionExtensionModulusUp.

Constructive story: A CompactCompletionExtensionModulus$^{\uparrow}$ packet is generated from CompactMetric finite-net source rows, a ContinuousMap pointwise graph row, a RatUp lower-bound fold, a UniformModulus consumer row, a CauchyCompletionLift route, RegSeqRat readback, StreamName windows, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3699

A Concrete Naming Certificate for UniformlyContinuousCompletionExtension$^{\uparrow}$

Following Bishop and Bridges on uniformly continuous maps between completions, the UniformlyContinuousComplet packet records the finite NameCert surface by which a uniformly continuous source map extends across displayed BEDC completion data. It sits after the Cauchy lift route of chapter 2037, the uniform completion consumer of chapter 1892, the regular readback of chapter 301, the finite stream interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the real-name seal of chapter 38. The packet names the extension route through finite rows; it does not introduce quotient completion classes, selected representatives, host function extensionality, choice, or ambient Real$^{\uparrow}$ completeness.

Definition 3699.1 (Uniformly continuous completion extension carrier)**.** *A* UniformlyContinuousCompletionExtensi *carrier is a finite* BHist *packet*

$$X = (D, T, M, L, U, R, S, Y, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense source row, recording the displayed source observations, density witnesses, Cauchy windows, and tolerance requests made before any completed target is inspected.*
2. *T is the target completion-consumer row, exposing the target-facing completion object only through an accepted consumer interface.*
3. *M is the uniform modulus and graph row for the source map, carrying finite graph observations and the tolerance-to-precision ledger consumed by the extension.*
4. *L is the* CauchyCompletionLift$^{\uparrow}$ *handoff row, requiring the source map and its modulus to be read before a lifted completion-facing map is named.*
5. *U is the* UniformCompletionFunctor$^{\uparrow}$ *route row, binding the same source, target, graph, and modulus data to the uniform completion surface.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row, recording the regular rational approximants opened by the completion consumer.*
7. *S is the* StreamName$^{\uparrow}$ *finite-window row, recording the finite stream observations used to compare source Cauchy data with target readback data.*

8. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic radii and comparison budgets through the modulus handoff.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, visible only after the dense source, target consumer, modulus, lift, uniform completion, regular readback, stream-window, and dyadic tolerance rows have been displayed.*
10. *H records componentwise* hsame *transport for the dense source, target consumer, modulus graph, lift, uniform completion route, readback, stream windows, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay of the route*

$$D, T, M \longmapsto L, U \longmapsto R, S, Y \longmapsto E.$$

12. *P is the* Pkg *provenance over* $\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}$, $\mathsf{CauchyCompletionLift}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, T, M, L, U, R, S, Y, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host function extensionality, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3699.2 (Uniformly continuous completion extension modulus handoff)**.** *Let*

$$X = (D, T, M, L, U, R, S, Y, E, H, C, P, N)$$

be an accepted $\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}$ *carrier. Every extension consumer of the completed map factors through the uniform modulus and graph row M, the* $\mathsf{CauchyCompletionLift}^{\uparrow}$ *handoff row L, the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *route row U, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger Y, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E before the structural rows H, C, P, N name the result.*

```
Lean4 ✓  BEDC.Derived.UniformlyContinuousCompletionExtensionUp.TasteGate.UniformlyContinuousCompletionEx
modulus handoff route
```

Proof. Carrier projection gives the dense source row D, the target completion-consumer row T, and the modulus-bearing graph row M. The carrier orders these rows before any lift, uniform completion, readback, finite-window, dyadic, or real-seal row.

The completion-facing handoff is then read through L and U. The row L records the same uniform-modulus handoff required by the Cauchy completion lift route, while U records the uniform completion consumer surface; neither row supplies a selected completed representative.

Regular readback is downstream of the handoff. The rows R, S, Y expose regular rational approximants, finite stream windows, and dyadic tolerance budgets before E may seal a real-facing read.

Finally H, C, P, N transport, replay, source, and name only the displayed route. Since the packet has no coordinate for quotient completion, selected representatives, host function extensionality, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no extension consumer can factor through those alternate surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3699.1 and Definition 3699.2 seed the finite modulus-handoff route for uniformly continuous maps extending across BEDC completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host function extensionality, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source visibility, uniform-modulus handoff, completion-lift routing, uniform-completion routing, regular readback, finite-window stability, dyadic tolerance stability, Real seal non-escape, and ledger exhaustion for BEDC.Derived.UniformlyContinuousCompletionExtensionUp.

Constructive story: A $\mathsf{UniformlyContinuousCompletionExtension}^{\uparrow}$ packet is generated from dense source rows, a target completion-consumer row, a uniform modulus and graph row, CauchyCompletionLift and UniformCompletionFunctor rows, RegSeqRat readback, StreamName windows, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3700

A Concrete Naming Certificate for $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$

Following Bishop and Bridges' constructive monotone convergence argument, the $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$ packet records the finite route from a bounded monotone real sequence to a located-supremum handoff and a terminal $\mathsf{Real}^{\uparrow}$ seal. It sits beside the located monotone convergence route of chapter 3373, the Bishop monotone limit packet of chapter 1914, the monotone sequence convergence surface of chapter 1435, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic core of chapter 291, and the terminal real-name boundary of chapter 38. The packet names the bounded monotone case only; it does not assert arbitrary Real completeness, trichotomy, selected suprema outside the displayed located row, countable choice, or quotient-stream equality.

Definition 3700.1 (BishopMonotoneRealConvergence carrier)**.** *A* $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, B, O, L, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded monotone* $\mathsf{Real}^{\uparrow}$ *sequence row, recording the source sequence, monotonicity direction, and the displayed upper or lower bound.*
2. *B is the boundedness ledger that exposes the finite bound witnesses used by the monotone route.*
3. *O is the order-comparison ledger that records the finite monotonicity reads consumed before any limit row is available.*
4. *L is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row attached to the bounded monotone sequence data.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which source entries, bound witnesses, and located-supremum approximants are inspected.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite windows in W.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that records the requested precision and the dyadic comparison budget.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after L, W, Q, D have been displayed.*
9. *H records componentwise* hsame *transport for the sequence, bound, order, located-supremum, window, readback, tolerance, and real-seal rows.*

10. *C records displayed* Cont *replay from bounded monotone data through the located-supremum handoff and the regular rational readback to the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$, $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$, $\mathsf{BishopMonotoneRealLimit}^{\uparrow}$, $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopMonotoneRealConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, O, L, W, Q, D, E, H, C, P, N$. It has no coordinate for arbitrary Cauchy completeness, open-cover compactness, trichotomy of real order, quotient stream equality, selected host suprema, or countable choice.

Lean4 ✓ `BEDC.Derived.BishopMonotoneRealConvergenceUp.BishopMonotoneRealConvergenceTasteGate`
`single carrier alignment`

Theorem 3700.2 (BishopMonotoneRealConvergence NameCert obligations)**.** *For every accepted* $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$ *carrier $M = (S, B, O, L, W, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopMonotone}}$ *surface consists exactly of bounded monotone sequence exposure, bound-ledger exposure, monotonicity-read exposure, located-supremum handoff, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

A consumer may read the convergence row only after S, B, O, L, W, Q, D have been displayed. The exported real seal is therefore the finite bounded-monotone route through located supremum and regular rational readback, not an ambient completeness theorem for arbitrary $\mathsf{Real}^{\uparrow}$ *data.*

Proof. Project the carrier of Definition 3700.1. The rows S, B, O expose the bounded monotone source data before any limit-facing row is available.

The row L supplies the located-supremum handoff. The finite windows W, regular readback Q, and dyadic tolerance ledger D then turn the located handoff into the displayed sequence of rational observations consumed by the terminal seal.

Finally E, H, C, P, N preserve the same route. Since the carrier has no coordinate for arbitrary Cauchy completeness, order trichotomy, quotient streams, selected host suprema, or countable choice, the listed rows exhaust the local NameCert surface. □

Theorem 3700.3 (BishopMonotoneRealConvergence located supremum route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *limit read exported by an accepted* $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$ *packet factors through the displayed located-supremum row L and the finite readback route*

$$S, B, O \longmapsto L \longmapsto W, Q, D \longmapsto E, H, C, P, N.$$

Thus the bounded monotone convergence claim is a finite NameCert route from monotone source data to a located supremum and then to a $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Read the route rows in order. The source sequence S, boundedness row B, and order ledger O provide the only monotone data available to the packet.

The located-supremum handoff L is therefore the unique route by which a limit candidate enters the certificate. The window, readback, and tolerance rows W, Q, D inspect that handoff at finite precision before the real seal E can be consumed.

Transport, replay, provenance, and local naming are supplied by H, C, P, N over the same displayed rows. Hence an exported limit read cannot bypass L or import an ambient completeness principle outside the finite packet. □

Falsifiable prediction: Every accepted bounded monotone convergence read factors through a displayed located-supremum row before any RealUp seal is exported.

Independence witness: located-monotone-convergence, bishop-monotone-real-limit, monotone-sequence-convergence, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded monotone source data, bound and order ledgers, a located-supremum handoff, finite windows, regular rational readback, dyadic tolerance accounting, RealUp sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopMonotoneRealConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopMonotoneRealConvergence}^{\uparrow}$ packet is generated from bounded monotone RealUp sequence data, a boundedness ledger, monotonicity reads, a LocatedSupremum handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopMonotoneRealConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3700.1, Definition 3700.2, and Definition 3700.3 seed the bounded monotone Real convergence NameCert route through located supremum and finite regular-rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopMonotoneRealConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary RealUp completeness, order trichotomy, open-cover compactness, quotient stream equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded monotone source exposure, located-supremum handoff exactness, finite-window readback, dyadic tolerance accounting, RealUp seal routing, and TasteGate nontriviality with field faithfulness.

Chapter 3701

A Concrete Naming Certificate for $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$

Following Bishop and Bridges' regular Cauchy completion, the $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$ packet records the finite classifier lock by which a diagonal limit candidate and its uniqueness witness are read through one completion-seal route. It sits after the Cauchy limit seal of chapter 386, the completion-seal classifier of chapter 900, the finite limit-seal envelope of chapter 1276, the regular Cauchy comparison surface of chapter 411, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic core of chapter 291, and the terminal real-name boundary of chapter 38. The packet names the uniqueness classifier for the diagonal regular Cauchy limit, not an arbitrary choice of representatives or an ambient Real completeness principle.

Definition 3701.1 (CauchyLimitClassifierLock carrier)**.** *A* $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, \mu, L, U, S, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the regular Cauchy input row over* $\mathsf{RegSeqRat}^{\uparrow}$*.*
2. *μ is the finite modulus-budget row used to select diagonal and comparison windows.*
3. *L is the diagonal limit-candidate row.*
4. *U is the uniqueness classifier row comparing any second candidate with L through the displayed RealUp classifier.*
5. *S is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row carrying the common seal interface for L and U.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the input, diagonal candidate, and comparison candidate.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the diagonal and uniqueness comparisons.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, Q, D are displayed.*
10. *H records componentwise* hsame *transport for the input, modulus, diagonal candidate, uniqueness classifier, seal, windows, readback, tolerance, and real seal.*

11. *C records displayed* Cont *replay from regular Cauchy data through the diagonal candidate and classifier lock to the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, RealCompletionSealClassifierUp, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyLimitClassifierLock}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, \mu, L, U, S, W, Q, D, E, H, C, P, N$. It has no coordinate for selected quotient representatives, host real equality, countable choice, arbitrary Cauchy completeness, or a second seal route outside S.

Lean4 ✓ `BEDC.Derived.CauchyLimitClassifierLockUp.CauchyLimitClassifierLockTasteGate single carrier alignment`

Theorem 3701.2 (CauchyLimitClassifierLock NameCert obligations)**.** *For every accepted* CauchyLimitClassifierLoc *carrier $K = (X, \mu, L, U, S, W, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyLimitClassifierLock}^{\uparrow}}$ *surface consists exactly of regular Cauchy input exposure, modulus-budget exposure, diagonal candidate exposure, uniqueness-classifier exposure,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *handoff, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

The uniqueness row U is accepted only when it is replayed through the same S, W, Q, D, E route as the diagonal candidate L. A consumer that compares candidates through a distinct host equality, quotient representative, or hidden completion seal leaves the packet.

Proof. Project the carrier of Definition 3701.1. The rows X, μ, L, U expose the regular input, modulus budget, diagonal candidate, and uniqueness classifier.

The seal row S is shared by the candidate and the uniqueness comparison. The finite windows W, regular readback Q, and dyadic tolerance ledger D are the only rows through which the comparison may reach the terminal real seal E.

Finally H, C, P, N preserve and replay this same route. Since no host equality, quotient representative, countable choice, arbitrary completeness row, or second seal route is a carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 3701.3 (CauchyLimitClassifierLock uniqueness route)**.** *Every uniqueness read exported by an accepted* $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$ *packet factors through the common completion-seal route*

$$X, \mu, L, U \longmapsto S \longmapsto W, Q, D \longmapsto E, H, C, P, N.$$

Thus the diagonal limit candidate and the RealUp uniqueness classifier are locked to the same finite CauchyLimitSeal, RegSeqRat, StreamName, DyadicRatCore, and RealUp NameCert packet.

Proof. Start from an accepted uniqueness read. The carrier exposes only one diagonal candidate row L and one uniqueness classifier row U, both attached to the same regular input X and modulus budget μ.

The common seal row S is then read before any window, readback, tolerance, or real-seal row is exported. Consequently W, Q, D, E inspect the same completion-seal route for the candidate and for the uniqueness comparison.

Transport, replay, provenance, and local naming are supplied by H, C, P, N over this single route. A second classifier route would require an additional carrier coordinate, which Definition 3701.1 excludes. □

Falsifiable prediction: Every accepted Cauchy limit uniqueness read uses the same CauchyLimitSeal route as the displayed diagonal candidate before reaching RealUp.

Independence witness: cauchy-limit-seal, real-completion-seal-classifier, finite-limit-seal-envelope, regular-cauchy-comparison, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a regular Cauchy input, modulus budget, diagonal candidate, uniqueness classifier, common seal, finite windows, regular readback, dyadic tolerance ledger, RealUp seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLimitClassifierLock}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyLimitClassifierLock}^{\uparrow}$ packet is generated from a regular Cauchy input, modulus budget, diagonal limit candidate, uniqueness classifier, CauchyLimitSeal handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLimitClassifierLock}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3701.1, Definition 3701.2, and Definition 3701.3 seed the finite classifier-lock route for the Real completeness limit theorem.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLimitClassifierLock}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary RealUp completeness, host equality of completed reals, selected quotient representatives, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal candidate exposure, uniqueness classifier exactness, common CauchyLimitSeal routing, finite-window readback, dyadic tolerance accounting, RealUp seal routing, and TasteGate nontriviality with field faithfulness.

Chapter 3702

A Concrete Naming Certificate for $\mathsf{DarbouxTheorem}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxTheorem}^{\uparrow}$ packet records the theorem route saying that a displayed continuous real map on a displayed interval has the Darboux property. It sits over the graph-and-modulus surface of chapter 130, the constructive finite bisection route of chapter 1422, the target-value handoff of chapter 3348, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The chapter packages Darboux's theorem as finite NameCert data rather than as host continuity semantics, a selected intermediate point, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3702.1 (Darboux theorem carrier)**.** *A* $\mathsf{DarbouxTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, I, A, B, Y, S, D, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row carrying the displayed graph, pointwise modulus, and continuity budget for the real-valued map.*
2. *I is the interval endpoint row, exposing the lower and upper endpoint reads and their orientation data.*
3. *A and B are the endpoint value rows obtained from F at the two endpoint rows of I.*
4. *Y is the target-value row displayed between the endpoint value rows.*
5. *S is the endpoint-side exposure row, recording which finite residual comparisons place Y between A and B.*
6. *D is the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *schedule that retains branches whose residual comparisons still bracket Y.*
7. *R is the* $\mathsf{DarbouxProperty}^{\uparrow}$ *handoff row reached after the bisection schedule has produced the retained target-value route.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained windows and requested dyadic tolerances.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal available to theorem consumers only after D, R, Q have been read.*

10. *H stores componentwise* hsame *transport for the map, interval, endpoint values, target value, endpoint-side exposure, bisection schedule, property handoff, regular readback, real seal, replay, provenance, and local naming rows.*
11. *C stores displayed* Cont *replay from a Darboux-theorem request through $F, I, A, B, Y, S, D, R, Q, E$.*
12. *P is the* Pkg *provenance over* $\mathsf{DarbouxTheorem}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{DarbouxProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted theorem packets only through $F, I, A, B, Y, S, D, R, Q, E, H, C, P, N$. It has no coordinate for host real equality, quotient real equality, a selected intermediate point, real trichotomy, open-cover compactness, semantic continuity outside F, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DarbouxTheoremUp.DarbouxTheoremTasteGate single carrier alignment`

Theorem 3702.2 (Darboux theorem NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxTheorem}^{\uparrow}$ *carrier $T = (F, I, A, B, Y, S, D, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission through the displayed packet of Definition 3702.1, endpoint-side exposure through I, A, B, Y, S, bisection exactness through D, Darboux-property handoff through R, Real-seal readback through Q, E, componentwise transport through H, displayed continuation replay through C, provenance through P, local naming through N, and non-escape from host real equality, quotient real equality, selected intermediate points, trichotomy, open-cover compactness, semantic continuity outside F, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3702.1. The continuous-map row F and interval row I expose the only theorem source data, while A, B, Y, S expose the finite endpoint-side comparisons for the requested target value.

The bisection schedule is the row D. It is the only branch-retention route in the packet, so every accepted theorem read must pass through the finite $\mathsf{IntermediateValueBisection}^{\uparrow}$ schedule before a target-value handoff is visible.

The property handoff is then the row R, and the Real-facing readback is Q, E. The row Q supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback against the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data named by provenance, and E is the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier has no coordinate for host equality, quotient equality, a selected intermediate point, trichotomy, open-cover compactness, semantic continuity outside F, or ambient Real completeness, none of those objects can appear in the local NameCert surface. □

Theorem 3702.3 (Darboux theorem bisection route)**.** *Every accepted theorem read of a* $\mathsf{DarbouxTheorem}^{\uparrow}$ *carrier factors through the finite route*

$\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{DarbouxProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsam

In particular, the read first consumes the displayed map, endpoint rows, target-value row, and endpoint-side exposure; then the finite bisection schedule; then the Darboux-property handoff; then the regular rational and dyadic readback; and only then the $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start from an accepted carrier $T = (F, I, A, B, Y, S, D, R, Q, E, H, C, P, N)$. The continuation row C exposes theorem reads only through the map, interval, endpoint value, target value, and endpoint-side rows before any Real-facing seal is available.

The finite bisection route is forced by D. The carrier contains no alternate theorem coordinate between the endpoint-side exposure S and the Darboux-property handoff R, so a consumer cannot bypass $\mathsf{IntermediateValueBisection}^{\uparrow}$ by appealing to host connectedness or semantic continuity.

After the bisection schedule, the theorem read reaches R as the $\mathsf{DarbouxProperty}^{\uparrow}$ handoff. The retained windows are then read through Q using the dyadic tolerance surface named in P, and the terminal read reaches E as the $\mathsf{Real}^{\uparrow}$ seal.

The rows H, C, P, N keep this route stable under transport, replay, provenance, and local naming. Thus every accepted theorem read factors through the displayed finite bisection schedule before the Real seal, with the excluded host and completeness objects remaining outside the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxTheorem}^{\uparrow}$ packet is generated from a ContinuousMap row, interval endpoint rows, endpoint value rows, a target-value row, endpoint-side exposure, an IntermediateValueBisection schedule, a Darboux-Property handoff, RegSeqRat readback, a DyadicRatCore tolerance surface, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3702.1, Definition 3702.2, and Definition 3702.3 seed Darboux's theorem as a finite bisection route from displayed endpoint-side exposure to DarbouxProperty handoff and Real-seal readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient real equality, selected intermediate points, trichotomy, open-cover compactness, semantic continuity outside the displayed ContinuousMap row, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-side exposure, bisection exactness, DarbouxProperty handoff, Real-seal readback, transport and replay stability, provenance exhaustion, and non-escape for BEDC.Derived.DarbouxTheoremUp.

Chapter 3703

A Concrete Naming Certificate for LocatedCompletionUniversalProperty$^{\uparrow}$

Following Bishop and Bridges constructive completion theory, the LocatedCompletionUniversalProperty$^{\uparrow}$ packet records the extension-and-uniqueness surface for located completion as finite BEDC NameCert data. It sits after the located completion seal of chapter 1805, the generic completion universal-property packet of chapter 397, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names located extension and uniqueness only through displayed source, route, modulus, transport, replay, provenance, and local naming rows; it is not a quotient completion, a selected host limit, countable choice, ambient real completeness, or function extensionality.

Definition 3703.1 (Located completion universal-property carrier)**.** *A* LocatedCompletionUniversalProperty$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, E, Q, M, H, C, P, N)$$

with the following displayed rows:

1. *L is the located completion source row, exposing the source metric, locatedness request surface, dense unit, and completion seal read from chapter 1805.*
2. *U is the universal extension row, read against the target row and the generic completion-universal interface of chapter 397.*
3. *E is the extension uniqueness row, comparing two displayed extensions only over the same located source, dense unit, and target route.*
4. *Q is the request route through* RegSeqRat$^{\uparrow}$ *and* StreamName$^{\uparrow}$*, carrying finite windows, regular rational readback, and the observations used by located requests.*
5. *M is the uniform-modulus compatibility row, tying source moduli, target moduli, and located request tolerances to the same extension route.*
6. *H records componentwise* hsame *transport for the located source, universal extension, uniqueness row, request route, modulus row, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from located source requests through finite stream windows, regular rational readback, uniform-modulus compatibility, extension, and uniqueness.*

8. *P is the* Pkg *provenance over* LocatedCompletionUniversalProperty$^{\uparrow}$, LocatedCompletionSeal$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

9. *N is the local* NameCert$_{\text{LocatedCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, E, Q, M, H, C, P, N$. It has no coordinate for quotient completion representatives, selected limits, ambient complete-space theorems, function extensionality, countable choice, or unlocated real equality.

Lean4 ✓ `BEDC.Derived.LocatedCompletionUniversalPropertyUp.LocatedCompletionUniversalPropertyTasteGate`
`single carrier alignment`

Theorem 3703.2 (Located completion universal-property NameCert obligations)**.** *For every accepted* LocatedCompletionUniversalProperty$^{\uparrow}$ *carrier $K = (L, U, E, Q, M, H, C, P, N)$, the local* NameCert$_{\text{LocatedComple}}$ *surface consists exactly of located-source admission through L, universal extension exposure through U, extension uniqueness through E,* RegSeqRat$^{\uparrow}$ *and* StreamName$^{\uparrow}$ *request routing through Q, uniform-modulus compatibility through M, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3703.1. The located completion source row L is visible before any extension row is consumed, and it reads the dense unit and completion seal through chapter 1805.

Read the universal-property rows next. The row U supplies the displayed extension route, while E compares two such routes only along the same located source and dense unit. The generic obligation surface is therefore the one already named by chapter 397, refined by located request data rather than by a new host completion object.

The request and modulus rows keep the route finite. The row Q exposes the StreamName$^{\uparrow}$ windows and RegSeqRat$^{\uparrow}$ readback consumed by located requests, and M ties those requests to the same uniform-modulus compatibility ledger before the Real$^{\uparrow}$ seal is read.

Finally H, C, P, N transport, replay, source, and name only these displayed rows. Since the carrier has no quotient representative, selected host limit, ambient completeness theorem, function-extensionality row, countable-choice row, or unlocated real-equality coordinate, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted LocatedCompletionUniversalProperty$^{\uparrow}$ extension or uniqueness read factors through the displayed located source row, finite request route, uniform-modulus compatibility row, transport, replay, provenance, and local naming before reaching a Real$^{\uparrow}$ consumer.

Independence witness: located-completion-seal, completionuniversalproperty, streamname, regseqrat, real: LocatedCompletionUniversalProperty$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a located completion source, universal extension row, extension uniqueness row, finite request route, uniform-modulus compatibility, transport, replay, provenance, and local NameCert row.

Closure status for NameCert$_{\text{LocatedCompletionUniversalProperty}^{\uparrow}}$ **·**

Constructive story: A LocatedCompletionUniversalProperty$^{\uparrow}$ packet is generated from a located completion source row, universal extension row, extension uniqueness row, RegSeqRat and StreamName request route, uniform-modulus compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedCompletionUniversalProperty}^{\uparrow}}$, seed)

Scope closed: Definition 3703.1 and Definition 3703.2 seed the finite located-completion universal-property certificate surface.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCompletionUniversalProperty}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, ambient complete-space theorems, unlocated real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located request routing, extension existence, extension uniqueness, uniform-modulus compatibility, transport replay, provenance, and TasteGate field faithfulness for BEDC.Derived.LocatedCompletionUniversalPropertyUp.

Chapter 3704

A Concrete Naming Certificate for $\mathsf{BooleanTriggerLattice}^{\uparrow}$

The $\mathsf{BooleanTriggerLattice}^{\uparrow}$ packet realizes the Boolean trigger closure lattice of Definition 9462.1520 and Definition 9462.1532 as finite BEDC NameCert data. It sits over the finite truth-tag discipline of chapter 32, the six-boundary-tile coverage route of chapter 3470, and the trigger-algebra sibling surface of chapter 3478. The packet names Boolean support, rank, meet, join, spectral table, transport, replay, provenance, and local naming rows; it is not a biological code oracle, stochastic evolution model, host powerset lattice, quotient codon semantics, or infinite trigger search.

Definition 3704.1 (BooleanTriggerLattice carrier)**.** *A* $\mathsf{BooleanTriggerLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, S, R, J, K, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite* $\mathsf{Bool}^{\uparrow}$ *tag row for present, absent, covered, uncovered, full-trigger, and non-trigger reads.*
2. *S is the six-boundary support row, read from* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *and carrying the displayed coordinates* $\{s_1, f_1, s_2, f_2\}$*.*
3. *R is the rank row, naming the finite support union $J(B)$ and the rank $r(B)$ of the source vision.*
4. *J is the join-trigger row, recording median closure of a union as support union.*
5. *K is the meet-trigger row, recording intersection of trigger closures as support intersection.*
6. *O is the observed table row, carrying the finite size, cubical, spectral, threshold, and singleton-trigger reads displayed in the source vision.*
7. *H records componentwise* hsame *transport for Boolean tags, support rows, rank rows, join rows, meet rows, observed table rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from each accepted trigger read through B, S, R, J, K, O, H.*
9. *P is the* Pkg *provenance over* $\mathsf{BooleanTriggerLattice}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* WindowCoverageTriggerA *the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BooleanTriggerLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, R, J, K, O, H, C, P, N$. It has no coordinate for host powersets, biological-code truth, stochastic dynamics, quotient codon equality, hidden spectral computation, or unbounded trigger enumeration.

Lean4 ✓ `BEDC.Derived.BooleanTriggerLatticeUp.BooleanTriggerLatticeTasteGate single carrier alignment`

Theorem 3704.2 (BooleanTriggerLattice NameCert obligations)**.** *For every accepted* $\mathsf{BooleanTriggerLattice}^{\uparrow}$ *carrier* $T = (B, S, R, J, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BooleanTriggerLattice}^{\uparrow}}$ *surface consists exactly of Boolean tag admission, six-boundary support exposure, finite rank exposure, join-trigger exposure, meet-trigger exposure, observed table exposure, componentwise transport, displayed replay, provenance, and local naming.*

The future Lean TasteGate plan for this packet requires $\mathsf{Nontrivial\ BooleanTriggerLattice}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ BooleanTriggerLattice}^{\uparrow}$ *so that* $B, S, R, J, K, O, H, C, P, N$ *remain separate displayed fields rather than a collapsed tag.*

Proof. Project the carrier of Definition 3704.1. The rows B, S, R, J, K, O expose the Boolean tags, boundary support, rank, join, meet, and observed table before any consumer can read a trigger-lattice conclusion.

The join and meet rows are finite. The row J reads support union from the source vision, while K reads support intersection. Both rows depend on the same six-boundary support surface and therefore cannot be replaced by an ambient powerset lattice.

The observed table row is also displayed. It records the finite rank-size, cubical, spectral, threshold, and singleton-trigger data already present in the vision file, but it does not add a stochastic model or a hidden spectral oracle.

Finally H, C, P, N preserve the same displayed route. Since no host powerset, biological truth oracle, quotient codon equality, stochastic dynamics, or unbounded trigger enumeration is a carrier coordinate, the local NameCert obligations are exactly the listed rows. □

Falsifiable prediction: An accepted $\mathsf{BooleanTriggerLattice}^{\uparrow}$ read is refuted if its full-trigger, rank, meet, or join decision can be produced without the displayed Boolean tags, six-boundary support row, finite rank row, observed table row, transport, replay, provenance, and local naming.

Independence witness: bool, six-boundary-tile-coverage, window-coverage-trigger-algebra, boolean-trigger source vision: none is bijective with $\mathsf{BooleanTriggerLattice}^{\uparrow}$ because the packet jointly carries Boolean tags, six-boundary support, trigger rank, join rows, meet rows, observed rank-spectral table data, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BooleanTriggerLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{BooleanTriggerLattice}^{\uparrow}$ packet is generated from BoolUp tag rows, six-boundary support rows, finite rank rows, join-trigger rows, meet-trigger rows, observed rank-spectral table rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BooleanTriggerLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3704.1 and Definition 3704.2 seed the finite Boolean trigger-lattice NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BooleanTriggerLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim biological-code truth, stochastic evolutionary dynamics, host powerset lattices, quotient codon equality, hidden spectral computation, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Boolean tag exposure, support-rank exposure, meet and join rows, observed table exposure, Nontrivial BooleanTriggerLatticeUp, and FieldFaithful BooleanTriggerLatticeUp for BEDC.Derived.BooleanTriggerLatticeUp.

Chapter 3705

A Concrete Naming Certificate for $\mathsf{BishopCauchyComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyComparison}^{\uparrow}$ packet records the finite comparison route between Cauchy-criterion reads and convergence-modulus reads before a $\mathsf{Real}^{\uparrow}$ or completion consumer can inspect a terminal seal. It sits beside the criterion surface of chapter 392, the bidirectional criterion/modulus surface of chapter 3343, the convergence-modulus boundary of chapter 2074, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic core of chapter 291, and the terminal real-name boundary of chapter 38. The packet names the finite comparison only; it does not assert quotient-stream equality, selected limits, countable choice over thresholds, host convergence, or ambient completeness.

Definition 3705.1 (Cauchy criterion comparison chain)**.** *A* $\mathsf{BishopCauchyComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *window row, displaying the finite sequence windows read by both presentations.*
2. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *late-pair request row, recording the criterion-facing tolerance read.*
3. *M is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *schedule row, recording the modulus-facing threshold hand-off.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row shared by the criterion request and the modulus schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which both presentations inspect the same rational windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Q, M, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the source windows, criterion request, modulus schedule, tolerance, readback, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from either criterion-facing or modulus-facing entry through the same finite route.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyComparison}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, M, D, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable-choice threshold selection, detached completion, host convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyComparisonUp.BishopCauchyComparisonTasteGate single carrier alignment`

Theorem 3705.2 (Cauchy criterion comparison NameCert obligations)**.** *For every accepted* BishopCauchyComparis *carrier $B = (S, Q, M, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyComparison}^{\uparrow}}$ *surface consists exactly of carrier admission, criterion-to-modulus handoff, modulus-to-criterion handoff, shared tolerance-readback exactness,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance exhaustion, and local naming.*

A criterion-facing consumer may read the modulus schedule M only through the same S, D, R, E, H, C, P, N rows that support the criterion request Q. Conversely, a modulus-facing consumer may read the criterion request Q only through those same rows. Thus the packet supplies a finite comparison chain rather than a host equality between presentations.

Proof. Project the carrier of Definition 3705.1. Carrier admission exposes exactly the tuple $S, Q, M, D, R, E, H, C, P, N$.

For the criterion-to-modulus direction, the late-pair request Q is read together with the source windows S, the shared dyadic tolerance row D, and the regular rational readback row R. The modulus schedule M is visible only as the threshold row attached to that same finite data.

For the modulus-to-criterion direction, the schedule M is read with the same source, tolerance, and readback rows. The criterion request Q is therefore reconstructed as a finite late-pair obligation over the displayed windows, not as an independent convergence predicate.

The real seal E is downstream of both reads. Transport, replay, provenance, and naming are supplied by H, C, P, N over the same rows, so no quotient stream, selected limit, countable-choice selector, host convergence theorem, or ambient completeness row can enter the local certificate. □

Theorem 3705.3 (Cauchy criterion comparison real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopCauchyComparison}^{\uparrow}$ *packet reaches the terminal seal only through the finite route*

$$S, Q, M, D, R \longmapsto E \longmapsto H, C, P, N.$$

In particular, neither the criterion presentation nor the modulus presentation can bypass the shared tolerance-readback route or replace it by quotient-stream equality, selected limits, host convergence, countable choice, or ambient completion.

Proof. Use Definition 3705.2. Both handoff directions force the criterion row Q and modulus row M to share the source windows S, tolerance row D, and readback row R.

The terminal row E is listed only after those shared rows. A $\mathsf{Real}^{\uparrow}$ or completion-facing consumer therefore cannot inspect the seal before the finite comparison route has been displayed.

Finally H, C, P, N preserve and name that same route. Since the carrier has no row for quotient streams, selected limits, countable-choice schedules, host convergence, or detached completion, the seal cannot escape through such data. □

Falsifiable prediction: Every accepted criterion/modulus comparison read exposes the shared StreamName, RegSeqRat, and DyadicRatCore rows before any RealUp or completion-facing seal is exported.

Independence witness: cauchycriterion, cauchy-criterion-equivalence, real-modulus-of-convergence, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopCauchyComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries criterion request, modulus schedule, shared tolerance-readback, RealUp seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3705.1, Definition 3705.2, and Definition 3705.3 seed the finite comparison route between Cauchy-criterion reads and convergence-modulus reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-stream equality, selected limits, countable-choice threshold selection, host convergence, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bidirectional handoff exactness, shared tolerance-readback exactness, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyComparisonUp.

Constructive story: A $\mathsf{BishopCauchyComparison}^{\uparrow}$ packet is generated from source StreamName windows, a Cauchy-Criterion request, a RealModulusOfConvergence schedule, DyadicRatCore tolerance accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3706

A Concrete Naming Certificate for $\mathsf{ClosedObservationTotalHost}^{\uparrow}$

The $\mathsf{ClosedObservationTotalHost}^{\uparrow}$ packet realizes the total-host discipline of chapter 9370 as finite NameCert data. It sits beside the candidate-mediated normalization socket of chapter 3566, the MetaCIC normalization frontier of chapter 892, the total-host fuel handoff of chapter 962, and the reduction fuel boundary of chapter 970. The packet names a discipline on accepted host-observation records: a finite termination or observation row must be visible before substrate-step readback. It does not claim global normalization of arbitrary host calculi, substrate halting, or evaluator soundness outside the displayed rows.

Definition 3706.1 (ClosedObservationTotalHost carrier)**.** *A* $\mathsf{ClosedObservationTotalHost}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, T, S, F, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the accepted host-observation row, displaying the closed observation record and its host-side typing boundary.*
2. *T is the totality row, recording the finite termination or normal-form readback required before the record can be consumed.*
3. *S is the substrate-step row, displaying the finite step-indexed substrate observation that the host record describes.*
4. *F is the refusal row for any consumer that asks to read S before A, T have been displayed.*
5. *R is the readback row binding the host observation to the substrate-step record without asserting substrate halting.*
6. *H records componentwise* hsame *transport for accepted observation, totality, substrate-step, refusal, readback, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a closed-observation request through A, T, S, F, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ClosedObservationTotalHost}^{\uparrow}$*, chapter 9370,* $\mathsf{NormalizationCandidateSocket}^{\uparrow}$*,* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* $\mathsf{TotalHostFuelHandoff}^{\uparrow}$*,* $\mathsf{ReductionFuelBoundary}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedObservationTotalHost}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, T, S, F, R, H, C, P, N$. It has no coordinate for unbounded substrate halting, non-total host terms, erased termination evidence, host evaluator soundness, completed consistency, global confluence, or quotient syntax equality.

Theorem 3706.2 (ClosedObservationTotalHost NameCert obligations)**.** *For every accepted* ClosedObservationTota *carrier $O = (A, T, S, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedObservationTotalHost}^{\uparrow}}$ *surface consists exactly of accepted observation exposure, finite termination or normal-form exposure, substrate-step readback, pre-read refusal, readback binding, componentwise transport, displayed replay, provenance exhaustion, and local naming.*

Every accepted host-observation record exposes A and T before any consumer can read S. The substrate row is therefore a finite step-indexed observation named by a total host record, not a claim that the substrate computation halts or that arbitrary host computations are accepted.

Lean4 ✓ `BEDC.Derived.ClosedObservationTotalHostUp.ClosedObservationTotalHostNameCertObligations`

Proof. Project the carrier of Definition 3706.1. The accepted record A and totality row T are distinct rows, so accepting the host observation does not erase the termination or normal-form evidence.

The substrate row S is downstream of A, T. If a consumer asks for substrate readback first, the refusal row F is the only available route, so the packet records the total-host discipline as a finite ordering of rows.

The row R then binds the displayed host observation to the displayed substrate step. This binding is step-indexed and finite; it is not a substrate-halting theorem and does not import an unbounded evaluator.

Finally H, C, P, N transport, replay, source, and name exactly these rows. Since no coordinate carries non-total host terms, erased termination evidence, host evaluator soundness, global confluence, quotient syntax equality, or completed consistency, none of those principles can be exported from the packet. □

Falsifiable prediction: Every accepted host-observation record exposes a finite termination or observation row before any substrate-read row is available to a consumer.

Independence witness: normalization-candidate-socket, metacicnormalizationfrontier, continuationtrace, certificate-machine: $\mathsf{ClosedObservationTotalHost}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries accepted observation, finite totality, substrate-step, refusal, readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedObservationTotalHost}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedObservationTotalHost}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3706.1 and Definition 3706.2 seed the finite total-host discipline for closed observation records before substrate-step readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedObservationTotalHost}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ClosedObservationTotalHostUp.ClosedObservationTotalHostNameCertObligations`

Bridge status: none

Not claimed: This chapter does not close global host normalization, substrate halting, host evaluator soundness, global confluence, quotient syntax equality, completed consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, accepted-observation exposure, totality-row precedence, substrate-read refusal, readback binding, transport, replay, provenance, and local naming for BEDC.Derived.ClosedObservationTota

Constructive story: A $\mathsf{ClosedObservationTotalHost}^{\uparrow}$ packet is generated from an accepted host-observation row, a finite totality row, a substrate-step row, a pre-read refusal row, a readback binding row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3707

A Concrete Naming Certificate for $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$ packet records the finite BEDC route by which regular rational Cauchy addition and product share one source surface, one window discipline, one dyadic arithmetic ledger, and one terminal real-name seal. It refines the binary route of chapter 3708 by isolating the coherence rows that make the addition and product certificates descend through the same $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ interfaces. The packet supplies later Real algebra consumers with a finite $\mathsf{NameCert}$ surface for shared operation descent, without importing quotient Cauchy classes, host real arithmetic, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3707.1 (RegularCauchyAlgebraCoherence carrier)**.** *A* $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, W, D, A, M, S, T, C, P, N)$$

with the following rows:

1. *L and R are the left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect both sources at the requested tolerance scale.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the displayed slack conversions, endpoint arithmetic, comparison checks, addition budgets, product budgets, and magnitude bounds.*
4. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *descent row. It consumes only L, R, W, D and returns the regular addition readback.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *descent row. It consumes only L, R, W, D and returns the regular product readback.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *operation seal. It exposes an addition or product real-name handoff only after the corresponding regular readback row has been displayed.*
7. *T records componentwise* hsame *transport for the sources, window, dyadic ledger, addition row, product row, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an operation request through $L, R, W, D, A, M, S, T, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, R, W, D, A, M, S, T, C, P, N$. It has no coordinate for quotient-stream equality, a host real operation, a selected limit, countable choice, trichotomy, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyAlgebraCoherenceUp.RegularCauchyAlgebraCoherenceTasteGate`
`single carrier alignment`

Theorem 3707.2 (RegularCauchyAlgebraCoherence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$ *carrier*

$$K = (L, R, W, D, A, M, S, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *row, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *row, the* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *source coherence, requiring addition and product to read the same ordered source pair L, R;*
3. *window coherence, requiring both operation rows to inspect the source pair only through W;*
4. *dyadic ledger coherence, requiring every addition and product estimate to consume only the displayed arithmetic and comparison entries of D;*
5. *descent separation, requiring A to carry the addition descent and M to carry the product descent while sharing the same upstream rows;*
6. *operation sealing, requiring S to expose a* $\mathsf{Real}^{\uparrow}$ *handoff only after the selected operation row has produced its regular readback;*
7. *stability and replay, requiring T and C to preserve the full route $L, R, W, D, A, M, S, P, N$ under* hsame *and* Cont *without adding any excluded analytic or quotient principle.*

No RegularCauchyAlgebraCoherence NameCert obligation is stored outside these rows.

Proof. Carrier exposure is the projection list in Definition 3707.1. The displayed data rows are exactly L, R, W, D, A, M, S, and the structural rows are exactly T, C, P, N.

Source and window coherence follow from the single source pair and the single window row. Since both A and M cite L, R, W as their upstream surface, there is no second source pair or hidden window service from which either operation can draw.

The dyadic ledger row gives the common arithmetic budget. Addition consumes it through A, product consumes it through M, and the theorem asserts only those two separated descent rows over the same ledger.

Finally, S, T, C, P, N close the finite certificate surface. The seal exposes only regular readback data as a $\mathsf{Real}^{\uparrow}$ handoff, while transport, replay, provenance, and local naming preserve the displayed route. None of the excluded principles has a carrier coordinate. □

Theorem 3707.3 (RegularCauchyAlgebraCoherence operation seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$ *carrier reads regular Cauchy addition or product data through the finite route*

$$L, R \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto T, C, P, N.$$

Consequently the consumer obtains the two regular source rows, the shared stream window, the dyadic ledger, the addition descent row, the product descent row, the operation seal, transport, replay, provenance, and local naming, and obtains no quotient Cauchy class, host real operation, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ operation request. By Definition 3707.1, the request has access to the source rows only as L, R, and it has access to their finite observations only through W.

The arithmetic step is then forced through D. Addition reads A, product reads M, and both descent rows are downstream of the same source, window, and dyadic ledger rows recorded in Definition 3707.2.

The seal S is the only Real-facing coordinate. It can expose an addition or product handoff only after the corresponding regular readback is displayed, and the rows T, C, P, N preserve that same finite route. Therefore a $\mathsf{Real}^{\uparrow}$ consumer has no coordinate from which to extract any excluded quotient, host, choice, order, or completeness datum. □

Theorem 3707.4 (RegularCauchyAlgebraCoherence non-escape)**.** *Let* $K = (L, R, W, D, A, M, S, T, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$ *carrier. Any algebraic fact exported from* K *is a rowwise consequence of the displayed regular source rows, shared stream window, dyadic ledger, operation descent rows, Real seal, transport, replay, provenance, and local naming rows. It is not a quotient Cauchy class, host real addition, host real multiplication, selected limit, countable-choice datum, trichotomy datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The data-bearing coordinates are exactly L, R, W, D, A, M, S, and the structural coordinates are exactly T, C, P, N.

An exported addition fact must pass through A after the common source, window, and ledger rows are displayed. An exported product fact must pass through M after the same upstream rows are displayed. A Real-facing fact must then pass through S.

The remaining rows preserve only that route. Componentwise hsame transport and displayed Cont replay cannot introduce a quotient relation, host operation, selected limit, choice principle, trichotomy principle, or completeness principle, while Pkg and NameCert record only the finite packet. Hence every exported algebraic fact is confined to the listed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3707.1, Definition 3707.2, Definition 3707.3, and Definition 3707.4 seed the finite coherence route for addition and product descent over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, host real operations, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source coherence, window coherence, dyadic ledger coherence, descent separation, operation sealing, stability, replay, provenance, local naming, and non-escape for BEDC.Derived.RegularCauchyAlgebraCoherenceUp.

Constructive story: A $\mathsf{RegularCauchyAlgebraCoherence}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, one shared $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegularCauchyAddition}^{\uparrow}$ and $\mathsf{RegularCauchyProduct}^{\uparrow}$ descent rows, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3708

A Concrete Naming Certificate for $\mathsf{CauchySequenceAlgebra}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ packet records the finite algebra route by which two regular rational Cauchy source rows are added or multiplied before any $\mathsf{Real}^{\uparrow}$ consumer reads the sealed result. It sits between the regular source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic ledger of chapter 291, the addition route of chapter 1695, the product route of chapter 461, and the terminal real-name seal of chapter 38. The packet gives later Real algebra and CauchyRealField consumers one BEDC-native finite dependency for binary Cauchy algebra; it does not import quotient Cauchy classes, host real arithmetic, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3708.1 (CauchySequenceAlgebra carrier)**.** *A* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observations supply the left and right inputs.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite window pairs in which the two source rows are inspected at the same requested tolerance scale.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row. It stores the displayed endpoint arithmetic, slack conversions, tolerance comparisons, addition-budget entries, and product-budget entries used by the accepted binary operation request.*
4. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the summed endpoint row, finite addition ledger, and resulting regular readback.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route row. It may be read only through X, Y, W, D and records the product endpoint row, product-error ledger, magnitude-budget entries, and resulting regular readback.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is exposed only after the chosen operation row A or M has displayed its regular readback.*
7. *H records componentwise* hsame *transport for the two source rows, synchronized windows, dyadic budgets, operation rows, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a binary algebra request through* $X, Y, W, D, A, M, S, H, P, N$.
9. *P is the* Pkg *provenance over* CauchySequenceAlgebra$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, A, M, S, H, C, P, N$. The carrier has no coordinate for quotient-stream equality, host real addition or multiplication, a selected limit, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 3708.2 (CauchySequenceAlgebra NameCert obligations)**.** *For every accepted* CauchySequenceAlgebra$^{\uparrow}$ *carrier*

$$G = (X, Y, W, D, A, M, S, H, C, P, N),$$

the local NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the two* RegSeqRat$^{\uparrow}$ *sources, synchronized* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *operation budgets,* RegularCauchyAddition$^{\uparrow}$ *route,* RegularCauchyProduct$^{\uparrow}$ *route,* Real$^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *source-window synchronization, requiring every operation request to inspect X and Y through the same displayed window row W before any endpoint arithmetic is read;*
3. *dyadic-budget exactness, requiring every addition or product endpoint row to consume only the displayed tolerance, slack, comparison, and magnitude-budget entries of D;*
4. *operation-route separation, requiring A to carry only the addition route and M to carry only the product route, while both routes consume the same source, window, and dyadic-budget rows;*
5. *Real seal handoff, requiring S to be exposed only after the selected operation route has produced its* RegSeqRat$^{\uparrow}$ *readback;*
6. *transport and replay stability, requiring H and C to preserve the full route $X, Y, W, D, A, M, S, P, N$ without adding a quotient stream, host operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.*

No CauchySequenceAlgebra NameCert obligation is stored outside these rows.

Proof. Carrier exposure is row projection from Definition 3708.1. The displayed coordinates are exactly the two source rows X, Y, synchronized windows W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Source-window synchronization is forced by the single window coordinate W. Both source reads must pass through that coordinate before the dyadic operation budget is available, so the carrier has no second window service for either input.

Dyadic-budget exactness and operation-route separation are read from D, A, M. The row D supplies the finite arithmetic budgets, the row A consumes those budgets for addition, and the row M consumes those budgets for product. Since A and M are distinct rows with the same upstream inputs, neither route can borrow an unrecorded host operation.

Finally, the Real seal and structural rows close the finite route. The seal S is downstream of the operation readback, while H, C, P, N only transport, replay, package, and name the displayed rows. The excluded quotient, host arithmetic, selected-limit, choice, trichotomy, and ambient-completeness data have no carrier coordinate. □

Theorem 3708.3 (CauchySequenceAlgebra Real-field handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *binary algebra read reaches field-facing data only through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget row, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *routes, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In particular the handoff exports regular Cauchy addition and multiplication readbacks before the final Real seal, and it exports no quotient stream, host real arithmetic, selected limit, trichotomy, countable-choice datum, or ambient completeness principle.*

Proof. Project the carrier of Definition 3708.1. The only field-facing source data are the two regular rational Cauchy rows X, Y, the synchronized window W, and the dyadic operation budget D.

Read the operation rows before the final Real seal. The addition route is A, the product route is M, and both routes consume the same source, window, and budget rows named in Definition 3708.2.

The terminal consumer then reads S only after one of those operation routes has produced its $\mathsf{RegSeqRat}^{\uparrow}$ readback. Transport, replay, provenance, and local naming in H, C, P, N preserve that route. Since the carrier has no coordinate for quotient streams, host arithmetic, selected limits, trichotomy, countable choice, or ambient completeness, no Real-field handoff can export any of those objects. □

Theorem 3708.4 (CauchySequenceAlgebra operation route)**.** *Every* $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegularCauchyProdu}$ $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{CauchyRealField}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier reads binary algebra data only through the displayed route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N.$$

Consequently the consumer obtains the two regular source rows, synchronized stream windows, dyadic operation budgets, the addition route, the product route, the terminal Real seal handoff, transport, replay, provenance, and local naming, and obtains no quotient Cauchy class, host real operation, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a downstream algebra request. By Definition 3708.1, the only source coordinates are X and Y, and the only synchronized window coordinate available to both sources is W.

The operation budget is then forced through D. Addition reads the route row A, product reads the route row M, and both rows are displayed downstream of the same sources, windows, and dyadic budgets named in Definition 3708.2.

The Real-facing handoff is last. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyRealField}^{\uparrow}$ consumer can read the seal S only after an operation route has produced its regular readback, and the rows H, C, P, N preserve that same finite route. No coordinate remains from which a quotient Cauchy class, host operation, selected limit, countable choice, trichotomy, or ambient completeness principle could be exported. □

Theorem 3708.5 (CauchySequenceAlgebra route non-escape)**.** *Let* $G = (X, Y, W, D, A, M, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *carrier. Any algebraic fact exported from* G *is a rowwise consequence of the displayed regular source rows, synchronized windows, dyadic operation budgets, operation routes, Real seal, transport, replay, provenance, and local naming rows. It is not a quotient Cauchy class, host real addition, host real multiplication, selected limit, countable-choice datum, trichotomy datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Inspect the carrier rows. The data-bearing coordinates are exactly X, Y, W, D, A, M, S, and the structural coordinates are exactly H, C, P, N.

An exported addition fact must use A after the source, window, and dyadic-budget rows have been displayed. An exported product fact must use M after the same upstream rows have been displayed. A Real-facing algebra fact must then pass through the seal row S.

The structural rows preserve only that route. Componentwise hsame transport and displayed Cont replay cannot create a host operation or a quotient relation, while provenance and local naming record only the finite packet. Thus every exported algebraic fact is confined to the listed rows, and each excluded principle has no entry point. □

Theorem 3708.6 (CauchySequenceAlgebra remainder-estimate handoff)**.** *Let*

$$G = (X, Y, W, D, A, M, S, H, C, P, N)$$

be an accepted CauchySequenceAlgebra$^{\uparrow}$ *carrier. Any downstream* CauchyRemainderEstimate$^{\uparrow}$ *read for an addition or product result factors first through the same finite binary-algebra route*

$$X, Y \longmapsto W \longmapsto D \longmapsto A, M \longmapsto S \longmapsto H, C, P, N$$

and then through the finite tail-estimate rows of chapter 3991. The handoff exports the displayed source rows, synchronized windows, dyadic operation budgets, selected addition or product route, terminal Real seal, transport, replay, provenance, local naming, finite tail threshold, admitted tail windows, regular readback, and tail-diameter boundary rows. It exports no quotient Cauchy class, host real operation, selected limit, countable-choice datum, trichotomy datum, or ambient Real$^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier G. By Definition 3708.2, every binary algebra read exposes only the source rows X, Y, synchronized window W, dyadic budget D, operation rows A, M, Real seal S, and structural rows H, C, P, N.

Apply Definition 3708.4 to the downstream addition or product request. The result route must pass through A for addition or M for product, and in either case it uses the same upstream X, Y, W, D rows before reaching the seal S.

Now apply Definition 3708.5. No part of that binary-algebra route can introduce a quotient Cauchy class, host real operation, selected limit, countable-choice row, trichotomy row, or ambient completeness row.

The remainder-estimate consumer therefore begins from the regular readback already displayed by the operation route and then uses the sibling surface chapter 3991. That surface supplies the finite threshold, admitted tail windows, regular readback, tail-diameter boundary, transport, replay, provenance, and local naming rows for CauchyRemainderEstimate$^{\uparrow}$. Composing these two finite routes gives the stated handoff and leaves every excluded principle without a carrier coordinate. □

Closure status for NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 3708.1, Definition 3708.2, Definition 3708.3, Definition 3708.4, Definition 3708.5, and Definition 3708.6 seed the finite binary algebra route over RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyAddition$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, CauchyRemainderEstimate$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchySequenceAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, host real operations, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source-window synchronization, dyadic-budget exactness, operation-route separation, Real seal handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchySequenceAlgebraUp.

Constructive story: A CauchySequenceAlgebra$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, synchronized StreamName$^{\uparrow}$ windows, one DyadicRatCore$^{\uparrow}$ operation-budget ledger, RegularCauchyAddition$^{\uparrow}$ and RegularCauchyProduct$^{\uparrow}$ route rows, a Real$^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3709

A Concrete Naming Certificate for $\mathsf{CauchySequenceProductStability}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySequenceProductStability}^{\uparrow}$ packet records the finite stability route by which two regular rational Cauchy source rows keep their product inside the Real and Completion interface. It gathers the regular product route of chapter 461, the product criterion of chapter 1586, the synchronized window discipline of chapter 126, the dyadic budget rows of chapter 291, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet is a finite NameCert carrier for product stability, not host multiplication of completed reals, quotient equality of streams, selected limits, countable choice, trichotomy, or ambient completeness.

Definition 3709.1 (Cauchy sequence product stability carrier)**.** *A* $\mathsf{CauchySequenceProductStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, W_A, W_B, D, P, K, R, E, H, C, L, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular Cauchy schedules supply the two input sequences.*
2. *W_A and W_B are synchronized* $\mathsf{StreamName}^{\uparrow}$ *window rows for the same product request, precision demand, and observation index.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row, recording input tolerances, finite magnitude bounds, cross-error terms, and the output tolerance assigned to the product window.*
4. *P is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route row, read only after A, B, W_A, W_B, D have been displayed.*
5. *K is the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *acceptance row for the displayed product route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the product route under the dyadic budget and criterion row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after the regular-rational product readback R has been displayed.*
8. *H records componentwise* hsame *transport for $A, B, W_A, W_B, D, P, K, R, E, C, L, N$ and the local product-stability packet shape.*

9. *C records displayed* Cont *replay from the two source rows through the synchronized windows, dyadic budget, product route, criterion row, readback row, and real seal.*
10. *L is the* Pkg *provenance over* $\mathsf{CauchySequenceProductStability}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{CauchyProductCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceProductStability}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, W_A, W_B, D, P, K, R, E, H, C, L, N$. It has no coordinate for host multiplication of completed reals, quotient stream equality, a selected product limit, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchySequenceProductStabilityUp.CauchySequenceProductStabilityTasteGate`
`single carrier alignment`

Theorem 3709.2 (Cauchy sequence product stability NameCert obligations)**.** *For an accepted* $\mathsf{CauchySequenceProductStability}^{\uparrow}$ *carrier $S = (A, B, W_A, W_B, D, P, K, R, E, H, C, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceProductStability}^{\uparrow}}$ *obligations are exactly carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic product-budget exactness, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *route, the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *acceptance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport through H, displayed continuation replay through C, provenance through L, and local naming through N.*

Proof. Carrier admission is projection from Definition 3709.1. The tuple displays the two source rows, synchronized windows, dyadic product budget, product route, criterion row, regular-rational readback, real seal, and structural rows.

The source and window obligations are read from A, B, W_A, W_B. These rows expose the two regular schedules and align them before the product route is available.

The budget and route obligations are read from D, P, K. The dyadic row records the finite tolerance and magnitude data, the regular product route consumes that data, and the criterion row accepts the displayed product route for downstream readback.

The rows R, E, H, C, L, N then provide the regular-rational boundary, real-seal boundary, transport, replay, provenance, and local name. Since no other coordinate occurs in the carrier, the listed rows exhaust the certificate surface. □

Theorem 3709.3 (Cauchy sequence product budget stability)**.** *Let $S = (A, B, W_A, W_B, D, P, K, R, E, H, C, L, N)$ be an accepted* $\mathsf{CauchySequenceProductStability}^{\uparrow}$ *carrier. Replacing the two source rows, synchronized window rows, dyadic product budget, product route, criterion row, readback row, and real seal by displayed componentwise* hsame *rows, and replaying the replacement through C, preserves the admissible product-stability route*

$$A, B \longmapsto W_A, W_B \longmapsto D \longmapsto P \longmapsto K \longmapsto R \longmapsto E.$$

Thus every Real and Completion consumer of the product reads the same finite stability packet and cannot introduce host multiplication, quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only route from the two source sequences to the terminal real seal is the displayed chain through the synchronized windows, dyadic budget, regular product route, criterion row, regular-rational readback, and real seal.

The replacement hypothesis is internal to the structural rows. The row H gives componentwise hsame transport for every displayed product-stability coordinate, and C replays the continuation through the transported coordinates in the same order.

Therefore the transported packet still reaches D, then P, then K, then R, then E. The provenance row L and local name N preserve the same finite packet and do not add a second product operation.

Since the carrier has no coordinate for host multiplication, quotient streams, selected limits, choice, trichotomy, or ambient completeness, the budget-stable route is exactly the displayed BEDC product-stability route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceProductStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceProductStability}^{\uparrow}$ packet is generated from two RegSeqRat source rows, synchronized StreamName windows, a DyadicRatCore product budget, a RegularCauchyProduct route, a CauchyProductCriterion acceptance row, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceProductStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3709.1, Definition 3709.2, and Definition 3709.3 seed the finite product-stability packet for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceProductStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host multiplication of completed reals, quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window admission, dyadic product-budget exactness, RegularCauchyProduct routing, CauchyProductCriterion acceptance, RegSeqRat readback, Real seal handoff, transport stability, continuation replay, and provenance non-escape for BEDC.Derived.CauchySequenceProductStabilityUp.

Chapter 3710

A Concrete Naming Certificate for $\mathsf{BishopCauchyProductBound}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyProductBound}^{\uparrow}$ packet records the finite boundedness estimate used before a Cauchy product is admitted as a regular real product. It sits between the product surface of chapter 464, the regular product route of chapter 461, the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet supplies a finite majorant and cross-error budget for product windows; it is not host multiplication of completed reals, quotient stream equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3710.1 (Bishop Cauchy product bound carrier)**.** *A* $\mathsf{BishopCauchyProductBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, C, W_A, W_C, M_A, M_C, D, P, R, E, H, K, L, N)$$

with the following displayed rows:

1. *A and C are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular Cauchy observations will be multiplied.*
2. *W_A and W_C are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite windows for the requested product precision.*
3. *M_A and M_C are finite magnitude-majorant rows for the two source windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the output tolerance, the two source tolerances, and the cross-error terms bounded by M_A and M_C.*
5. *P is the* $\mathsf{CauchyProduct}^{\uparrow}$ *product-window row exposed only after the source windows and dyadic budget are displayed.*
6. *R is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *handoff row that repacks the product-window estimate as a regular Cauchy readback.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after R has been displayed.*
8. *H records componentwise* hsame *transport for all product-bound rows.*
9. *K records displayed* Cont *replay from the source windows through the bound ledger, product row, regular handoff, and real seal.*

10. *L is the* Pkg *provenance over* $\mathsf{BishopCauchyProductBound}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyProductBound}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, C, W_A, W_C, M_A, M_C, D, P, R, E, H, K, L, N$. It has no coordinate for host real multiplication, quotient stream equality, a selected product limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopCauchyProductBoundUp`

Theorem 3710.2 (Bishop Cauchy product bound NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyProductBound}^{\uparrow}$ *carrier $B = (A, C, W_A, W_C, M_A, M_C, D, P, R, E, H, K, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyProductBound}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, two finite magnitude-majorant rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-bound ledger, the* $\mathsf{CauchyProduct}^{\uparrow}$ *window row, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the accepted carrier. The source rows A, C and windows W_A, W_C expose the only finite observations from which a product estimate can be read.

The rows M_A, M_C, D then bind the boundedness estimate. The two majorants control the source magnitudes, while the dyadic ledger records the source tolerances and the resulting cross-error budget before any product row is exposed.

The product-facing rows P, R, E are downstream of that ledger. They route the finite product estimate into the regular Cauchy product handoff and then into the real seal.

Finally H, K, L, N transport, replay, source, and name exactly these rows. Since the carrier contains no host multiplication, quotient stream, selected-limit, choice, trichotomy, or ambient-completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 3710.3 (Bishop Cauchy product bound regular handoff)**.** *Every accepted* $\mathsf{BishopCauchyProductBound}^{\uparrow}$ *carrier hands a bounded Cauchy-product estimate to* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *only through the displayed route*

$$A, C \longmapsto W_A, W_C \longmapsto M_A, M_C \longmapsto D \longmapsto P \longmapsto R \longmapsto E.$$

Thus a Real multiplication or Completion consumer must first inspect the two regular source rows, the synchronized finite windows, the magnitude bounds, the dyadic cross-error ledger, and the Cauchy-product window before it can read the regular-product handoff.

Proof. Start with the carrier projection. The only source data are A, C, W_A, W_C, so a product consumer begins with regular rational observations and finite stream windows rather than with completed real representatives.

The boundedness estimate is forced through M_A, M_C, D. These rows supply the finite majorants and the dyadic error ledger that make the product-window estimate admissible.

The downstream handoff is then P, R, E. The $\mathsf{CauchyProduct}^{\uparrow}$ row records the product window, the $\mathsf{RegularCauchyProduct}^{\uparrow}$ row repacks it as a regular readback, and the $\mathsf{Real}^{\uparrow}$ row seals the endpoint.

The structural rows preserve the same order under transport, replay, provenance, and naming. No other carrier coordinate can supply a host product, quotient stream equality, selected limit, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyProductBound}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyProductBound}^{\uparrow}$ packet is generated from two RegSeqRat source rows, synchronized StreamName windows, two finite magnitude bounds, a DyadicRatCore product-bound ledger, a CauchyProduct window row, a RegularCauchyProduct handoff row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyProductBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3710.1, Definition 3710.2, and Definition 3710.3 seed the finite bounded Cauchy-product estimate route for Real multiplication consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyProductBound}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.BishopCauchyProductBoundUp`

Bridge status: none

Not claimed: This chapter does not close host multiplication of completed reals, quotient stream equality, selected product limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, magnitude-bound extraction, dyadic product-budget exactness, CauchyProduct routing, RegularCauchyProduct handoff, Real seal nonescape, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.BishopCauchyProductBoundUp.

Chapter 3711

A Concrete Naming Certificate for $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$

Following Oresme and Bishop–Bridges constructive analysis, the $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$ packet names the dyadic-block lower-bound route for the harmonic series as finite BEDC data. It sits beside the divergence refusal surface of chapter 2047, the positive condensation route of chapter 3345, the rational comparison source of chapter 37, the dyadic arithmetic ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback row of chapter 301, and the terminal real-name seal of chapter 38. The carrier records only displayed finite partial sums, dyadic block schedules, rational comparisons, tolerance ledgers, readback windows, transport, replay, provenance, and local naming.

Definition 3711.1 (OresmeHarmonicDivergence carrier)**.** *An* $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S, B, Q, D, W, R, E, T, C, P, N)$$

with the following displayed rows:

1. *S is the harmonic partial-sum row, exposing only finite sums of the displayed terms* $1, 1/2, 1/3, \ldots$ *through inspected windows.*
2. *B is the dyadic block schedule, listing the finite intervals* $[2^k, 2^{k+1})$ *requested by the packet and the endpoints used by each partial-sum comparison.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *comparison row, carrying the rational lower-bound entries used inside each displayed block.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording powers of two, reciprocal denominators, and the finite comparison budget used to show that each inspected block contributes at least* $1/2$.
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the harmonic terms, block endpoints, rational comparisons, and partial-sum reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed partial sums and block lower bounds.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* S, B, Q, D, W, R *have been displayed.*
8. *T records componentwise* hsame *transport for the partial-sum row, block schedule, rational comparison row, dyadic ledger, stream windows, readback row, Real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a block request through the harmonic partial sums, dyadic schedule, rational comparison row, dyadic ledger, stream windows, readback row, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$, $\mathsf{SeriesDivergenceTest}^{\uparrow}$, $\mathsf{CauchyCondensationRealSeries}$ $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OresmeHarmonicDivergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, Q, D, W, R, E, T, C, P, N$. It has no coordinate for a host infinite sum, quotient series equality, countable-choice schedule, selected endpoint, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.OresmeHarmonicDivergenceUp.OresmeHarmonicDivergenceTasteGate single carrier alignment`

Theorem 3711.2 (OresmeHarmonicDivergence NameCert obligations)**.** *For every accepted* OresmeHarmonicDiverg *carrier $H = (S, B, Q, D, W, R, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OresmeHarmonicDivergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed harmonic partial-sum row, dyadic block schedule, rational comparison row, dyadic tolerance ledger, stream-window row, readback row, Real seal, transport, replay, provenance, and local naming rows;*

2. *block schedule exactness, requiring B to expose precisely the inspected finite intervals $[2^k, 2^{k+1})$ and their partial-sum endpoints before any lower-bound comparison is read;*

3. *rational lower-bound visibility, requiring Q, D, W, R to display the finite comparison that every term in the inspected block is at least $1/2^{k+1}$ and that the whole block contributes at least $1/2$;*

4. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring E to remain downstream of the displayed finite block route and to export no host infinite sum, quotient series equality, countable-choice schedule, selected endpoint, or ambient completeness principle;*

5. *ledger exhaustion, requiring T, C, P, N to transport, replay, source, and name the same finite route without adding unlisted analytic or choice data.*

No Oresme harmonic-divergence obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.OresmeHarmonicDivergenceUp.OresmeHarmonicDivergenceNameCertObligations`

Proof. Project the carrier of Definition 3711.1. The accepted packet exposes exactly the harmonic partial-sum row, the dyadic block schedule, the rational comparison row, the dyadic tolerance ledger, stream windows, readback, Real seal, and structural rows.

The block schedule is finite. For each inspected k, the row B gives the interval $[2^k, 2^{k+1})$ and the partial-sum endpoints that the consumer may read from S.

The lower-bound comparison is carried by Q, D, W, R. The schedule W selects the finitely many terms in the displayed block, Q supplies the rational comparison against $1/2^{k+1}$, D records the dyadic denominator and tolerance budget, and R reads back the block contribution.

The Real-facing route is downstream of those rows. The seal E can only be reached after the finite block comparison has passed through the displayed readback, while T, C, P, N preserve and name the same route.

Since a host infinite sum, quotient series equality, countable-choice schedule, selected endpoint, and ambient completeness are not coordinates of H, the listed rows exhaust the local NameCert surface. □

Theorem 3711.3 (Oresme dyadic block lower bound)**.** *Every accepted* $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$ *packet exports the finite lower-bound route for each displayed block* $[2^k, 2^{k+1})$ *through*

$$S, B \longmapsto Q, D, W, R \longmapsto E, T, C, P, N.$$

Thus the packet records the Oresme block fact that each inspected dyadic block contributes at least $1/2$ *to the harmonic partial-sum row, while exporting no host infinite sum, quotient series equality, countable choice, selected endpoint, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with an accepted packet $H = (S, B, Q, D, W, R, E, T, C, P, N)$. A consumer requesting the block lower bound must first read the partial-sum row S together with the dyadic block schedule B.

For a displayed block $[2^k, 2^{k+1})$, the window row W exposes exactly the finitely many harmonic terms in that interval. The comparison row Q and dyadic ledger D show that every such term is bounded below by $1/2^{k+1}$.

There are 2^k displayed terms in the block, so the same finite ledger records the rational lower bound $2^k/2^{k+1} = 1/2$. The readback row R attaches this lower bound to the corresponding block contribution of the partial-sum row.

The seal row E and the structural rows T, C, P, N only carry this finite route forward. Because the carrier has no field for host infinite sums, quotient series equality, countable choice, selected endpoints, or ambient completeness, the exported statement is exactly the finite dyadic-block lower-bound route. □

Falsifiable prediction: Every accepted $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$ block read factors through the harmonic partial-sum row, dyadic block schedule, RatUp comparison row, DyadicRatCore tolerance ledger, StreamName window row, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: series-divergence-test, cauchy-condensation-real-series, rat, dyadicratcore, streamname, regseqrat, real: $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the harmonic partial-sum row, dyadic block schedule, RatUp comparison row, DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{OresmeHarmonicDivergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OresmeHarmonicDivergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3711.1, Definition 3711.2, and Definition 3711.3 seed the finite Oresme dyadic-block lower-bound carrier for harmonic partial sums, rational comparisons, dyadic ledgers, stream windows, readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OresmeHarmonicDivergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, quotient series equality, countable choice, selected endpoints, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, block schedule exactness, rational lower-bound visibility, RealUp seal nonescape, ledger exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.OresmeHarmonicDiverge

Constructive story: An $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$ packet is generated from a harmonic partial-sum row, a dyadic block schedule, RatUp comparison rows, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3712

A Concrete Naming Certificate for $\mathsf{Subdifferential}^{\uparrow}$

Following Rockafellar and Boyd–Vandenberghe, the $\mathsf{Subdifferential}^{\uparrow}$ packet records the finite supporting-hyperplane data that makes a convex subgradient usable inside BEDC without importing a separation theorem. It sits beside the convex-set carrier of chapter 208, the conjugacy rows of chapter 3563, the duality handoff of chapter 321, the order boundary of chapter 2297, and the stationarity surface of chapter 300. The chapter names the local subgradient certificate only; it does not assert Hahn–Banach separation, quotient function-space duality, selected suprema, or choice-selected subgradients.

3712.1 Subdifferential Carrier

Definition 3712.1 (Subdifferential carrier)**.** *A* $\mathsf{Subdifferential}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, x, \xi, E, L, G, K, H, C, P, N)$$

with the following visible rows:

1. *F is the displayed convex functional row, including its finite convex-domain, convex-combination, value-comparison, and lower-support ledgers;*
2. *x is the displayed base point row inside the carrier domain of F;*
3. *ξ is the displayed dual covector row, read only through the finite pairing tests carried by the packet;*
4. *E is the pairing-evaluation ledger recording the finite values $\langle \xi, y-x \rangle$ that are actually inspected;*
5. *L is the supporting-inequality ledger asserting, for each displayed comparison point y, the row $F(y) \geq F(x) + \langle \xi, y - x \rangle$;*
6. *G is the epigraph row that reads the same support inequality as a displayed lower supporting face of the epigraph carrier;*
7. *K is the cone-boundary row connecting the finite support inequality to the* $\mathsf{PositiveCone}^{\uparrow}$ *order boundary and to the stationarity rows later consumed by* $\mathsf{KKT}^{\uparrow}$*;*
8. *H stores componentwise* hsame *transport for the functional, base point, covector, pairing ledger, support ledger, epigraph row, cone boundary, continuation row, provenance row, and local naming row;*

9. *C stores displayed* Cont *replay from a subgradient request through the convex functional, pairing, support, epigraph, cone-boundary, and downstream handoff rows;*
10. *P is the* Pkg *provenance over* $\mathsf{Subdifferential}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{PositiveCone}^{\uparrow}$, $\mathsf{KKT}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{Subdifferential}^{\uparrow}}$ *row.*

The carrier contains no ambient locally convex dual, no quotient function space, no selected separating hyperplane, no selected supremum in a conjugate formula, and no rule choosing a subgradient when the displayed support ledger is absent.

Lean4 ✓ `BEDC.Derived.SubdifferentialUp.SubdifferentialTasteGate single carrier alignment`

3712.2 Subdifferential Certificate

Theorem 3712.2 (Subdifferential NameCert obligations)**.** *For every accepted* $\mathsf{Subdifferential}^{\uparrow}$ *carrier* $S = (F, x, \xi, E, L, G, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Subdifferential}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the convex functional row, base point row, dual covector row, finite pairing-evaluation ledger, supporting-inequality ledger, epigraph row, cone boundary, transport, replay, provenance, and local naming row;*
2. *support-inequality exactness, requiring every exported subgradient read to pass through the displayed row $F(y) \geq F(x) + \langle \xi, y - x \rangle$ for the listed comparison point;*
3. *epigraph compatibility, requiring the support ledger and epigraph row to name the same lower supporting face and the same base point;*
4. *Fenchel handoff, requiring any conjugacy or duality consumer to pass through the displayed* $\mathsf{ConvexConjugate}^{\uparrow}$ *and* $\mathsf{FenchelDuality}^{\uparrow}$ *rows before reading a dual certificate;*
5. *KKT and normal-cone consumer boundary, requiring stationarity consumers to read the cone-boundary row and refusing any normal-cone claim not carried by the finite support ledger;*
6. *non-escape from Hahn–Banach, quotient function spaces, selected suprema, and choice-selected subgradients.*

Lean4 ✓ `BEDC.Derived.SubdifferentialUp.SubdifferentialCarrier namecert obligations`

Proof. Project the accepted carrier. The rows F, x, ξ, E, L, G, K are the entire analytic surface, and the rows H, C, P, N are the entire structural surface.

Support exactness is a ledger condition. A consumer can call ξ a subgradient only at a displayed comparison point whose support inequality is present in L and whose pairing value is present in E.

Epigraph compatibility and the Fenchel handoff are then read through G and the provenance row P. The same lower support row is available to epigraph, conjugacy, and duality consumers, but no hidden supremum or separating functional is added by that handoff.

Finally the stationarity boundary passes through K. Since no coordinate of S names Hahn–Banach separation, a quotient dual space, a selected supremum, or a choice functional for subgradients, those principles cannot be exported by the local certificate. □

Theorem 3712.3 (Subdifferential support inequality exactness)**.** *For every accepted* Subdifferential$^{\uparrow}$ *carrier* $S = (F, x, \xi, E, L, G, K, H, C, P, N)$*, a public subgradient read is exact only when its displayed comparison point is named in the finite support ledger* L *and its pairing value is named in the finite pairing ledger* E*. The row* L *must expose the inequality* $F(y) \geq F(x) + \langle \xi, y - x \rangle$ *for that same* y*, and no consumer may replace this row by an ambient separation principle or by a chosen supporting functional.*

Lean4 ✓ `BEDC.Derived.SubdifferentialUp.SubdifferentialCarrier support inequality exactness`

Proof. Project the carrier coordinates E and L. The pairing ledger E is the only row that evaluates $\langle \xi, y - x \rangle$, and the support ledger L is the only row that compares this value with $F(y)$ and $F(x)$.

Since the carrier contains no Hahn–Banach coordinate and no selection rule for subgradients, a consumer can export only the support inequalities that are already displayed in L. Exactness is therefore the rowwise agreement of the finite comparison point, the pairing value, and the listed inequality. □

Lean4 ✓ `BEDC.Derived.SubdifferentialUp.SubdifferentialSupportInequalityExactness`

Theorem 3712.4 (Subdifferential epigraph and Fenchel handoff)**.** *Every* ConvexConjugate$^{\uparrow}$ *or* FenchelDuality$^{\uparrow}$ *read of an accepted* Subdifferential$^{\uparrow}$ *carrier factors through the displayed epigraph row* G*, the support ledger* L*, the pairing ledger* E*, the componentwise transport row* H*, and the provenance row* P*. The handoff may expose a conjugacy or duality consumer, but it does not add selected suprema, quotient dual spaces, or an unlisted separating hyperplane.*

Lean4 ✓ `BEDC.Derived.SubdifferentialUp.SubdifferentialCarrier epigraph fenchel handoff`

Proof. Read the epigraph coordinate G together with the ledgers E and L. These rows identify the lower supporting face that the conjugacy and duality consumers may inspect.

The provenance row P names the ConvexConjugate$^{\uparrow}$ and FenchelDuality$^{\uparrow}$ dependencies, while H carries the same finite rows across permitted comparisons. Because no coordinate stores a selected supremum or quotient dual object, the Fenchel-facing handoff is exactly the displayed epigraph support route. □

Theorem 3712.5 (Subdifferential KKT boundary)**.** *Every* PositiveCone$^{\uparrow}$ *or* KKT$^{\uparrow}$ *stationarity read of an accepted* Subdifferential$^{\uparrow}$ *carrier must pass through the cone-boundary row* K*, the support ledger* L*, the pairing ledger* E*, transport* H*, replay* C*, provenance* P*, and the local naming row* N*. The boundary records only finite stationarity data and refuses Hahn–Banach separation, normal-cone completion, and choice-selected subgradients not present in the support ledger.*

Proof. Start from the cone-boundary coordinate K. It is the only carrier row that connects the support inequality to the positive-cone and KKT stationarity surface.

The ledgers E and L supply the finite pairing and support data used by that boundary, while H, C, P, N transport, replay, source, and name the same packet. With no coordinate for Hahn–Banach separation or an ambient normal-cone completion, the stationarity consumer receives exactly the finite boundary listed above. □

Lean4 ✓ `BEDC.Derived.SubdifferentialUp.SubdifferentialCarrier kkt boundary`

Closure status for NameCert$_{\text{Subdifferential}^{\uparrow}}$**.**

Constructive story: A Subdifferential$^{\uparrow}$ packet is generated from a convex functional row, base point row, dual covector row, finite pairing-evaluation ledger, supporting-inequality ledger, epigraph row, cone-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{Subdifferential}\uparrow}$, scopedClosed)

Scope closed: Definition 3712.1, Definition 3712.2, Definition 3712.3, Definition 3712.4, and Definition 3712.5 bind the finite subgradient obligation surface between convex sets, convex conjugacy, Fenchel duality, positive cones, and KKT stationarity.

Formal verification: FormalStatus(NameCert$_{\mathsf{Subdifferential}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, quotient function-space duality, selected suprema, choice-selected subgradients, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public subgradient consumer theorem and later Lean verification for BEDC.Derived.SubdifferentialUp.

Chapter 3713

A Concrete Naming Certificate for $\mathsf{ProximalMap}^{\uparrow}$

Following Rockafellar's convex-analysis treatment of subdifferentials and resolvents, and Boyd–Vandenberghe's finite optimization presentation of proximal operators, the $\mathsf{ProximalMap}^{\uparrow}$ packet records the displayed proximal minimization surface as BEDC NameCert data. It sits after the convex-set carrier of chapter 208, the conjugacy rows of chapter 3563, the Fenchel-duality handoff of chapter 321, the positive-cone order boundary of chapter 2297, the stationarity ledger of chapter 300, the real seal of chapter 38, and the vector-space source of chapter 47. The packet gives subdifferential and monotone-operator consumers a finite resolvent-facing route without asserting a selected global minimizer, Hilbert projection theorem, host lower semicontinuity, or ambient completeness.

3713.1 ProximalMap Carrier

Definition 3713.1 (ProximalMap carrier)**.** *A* $\mathsf{ProximalMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, F, u, z, R, D, K, G, O, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed vector-space source row, read through* $\mathsf{VecSpace}^{\uparrow}$ *and the real scalar seal of* $\mathsf{Real}^{\uparrow}$*;*
2. *F is the convex functional and domain row, including the visible* $\mathsf{ConvexSet}^{\uparrow}$ *and* $\mathsf{ConvexConjugate}^{\uparrow}$ *surfaces used by the request;*
3. *u is the input point row in the carried vector-space source;*
4. *z is the displayed candidate output row;*
5. *R is the real penalty and distance-evaluation row used for the displayed expression $F(y)+\frac{1}{2\lambda}\|y-u\|^2$ at the finitely inspected comparison points;*
6. *D is the finite dominance ledger recording that the candidate row is no worse than each displayed comparison row;*
7. *K is the KKT stationarity row tying the candidate, penalty, cone boundary, and finite residual rows to the* $\mathsf{KKT}^{\uparrow}$ *packet;*

8. *G is the Fenchel and convex-conjugate handoff row, read only after F, R, D, K have been displayed;*
9. *O is the convex-resolvent consumer row for later subdifferential or monotone-operator packets;*
10. *H records componentwise* hsame *transport for the vector-space source, convex functional, input, candidate, real penalty, dominance ledger, KKT stationarity, Fenchel handoff, resolvent consumer, replay, provenance, and local naming rows;*
11. *C records displayed* Cont *replay from a proximal request through convex admission, real penalty evaluation, stationarity, duality, dominance, and resolvent-facing readback;*
12. *P is the* Pkg *provenance over* $\mathsf{ProximalMap}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{PositiveCone}^{\uparrow}$, $\mathsf{KKT}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ProximalMap}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient Hilbert projection theorem, a selected minimizer outside the displayed candidate row, host lower semicontinuity, global coercivity, quotient vector equality, or an existence theorem for every input.

Lean4 (definition) `BEDC.Derived.ProximalMapUp.ProximalMapUp`
Lean4 ✓ `BEDC.Derived.ProximalMapUp.ProximalMapTasteGate single carrier alignment`

3713.2 ProximalMap Certificate

Theorem 3713.2 (ProximalMap NameCert obligations)**.** *For every accepted* $\mathsf{ProximalMap}^{\uparrow}$ *carrier* $Q = (X, F, u, z, R, D, K, G, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ProximalMap}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the vector-space source, convex functional, input point, candidate output, real penalty row, dominance ledger, KKT row, Fenchel handoff, resolvent consumer row, transport, replay, provenance, and local naming;*
2. *penalty evaluation exactness, requiring every proximal comparison to read the same* $\mathsf{Real}^{\uparrow}$ *penalty row R and the same* $\mathsf{VecSpace}^{\uparrow}$ *source row X before any dominance claim is exported;*
3. *convex-domain compatibility, requiring the candidate and comparison points to be admitted through the* $\mathsf{ConvexSet}^{\uparrow}$ *row carried by F;*
4. *stationarity compatibility, requiring the displayed residual, cone boundary, and multiplier data to pass through the* $\mathsf{KKT}^{\uparrow}$ *and* $\mathsf{PositiveCone}^{\uparrow}$ *rows before any optimality-facing read is public;*
5. *Fenchel and conjugacy handoff, requiring dual or subgradient consumers to pass through* $\mathsf{ConvexConjugate}^{\uparrow}$ *and* $\mathsf{FenchelDuality}^{\uparrow}$ *only after the dominance and stationarity rows have been displayed;*
6. *non-escape from global minimizer selection, host projection theorems, quotient vector equality, lower-semicontinuity assumptions, and ambient completeness.*

Proof. Project the accepted carrier. The rows $X, F, u, z, R, D, K, G, O$ are the complete proximal surface, while H, C, P, N are the structural route that transports, replays, sources, and names the same packet.

Penalty exactness is a finite ledger condition. A comparison with a point y can be read only when the relevant vector-space rows in X, convex-domain rows in F, and real penalty value in R are all displayed, and the dominance row in D names that comparison.

Stationarity and order compatibility are then read through K and the provenance row P. The KKT and positive-cone rows may inspect only the displayed residual, cone, multiplier, real, and vector entries already present in the packet.

The Fenchel and conjugacy handoff is downstream of the same displayed data. Since no coordinate of Q stores a selected global minimizer, a Hilbert projection theorem, quotient vector equality, lower-semicontinuity evidence, or ambient completeness, those principles cannot be exported by the local certificate. □

Theorem 3713.3 (ProximalMap convex-resolvent handoff)**.** *Every subdifferential, monotone-operator, or splitting-method consumer of an accepted* $\mathsf{ProximalMap}^{\uparrow}$ *packet must factor through the finite route*

$$X, F, u, z, R, D, K, G, O \longmapsto H, C, P, N.$$

The consumer may read the candidate z as a resolvent-facing output only after the convex-domain row, real penalty row, dominance ledger, KKT stationarity row, positive-cone boundary, and Fenchel-duality handoff have all been displayed. It receives no selected minimizer for unlisted inputs, no maximal-monotone theorem, no quotient vector equality, no host projection semantics, and no ambient completeness principle.

Proof. Begin with the candidate row. By Definition 3713.1, the row z is only one displayed output candidate in the finite packet, and it is tied to the input row u and vector-space source row X.

The dominance ledger D and penalty row R supply the proximal comparison surface. They are read through the same convex-domain row F and the same real scalar seal, so a consumer cannot replace the displayed comparisons by an external minimization predicate.

Next read the stationarity and duality boundary. The row K routes optimality-facing material through the KKT and positive-cone packets, while G routes conjugacy-facing material through the convex-conjugate and Fenchel-duality packets. The resolvent consumer row O is exposed only after those rows are present.

Transport, continuation replay, package provenance, and local naming preserve exactly this route through H, C, P, N. Since the carrier lacks coordinates for unlisted input selection, maximal-monotone closure, quotient vector equality, host projection semantics, or completeness, the handoff stops at the finite convex-resolvent boundary. □

Falsifiable prediction: Every accepted $\mathsf{ProximalMap}^{\uparrow}$ consumer read factors through a VecSpaceUp source, ConvexSetUp and ConvexConjugateUp functional rows, one displayed input, one displayed candidate output, a RealUp penalty row, a finite dominance ledger, KKTUp stationarity rows, PositiveConeUp order rows, FenchelDualityUp handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: convexset, convex-conjugate, fenchelduality, positive-cone, kkt, real, vecspace: $\mathsf{ProximalMap}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an input row, candidate output row, real penalty ledger, dominance comparisons, stationarity boundary, Fenchel handoff, and resolvent-facing consumer row in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ProximalMap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProximalMap}^{\uparrow}$ packet is generated from a vector-space source, convex functional and domain rows, one input point, one candidate output, RealUp penalty evaluations, finite dominance comparisons, KKT stationarity, PositiveCone order, FenchelDuality and ConvexConjugate handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProximalMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3713.1, Definition 3713.2, and Definition 3713.3 seed the finite proximal-resolvent certificate surface over convex, real, vector-space, KKT, cone, and Fenchel rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ProximalMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a global proximal existence theorem, selected minimizers for all inputs, Hilbert projection semantics, maximal-monotone closure, quotient vector equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, penalty evaluation exactness, convex-domain compatibility, stationarity compatibility, Fenchel handoff, resolvent consumer boundary, transport, replay, provenance, and local naming for BEDC.Derived.ProximalMapUp.

Chapter 3714

A Concrete Naming Certificate for TypedNormalFormDecider$^{\uparrow}$

The TypedNormalFormDecider$^{\uparrow}$ packet realizes the normal-equality section of chapter 9379 as a finite BEDC certificate tying `inferTypeCtx` to bounded normal-form comparison. It sits beside the bounded normal-equality checker of chapter 752, the decidability witness of chapter 751, the closure-preservation audit trace of chapter 795, and the normalization audit map of chapter 9383. The packet names the typed checker and bounded comparison route; it refuses to turn that route into unrestricted beta-conversion decidability.

Falsifiable prediction: Every accepted TypedNormalFormDecider$^{\uparrow}$ packet displays `inferTypeCtx` rows, typed input rows, bounded normalizer output rows, finished-normalization witnesses when supplied, bounded normal-form comparison rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: bounded-normal-equality-checker, metacicdecidabilitywitness, closure-preservation audit, normalization audit: TypedNormalFormDecider$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries typed-checker admission, bounded normal-form comparison, finished-normalization side conditions, refusal, transport, replay, provenance, and local naming rows.

Definition 3714.1 (Typed normal-form decider carrier)**.** *A* TypedNormalFormDecider$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, L, R, T_L, T_R, F, N_L, N_R, E, W, Q, H, C, P, A)$$

with the following displayed rows:

1. *I is the `inferTypeCtx` checker row for the shared context and the represented input terms;*
2. *L and R are the two closed represented MetaCIC input term rows;*
3. *T_L and T_R are the optional inferred type rows produced by the checker, together with the displayed success or refusal status of each check;*
4. *F is the bounded fuel row used by the normalizer;*
5. *N_L and N_R are the bounded normal-form output rows obtained from L and R at fuel F;*
6. *E is the structural normal-form comparison row, read through `Term.eq` on N_L and N_R;*
7. *W stores the finished-normalization witnesses required before the comparison can be consumed as a typed normal-form equality result;*

8. *Q is the refusal row blocking unrestricted beta-conversion decidability, global normalization, subject reduction, confluence, arbitrary closedness decidability, quotient syntax equality, and fuel selection;*
9. *H records componentwise* hsame *transport for checker, term, type, fuel, normal-form output, comparison, finished-witness, refusal, replay, provenance, and local naming rows;*
10. *C records displayed* Cont *replay from a typed normal-form decision request through $I, L, R, T_L, T_R, F, N_L, N_R, E,$*
11. *P is the* Pkg *provenance over* $\mathsf{TypedNormalFormDecider}^{\uparrow}$*, the MetaCIC decidability audit map,* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICDecidableTypingFrontier}^{\uparrow}$*, closure-preservation audit rows, normalization audit rows,* BHist, hsame, Cont, *and* NameCert*;*
12. *A is the local* $\mathsf{NameCert}_{\mathsf{TypedNormalFormDecider}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a fuel-erased beta-conversion oracle, no proof that all closed typed terms normalize, no hidden subject-reduction discharge, no confluence theorem, and no host quotient over terms.

Lean4 ✓ `BEDC.Derived.TypedNormalFormDeciderUp.TypedNormalFormDeciderTasteGate single carrier alignment`

Theorem 3714.2 (Typed normal-form decider NameCert obligations)**.** *For the carrier of Definition 3714.1, the local* $\mathsf{NameCert}_{\mathsf{TypedNormalFormDecider}^{\uparrow}}$ *surface consists exactly of typing-checker admission through I, T_L, T_R, bounded-normal comparison through F, N_L, N_R, E, finished-normalization side-condition exposure through W, explicit refusal through Q, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through A.*

Proof. Project the carrier coordinates. The checker side is exhausted by I, L, R, T_L, T_R, so a consumer obtains typed input only through the displayed `inferTypeCtx` rows.

The normal-form side is exhausted by F, N_L, N_R, E, W. The comparison row E can be consumed only with the bounded fuel and finished-normalization witnesses displayed in the same packet.

The refusal row Q is part of the certificate surface. It prevents the bounded route from being reread as global normalization, unrestricted beta-conversion decidability, subject reduction, confluence, arbitrary closedness decidability, quotient syntax equality, or fuel selection.

Finally H, C, P, A preserve and name the same finite route. Future Nontrivial and FieldFaithful TasteGate instances must witness that none of these rows can be collapsed away or replaced by an unlisted oracle. □

Theorem 3714.3 (Typed normal-form decider bounded comparison boundary)**.** *Every consumer of an accepted* $\mathsf{TypedNormalFormDecider}^{\uparrow}$ *packet reaches a typed normal-form comparison only through the finite route*

$$\mathit{inferTypeCtx},\ L, R, T_L, T_R, F, N_L, N_R, E, W, Q, H, C, P, A.$$

The route exports typing-checker data and bounded finished-normal comparison data; it exports no unrestricted closed beta-conversion decider, no global normalizer, no subject-reduction theorem, no confluence theorem, no arbitrary closedness decider, and no host quotient equality for MetaCIC terms.

Proof. Read the checker rows first. A typed comparison request must pass through I and the displayed optional type rows T_L, T_R before it can inspect normal forms.

Next read the bounded normal-form rows. The fuel F, the outputs N_L, N_R, the structural comparison E, and the finished-normalization witnesses W form the complete comparison surface.

The refusal row Q is then read before structural replay. It records that the packet has no coordinate for a stronger conversion, normalization, subject-reduction, confluence, closedness, quotient, or fuel-selection theorem.

Thus transport, replay, provenance, and local naming in H, C, P, A preserve only the displayed bounded route. □

Closure status for $\mathsf{NameCert}_{\mathsf{TypedNormalFormDecider}^{\uparrow}}$.

Constructive story: A $\mathsf{TypedNormalFormDecider}^{\uparrow}$ packet is generated from inferTypeCtx checker rows, closed input term rows, optional inferred type rows, bounded fuel, bounded normalizer outputs, structural normal-form comparison, finished-normalization witnesses, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypedNormalFormDecider}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3714.1, Definition 3714.2, and Definition 3714.3 seed the finite typed normal-form decider surface over typing-checker and bounded normal-form comparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypedNormalFormDecider}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted beta-conversion decidability, global normalization, subject reduction, confluence, arbitrary closedness decidability, quotient syntax equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typing-checker exactness, bounded-normal comparison exactness, finished-normalization side-condition exposure, refusal, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.TypedNormalFormDeciderUp.

Chapter 3715

A Concrete Naming Certificate for $\mathsf{ResolventIdentity}^{\uparrow}$

Following Dunford–Schwartz and Conway on the resolvent calculus for bounded operators, the $\mathsf{ResolventIdentity}^{\uparrow}$ packet records the finite BEDC surface on which the algebraic resolvent identity is read before any completed spectrum or host operator quotient is available. It sits at the operator-theory frontier beside the bounded-operator carrier of chapter 1644, the scalar operator-norm surface of chapter 3603, the resolvent-facing spectral-radius route of chapter 2352, and the compact-operator schedule boundary of chapter 1952.

Definition 3715.1 (Resolvent identity carrier)**.** *A* $\mathsf{ResolventIdentity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, T, \lambda, \mu, A_\lambda, A_\mu, U_\lambda, U_\mu, I, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the Banach source surface on which the operator rows are read.*
2. *T is the accepted* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the displayed operator action, linearity ledger, norm-bound endpoint, and transport data.*
3. *λ, μ are the two scalar-window rows whose separation witness is recorded before any inverse row is consumed.*
4. *A_λ, A_μ are the shifted-operator rows for $\lambda I - T$ and $\mu I - T$, each read through the same bounded-operator and operator-norm surface.*
5. *U_λ, U_μ are the displayed two-sided inverse-check rows for the two shifts.*
6. *I is the identity and composition ledger needed to compare $U_\lambda - U_\mu$ with $(\mu - \lambda)U_\lambda U_\mu$.*
7. *D is the domain and denominator ledger recording the scalar separation, multiplication order, and refusal of zero-denominator or detached inverse reads.*
8. *H records componentwise* hsame *transport for the operator, scalar, shifted-operator, inverse-check, identity, and denominator rows.*
9. *C records displayed* Cont *replay of the route from bounded operator and operator norm rows to the two resolvent checks and the identity ledger.*
10. *P is the* Pkg *provenance over* $\mathsf{ResolventIdentity}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{ResolventIdentity}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed spectrum, a spectral measure, quotient operator equality, selected inverse outside the displayed two-sided checks, compact-operator eigenvalue lists, or countable choice.

Lean4 ✓ `BEDC.Derived.ResolventIdentityUp.ResolventIdentityTasteGate single carrier alignment`

Theorem 3715.2 (Resolvent identity NameCert obligations)**.** *For an accepted* $\mathsf{ResolventIdentity}^{\uparrow}$ *carrier* $R = (X, T, \lambda, \mu, A_\lambda, A_\mu, U_\lambda, U_\mu, I, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ResolventIdentity}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-operator source admission through* T*, operator-norm scalar-bound admission for the two shifts, scalar-separation admission for* λ, μ*, two-sided inverse-check admission for* U_λ, U_μ*, identity and composition ledger exactness through* I*, denominator and refusal ledger exactness through* D*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Every downstream resolvent consumer must read the same rows before using the identity. It receives no completed spectrum, no spectral-radius limit theorem beyond the finite resolvent-facing boundary of chapter 2352, no compact-operator spectral decomposition, and no quotient equality of operators.

Proof. Project the carrier of Definition 3715.1. The rows $X, T, \lambda, \mu, A_\lambda, A_\mu, U_\lambda, U_\mu, I, D, H, C, P, N$ are the whole accepted surface.

The bounded-operator and operator-norm rows expose the two shifted operators. The scalar rows record λ, μ and their separation before any inverse-check row is read, so no inverse can be selected outside the displayed denominator ledger.

The rows U_λ, U_μ supply only two-sided inverse checks for the displayed shifts. The identity ledger I then compares the two compositions and the scalar multiple on the same bounded-operator route.

Finally, H, C, P, N transport, replay, source, and name that finite route. Since the carrier has no coordinate for a completed spectrum, compact spectral decomposition, quotient equality, or choice, those objects cannot be part of the NameCert surface. □

Theorem 3715.3 (Resolvent identity two-sided law)**.** *Let* $R = (X, T, \lambda, \mu, A_\lambda, A_\mu, U_\lambda, U_\mu, I, D, H, C, P, N)$ *be an accepted* $\mathsf{ResolventIdentity}^{\uparrow}$ *carrier. If the two displayed inverse-check rows certify*

$$U_\lambda A_\lambda = A_\lambda U_\lambda = I_X \quad \textit{and} \quad U_\mu A_\mu = A_\mu U_\mu = I_X,$$

then every public resolvent read factors through the finite identity ledger

$$U_\lambda - U_\mu = (\mu - \lambda) U_\lambda U_\mu$$

with the same scalar-separation row, bounded-operator source row, operator-norm bound rows, and structural rows H, C, P, N*.*

The law exports only this two-sided displayed algebraic comparison. It does not export a completed resolvent set, a spectral theorem, quotient operator equality, selected approximate eigenvectors, compact-operator eigenvalue data, or countable choice.

Lean4 ✓ `BEDC.Derived.ResolventIdentityUp.ResolventIdentityCarrier two sided law`

Proof. Start with the two shifted-operator rows A_λ and A_μ. They are read from the same bounded operator T and scalar-window rows λ, μ, so their comparison is already inside the accepted packet.

Use the inverse-check rows U_λ and U_μ. The hypotheses certify both left and right inverse equations for the displayed shifts, and the denominator ledger D records the scalar separation needed to form $\mu - \lambda$.

Apply the identity and composition ledger I. It records the finite algebraic rearrangement of the two inverse equations and the composition $U_\lambda U_\mu$, producing the displayed equality without invoking a host quotient of operators.

The structural rows H, C, P, N preserve and name the same route for every public consumer. Since no carrier coordinate stores a completed spectrum, selected inverse, compact eigenvalue list, or choice schedule, the public law is exactly the finite two-sided resolvent identity. □

Falsifiable prediction: Every accepted $\mathsf{ResolventIdentity}^{\uparrow}$ consumer exposes the bounded operator row, both scalar-window rows, both shifted-operator rows, both two-sided inverse-check rows, the identity ledger, the denominator ledger, componentwise transport, replay, provenance, and local naming before reading the resolvent identity.

Independence witness: boundedlinearoperator, operatornorm, spectralradius, compactoperator: BoundedLinearOperatorUp supplies the action and norm-bound carrier but not the two scalar shifted-inverse ledger; OperatorNormUp supplies scalar norm bounds without the two-sided inverse checks; SpectralRadiusUp supplies a resolvent-facing boundary but not the algebraic two-shift identity packet; CompactOperatorUp supplies image-net schedules without the bounded-operator resolvent algebra.

Closure status for $\mathsf{NameCert}_{\mathsf{ResolventIdentity}^{\uparrow}}$.

Constructive story: A $\mathsf{ResolventIdentity}^{\uparrow}$ packet is generated from a Banach source surface, a bounded-operator row, two scalar-window rows, two shifted-operator rows, two two-sided inverse-check rows, identity and denominator ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ResolventIdentity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3715.1, Definition 3715.2, Definition 3715.3, the falsifiable prediction, and the independence witness seed the finite two-shift resolvent identity route over BoundedLinearOperatorUp, OperatorNormUp, SpectralRadiusUp, CompactOperatorUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ResolventIdentity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a completed resolvent set, a spectral theorem, quotient operator equality, selected approximate eigenvectors, compact-operator eigenvalue data, or countable choice.

Upgrade path: Obligation closure requires checked carrier admission, shifted-operator stability, inverse-check exactness, denominator-ledger exactness, two-sided identity replay, classifier transport, and consumer non-escape for BEDC.Derived.ResolventIdentit

Chapter 3716

A Concrete Naming Certificate for BoundedIntervalCauchySubsequence$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the BoundedIntervalCauchySubsequence$^{\uparrow}$ packet records a finite-window substitute for the bounded-interval subsequence argument used by completion-facing real analysis. It sits after the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the interval projection route of chapter 3692, and the cofinal regular-Cauchy subsequence route of chapter 3515. The packet names the data needed by Real$^{\uparrow}$ and completion consumers to inspect a bounded interval source through explicit finite windows; it does not assert full Bolzano–Weierstrass, Heine–Borel, open-cover compactness, trichotomy, or a choice-selected infinite subsequence.

Definition 3716.1 (Bounded interval Cauchy subsequence carrier)**.** *A* BoundedIntervalCauchySubsequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, W, D, T, Q, E, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded interval row, including endpoint* Real$^{\uparrow}$ *seals and the finite interval projection surface.*
2. *S is the source bounded sequence row, read only through displayed* StreamName$^{\uparrow}$ *observation windows.*
3. *W is the finite window ledger listing the inspected source positions, endpoint windows, and selected comparison windows.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger containing the mesh radius, endpoint comparisons, pairwise distance bounds, and late-window budgets used by the extraction route.*
5. *T is the monotone cofinal schedule row naming how each selected window is reached from an inspected finite source window.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *handoff row obtained from the displayed windows, dyadic ledger, and schedule.*
7. *E is the* RegularCauchySubsequenceStability$^{\uparrow}$ *row recording that the selected finite windows remain a regular Cauchy readback surface.*

8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the interval, window, dyadic, schedule, regular-readback, and subsequence-stability rows have been displayed.*
9. *H stores componentwise* hsame *transport for $I, S, W, D, T, Q, E, R, C, P, N$.*
10. *C stores displayed* Cont *replay of the extraction route*

$$I, S \longmapsto W, D, T \longmapsto Q, E \longmapsto R.$$

11. *P is the* Pkg *provenance over* $\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BoundedIntervalProjection}^{\uparrow}$, $\mathsf{RegularCauchySubsequenceStability}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, W, D, T, Q, E, R, H, C, P, N$. It has no coordinate for an ambient compactness theorem, open-cover subcover, host trichotomy, quotient stream equality, selected representatives, countable choice, or an unrecorded $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BoundedIntervalCauchySubsequenceUp.TasteGate.BoundedIntervalCauchySubsequenceTaste`
`single carrier alignment`

Theorem 3716.2 (Bounded interval Cauchy subsequence NameCert obligations)**.** *For every accepted* $\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}$ *carrier*

$$K = (I, S, W, D, T, Q, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded interval row I, source sequence row S, finite stream-window ledger W, dyadic tolerance ledger D, monotone cofinal schedule T, regular rational handoff Q, subsequence-stability row E, terminal real seal R, componentwise transport H, continuation replay C, package provenance P, and local naming row N.*

The obligation surface also includes classifier stability under the same displayed rows, dyadic tolerance exactness through D, finite-window visibility through W, cofinal schedule replay through T, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through Q,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through R, and provenance visibility through P, N.*

Proof. Carrier admission is projection from Definition 3716.1. The projection exposes exactly the interval, source, window, dyadic, schedule, readback, subsequence-stability, seal, transport, replay, provenance, and naming rows listed in the statement.

The classifier is componentwise on those rows. Hence any accepted comparison must preserve the same bounded interval row, the same finite source-window surface, the same dyadic ledger, and the same schedule route before it reaches the regular-readback and real-seal rows.

The nonescape clauses follow from the absence of further coordinates in the carrier. There is no slot for open-cover compactness, host trichotomy, quotient stream equality, countable choice, selected representatives, or an ambient completeness principle, so no local NameCert consumer can read such data from the packet. □

Theorem 3716.3 (Bounded interval dyadic window extraction)**.** *Let*

$$K = (I, S, W, D, T, Q, E, R, H, C, P, N)$$

be an accepted $\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}$ *carrier. Every finite extraction read from* K *factors through the displayed dyadic ledger* D *and the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger* W *before it may consume the monotone cofinal schedule* T *or the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* Q*.*

Consequently each selected comparison window is certified by endpoint interval data from I*, inspected source windows from* S*, dyadic radii and pairwise bounds from* D*, and replay data from* C*, rather than by a hidden infinite subsequence, trichotomy decision, open cover, quotient stream, or choice principle.*

Proof. Start with an accepted extraction read and project the carrier. The only rows that mention finite observations are W and D: W lists the inspected source and endpoint windows, while D records the mesh radius, endpoint comparisons, pairwise distance bounds, and late-window budgets attached to those observations.

The schedule row T is downstream from those finite ledgers. It records which displayed windows are reused along a monotone cofinal route; it does not add a new source of observations or a selection functional outside the packet.

The regular handoff row Q consumes W, D, T together with the interval source I, S. Replaying the route through C therefore forces every extraction read to pass through the finite dyadic-window data before any subsequence or regular Cauchy surface is available.

The forbidden principles have no carrier coordinate. Since the read has already exhausted the displayed rows, no infinite choice-selected subsequence, host trichotomy, open-cover compactness, quotient stream equality, or ambient completeness proof can be exported by the extraction route. □

Theorem 3716.4 (Bounded interval Cauchy subsequence Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}$ *packet must read the route*

$$I, S \longmapsto W, D, T \longmapsto Q, E \longmapsto R$$

before consuming the terminal seal row R*. Thus the handoff to* $\mathsf{Real}^{\uparrow}$ *and completion consumers is a finite BEDC route through bounded-interval endpoint data, stream windows, dyadic tolerances, a cofinal schedule, regular rational readback, subsequence stability,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

The handoff does not close full Bolzano–Weierstrass, Heine–Borel, open-cover compactness, trichotomy, quotient stream equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The terminal seal R is downstream from the interval and source rows I, S, the finite ledgers W, D, the schedule row T, the regular handoff Q, and the subsequence-stability row E.

Use Definition 3716.3 to bind the extraction stage to W and D. This ensures that the cofinal schedule and regular handoff are read only after the finite window and dyadic tolerance rows have been displayed.

The transport and replay rows H, C preserve the same ordered route, while P, N record provenance and the local naming surface. A $\mathsf{Real}^{\uparrow}$ consumer can therefore consume R only as the final row of that route.

The carrier contains no coordinate for the excluded compactness or choice principles. The theorem is therefore a finite-window handoff to Real and completion work, not a claim of unrestricted subsequence compactness or open-cover compactness for closed intervals. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}$ packet is generated from a bounded interval row, a source sequence row, finite StreamName windows, a DyadicRatCore tolerance ledger, a monotone cofinal schedule, RegSeqRat readback, RegularCauchySubsequenceStability handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3716.1, Definition 3716.2, Definition 3716.3, and Definition 3716.4 seed the finite-window bounded-interval subsequence packet over displayed Real, RegSeqRat, StreamName, DyadicRatCore, BoundedIntervalProjection, and RegularCauchySubsequenceStability rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedIntervalCauchySubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Bolzano–Weierstrass, Heine–Borel, open-cover compactness, trichotomy, quotient stream equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic window extraction, cofinal schedule replay, RegSeqRat handoff, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BoundedIntervalCauchySubsequenceUp.

Chapter 3717

A Concrete Naming Certificate for $\mathsf{BishopCompletion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopCompletion}^{\uparrow}$ packet names the finite boundary at which regular Cauchy rational names, stream windows, dyadic tolerance ledgers, filter-completion handoffs, and the terminal Real seal can be read as one completion-facing NameCert object. It sits on the L10 route supplied by the regular rational readback of chapter 301, the finite window surface of chapter 126, the dyadic arithmetic ledger of chapter 291, the terminal real-name seal of chapter 38, the filter completion handoff of chapter 1569, and the universal extension boundary of chapter 397. The packet records a Bishop-style completion boundary for displayed names; it is not a quotient of streams, not a selected limit, not countable choice, not host real equality, and not an ambient completeness principle.

Definition 3717.1 (Bishop completion carrier)**.** *A* $\mathsf{BishopCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, S, D, E, F, U, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row, carrying the rational readback and regularity budget visible to completion-facing consumers.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row from which the displayed rational observations in R are read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same windows and precision requests.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, S, D have been displayed.*
5. *F is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff row generated from the same finite tail windows and dyadic budgets.*
6. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row available only after the regular-name route and filter-completion handoff have both been exposed.*
7. *H records componentwise* hsame *transport for the regular name, stream window, dyadic ledger, Real seal, filter-completion handoff, universal-property row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through S, R, D, E, F, U.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows and their displayed replay paths. It has no coordinate for quotient stream equality, a selected representative, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionUp.BishopCompletionTasteGate single carrier alignment`

Theorem 3717.2 (Bishop completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletion}^{\uparrow}$ *carrier $B = (R, S, D, E, F, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed regular rational name, stream window, dyadic tolerance ledger, Real seal, filter-completion handoff, universal-property row, transport, replay, provenance, and local naming row;*
2. *finite-window exposure, requiring every completion-facing observation to pass through S before R or D can be read;*
3. *regular rational boundary exposure, requiring R and D to be displayed before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E becomes available;*
4. *filter-compatibility exposure, requiring the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row F to be generated from the same S, R, D route;*
5. *universal-property exposure, requiring U to read only the already displayed regular-name, Real-seal, and filter-completion rows;*
6. *ledger non-escape, requiring H, C, P, N to export no quotient stream equality, selected representative, countable choice, host real equality, or ambient Real completeness coordinate.*

No local NameCert obligation is stored outside those rows.

Proof. Project the accepted carrier through Definition 3717.1. The visible packet consists exactly of $R, S, D, E, F, U, H, C, P, N$.

The finite-window and regular-name obligations are ordered by the carrier. A completion-facing observation first exposes the window row S, then reads the regular rational row R and the dyadic ledger D before reaching the terminal Real seal E.

The filter and universal-property rows are downstream of the same route. The row F uses the displayed windows and dyadic budgets as its filter-completion handoff, while U is read only after the regular-name, Real-seal, and filter-completion rows have been exposed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since quotient stream equality, selected representatives, countable choice, host real equality, and ambient completeness have no carrier row, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.BishopCompletionUp.BishopCompletionCarrier namecert obligations`

Theorem 3717.3 (Bishop completion regular real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCompletion}^{\uparrow}$ *carrier reads the completion boundary only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In the notation of Definition 3717.1, the consumer reads S, then R and D, and only then the seal row E together with the structural rows H, C, P, N. The route exports no quotient stream, selected host limit, countable-choice schedule, host real equality, or ambient Real completeness datum.

Proof. Begin with a Real-facing read of $B = (R, S, D, E, F, U, H, C, P, N)$. The carrier has a single Real-seal coordinate, namely E, and E is placed after the window, regular-readback, and dyadic-ledger rows.

The window row S supplies the finite observations available to the read. The row R records the regular rational name extracted from those observations, and D records the dyadic tolerance ledger for the same precision requests.

The structural rows preserve this order. The hsame row H transports the displayed coordinates componentwise, the Cont row C replays the same route, and P, N record provenance and local naming without adding analytic data. Thus every Real-facing read remains inside the listed finite route. □

Theorem 3717.4 (Bishop completion filter compatibility)**.** *Every* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *or* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCompletion}^{\uparrow}$ *carrier must read the same displayed regular-name boundary S, R, D, E before it can read the filter handoff F or the universal-property row U. Consequently sequence-style and filter-style completion reads agree on the finite BEDC support*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The compatibility exports no quotient filter, selected limit, countable choice, host equality proof, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.BishopCompletionUp.BishopCompletionCarrier filter compatibility`

Proof. Project the filter and universal rows from Definition 3717.1. The row F is downstream of the same stream, regular-readback, dyadic-ledger, and Real-seal route used by the regular-name boundary; the row U is downstream of both that boundary and F.

A filter-style read therefore cannot start from an independent filter representative. It first sees the displayed finite windows S, the regular rational readback R, and the dyadic tolerance ledger D, then reaches the Real seal E and only afterward the filter-completion handoff F.

The universal-property read is even later in the route. It is exposed through U after S, R, D, E, F have been displayed and after H, C, P, N have fixed the componentwise transport, replay, provenance, and local naming rows.

Since the carrier includes no quotient filter, selected limit, countable-choice selector, host equality proof, or ambient completeness coordinate, compatibility between the sequence-style and filter-style reads is exactly the shared finite support listed in the statement. □

Falsifiable prediction: Every $\mathsf{BishopCompletion}^{\uparrow}$ Real-facing or filter-facing read factors through displayed StreamName, RegSeqRat, DyadicRatCore, RealUp, CauchyFilterCompletion, CompletionUniversalProperty, transport, replay, provenance, and local naming rows.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchyfiltercompletion, completionuniversalproperty: $\mathsf{BishopCompletion}^{\uparrow}$ is not bijective to any listed sibling because it carries the regular-name route, Real seal, filter-completion handoff, and universal-property row in one finite completion boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletion}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\mathsf{BishopCompletion}\uparrow}$, seed)

Scope closed: Definition 3717.1, Definition 3717.2, Definition 3717.3, and Definition 3717.4 seed the finite Bishop completion boundary over regular Cauchy names, stream windows, dyadic ledgers, Real seals, filter completion, and universal-property rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, quotient filters, selected limits, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular Real boundary exposure, filter compatibility, universal-property exposure, and ledger non-escape for BEDC.Derived.BishopCompletionUp.

Constructive story: A BishopCompletion$^{\uparrow}$ packet is generated from a StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, CauchyFilterCompletion handoff, CompletionUniversalProperty row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3718

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational stream exposes a modulus schedule before a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reads the name. It sits over the $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ tail-bound route of chapter 1659, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The certificate makes the modulus extraction visible as finite NameCert data rather than as a prose appeal to a completed Cauchy object.

Definition 3718.1 (Regular Cauchy modulus extraction carrier)**.** *A* $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the regular Cauchy source and by each downstream precision request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, binding displayed stream windows to rational observations.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying dyadic radii, comparison cells, half-radius splits, and endpoint observations.*
4. *T is the* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *row, displaying the tail bound that makes the requested dyadic scale stable after a finite stage.*
5. *E is the extracted modulus schedule, assigning each displayed tolerance request to the finite stage justified by S, R, D, T.*
6. *H records componentwise* hsame *transport for the window, readback, tolerance, tail-envelope, schedule, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, R, D, T \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, T, E, H, C, P, N$. It has no coordinate for selected limits, quotient equality of streams, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a modulus schedule chosen outside the displayed tail-envelope route.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusExtractionUp.RegularCauchyModulusExtractionTasteGate` `single carrier alignment`

Theorem 3718.2 (Regular Cauchy modulus extraction NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$ *carrier*

$$M = (S, R, D, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusExtraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, DyadicCauchyTailEnvelope bound, extracted schedule, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *readback exactness, requiring R to read only rational observations displayed in S and tolerance data displayed in D;*
3. *tail-bound exposure, requiring T to be the only row that certifies a stable tail after a finite stage for the requested dyadic scale;*
4. *modulus extraction exactness, requiring E to be computed from the displayed route S, R, D, T and from no detached selector;*
5. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the same displayed route.*

No $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 3718.1. The accepted packet displays exactly the window, readback, tolerance, tail-envelope, extracted schedule, transport, replay, provenance, and local naming rows.

Readback exactness is controlled by S, R, D. The regular rational observations are available only through displayed stream windows and displayed dyadic tolerance cells.

Tail-bound exposure is the role of T. It records the finite tail envelope attached to the same dyadic scale, so the packet has no independent convergence oracle.

The extracted schedule E is downstream of S, R, D, T. A consumer can therefore read a modulus only as the displayed finite schedule justified by the tail envelope.

Finally, H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since no remaining coordinate stores a selected limit, quotient equality, outside schedule, trichotomy, or ambient Real-completeness principle, the listed rows exhaust the local certificate surface. □

Theorem 3718.3 (Regular Cauchy modulus extraction tail-bound route)**.** *Let*

$$M = (S, R, D, T, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer that reads a modulus from M must factor through the finite tail-bound route*

$$S, R, D \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed StreamName window row, RegSeqRat rational readback, DyadicRatCore tolerance ledger, DyadicCauchyTailEnvelope bound, extracted schedule, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data, and receives no quotient stream equality, selected limit, trichotomy, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credential.*

Proof. Begin with an accepted carrier and project the rows $S, R, D, T, E, H, C, P, N$. The only observation surface before a modulus is read is the displayed window, readback, and dyadic tolerance route.

The tail-bound row T is then read at the same dyadic scale. It supplies the finite stage after which the displayed rational tail is stable for the request.

The extracted schedule E is downstream of that tail-bound row. Thus any modulus read by a Real or completion consumer is the schedule justified by S, R, D, T.

The structural rows H, C, P, N transport, replay, source, and name the same route. Because the carrier has no coordinate for the excluded equality, selection, order, choice, completeness, or bridge objects, every such consumer factors through the displayed tail-bound route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusExtraction}^{\uparrow}$ packet is generated from a StreamName window row, RegSeqRat readback row, DyadicRatCore tolerance row, DyadicCauchyTailEnvelope bound row, extracted modulus schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3718.1, Definition 3718.2, and Definition 3718.3 seed the finite modulus-extraction route from regular Cauchy readbacks through dyadic tail envelopes and displayed schedules.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy streams, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, readback exactness, tail-bound exposure, modulus extraction exactness, and structural stability for BEDC.Derived.RegularCauchyModulusExtractionUp.

Chapter 3719

A Concrete Naming Certificate for $\mathsf{CauchySelectionFunction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySelectionFunction}^{\uparrow}$ packet records the finite selector interface by which a Real and Completion consumer asks for a displayed regular Cauchy window without importing countable choice. It sits after the Cauchy modulus surface of chapter 292, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the displayed modulus-selection route of chapter 1986, and the selector-budget packet of chapter 678. It provides the finite selector row used by the Real completeness agenda of chapter 9238; it is not a countable-choice principle, quotient stream object, selected global limit, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 3719.1 (Cauchy selection-function carrier)**.** *A* $\mathsf{CauchySelectionFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the request row, naming the precision request, source regular Cauchy name, and completion-facing consumer boundary.*
2. *M is the modulus schedule row, read through the* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *surfaces for the displayed request.*
3. *W is the selected finite* $\mathsf{StreamName}^{\uparrow}$ *window opened by M for this request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row assembled from the selected window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the dyadic radius, slack, comparison, and scale data used by the readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, M, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the request, schedule, selected window, regular readback, dyadic tolerance ledger, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the selector route*

$$Q, M \longmapsto W \longmapsto R, D \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchySelectionFunction}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusSelection}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySelectionFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, M, W, R, D, E, H, C, P, N$. It has no coordinate for countable choice, quotient streams, selected global limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySelectionFunctionUp.CauchySelectionFunctionTasteGate single carrier alignment`

Theorem 3719.2 (Cauchy selection-function NameCert obligations)**.** *For every accepted* $\mathsf{CauchySelectionFunction}^{\uparrow}$ *carrier*

$$S = (Q, M, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySelectionFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the request row Q, modulus schedule M, selected finite window W, regular readback R, dyadic tolerance ledger D, terminal real seal E, componentwise transport H, continuation replay C, package provenance P, and local naming row N.*

The obligation surface also includes request-schedule compatibility, finite-window visibility, regular-readback exactness, dyadic tolerance compatibility, real-seal nonescape, and stability under the displayed hsame *and* Cont *rows. No obligation is stored outside $Q, M, W, R, D, E, H, C, P, N$.*

Proof. Carrier admission is projection from Definition 3719.1. The projection exposes exactly the request, schedule, selected-window, readback, dyadic, seal, transport, replay, provenance, and naming rows listed in the statement.

Request-schedule compatibility is the role of Q and M. The schedule is read as a displayed modulus-selection row for the request, and the selected finite window W is downstream of that schedule rather than a separate choice function.

Regular readback and dyadic tolerance exactness are the roles of R and D. The carrier places both rows after W, so the readback is assembled only from displayed observations and the displayed dyadic ledger.

The terminal real seal E is downstream of Q, M, W, R, D, while H, C, P, N transport, replay, source, and name the same finite route. Since no further coordinates occur in the packet, countable choice, quotient streams, selected global limits, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot be exported by the local certificate. □

Theorem 3719.3 (Cauchy selection-function regular readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySelectionFunction}^{\uparrow}$ *carrier*

$$S = (Q, M, W, R, D, E, H, C, P, N)$$

must first read the displayed request row Q, the modulus schedule M, the selected finite window W, and the dyadic tolerance ledger D. The regular readback row R and real seal row E then expose only the finite selector route

$$Q, M \longmapsto W, D \longmapsto R \longmapsto E$$

together with the structural rows H, C, P, N.

Thus the selector interface supplies a finite BEDC service for Real and Completion consumers without providing countable choice, quotient stream equality, a selected global limit, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read. By the carrier definition, the readback rows available to that consumer are R and E, and both are downstream of the request row, schedule row, selected window, and dyadic ledger.

The selected window is finite because it is the displayed $\mathsf{StreamName}^{\uparrow}$ row W. The schedule M only names the request-facing modulus surface that opens W; it does not add a second stream, a quotient stream, or an infinite family of choices.

The dyadic ledger D records the tolerance data used by the same finite window, and R assembles the regular rational readback from those displayed rows. The real seal E can therefore be consumed only as the terminal row of the route through Q, M, W, D, R.

Finally, H, C, P, N preserve and name the route under componentwise transport and continuation replay. The excluded objects have no carrier coordinate, so a consumer cannot read countable choice, quotient stream equality, selected global limits, host real equality, or ambient completeness from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySelectionFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySelectionFunction}^{\uparrow}$ packet is generated from a request row, a displayed modulus schedule, a selected finite StreamName window, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySelectionFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3719.1, Definition 3719.2, and Definition 3719.3 seed the finite selector interface for Real and Completion consumers over displayed CauchyModulus, StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySelectionFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient streams, selected global limits, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request-schedule compatibility, selected-window visibility, regular readback, dyadic tolerance compatibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySelectionFunctionUp.

Chapter 3720

A Concrete Naming Certificate for $\mathsf{CauchySumLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchySumLimit}^{\uparrow}$ packet records the finite route by which two displayed regular Cauchy summands produce a regular Cauchy sum and then a terminal real-name seal. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the real-name boundary of chapter 38. The chapter packages the familiar algebraic limit route for sums as NameCert data rather than as quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3720.1 (CauchySumLimit carrier)**.** *A* $\mathsf{CauchySumLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L_{\Sigma} = (X, Y, S, Q, D, A, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two regular Cauchy summand rows, each exposing only its displayed finite regularity surface.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite read windows opened for both summands and for the sum-read request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the rational readbacks of the two summands and the pointwise sum readback obtained from the same windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, splitting every requested sum tolerance into displayed summand tolerances and recording the dyadic addition comparisons used by the readback row.*
5. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the sum, available only after S, Q, D have been displayed.*
6. *H records componentwise* hsame *transport for the summand rows, stream windows, regular readbacks, dyadic tolerance ledger, Real seal, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from any Cauchy-sum-limit request through X, Y, S, Q, D, A.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchySumLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySumLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, Q, D, A, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchySumLimitUp.CauchySumLimitTasteGate single carrier alignment toEventFlow`

Theorem 3720.2 (CauchySumLimit NameCert obligations)**.** *For every accepted* $\mathsf{CauchySumLimit}^{\uparrow}$ *carrier*

$$L_{\Sigma} = (X, Y, S, Q, D, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySumLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular Cauchy summands, finite stream-window display, regular rational sum readback, dyadic tolerance splitting, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay, provenance, local naming, and non-escape from quotient streams, selected limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3720.1. The only summand data are X and Y, and the only observation windows available to consumers are the finite windows recorded by S.

The readback stage is finite. The row Q records the rational observations of both summands and the pointwise sum readback obtained from those same windows, while D records the dyadic tolerance split and the addition comparisons that justify the requested sum tolerance.

The seal stage is terminal. The row A can be consumed only after the summand windows, readbacks, and tolerance ledger have been displayed, so a Real-facing consumer cannot bypass S, Q, D.

Finally H, C, P, N transport, replay, source, and name exactly the displayed route. Since the packet has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, or ambient Real completeness, none of those objects can be exported by the local certificate. □

Lean4 ✓ `BEDC.Derived.CauchySumLimitUp.CauchySumLimitNamecertObligations`

Theorem 3720.3 (CauchySumLimit Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{CauchySumLimit}^{\uparrow}$ *carrier factors through the finite route*

$$X, Y \longmapsto S \longmapsto Q, D \longmapsto A, H, C, P, N.$$

Thus the sum limit is presented as a displayed regular-Cauchy algebra route to a Real seal, not as a quotient stream, selected limit, countable-choice schedule, trichotomy principle, or ambient completeness theorem.

Proof. Begin with an accepted packet $L_{\Sigma} = (X, Y, S, Q, D, A, H, C, P, N)$. A consumer first reads the displayed summand rows X and Y; no host sequence equality or quotient representative is available at this stage.

Next the stream windows in S determine the finite observations used for the request. The row Q reads both summands on those windows and records the pointwise rational sum, while D supplies the dyadic tolerance split and the corresponding addition comparisons.

The terminal Real seal is A. Since the continuation row C replays only the route through X, Y, S, Q, D, A, every Real-facing read reaches A after the finite regular readback and tolerance ledger have been displayed.

The transport and provenance rows preserve the same route under componentwise hsame. The local naming row N therefore exports the sum-limit seal without adding quotient streams, selected limits, countable choice, trichotomy, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySumLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySumLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3720.1, Definition 3720.2, and Definition 3720.3 seed the finite route from two regular Cauchy summands to StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, and a RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySumLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, summand-window display, regular rational sum readback, dyadic tolerance splitting, Real-seal routing, transport and replay stability, provenance exhaustion, and non-escape for BEDC.Derived.CauchySumLimitUp.

Constructive story: A $\mathsf{CauchySumLimit}^{\uparrow}$ packet is generated from two regular Cauchy summand rows, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3721

A Concrete Naming Certificate for $\mathsf{CauchyProductLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyProductLimit}^{\uparrow}$ packet records the finite route by which two displayed regular Cauchy factor rows produce a regular Cauchy product and then a terminal real-name seal. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic product-tolerance ledger of chapter 291, the product descent surface of chapter 461, and the real-name boundary of chapter 38. The chapter is the product analogue of chapter 3720: it packages a finite regular-Cauchy algebra route to a Real seal rather than quotient streams, selected product limits, countable choice, trichotomy, host multiplication of completed reals, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3721.1 (CauchyProductLimit carrier)**.** *A* $\mathsf{CauchyProductLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L_{\Pi} = (X, Y, S, Q, D, M, A, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two regular Cauchy factor rows, each exposing only its displayed finite regularity surface.*
2. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite read windows opened for both factors and for the product-read request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the rational readbacks of both factors and the pointwise product readback obtained from the same shared window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product tolerance ledger, recording factor bounds, product-error splitting, dyadic multiplication comparisons, and the tolerance entries consumed by the product readback.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *descent row. It can be read only after X, Y, S, Q, D have been displayed.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the product, available only after the regular product descent has reached the displayed readback boundary.*
7. *H records componentwise* hsame *transport for the factor rows, shared windows, regular readbacks, dyadic product ledger, product descent row, Real seal, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay from any product-limit request through X, Y, S, Q, D, M, A.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyProductLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, Q, D, M, A, H, C, P, N$. It has no coordinate for quotient stream equality, selected product limits, countable choice, trichotomy, host multiplication of completed reals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyProductLimitUp.CauchyProductLimitTasteGate single carrier alignment`

Theorem 3721.2 (CauchyProductLimit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductLimit}^{\uparrow}$ *carrier*

$$L_{\Pi} = (X, Y, S, Q, D, M, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular Cauchy factors, shared finite stream-window display, regular rational product readback, dyadic product-tolerance accounting,* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *descent, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay, provenance, local naming, and non-escape from quotient streams, selected product limits, countable choice, trichotomy, host multiplication of completed reals, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3721.1. The only factor data are X and Y, and the only observation windows available to consumers are the finite shared windows recorded by S.

The readback stage is finite. The row Q records the rational observations of both factors and the pointwise product readback obtained from those same windows, while D records the dyadic factor bounds, product-error split, and multiplication comparisons that justify the requested product tolerance.

The descent stage is forced by row order. The row M is downstream of X, Y, S, Q, D, so a product-limit consumer cannot read $\mathsf{RegularCauchyProduct}^{\uparrow}$ evidence before the factor windows, product readback, and dyadic ledger have been displayed.

Finally A, H, C, P, N seal, transport, replay, source, and name the same displayed route. Since the packet has no coordinate for quotient stream equality, selected product limits, countable choice, trichotomy, host multiplication of completed reals, or ambient Real completeness, none of those objects can be exported by the local certificate. □

Theorem 3721.3 (CauchyProductLimit Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{CauchyProductLimit}^{\uparrow}$ *carrier factors through the finite route*

$$X, Y \longmapsto S \longmapsto Q, D \longmapsto M \longmapsto A, H, C, P, N.$$

Thus the product limit is presented as a displayed regular-Cauchy algebra route to a Real seal, not as a quotient stream, selected product limit, countable-choice schedule, trichotomy principle, host multiplication of completed reals, or ambient completeness theorem.

Proof. Begin with an accepted packet $L_{\Pi} = (X, Y, S, Q, D, M, A, H, C, P, N)$. A consumer first reads the displayed factor rows X and Y; no host sequence equality, quotient representative, or completed-real multiplication primitive is available at this stage.

Next the shared stream windows in S determine the finite observations used for the request. The row Q reads both factors on those windows and records the pointwise rational product, while D supplies the dyadic factor bounds and product-tolerance ledger.

The regular product descent is M. Since M is downstream of the factor windows, readbacks, and tolerance ledger, the terminal Real seal A is reached only after the finite product route has already been displayed.

The transport and provenance rows preserve the same route under componentwise hsame. The local naming row N therefore exports the product-limit seal without adding quotient streams, selected limits, countable choice, trichotomy, host multiplication of completed reals, or ambient Real completeness. □

Theorem 3721.4 (CauchyProductLimit shared-window stability)**.** *Let*

$$L_\Pi = (X, Y, S, Q, D, M, A, H, C, P, N)$$

and

$$L'_\Pi = (X', Y', S', Q', D', M', A', H', C', P', N')$$

be accepted $\mathsf{CauchyProductLimit}^\uparrow$ *carriers. If the two packets preserve the two factor rows, the shared* $\mathsf{StreamName}^\uparrow$ *window, the* $\mathsf{RegSeqRat}^\uparrow$ *readback, the* $\mathsf{DyadicRatCore}^\uparrow$ *product ledger, the* $\mathsf{RegularCauchyProduct}^\uparrow$ *descent row, and the terminal* $\mathsf{Real}^\uparrow$ *seal componentwise under* hsame*, then every product-limit consumer reads the same finite route through* $S, Q, D, M, A, H, C, P, N$*. In particular the read is stable under the displayed product-limit route and cannot be replaced by quotient streams, selected product limits, countable choice, trichotomy, host multiplication of completed reals, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the two carrier displays from Definition 3721.1. The admissible coordinates of a product-limit read are exactly the factor rows, the shared window row, the regular rational readback, the dyadic product ledger, the product descent row, the Real seal, the componentwise transport, replay, provenance, and local naming rows.

Apply Definition 3721.2 to both packets. Carrier admission binds every accepted read to the displayed rows, while the shared-window, readback, dyadic-ledger, descent, and seal clauses rule out any extra route not present in L_Π or L'_Π.

Use the componentwise hsame hypotheses next. They identify the two factor rows, S with S', Q with Q', D with D', M with M', and A with A' at the exact sites where a consumer can inspect the product-limit packet.

Finally apply the Real-seal route theorem Definition 3721.3. Since the terminal read must pass through the finite route from X, Y to $S, Q, D, M, A, H, C, P, N$, the preserved components force the same product-limit route and keep quotient streams, selected product limits, countable choice, trichotomy, host multiplication, and ambient Real completeness outside the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductLimit}\uparrow}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductLimit}\uparrow}$, seed)

Scope closed: Definition 3721.1, Definition 3721.2, and Definition 3721.3 seed the finite route from two regular Cauchy factor rows to shared StreamName windows, RegSeqRat readbacks, a DyadicRatCore product ledger, RegularCauchyProduct descent, and a RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyProductLimit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected product limits, countable choice, trichotomy, host multiplication of completed reals, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window display, regular rational product readback, dyadic product-tolerance accounting, RegularCauchyProduct descent, Real-seal routing, transport and replay stability, provenance exhaustion, and non-escape for BEDC.Derived.CauchyProductLimitUp.

Constructive story: A $\mathsf{CauchyProductLimit}^\uparrow$ packet is generated from two regular Cauchy factor rows, shared finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore product-tolerance ledger, a RegularCauchyProduct descent row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3722

A Concrete Naming Certificate for $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$ packet records the finite diagonal selector route used by the real-completeness corridor of chapter 9238. It concretizes the transported stationary diagonal theorem of Definition 9238.17 as a NameCert packet over the no-choice selector boundary of chapter 695, the cofinal tail route of chapter 697, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The selector is a displayed Bishop-style regular-Cauchy diagonal construction, not a host choice function, quotient stream, selected completed limit, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness primitive.

Definition 3722.1 (RealCompletenessDiagonalSelector carrier)**.** *A* $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, E, T, S, Q, D, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the regular Cauchy source-family row whose finite observations are available through the displayed real-completeness route.*
2. *E is the* $\mathsf{ChoiceFreeDiagonalSelector}^{\uparrow}$ *row, recording the explicit precision request, selected finite window, and refusal of a host choice function.*
3. *T is the* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *row, recording the cofinal tail index and the finite tail-window handoff consumed by the diagonal route.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row shared by the selector, tail, and readback requests.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected diagonal windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the precision budget, selected-window comparisons, and tail-cofinality tolerance entries.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the selected diagonal representative, available only after E, T, S, Q, D have been displayed.*
8. *H records componentwise* hsame *transport for the source-family, selector, tail, window, readback, dyadic ledger, Real seal, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from any diagonal-selector request through R, E, T, S, Q, D, A.*
10. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$, $\mathsf{ChoiceFreeDiagonalSelector}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, E, T, S, Q, D, A, H, C, P, N$. It has no coordinate for host choice, quotient stream equality, selected completed limits, hidden tail oracles, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3722.2 (RealCompletenessDiagonalSelector NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$ *carrier*

$$G = (R, E, T, S, Q, D, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular Cauchy source family, choice-free finite selector admission, cofinal diagonal-tail routing, shared StreamName window display, RegSeqRat selected-window readback, DyadicRatCore precision and tail-cofinality ledgers, terminal RealUp seal routing, componentwise* hsame *transport, displayed* Cont *replay, provenance, local naming, and non-escape from host choice, quotient streams, selected completed limits, hidden tail oracles, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3722.1. The source-family row R is only readable through the finite selector and tail rows E and T, so no host family choice or completed-limit selector is available before the displayed rows have been opened.

The finite selector stage is explicit. The row E records the precision request and selected window without a host choice function, while T records the cofinal tail handoff used by the same request.

The observation stage is also finite. The shared window row S, readback row Q, and dyadic ledger D name the StreamName, RegSeqRat, and DyadicRatCore data consumed by the diagonal representative before the Real seal A can be read.

Finally H, C, P, N transport, replay, source, and name exactly this route. Since the carrier has no coordinate for host choice, quotient stream equality, selected completed limits, hidden tail oracles, trichotomy, or ambient Real completeness, none of those objects can be exported by the local certificate. □

Theorem 3722.3 (RealCompletenessDiagonalSelector non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or real-completeness-facing consumer of an accepted* $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$ *carrier factors through the finite route*

$$R \longmapsto E, T \longmapsto S, Q, D \longmapsto A, H, C, P, N.$$

The transported stationary diagonal row of Definition 9238.17 is therefore consumed as finite selector, tail, window, readback, dyadic, seal, transport, replay, provenance, and local naming data, not as host choice, quotient stream equality, selected completed limit, hidden tail oracle, trichotomy, or ambient completeness.

Proof. Start with an accepted packet $G = (R, E, T, S, Q, D, A, H, C, P, N)$. The source-family row R is not a completed real carrier; it becomes visible to a consumer only through the displayed selector and tail rows.

The selector rows E and T fix the finite observation request. The former records the no-choice selection boundary, and the latter records the cofinal tail route that serves the same diagonal window.

The rows S, Q, D then supply the finite StreamName window, RegSeqRat readback, and DyadicRatCore tolerance ledger. The Real seal A is downstream of these rows, so a consumer cannot bypass them to obtain an independent RealUp limit.

Transport and replay preserve the row order under componentwise hsame. The local naming row N therefore exports only the displayed diagonal-selector route and cannot export host choice, quotient streams, selected completed limits, hidden tail oracles, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3722.1, Definition 3722.2, and Definition 3722.3 seed the finite Bishop-style diagonal selector route from regular Cauchy source rows through ChoiceFreeDiagonalSelector and DiagonalTailSelector rows to StreamName windows, RegSeqRat readbacks, a DyadicRatCore ledger, and a RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host choice, quotient streams, selected completed limits, hidden tail oracles, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, choice-free selector admission, cofinal tail routing, selected-window readback, dyadic precision and tail-cofinality ledgers, Real-seal routing, transport and replay stability, provenance exhaustion, and non-escape for BEDC.Derived.RealCompletenessDiagonalSelectorUp.

Constructive story: A $\mathsf{RealCompletenessDiagonalSelector}^{\uparrow}$ packet is generated from a regular Cauchy source-family row, a ChoiceFreeDiagonalSelector row, a DiagonalTailSelector row, shared StreamName windows, RegSeqRat selected-window readbacks, a DyadicRatCore precision ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3723

A Concrete Naming Certificate for $\mathsf{LeibnizSeriesTest}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of alternating series, the $\mathsf{LeibnizSeriesTest}^{\uparrow}$ packet records the classical alternating-series tail-bound route as finite BEDC data before any completion-facing consumer may read a regular rational handoff or a real seal. It refines the convergence-test surface of chapter 1483, uses the regular rational readback of chapter 301, opens only the finite observation windows of chapter 126, measures tail tolerances through the dyadic core of chapter 291, and terminates at the real-name boundary of chapter 38. The packet names the finite Leibniz tail-bound route; it does not import selected sums, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3723.1 (LeibnizSeriesTest carrier)**.** *A* $\mathsf{LeibnizSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L_\lambda = (S, \Sigma, M, T, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, listing the finite partial-sum and summand windows opened by the request.*
2. *Σ is the finite alternating-sign row, recording the parity and sign entries visible on the displayed windows.*
3. *M is the monotone magnitude row, recording nonnegative dyadic magnitude reads and their finite monotonicity comparisons on the inspected tail.*
4. *T is the tail-bound schedule, assigning each requested dyadic tolerance to a displayed tail index whose next visible magnitude is within that tolerance.*
5. *Q is the* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *handoff row, accepting the source, alternating-sign, monotone-magnitude, and tail-bound rows as the local convergence-test face.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed partial-sum stream after the handoff row has been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, Σ, M, T, Q, R have been read.*
8. *H records componentwise* hsame *transport for the source, sign, magnitude, tail-bound, handoff, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from any Leibniz-series-test request through* S, Σ, M, T, Q, R, E.
10. *P is the* Pkg *provenance over* $\mathsf{LeibnizSeriesTest}^{\uparrow}$, $\mathsf{AlternatingSeriesTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LeibnizSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, \Sigma, M, T, Q, R, E, H, C, P, N$. It has no coordinate for selected sums, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LeibnizSeriesTestUp.LeibnizSeriesTestTasteGate single carrier alignment`

Theorem 3723.2 (LeibnizSeriesTest NameCert obligations)**.** *For every accepted* $\mathsf{LeibnizSeriesTest}^{\uparrow}$ *carrier*

$$L_\lambda = (S, \Sigma, M, T, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LeibnizSeriesTest}^{\uparrow}}$ *surface consists exactly of finite source-window admission, alternating-sign display, monotone magnitude display, dyadic tail-bound scheduling,* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay, provenance, local naming, and non-escape from selected sums, quotient series equality, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LeibnizSeriesTestUp.LeibnizSeriesTestNameCertObligations`

Proof. Project the carrier of Definition 3723.1. The only source observations are the finite windows in S, and the only sign information is the displayed parity ledger Σ.

The tail estimate is finite. The row M gives the visible monotone magnitude comparisons, while T records the tail index chosen for each requested dyadic tolerance. The handoff row Q then accepts exactly those source, sign, magnitude, and tail-bound rows through the $\mathsf{AlternatingSeriesTest}^{\uparrow}$ surface.

The completion-facing route is also finite. The regular readback R may be read only after Q, and the terminal seal E receives only R together with the displayed source, sign, magnitude, and tail-bound route.

Finally H, C, P, N transport, replay, source, and name that same route. Since no carrier coordinate stores a selected sum, quotient series equality, countable-choice schedule, trichotomy premise, or ambient completeness theorem, none of those objects can be exported by the local certificate. □

Theorem 3723.3 (LeibnizSeriesTest Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal-facing read exported by an accepted* $\mathsf{LeibnizSeriesTest}^{\uparrow}$ *carrier factors through the finite route*

$$S, \Sigma, M, T \longmapsto Q \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the Leibniz tail-bound route reaches the terminal Real seal only through displayed alternating signs, monotone magnitudes, dyadic tail bounds, the alternating-series-test handoff, and regular rational readback; it does not expose selected sums, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted packet $L_\lambda = (S, \Sigma, M, T, Q, R, E, H, C, P, N)$. A Real-facing consumer must first open the displayed source windows S, because no partial-sum observation is available outside those windows.

The sign and magnitude checks are then forced by Σ and M. The tail-bound schedule T is the only row that converts a requested dyadic tolerance into a displayed tail index, and the handoff row Q records that those finite rows enter the alternating-series-test surface.

The regular rational handoff is R, and the Real seal is E. Since E is available only after R and the finite handoff route have been displayed, any seal-facing read stays inside the named route.

The transport, replay, provenance, and local naming rows preserve that route componentwise. Hence the exported boundary cannot contain selected sums, quotient series equality, countable choice, trichotomy, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LeibnizSeriesTest}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LeibnizSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3723.1, Definition 3723.2, and Definition 3723.3 seed the finite Leibniz tail-bound route from displayed alternating signs and monotone magnitudes through RegSeqRat readback to a RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LeibnizSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected sums, quotient series equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign and magnitude display, tail-bound scheduling, alternating-series-test handoff, regular rational readback, Real-seal routing, transport and replay stability, provenance exhaustion, and non-escape for BEDC.Derived.LeibnizSeriesTestUp.

Constructive story: A $\mathsf{LeibnizSeriesTest}^{\uparrow}$ packet is generated from finite StreamName windows, an alternating-sign row, monotone magnitude row, dyadic tail-bound schedule, AlternatingSeriesTestUp handoff, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3724

A Concrete Naming Certificate for $\mathsf{LipschitzModulus}^{\uparrow}$

Following Bishop–Bridges constructive metric analysis and Kelley-style uniform-space bookkeeping, the $\mathsf{LipschitzModulus}^{\uparrow}$ packet records the finite tolerance object carried by a displayed Lipschitz bound. It sits over the source and target metric rows of chapter 57, the real-bound seal of chapter 38, the Lipschitz map and constant surfaces of chapter 410 and chapter 2328, the division and rounding ledger of chapter 291, and the exported modulus and continuity consumers of chapter 369 and chapter 391. The packet names a finite tolerance-only route; it is not a host proof of continuity, a quotient of maps, a selected inverse for a real bound, or an ambient completeness theorem.

Definition 3724.1 (LipschitzModulus carrier)**.** *A* $\mathsf{LipschitzModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, F, K, E, D, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row and Y is the target* $\mathsf{Met}^{\uparrow}$ *row.*
2. *F is the* $\mathsf{LipschitzMap}^{\uparrow}$ *row whose graph and source-distance reads use X and Y.*
3. *K is the* $\mathsf{LipschitzConstant}^{\uparrow}$ *row for the same source, target, and graph data.*
4. *E is the positive target-tolerance row, read through* $\mathsf{Real}^{\uparrow}$ *rather than through a host scalar.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *division and rounding ledger that turns E and the displayed bound in K into a source-tolerance request.*
6. *U is the exported* $\mathsf{UniformModulus}^{\uparrow}$ *row consumed by* $\mathsf{UniformContinuity}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *routes.*
7. *H records componentwise* hsame *transport for metric rows, map rows, constant rows, tolerance rows, dyadic division and rounding rows, the exported modulus, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from a target-tolerance request through E, K, D to the source-tolerance row exported by U.*
9. *P is the* Pkg *provenance over* $\mathsf{LipschitzModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{LipschitzConstant}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzModulus}^{\uparrow}}$ *row.*

The classifier accepts only packets with these rows. It has no coordinate for an unbounded host Lipschitz proof, a quotient-function equality, a hidden choice of reciprocal, a completed function space, or an ambient real-completeness argument.

Lean4 ✓ `BEDC.Derived.LipschitzModulusUp.LipschitzModulusTasteGate single carrier alignment`

Theorem 3724.2 (LipschitzModulus NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzModulus}^{\uparrow}$ *carrier* $M = (X, Y, F, K, E, D, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LipschitzModulus}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the source metric, target metric, Lipschitz map, Lipschitz constant, positive tolerance, dyadic division and rounding, exported modulus, transport, replay, provenance, and local naming rows;*
2. *bound alignment, requiring F and K to read the same source, target, and graph rows before a tolerance conversion is exported;*
3. *tolerance positivity, requiring E to be displayed before the dyadic ledger is read;*
4. *modulus export, requiring every* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer to pass through E, K, D, U in that order;*
5. *ledger non-escape, excluding host Lipschitz proofs, quotient map equality, hidden reciprocal choice, completed function spaces, selected limits, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 3724.1. The displayed packet exposes exactly the metric, Lipschitz-map, Lipschitz-constant, positive-tolerance, dyadic-ledger, modulus, transport, replay, provenance, and naming rows.

The bound-alignment and positivity obligations are row-order checks. The map row F and constant row K share the source and target metric rows, and the tolerance row E is the only positive target request available to the dyadic ledger D.

The export obligation follows because U is the only $\mathsf{UniformModulus}^{\uparrow}$ row in the carrier. A continuity consumer therefore reaches U only after reading the displayed tolerance, constant, and dyadic division and rounding route.

The refusal clause is an inventory check on the carrier. None of the displayed rows supplies host continuity, quotient map equality, hidden reciprocal selection, completed function-space data, selected limits, choice, or ambient completeness. □

Theorem 3724.3 (LipschitzModulus uniform-continuity handoff)**.** *Let* $M = (X, Y, F, K, E, D, U, H, C, P, N)$ *be an accepted* $\mathsf{LipschitzModulus}^{\uparrow}$ *carrier. Every* $\mathsf{UniformContinuity}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer that requests a target tolerance receives only the source-tolerance route exported by U after the packet has displayed the target tolerance E, the aligned Lipschitz constant K, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *division and rounding ledger D. Thus the handoff is a finite modulus route, not a rereading of a host Lipschitz proof.*

Proof. Start from the carrier of Definition 3724.1. The source and target metrics are X and Y, the graph and bound rows are F and K, and the only target-tolerance request is E.

The dyadic ledger D performs the finite division and rounding step from the displayed tolerance and bound data. Since D is the only arithmetic route in the packet, no consumer can replace it by a host reciprocal or by a selected real approximation.

The exported row U is then read by the $\mathsf{UniformModulus}^{\uparrow}$ surface and by downstream $\mathsf{UniformContinuity}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ consumers. Transport through H and replay through C preserve this order, so the consumer receives only the displayed finite modulus route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3724.1, Definition 3724.2, and Definition 3724.3 seed the finite Lipschitz tolerance route from displayed metric, Lipschitz-map, Lipschitz-constant, positive-tolerance, dyadic division and rounding, and uniform-modulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient function spaces, host continuity proofs, reciprocal choice, completed Sobolev or function-space carriers, selected limits, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, bound alignment, tolerance positivity, dyadic division and rounding exactness, uniform-modulus export, transport stability, and replay stability for BEDC.Derived.LipschitzModulusUp.

Constructive story: A $\mathsf{LipschitzModulus}^{\uparrow}$ packet is generated from source and target metric rows, Lipschitz map and constant rows, a positive tolerance row, a DyadicRatCore division and rounding ledger, an exported UniformModulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 3725

A Concrete Naming Certificate for $\mathsf{ModulusCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ModulusCauchyCompletion}^{\uparrow}$ packet records the finite completion endpoint surface obtained when a displayed Cauchy modulus is bound to regular rational readback and a terminal real seal. It sits over the modulus interface of chapter 292, the regular rational surface of chapter 301, the finite stream-window route of chapter 126, the dyadic tolerance ledger of chapter 291, the Bishop regular Cauchy completion packet of chapter 1639, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a modulus-driven endpoint handoff; it does not choose a quotient representative, assert ambient completeness, or select limits by countable choice.

Definition 3725.1 (Modulus Cauchy completion carrier)**.** *A* $\mathsf{ModulusCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row, carrying the finite precision-to-window schedule used by the completion endpoint request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, exposing the finite source windows admitted by the modulus schedule.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the displayed stream windows as regular rational Cauchy data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic thresholds, comparison rows, and endpoint error budgets used by M, S, R.*
5. *E is the endpoint seal row, read through the Bishop regular completion boundary and then through the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
6. *H stores componentwise* hsame *transport for the modulus, stream, readback, dyadic ledger, endpoint seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from the modulus schedule to source windows, from source windows to regular readback, from the dyadic ledger to endpoint tolerances, and from the regular completion handoff to the real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{ModulusCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *Bishop regular Cauchy completion,* $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{ModulusCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, S, R, D, E, H, C, P, N$. It contains no coordinate for quotient completion equality, selected host limits, countable choice, ambient real completeness, or a bridge-checked standard endpoint.

Lean4 ✓ `BEDC.Derived.ModulusCauchyCompletionUp.ModulusCauchyCompletionTasteGate single carrier alignment`

Theorem 3725.2 (Modulus Cauchy completion NameCert obligations)**.** *For every accepted* ModulusCauchyComple *carrier $Q = (M, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusCauchyCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed modulus, stream-window, regular readback, dyadic tolerance, endpoint seal, transport, replay, provenance, and local naming rows;*
2. *modulus compatibility, requiring every endpoint request to read its threshold and observation window through the same* $\mathsf{CauchyModulus}^{\uparrow}$ *row M and* $\mathsf{StreamName}^{\uparrow}$ *row S;*
3. *regular-readback stability, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to be transported componentwise from the displayed stream windows and dyadic tolerance rows;*
4. *endpoint handoff, requiring the endpoint row E to be exposed only after the Bishop regular completion boundary and terminal* $\mathsf{Real}^{\uparrow}$ *seal have read M, S, R, D;*
5. *ledger nonescape, excluding quotient completion equality, host real equality, selected limits, countable choice, ambient completeness, and bridge checking from the local carrier.*

Proof. Project the carrier of Definition 3725.1. The rows $M, S, R, D, E, H, C, P, N$ are the full accepted inventory, so carrier admission and classifier comparison are finite.

The modulus and stream rows are read together. A precision request reaches an observation window only through M and S, and the dyadic row D records the tolerance ledger attached to that same read.

The regular readback and endpoint handoff are downstream. The row R is obtained from the displayed windows and tolerance data, while E is exposed only after the Bishop regular completion boundary and the $\mathsf{Real}^{\uparrow}$ seal consume the same rows.

Finally inspect the missing coordinates. Since the carrier has no quotient equality, host real equality, selected limit, countable-choice, ambient-completeness, or bridge-checking row, the local NameCert surface cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusCauchyCompletion}^{\uparrow}$ packet is generated from a CauchyModulus row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, an endpoint Real/completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ModulusCauchyCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 3725.1 and Definition 3725.2 seed the finite modulus-to-endpoint packet over completion-facing regular rational Cauchy data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ModulusCauchyCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient completion equality, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus compatibility, regular-readback stability, endpoint handoff, and ledger nonescape for the same finite packet.

Chapter 3726

A Concrete Naming Certificate for $\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}$ packet records the finite-cover substrate used by located compact-uniform-continuity arguments on closed bounded interval data. It refines the closed interval source of chapter 1591, the finite ball-cover carrier of chapter 2377, the positive-radius ledger of chapter 3606, the compact uniform-continuity route of chapter 2292, and the metric-ball observation surface of chapter 1450. The packet names only finite located cover rows, local membership witnesses, Lebesgue-number handoff data, transport, replay, provenance, and local naming evidence.

Definition 3726.1 (Uniformly located finite cover carrier)**.** *A* $\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, F, L, M, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, including endpoint order, rational and dyadic containment ledgers,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *F is the* $\mathsf{FiniteRealCover}^{\uparrow}$ *row whose ball cells, centers, dyadic radii, coverage witnesses, and refinement ledger cover the inspected interval windows.*
3. *L is the* $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$ *ledger row that records the positive-radius handoff for the displayed finite cover.*
4. *M is the metric-ball and local locatedness membership row: each inspected interval window is paired with an admitted* $\mathsf{MetricBall}^{\uparrow}$ *cell and a finite locatedness witness for membership in that cell.*
5. *H records componentwise* hsame *transport for I, F, L, M, C, P, N and for the endpoint, cover, radius, ball, membership, and local naming coordinates exposed by those rows.*
6. *C records displayed* Cont *replay from interval containment rows to finite cover coverage checks, from coverage checks to local locatedness membership, and from the cover ledger to the Lebesgue-number handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{FiniteRealCover}^{\uparrow}$, $\mathsf{FiniteCoverLebesgueNumber}^{\uparrow}$, $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open-cover compactness, a choice-selected subcover, a host-set membership oracle, quotient real equality, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.UniformlyLocatedFiniteCoverUp.UniformlyLocatedFiniteCoverTasteGate single carrier alignment`

Theorem 3726.2 (Uniformly located finite cover NameCert obligations)**.** *For an accepted* UniformlyLocatedFiniteC *carrier* $U = (I, F, L, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple; finite cover coverage through* F *over the interval source* I*; local locatedness preservation through the metric-ball membership row* M*; Lebesgue-number handoff through* L*; componentwise transport stability through* H*; displayed replay through* C*; provenance through* P*; local naming through* N*; and ledger nonescape from open-cover compactness, selected subcovers, host membership oracles, quotient real equality, trichotomy, and ambient completeness.*

Proof. Project the carrier of Definition 3726.1. The displayed tuple exposes the closed bounded interval source, finite cover row, positive-radius ledger, local metric-ball membership row, and the structural rows H, C, P, N.

Coverage is read only through F after I has supplied its endpoint, containment, window, readback, and Real-seal data. Locatedness preservation is read through M, where each finite cell membership remains attached to an admitted $\mathsf{MetricBall}^{\uparrow}$ row and to the same interval window.

The Lebesgue-number handoff is downstream of the displayed finite cover: L may be consumed only after the cover row and local membership ledger have been replayed. The transport and replay rows then preserve the same interval-cover-membership route componentwise.

No excluded object is a coordinate of U. The local certificate therefore exports only the displayed finite located cover route, with P and N recording provenance and naming for that route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}$ packet is generated from a closed bounded interval source, a finite real cover row, a finite-cover Lebesgue-number ledger, metric-ball located membership rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3726.1 and Definition 3726.2 seed the finite located cover substrate consumed by compact uniform-continuity routes over closed bounded interval data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyLocatedFiniteCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, choice-selected subcovers, host-set membership oracles, quotient real equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coverage exactness, locatedness preservation, Lebesgue-number handoff, transport and replay stability, and provenance exhaustion for BEDC.Derived.UniformlyLocatedFiniteCoverUp.

Chapter 3727

Cauchy Condensation Theorem NameCert Construction

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ packet records the theorem-level NameCert surface that turns a monotone nonnegative $\mathsf{RealSeries}^{\uparrow}$ tail into the dyadic block series and back through Cauchy criteria. It sits after the dyadic-block packet of chapter 1464, the comparison-test surface of chapter 1478, the Real-series carrier of chapter 3345, and the finite dyadic partition ledger of chapter 1863. The packet is a theorem certificate over displayed tails, block ledgers, and Cauchy handoff rows; it is not a host summability principle, a quotient of infinite series, a selected sum, countable choice, arbitrary trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3727.1 (Cauchy condensation theorem carrier)**.** *A* $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, M, D, B, G, Q, U, V, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the monotone nonnegative* $\mathsf{RealSeries}^{\uparrow}$ *source row, read only through finite term windows and partial-sum windows.*
2. *M is the monotone-tail ledger, recording the nonnegativity row, decreasing transport, and the finite tail cut from which the theorem is applied.*
3. *D is the* $\mathsf{DyadicPartition}^{\uparrow}$ *block schedule, listing the powers of two, block endpoints, and finite block intervals used by the theorem.*
4. *B is the original block-sum ledger, storing the finite sums of A over the dyadic intervals named by D.*
5. *G is the condensed-series row, displaying the dyadic terms $2^n a_{2^n}$ on the same block schedule.*
6. *Q is the blockwise comparison ledger, recording the lower and upper estimates that monotonicity supplies between B and G.*
7. *U is the original-series Cauchy criterion row, expressed through displayed partial-sum windows of A.*
8. *V is the condensed-series Cauchy criterion row, expressed through displayed partial-sum windows of G.*

9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the original and condensed partial-sum windows.*
10. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached only after the Cauchy criterion handoff has passed through U, V, R.*
11. *H records componentwise* hsame *transport for the source, monotone ledger, dyadic schedule, block sums, condensed terms, comparison ledger, Cauchy rows, readback row, seal row, continuation, provenance, and local naming rows.*
12. *C records displayed* Cont *replay from each finite tail request through the dyadic blocks, comparison ledger, Cauchy criteria, regular readback, and seal-facing row.*
13. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationTheorem}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchyCondensation}^{\uparrow}$, $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{CauchyCondensationRealSeries}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, M, D, B, G, Q, U, V, R, E, H, C, P, N$. It has no coordinate for a host infinite sum, quotient equality of series, selected endpoint, countable choice, an arbitrary trichotomy split, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyCondensationTheoremUp.CauchyCondensationTheoremTasteGate single carrier alignment`

Definition 3727.2 (Blockwise Cauchy comparison classifier)**.** *Two accepted* $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ *carriers are blockwise Cauchy equivalent when their displayed* $\mathsf{RealSeries}^{\uparrow}$ *source rows, monotone-tail ledgers, dyadic schedules, original block sums, condensed terms, comparison rows, original and condensed Cauchy criterion rows, regular readbacks, seal-facing rows, transports, continuations, provenance, and local names are pairwise* hsame *through the rows named in Definition 3727.1. Equivalence is not allowed to inspect an unlisted host limit, a quotient of streams, or a chosen infinite sum.*

Theorem 3727.3 (Cauchy condensation theorem NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ *carrier $K = (A, M, D, B, G, Q, U, V, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyConden}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed fourteen-row packet;*
2. *monotone nonnegative source exposure through A and M;*
3. *dyadic block scheduling through D and original block-sum formation through B;*
4. *condensed dyadic-term formation through G;*
5. *blockwise tail comparison through Q, using only monotone transport on displayed finite windows;*
6. *original-to-condensed Cauchy transport through U, V, R;*
7. $\mathsf{Real}^{\uparrow}$ *seal exposure through E only after the Cauchy handoff has reached the regular readback row;*
8. *transport stability, continuation replay, provenance, and local naming through H, C, P, N.*

No obligation row asserts host summability, a selected infinite sum, quotient equality of real streams, countable choice, arbitrary trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $K = (A, M, D, B, G, Q, U, V, R, E, H, C, P, N)$. The carrier row exposes exactly the monotone Real-series source, monotone-tail ledger, dyadic block schedule, original block sums, condensed terms, comparison ledger, two Cauchy criterion rows, regular readback, seal-facing row, and structural rows.

The source and classifier obligations are finite. The rows A and M provide nonnegativity and decreasing behavior only on displayed term windows, while Definition 3727.2 permits comparison only through the carrier coordinates named in Definition 3727.1.

The dyadic block ledger is then read. The schedule D fixes the inspected powers of two and finite intervals, B records the original block sums on those intervals, and G records the condensed terms $2^n a_{2^n}$ on the same indices.

Monotone transport enters only through Q. Each block comparison is a finite estimate between rows already displayed by A, M, D, B, G, so the theorem-level packet does not appeal to an infinite selector of blocks or to host equality of series.

Finally the Cauchy-convergence handoff is read through U, V, R, E. The original and condensed Cauchy criterion rows route the two partial-sum tails into the same regular readback boundary before the $\mathsf{Real}^{\uparrow}$ seal row is visible. The rows H, C, P, N preserve, replay, source, and name that route, so the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ consumer that claims theorem-level condensation without reading the monotone source row, dyadic block schedule, original block sums, condensed terms, blockwise comparison ledger, Cauchy criterion rows, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: cauchycondensation, cauchy-condensation-test, cauchy-condensation-real-series, dyadic-partition, realseries, regseqrat, real: no listed sibling supplies the whole fourteen-row theorem packet $K = (A, M, D, B, G, Q, U, V, R, E, H, C, P, N)$, because each sibling contributes only a dyadic block, comparison-test, Real-series, partition, readback, or seal face while this chapter binds the theorem-level equivalence through blockwise comparison and Cauchy handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ packet is generated from a monotone nonnegative RealSeries source row, a monotone-tail ledger, a DyadicPartition block schedule, original block sums, condensed dyadic terms, a blockwise comparison ledger, original and condensed Cauchy criterion rows, RegSeqRat readback, a RealUp seal-facing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3727.1, Definition 3727.2, and Definition 3727.3 seed the theorem-level dyadic block carrier, classifier, monotone transport ledger, and Cauchy-convergence handoff for monotone nonnegative real series.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient equality of series, selected sums, countable choice, arbitrary trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode BEDC.Derived.CauchyCondensationTheoremUp and prove carrier admission, blockwise classifier stability, monotone dyadic transport, the block ledger, and the Cauchy criterion handoff.

Chapter 3728

A Concrete Naming Certificate for $\mathsf{Sylow}^{\uparrow}$

Following Sylow's finite group theorem, the $\mathsf{Sylow}^{\uparrow}$ packet records a prime-power subgroup witness inside a displayed finite $\mathsf{Group}^{\uparrow}$ carrier. It consumes the group and subgroup rows of chapter 41 and chapter 80, the prime and unary counting rows of chapter 64 and chapter 28, and the finite action surface of chapter 3662. The packet names only a displayed p-subgroup carrier, maximal prime-power coverage, conjugacy transport, and representation-facing consumer boundary; it does not assert a host subgroup lattice, quotient group classification, character table, arbitrary normalizer computation, or complete finite-group structure theorem.

Definition 3728.1 (Sylow carrier)**.** *A* $\mathsf{Sylow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (G, S, p, n, W, A, T, C, H, P, N)$$

with the following displayed rows:

1. *G is the consumed finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *source row, including multiplication, unit, inverse, finite support, and componentwise group transport.*
2. *S is the consumed* $\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$ *row naming the candidate subgroup inside G.*
3. *p is the* $\mathsf{NameCert}_{\mathsf{Prime}^{\uparrow}}$ *row naming the prime whose power controls the subgroup order.*
4. *n is the* $\mathsf{Nat}^{\uparrow}$ *unary exponent row recording the displayed prime-power size p^n.*
5. *W is the membership and order witness row saying that the subgroup carrier has exactly the displayed p^n support and that no larger displayed p-subgroup row is present in the packet.*
6. *A is the finite conjugation-action row, read through the group operation of G and through the action discipline of* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *when a downstream representation consumer asks for transport of a Sylow row.*
7. *T is the conjugacy-transport row sending any displayed Sylow witness with the same prime-power coverage to a conjugate subgroup row inside G.*
8. *C is the consumer ledger for representation, character, and subgroup-normalizer reads; it exposes only the rows G, S, p, n, W, A, T before a consumer may name a Sylow conclusion.*
9. *H records componentwise* hsame *transport for group, subgroup, prime, exponent, coverage, action, conjugacy, consumer, replay, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{Sylow}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{Sylow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, S, p, n, W, A, T, C, H, P, N$. It has no coordinate for an ambient subgroup lattice, quotient classification, selected normalizer, character-table computation, or host finite-group theorem.

Lean4 (definition) `BEDC.Derived.SylowUp.SylowCarrier`

Lean4 ✓ `BEDC.Derived.SylowUp.SylowTasteGate single carrier alignment`

Theorem 3728.2 (Sylow NameCert obligations)**.** *For every accepted* $\mathsf{Sylow}^{\uparrow}$ *carrier* $Y = (G, S, p, n, W, A, T, C, H,$ *the local* $\mathsf{NameCert}_{\mathsf{Sylow}^{\uparrow}}$ *surface consists exactly of finite group admission through G, subgroup admission through S, prime admission through p, unary exponent exposure through n, prime-power coverage through W, conjugation-action exposure through A, conjugacy transport through T, consumer-boundary exposure through C, componentwise transport through H, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3728.1. The rows G, S, p, n, W expose the finite group, candidate subgroup, prime, unary exponent, and prime-power coverage before any Sylow read can be consumed.

The conjugation row A is finite because it is read from the displayed group operation and, when representation-facing consumers are present, through the finite action surface of chapter 3662. The transport row T is therefore a row of the packet, not a host orbit theorem.

Finally C, H, P, N preserve, source, and name the same route. Since no ambient subgroup lattice, quotient classification, selected normalizer, character-table computation, or complete finite-group structure theorem is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.SylowUp.SylowCarrier namecert obligations`

Theorem 3728.3 (Sylow conjugacy transport)**.** *Let $Y = (G, S, p, n, W, A, T, C, H, P, N)$ and $Y' = (G, S', p, n, W', A', T', C', H', P', N')$ be accepted* $\mathsf{Sylow}^{\uparrow}$ *packets over the same displayed finite* $\mathsf{Group}^{\uparrow}$ *row and the same* $\mathsf{Prime}^{\uparrow}$ *and* $\mathsf{Nat}^{\uparrow}$ *rows. If both coverage ledgers display maximal p^n support inside G, then every consumer that identifies S with S' must pass through the conjugation-action rows A, A' and the transport rows T, T'. The exported comparison is a displayed conjugacy transport inside G, not equality of host subgroup sets or a quotient of all subgroups.*

Lean4 ✓ `BEDC.Derived.SylowUp.SylowCarrier conjugacy transport`

Proof. Read the two carriers and their shared rows G, p, n. The only rows that connect subgroup witnesses with the ambient group operation are the coverage rows W, W' and the conjugation-action rows A, A'.

The transport rows T, T' record the allowed movement between displayed maximal prime-power subgroup rows. Thus a consumer comparing S and S' must use those rows before it may name a conjugacy result.

The consumer and structural rows $C, C', H, H', P, P', N, N'$ preserve the same displayed route. Because neither carrier contains a host subgroup lattice or quotient over all subgroup rows, the comparison remains a finite conjugacy-transport packet inside G. □

Theorem 3728.4 (Sylow prime-power coverage)**.** *For an accepted* $\mathsf{Sylow}^{\uparrow}$ *carrier* $Y = (G, S, p, n, W, A, T, C, H, P, N$ *every prime-power coverage read of* S *in* G *factors through the prime row* p*, the unary exponent row* n*, and the coverage ledger* W*. The packet may expose that the displayed subgroup has maximal* p^n *support among the subgroup rows named by the packet, but it does not compute the full host order of* G*, enumerate all subgroups of* G*, or choose a canonical Sylow subgroup.*

Proof. Project p, n, W from the carrier. The prime row supplies the arithmetic base, the unary exponent row supplies the finite counting index, and the coverage ledger records the displayed p^n support for the subgroup row S.

Apply Definition 3728.2. No coverage conclusion is available before G, S, p, n, W have been read, and no later row can replace W with an ambient order computation.

The action, transport, consumer, and structural rows A, T, C, H, P, N only replay the same coverage route. Therefore prime-power coverage is a packet-level finite witness, with full subgroup enumeration and canonical selection outside the chapter. □

Lean4 ✓ `BEDC.Derived.SylowUp.SylowCarrier prime power coverage`

Theorem 3728.5 (Sylow obligation closure surface)**.** *The* $\mathsf{Sylow}^{\uparrow}$ *obligation surface is exactly the carrier admission, prime-power coverage, conjugacy transport, and consumer-boundary route exposed by Definition 3728.2, Definition 3728.3, and Definition 3728.4.*

Proof. Apply Definition 3728.2 for the carrier-admission and consumer-boundary rows. Apply Definition 3728.4 for the prime-power ledger, and apply Definition 3728.3 for the displayed conjugacy route.

Together these three blocks expose the finite group, subgroup, prime, exponent, coverage, action, transport, consumer, structural, provenance, and local naming rows before any Sylow consumer can read the packet. No further host subgroup lattice, canonical selector, quotient classification, or character-table computation is a coordinate of the carrier. □

Lean4 ✓ `BEDC.Derived.SylowUp.SylowCarrier obligation closure surface`

Theorem 3728.6 (Sylow scope dependency lock)**.** *Every* $\mathsf{Sylow}^{\uparrow}$ *consumer must first read the* $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 3728.1. Only after those rows are exposed may the consumer name any prime-power coverage, conjugacy transport, or representation-facing consumer-boundary conclusion.*

Proof. Project the carrier and apply Definition 3728.2. The rows $G, S, p, n, W, A, T, C, H, P, N$ are the only admission, arithmetic, transport, replay, provenance, and local naming coordinates available to a consumer.

Apply Definition 3728.4 for the coverage read and Definition 3728.3 for the transport read. Both conclusions depend on the displayed rows already named by the carrier.

The consumer-boundary row C and the structural rows H, P, N then prevent any conclusion from escaping to an ambient subgroup lattice, quotient classification, character table, normalizer computation, or canonical Sylow selector. Thus the dependency scope is locked before the chapter exposes any Sylow conclusion. □

Lean4 ✓ `BEDC.Derived.SylowUp.SylowCarrier scope dependency lock`

Closure status for $\mathsf{NameCert}_{\mathsf{Sylow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Sylow}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 3728.1, Definition 3728.2, Definition 3728.3, and Definition 3728.4 seed the finite prime-power subgroup packet over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, and $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{Sylow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host subgroup lattices, quotient group classification, character-table computation, arbitrary normalizer calculation, canonical Sylow selection, Lean verification, or bridge checking.

Upgrade path: Carrier admission, prime-power coverage, and conjugacy transport already have checked targets; the remaining next step is checked representation-facing consumer-boundary and public-scope coverage, followed by bridge discipline for BEDC.Derived.SylowUp.

Constructive story: A Sylow$^{\uparrow}$ packet is generated from a finite GroupUp row, a SubgroupUp row, a PrimeUp row, a NatUp exponent row, a prime-power coverage ledger, conjugation-action and transport rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3729

A Concrete Naming Certificate for $\mathsf{SylowTheorem}^{\uparrow}$

Following Sylow and the finite-group presentation in Rotman, the $\mathsf{SylowTheorem}^{\uparrow}$ packet names the theorem-facing finite-action route over the existing $\mathsf{Sylow}^{\uparrow}$ witness packet. It consumes the displayed finite $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Sylow}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, and $\mathsf{ClassEquation}^{\uparrow}$ rows of chapter 41, chapter 80, chapter 64, chapter 28, chapter 3728, chapter 6559, and chapter 6631. The packet records only the finite action and counting route that a theorem consumer may read; it is not a host subgroup-lattice oracle, quotient classification, canonical Sylow selector, normalizer calculator, or complete finite-group structure theorem.

Definition 3729.1 (Sylow theorem carrier)**.** *A* $\mathsf{SylowTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, p, n, Y, A, O, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *source row whose multiplication, unit, inverse, and finite support are already displayed.*
2. *p is the consumed* $\mathsf{NameCert}_{\mathsf{Prime}^{\uparrow}}$ *row and n is the* $\mathsf{Nat}^{\uparrow}$ *exponent row for the displayed p^n divisor route.*
3. *Y is the consumed* $\mathsf{Sylow}^{\uparrow}$ *packet naming the prime-power subgroup witness and its coverage ledger inside G.*
4. *A is the finite conjugation-action row read through* $\mathsf{OrbitStabilizer}^{\uparrow}$*.*
5. *O is the orbit-stabilizer counting row for the displayed conjugation orbit of Sylow witnesses.*
6. *Q is the class-equation remainder row recording the finite congruence and divisibility boundary used by the theorem-facing route.*
7. *R is the theorem-read row assembling existence, conjugacy, and counting conclusions only as finite BEDC rows over G, p, n, Y, A, O, Q.*
8. *H records componentwise* hsame *transport for the group, prime, exponent, Sylow witness, action, counting, theorem-read, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a theorem request through the same finite action and counting route.*

10. *P is the* Pkg *provenance over* $\mathsf{SylowTheorem}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Sylow}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, $\mathsf{ClassEquation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SylowTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient subgroup lattice, quotient group classification, selected canonical Sylow subgroup, arbitrary normalizer computation, character table, or complete finite-group structure theorem.

Theorem 3729.2 (Sylow theorem NameCert obligations)**.** *For every accepted* $\mathsf{SylowTheorem}^{\uparrow}$ *carrier* $T = (G, p, n, Y, A, O, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SylowTheorem}^{\uparrow}}$ *surface consists exactly of finite group admission through G, prime and exponent admission through p, n, Sylow witness consumption through Y, conjugation-action exposure through A, orbit-stabilizer counting through O, class-equation remainder exposure through Q, theorem-read assembly through R, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3729.1. The group, prime, exponent, and Sylow rows G, p, n, Y are displayed before any theorem-facing read may inspect existence, conjugacy, or counting conclusions.

The finite action rows A, O are read through the orbit-stabilizer packet, and the remainder row Q is read through the class-equation packet. Thus the theorem-read row R can assemble only the displayed finite action and counting route.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since no carrier coordinate stores a host subgroup lattice, quotient classification, canonical Sylow selector, normalizer calculator, character table, or complete finite-group structure theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 3729.3 (Sylow theorem finite-action route)**.** *Every theorem-facing read from an accepted* $\mathsf{SylowTheorem}^{\uparrow}$ *packet factors through the displayed finite route*

$$\mathsf{Sylow}^{\uparrow} \longmapsto \mathsf{OrbitStabilizer}^{\uparrow} \longmapsto \mathsf{ClassEquation}^{\uparrow}.$$

The route may expose the existence, conjugacy, and counting rows assembled in R, but only after the group row G, prime row p, exponent row n, Sylow witness row Y, conjugation-action row A, orbit-stabilizer row O, and class-equation row Q have all been displayed.

Proof. Start with Definition 3729.2. It requires a theorem request to read G, p, n, Y before the finite action and counting rows become available.

Next consume the $\mathsf{Sylow}^{\uparrow}$ witness row Y. Its own carrier already exposes the prime-power subgroup witness inside the displayed group row, so the theorem-facing packet does not select a new subgroup.

Finally route the conjugation action through A, O and the counting remainder through Q. The replay and provenance rows C, P, N can name only this finite route, so R is a theorem-facing readback of displayed action and counting data rather than a host finite-group theorem. □

Theorem 3729.4 (Sylow theorem nonescape)**.** *An accepted* $\mathsf{SylowTheorem}^{\uparrow}$ *carrier cannot be used to recover data outside the displayed tuple $G, p, n, Y, A, O, Q, R, H, C, P, N$. In particular, it exports no host subgroup lattice, quotient classification of subgroups, canonical Sylow selector, arbitrary normalizer computation, character table, or complete finite-group structure theorem.*

Proof. Read the carrier in Definition 3729.1. The only theorem-facing mathematical rows are the displayed group, prime, exponent, Sylow witness, finite action, orbit-stabilizer, class-equation, and theorem-read rows.

Apply Definition 3729.3. Every theorem read must pass through $\mathsf{Sylow}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, and $\mathsf{ClassEquation}^{\uparrow}$ before R may be consumed.

The structural rows H, C, P, N preserve that same finite packet. Because no row contains a subgroup lattice, quotient classification, canonical selector, normalizer calculator, character table, or complete structure theorem, no such object can be recovered from the carrier. □

Falsifiable prediction: An accepted $\mathsf{SylowTheorem}^{\uparrow}$ read is refuted if it preserves the theorem-read row R while removing the consumed $\mathsf{Sylow}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, or $\mathsf{ClassEquation}^{\uparrow}$ rows.

Independence witness: sylow, orbit-stabilizer, class-equation: none of the sibling packets is bijective with $\mathsf{SylowTheorem}^{\uparrow}$ because this packet jointly carries a Sylow witness row, a conjugation-action route, an orbit-stabilizer count, a class-equation remainder, theorem-read assembly, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SylowTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{SylowTheorem}^{\uparrow}$ packet is generated from a finite GroupUp row, a PrimeUp row, a NatUp exponent row, a SylowUp witness row, OrbitStabilizerUp action-counting rows, ClassEquationUp remainder rows, theorem-read assembly, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SylowTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3729.1, Definition 3729.2, Definition 3729.3, and Definition 3729.4 seed the theorem-facing finite-action Sylow route over displayed group, subgroup, prime, natural-number, Sylow, orbit-stabilizer, and class-equation rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SylowTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subgroup lattices, quotient classification, canonical Sylow selection, arbitrary normalizer calculation, character-table computation, complete finite-group structure, Lean verification, or bridge checking.

Upgrade path: Formal closure requires checked carrier admission, finite-action routing, orbit-stabilizer counting, class-equation remainder exposure, theorem-read assembly, transport, replay, provenance, and nonescape for BEDC.Derived.SylowTheoremUp.

Chapter 3730

A Concrete Naming Certificate for $\mathsf{BernsteinPolynomial}^{\uparrow}$

Following Bernstein and Bishop–Bridges constructive analysis, the $\mathsf{BernsteinPolynomial}^{\uparrow}$ packet records constructive uniform approximation over displayed $\mathsf{Real}^{\uparrow}$ interval data as finite BEDC rows. It sits after the polynomial carrier of chapter 50, the real-name surface of chapter 38, the compact-uniform continuity packet of chapter 388, the uniform-modulus carrier of chapter 369, and the rational observation rows of chapter 37. The chapter names the finite Bernstein basis, coefficient, mesh, and error-ledger surface; it does not import a host Weierstrass theorem, a selected infinite approximation sequence, quotient equality of real functions, or ambient completeness beyond the cited rows.

Definition 3730.1 (Bernstein polynomial carrier)**.** *A* $\mathsf{BernsteinPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, F, U, M, S, K, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *closed interval row, exposing the endpoint names and the interval membership boundary used by the approximation request.*
2. *F is the sampled* $\mathsf{Real}^{\uparrow}$ *function-read row over I, read only through the compact-uniform continuity surface.*
3. *U is the* $\mathsf{CompactUniformContinuity}^{\uparrow}/\mathsf{UniformModulus}^{\uparrow}$ *row that supplies a finite modulus request for the interval.*
4. *M is the dyadic mesh row, recording the chosen mesh scale, mesh points, and interval subdivision ledger.*
5. *S is the* $\mathsf{Rat}^{\uparrow}$ *coefficient row, listing the rational sample and binomial-weight reads used by the displayed Bernstein polynomial.*
6. *K is the* $\mathsf{Poly}^{\uparrow}$ *Bernstein-basis row, recording the finite basis terms and the polynomial assembly route.*
7. *E is the uniform-error ledger, comparing each mesh and interval cell read against the requested tolerance by rational bounds.*
8. *H records componentwise* hsame *transport for interval, function-read, modulus, mesh, coefficient, basis, error, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from interval admission through compact-uniform modulus selection, dyadic mesh construction, rational coefficient readback, polynomial assembly, and uniform-error certification.*

10. *P records* Pkg *provenance over* $\mathsf{BernsteinPolynomial}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BernsteinPolynomial}^{\uparrow}}$ *row.*

The classifier compares accepted Bernstein packets only through $I, F, U, M, S, K, E, H, C, P, N$. It has no coordinate for host function equality, a nonconstructive supremum, a choice-selected polynomial sequence, or an external real-analysis theorem.

Lean4 ✓ `BEDC.Derived.BernsteinPolynomialUp.BernsteinPolynomialTasteGate single carrier alignment`

Theorem 3730.2 (Bernstein polynomial NameCert obligations)**.** *For every accepted* $\mathsf{BernsteinPolynomial}^{\uparrow}$ *carrier*

$$B = (I, F, U, M, S, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BernsteinPolynomial}^{\uparrow}}$ *surface consists exactly of interval admission, compact-uniform modulus exposure, dyadic mesh construction, rational coefficient readback, Bernstein-basis polynomial assembly, uniform-error ledger exactness, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Every approximation-facing consumer must read

$\mathsf{Real}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert

through these rows before it receives a Bernstein approximation certificate.

Theorem 3730.3 (Bernstein uniform approximation boundary)**.** *Given an accepted* $\mathsf{BernsteinPolynomial}^{\uparrow}$ *packet and a displayed tolerance request, the exported approximation boundary is the finite route*

$$I, F, U \longmapsto M \longmapsto S, K \longmapsto E \longmapsto H, C, P, N.$$

The packet may certify only that the displayed Bernstein polynomial row meets the displayed uniform-error ledger over the displayed interval. It does not claim a free-standing Weierstrass theorem, an ambient complete function space, a quotient equality class of continuous functions, or a selected infinite chain of approximants.

Closure status for $\mathsf{NameCert}_{\mathsf{BernsteinPolynomial}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BernsteinPolynomial}^{\uparrow}$ packet is generated from Real interval rows, compact-uniform modulus rows, dyadic mesh rows, Rat coefficient rows, Polynomial Bernstein-basis rows, a uniform-error ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BernsteinPolynomial}^{\uparrow}}$, seed)

Scope closed: Definition 3730.1, Definition 3730.2, and Definition 3730.3 seed the finite constructive approximation certificate over interval, modulus, mesh, coefficient, basis, error, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BernsteinPolynomial}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the Weierstrass approximation theorem, host function equality, selected approximation sequences, ambient complete function spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval admission, modulus exposure, dyadic mesh construction, rational coefficient readback, polynomial assembly, uniform-error exactness, transport, replay, provenance, and local naming for BEDC.Derived.BernsteinPolynomialUp.

Chapter 3731

A Concrete Naming Certificate for $\mathsf{SequentialCauchySelector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SequentialCauchySelector}^{\uparrow}$ packet records the finite selector rows needed when a displayed finite family of Cauchy requests is answered one request at a time, without turning that finite ledger into countable choice or ambient real completeness. It sits after the single-request selection surface of chapter 3719, the choice-sequence boundary of chapter 1482, the located choice-sequence boundary of chapter 2088, the stream-window carrier of chapter 126, the regular rational readback row of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names a finite sequential handoff; it does not choose an infinite sequence of witnesses, quotient-identify completed reals, or assert a general completeness principle.

Definition 3731.1 (Sequential Cauchy selector carrier)**.** *A* $\mathsf{SequentialCauchySelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, M, I, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request ledger, listing the Cauchy-selection queries whose answers are demanded by the packet.*
2. *M is the modulus schedule, assigning each listed request its displayed precision and finite window budget.*
3. *I is the finite index ledger, ordering the listed requests and recording which rows have already been answered.*
4. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the finite stream windows admitted by Q, M, I.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and their regular rational comparison data.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, recording dyadic thresholds, comparison rows, and error budgets for every listed request.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing a terminal real-facing name only after the selected stream window, regular readback, and dyadic tolerance rows have been read.*

8. *H records componentwise* hsame *transport for the request, modulus, index, window, readback, dyadic, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each finite request through its modulus schedule, index row, stream window, regular readback, dyadic ledger, and real seal.*

10. *P records* Pkg *provenance over* $\mathsf{SequentialCauchySelector}^{\uparrow}$, $\mathsf{CauchySelectionFunction}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{LocatedChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCauchySelector}^{\uparrow}}$ *row.*

The classifier compares accepted selector packets only through $Q, M, I, W, R, D, E, H, C, P, N$. It has no coordinate for countable choice, an infinite choice sequence, quotient real equality, ambient real completeness, or a choice-selected family beyond the listed requests.

Lean4 ✓ `BEDC.Derived.SequentialCauchySelectorUp.SequentialCauchySelectorTasteGate single carrier alignment`

Theorem 3731.2 (Sequential Cauchy selector NameCert obligations)**.** *For every accepted* SequentialCauchySelector *carrier $S = (Q, M, I, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialCauchySelector}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the request ledger, modulus schedule, index ledger, selected stream windows, regular rational readback, dyadic tolerance ledger, real seal, transport, replay, provenance, and local naming rows;*

2. *request-index exactness, requiring every selected row to be indexed by I and sourced from a displayed query in Q;*

3. *modulus-window compatibility, requiring every precision demand to pass through M before it reads a finite* $\mathsf{StreamName}^{\uparrow}$ *window in W;*

4. *readback and seal stability, requiring R, D, E to be transported componentwise from the same request, modulus, index, and window rows;*

5. *boundary refusal, excluding countable choice, infinite choice sequences, quotient real equality, ambient real completeness, and unlisted selected witnesses from the local carrier.*

Proof. Project the carrier of Definition 3731.1. The tuple $Q, M, I, W, R, D, E, H, C, P, N$ is the full accepted inventory, so each NameCert obligation must be read from one of these finite rows.

The request-index and modulus-window clauses are internal to Q, M, I, W. A selected window is exposed only after the query appears in Q, its finite index appears in I, and its precision demand passes through M.

The readback and seal clauses are downstream. The rows R and D read the displayed windows as regular rational and dyadic data, while E records the terminal real-facing seal obtained from the same finite route.

Finally H and C preserve the route under transport and replay, and P, N record provenance and local naming. Since no row stores countable choice, an infinite sequence, quotient real equality, ambient completeness, or an unlisted witness, the NameCert surface cannot export any of those objects. □

Theorem 3731.3 (Sequential Cauchy selector finite-window determinacy)**.** *Every consumer of an accepted* $\mathsf{SequentialCauchySelector}^{\uparrow}$ *packet reads each selected Cauchy answer through the finite*

route

$$Q, I \longmapsto M \longmapsto W \longmapsto R, D \longmapsto E \longmapsto H, C, P, N.$$

Consequently two accepted reads agreeing on $Q, M, I, W, R, D, E, H, C, P, N$ determine the same finite selected windows, the same regular rational readback rows, the same dyadic tolerance ledgers, and the same terminal real-seal rows for the listed requests.

Proof. Fix an accepted carrier and a listed request. The index ledger I identifies the request row in Q, and the modulus schedule M fixes the precision and finite window budget attached to that row.

The selected window row W is read only after those rows have been fixed. Thus any second accepted read agreeing on Q, M, I, W reaches the same finite stream windows.

The rows R and D are readbacks from those windows, and the seal row E is exposed only after the same readback and tolerance data. Agreement on R, D, E therefore fixes the regular rational, dyadic, and real-facing coordinates for the listed request.

Transport, replay, provenance, and naming do not add fresh selector data. The rows H, C, P, N preserve and certify the same finite route, so determinacy is exactly the equality of the displayed packet rows. □

Theorem 3731.4 (Sequential Cauchy selector choice-boundary nonescape)**.** *Every read from an accepted* $\mathsf{SequentialCauchySelector}^{\uparrow}$ *packet into* $\mathsf{CauchySelectionFunction}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*,* $\mathsf{LocatedChoiceSequence}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *factors through the finite rows $Q, M, I, W, R, D, E, H, C, P, N$. The read may reuse the listed finite selections, but it cannot produce a countable-choice functional, an infinite choice sequence, quotient real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or selector rows for requests absent from Q.*

Proof. Start with the factorization route in Definition 3731.3. Every consumer sees the request, index, modulus, stream-window, readback, tolerance, and seal rows before it can inspect the structural rows.

The single-request surface of $\mathsf{CauchySelectionFunction}^{\uparrow}$ is therefore available only for the finitely listed requests. The $\mathsf{ChoiceSequence}^{\uparrow}$ and $\mathsf{LocatedChoiceSequence}^{\uparrow}$ chapters can read those displayed rows as finite sequence data, but no row supplies a law assigning witnesses to all future requests.

The regular rational, dyadic, and real-facing consumers likewise receive only R, D, E as finite downstream rows. These rows certify the listed readbacks and seals, not quotient equality of completed reals or ambient completeness.

Thus the packet remains inside its displayed BHist carrier. Any claimed countable-choice functional, infinite choice sequence, unlisted selector row, quotient real equality, or real-completeness theorem would require a coordinate absent from $Q, M, I, W, R, D, E, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCauchySelector}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCauchySelector}^{\uparrow}$ packet is generated from a finite request ledger, modulus schedule, index ledger, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCauchySelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3731.1, Definition 3731.2, Definition 3731.3, and Definition 3731.4 seed the finite sequential selector boundary over request, modulus, window, readback, tolerance, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCauchySelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, an infinite choice sequence, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, selector rows outside the finite request ledger, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request-index exactness, modulus-window compatibility, readback and seal stability, and boundary-refusal proofs for BEDC.Derived.SequentialCauchySelectorUp.

Chapter 3732

A Concrete Naming Certificate for HyperbolicBusemannBoundary$^{\uparrow}$

The HyperbolicBusemannBoundary$^{\uparrow}$ packet realizes the boundary-fixed disk transport and horocycle reading of Definition 9463.10 as finite Busemann-level boundary data. It sits after the metric-read surface of chapter 3474, the horocycle packet of chapter 3534, the boundary-fixed transport route of chapter 3500, the disk phase-transport packet of chapter 3455, and the Denjoy-Wolff boundary-dynamics packet of chapter 3575. The chapter names a finite boundary metric and horocycle ledger; it does not turn the ideal boundary into a quotient compactification, select a global geodesic representative, or identify boundary dynamics with a host analytic fixed-point theorem.

Definition 3732.1 (Hyperbolic Busemann boundary carrier)**.** *A* HyperbolicBusemannBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, M, O, T, R, B, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* PoincareDiskPhaseTransport$^{\uparrow}$ *disk-phase row exposing the finite source, target, and reversible disk-coordinate route.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row over the same displayed disk observations.*
3. *O is the* HyperbolicHorocycle$^{\uparrow}$ *horocycle row, recording the boundary-tangent horocycle read used by the packet.*
4. *T is the* PoincareBoundaryFixedTransport$^{\uparrow}$ *row, requiring the displayed boundary end to remain fixed during the disk transport.*
5. *R is the* DenjoyWolffBoundaryDynamics$^{\uparrow}$ *boundary-dynamics row consumed only as displayed finite boundary-dynamics data.*
6. *B is the Busemann-level row, recording the finite distance-difference read against the fixed boundary end.*
7. *L is the boundary-horocycle ledger, pairing the Busemann-level row with the horocycle row and the boundary-fixed transport audit.*
8. *H records componentwise* hsame *transport for disk phase, metric, horocycle, boundary-fixed transport, boundary dynamics, Busemann-level, ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through disk phase, hyperbolic metric, horocycle read, boundary-fixed transport, boundary dynamics, Busemann-level comparison, and boundary-horocycle ledger exposure.*

10. *P records* Pkg *provenance over* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{DenjoyWolffBoundaryDynamics}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted boundary packets only through $D, M, O, T, R, B, L, H, C, P, N$. It has no coordinate for quotient ideal-boundary equality, a selected geodesic representative, a host compactification, or an analytic fixed-point theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.HyperbolicBusemannBoundaryUp.HyperbolicBusemannBoundaryTasteGate single carrier alignment`

Theorem 3732.2 (Hyperbolic Busemann boundary NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *carrier*

$$G = (D, M, O, T, R, B, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannBoundary}^{\uparrow}}$ *surface consists exactly of disk-phase admission, hyperbolic-metric read compatibility, horocycle read exposure, boundary-fixed transport, boundary-dynamics provenance, Busemann-level distance-difference reading, boundary-horocycle ledger exactness, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

The Lean follow-up for this packet must provide `Nontrivial` *and* `FieldFaithful` *instances in* `lean4/BEDC/Derived/HyperbolicBusemannBoundaryUp/TasteGate.lean`*; the paper packet itself records only the finite NameCert obligation surface.*

Theorem 3732.3 (Hyperbolic Busemann horocycle route)**.** *Every accepted* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary read factors through*

$\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, DenjoyW

before the Busemann-level row and boundary-horocycle ledger are exposed. A consumer that bypasses the metric read, horocycle read, boundary-fixed transport, provenance, or local NameCert *row is outside the accepted packet.*

Falsifiable prediction: Any accepted boundary consumer omitting $\mathsf{HyperbolicMetric}^{\uparrow}$, horocycle, boundary-fixed transport, provenance, or local NameCert rows refutes the $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ packet.

Independence witness: `hyperbolic_metric`, `hyperbolic_horocycle`, `poincare_boundary_fixed_transport` `poincare_disk_phase_transport`, `denjoy_wolff_boundary_dynamics`: none is bijective to HyperbolicBusemannB because the packet adds the Busemann-level row and the boundary-horocycle ledger tying metric, horocycle, fixed-boundary transport, boundary dynamics, provenance, replay, and local naming into one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ packet is generated from disk-phase transport rows, HyperbolicMetric reads, HyperbolicHorocycle rows, boundary-fixed transport, Denjoy-Wolff boundary-dynamics rows, a Busemann-level distance-difference row, a boundary-horocycle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{HyperbolicBusemannBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 3732.1, Definition 3732.2, and Definition 3732.3 seed the finite boundary metric, horocycle, fixed-transport, Busemann-level, ledger, provenance, replay, and local naming surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{HyperbolicBusemannBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient ideal-boundary equality, selected geodesic representatives, host compactifications, analytic fixed-point theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-phase admission, metric-read compatibility, horocycle exposure, boundary-fixed transport, Busemann-level reading, boundary-horocycle ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicBusemannBoundaryUp.

The BooleanAlgebra$^{\uparrow}$ hub routes its finite join, meet, complement, endpoint, order, transport, replay, provenance, and local naming rows to the lattice and Stone-duality consumers of chapter 55 and chapter 261.

Chapter 3733

A Concrete Naming Certificate for $\mathsf{BooleanAlgebra}^{\uparrow}$

Following Stone and Birkhoff, the $\mathsf{BooleanAlgebra}^{\uparrow}$ packet records the finite algebraic endpoint where complemented distributive lattice operations meet two-element truth rows. It sits beside the order carrier of chapter 53, the meet–join interface of chapter 55, and the endpoint discriminator of chapter 32; it supplies a finite order-algebra neighbour for later Stone-duality and topology bridges without assuming a host Boolean algebra. The packet consumes the finite meet/join order rows of chapter 55 and the endpoint discriminator of chapter 32 before the Stone-duality handoff of chapter 261. Its complemented distributive-lattice rows require the meet and join witnesses, the order comparison, and the complement-to-zero and complement-to-one endpoint checks before they can serve as the algebraic input exported to chapter 261. Before any local Boolean-algebra NameCert row is accepted, the packet must display the $\mathsf{Bool}^{\uparrow}$ truth-value rows of chapter 32 and the $\mathsf{Lattice}^{\uparrow}$ meet, join, and complement-stability rows of chapter 55; the Boolean classifier then reads endpoints and operations only through those sibling certificates. The finite complemented distributive-lattice rows are the algebraic input later consumed by chapter 261, while this chapter itself does not construct the Stone space, ultrafilters, or topology. The same rows also serve topology-facing consumers: when a displayed open-set regularization route is read as Boolean meet, join, and complement, the consumer must first expose the finite complemented distributive-lattice packet here, then pass through the indexed-open surface of chapter 88 and the clopen ledger of chapter 261. Thus regular-open and clopen uses receive the same algebraic rows, not a second host Boolean algebra or a powerset representation.

Definition 3733.1 (BooleanAlgebra BHist carrier)**.** *A* $\mathsf{BooleanAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (J, M, K, Z, O, R, H, C, P, N)$$

with the following displayed rows:

1. *J is the binary join row, read as the finite least-upper-bound operation inherited from the lattice-facing surface.*
2. *M is the binary meet row, read as the finite greatest-lower-bound operation inherited from the lattice-facing surface.*
3. *K is the complement row, assigning to each displayed carrier element its finite complement witness.*
4. *Z is the zero row, the finite bottom endpoint of the order surface.*

5. *O is the one row, the finite top endpoint of the order surface.*
6. *R is the partial-order row tying J, M, Z, O to the displayed* $\mathsf{Poset}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *obligations.*
7. *H records componentwise* hsame *transport for join, meet, complement, endpoint, order, provenance, and local naming rows.*
8. *C records displayed* Cont *replay routes by which a consumer reads the operation, endpoint, order, transport, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{Bool}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BooleanAlgebra}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host powerset algebra, excluded-middle oracle, ultrafilter space, locale of opens, quotient lattice, or ambient topological representation.

Lean4 (definition) `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier`

Theorem 3733.2 (BooleanAlgebra NameCert obligation surface)**.** *For the carrier of Definition 3733.1, the local* $\mathsf{NameCert}_{\mathsf{BooleanAlgebra}^{\uparrow}}$ *surface consists of exactly five finite obligation rows: carrier exposure for $J, M, K, Z, O, R, H, C, P, N$; lattice-order compatibility with the* $\mathsf{Poset}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *rows; complement endpoint exactness, requiring $x \wedge Kx$ to read through Z and $x \vee Kx$ to read through O inside the displayed route; endpoint transport under componentwise* hsame *and displayed* Cont *replay; and non-escape from host Boolean algebras, powersets, ultrafilter spaces, locale carriers, quotient lattices, and topological representation theorems.*

Proof. Project the accepted carrier. The rows $J, M, K, Z, O, R, H, C, P, N$ are the complete visible inventory, with R carrying the order comparison and P naming the Bool, Poset, and Lattice sources.

Apply the sibling order surfaces. The poset row supplies the comparison route, while the lattice row supplies the meet and join readings; the Bool row supplies only finite endpoint discrimination, not an external truth oracle.

The complement row is checked against the displayed endpoints. The meet-with-complement route lands at Z, the join-with-complement route lands at O, and both reads are transported only by H and replayed only by C.

Since no row names a powerset algebra, ultrafilter space, locale carrier, quotient lattice, or ambient topology, coordinate exhaustion gives the stated non-escape boundary for the local naming certificate. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier namecert obligation surface`

Theorem 3733.3 (BooleanAlgebra Stone-duality forward route)**.** *Every* $\mathsf{StoneDuality}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BooleanAlgebra}^{\uparrow}$ *packet must read the finite join row J, meet row M, complement row K, zero row Z, one row O, order row R, componentwise* hsame *row H, displayed* Cont *replay row C,* Pkg *provenance row P, and local* NameCert *row N before any Stone-space, ultrafilter, clopen-ledger, or topology bridge is public. Thus the Stone-duality source of chapter 261 starts from the displayed Boolean-algebra rows rather than from a host Boolean algebra or ambient Stone representation theorem.*

Proof. Project the accepted Boolean-algebra carrier. The rows $J, M, K, Z, O, R, H, C, P, N$ are the complete operation, endpoint, order, transport, replay, provenance, and naming inventory.

Apply the NameCert obligation surface. It requires the join, meet, complement, zero, one, and order rows to be displayed and transported before any downstream consumer can treat the packet as a Boolean-algebra source.

The Stone-duality chapter consumes exactly such a source row before it constructs clopen or topology-facing ledgers. Since the Boolean-algebra carrier contains no powerset algebra, ultrafilter space, locale carrier, quotient lattice, or ambient topology coordinate, no Stone-space or topology bridge can be public before these displayed rows are read. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier stone duality forward route`

Theorem 3733.4 (BooleanAlgebra Stone-source lattice determinacy)**.** *Any* StoneDuality$^{\uparrow}$ *consumer reading an accepted* BooleanAlgebra$^{\uparrow}$ *source receives the same finite join row J, meet row M, complement row K, zero row Z, one row O, order row R, componentwise* hsame *row H, displayed* Cont *replay row C,* Pkg *provenance row P, and local* NameCert *row N from the carrier of Definition 3733.1. The endpoint discriminator is the* Bool$^{\uparrow}$ *row named by P, while the meet/join order is read through the* Poset$^{\uparrow}$ *and* Lattice$^{\uparrow}$ *rows also named by P.*

Thus two Stone-duality consumers that agree on the accepted Boolean-algebra packet cannot diverge by choosing different host Boolean algebras, powerset representations, ultrafilter spaces, locale carriers, quotient lattices, or topology bridges before those displayed rows have been read.

Proof. Project the accepted carrier. The inventory $J, M, K, Z, O, R, H, C, P, N$ is exactly the finite operation, endpoint, order, transport, replay, provenance, and naming surface exposed by Definition 3733.1.

Apply Definition 3733.2. It forces the complement endpoint reads to pass through Z and O, and it forces the order comparison to be the displayed Poset$^{\uparrow}$/Lattice$^{\uparrow}$ route recorded by R and named by P.

Now use Definition 3733.3. Every StoneDuality$^{\uparrow}$-facing read starts from those Boolean-algebra rows before any Stone-space or topology-facing ledger is public. Since the carrier has no coordinate for a host Boolean algebra or alternate representation, the source boundary is deterministic. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier stone source lattice determinacy`

Closure status for NameCert$_{\text{BooleanAlgebra}^{\uparrow}}$.

Constructive story: A BooleanAlgebra$^{\uparrow}$ packet is generated from finite join, meet, complement, zero, one, order, componentwise hsame transport, displayed Cont replay, provenance, and local NameCert rows, with Bool, Poset, and Lattice sources read only through their displayed NameCert surfaces.

Theory closure: TheoryGate(NameCert$_{\text{BooleanAlgebra}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 3733.2, Definition 3733.3, Definition 3733.4, Definition 3733.7, Definition 3733.8, and Definition 3733.10 bind the mature finite Bool, Poset, Lattice, Stone-source, and RegularOpenAlgebra route for Boolean algebra packets through the displayed finite order and algebra rows.

Formal verification: FormalStatus(NameCert$_{\text{BooleanAlgebra}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close Stone duality, Heyting algebra, locale theory, frame theory, ultrafilter construction, quotient Boolean algebra equality, host powerset semantics, or a Lean theorem.

Upgrade path: Lean verification requires checked carrier habitation, order-lattice compatibility, complement endpoint exactness, transport replay, and non-escape for the same finite packet.

Theorem 3733.5 (BooleanAlgebra dossier lattice route)**.** *Every top-level* BooleanAlgebra$^{\uparrow}$ *dossier read first consumes the* Bool$^{\uparrow}$ *endpoint rows and the* Lattice$^{\uparrow}$ *meet, join, and complement rows of the local carrier before it is available as a Boolean source for* StoneDuality$^{\uparrow}$*. The route adds no Stone space, ultrafilter, powerset representation, quotient lattice, or host Boolean-algebra equality row.*

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraDossierLatticeRoute`

Proof. Project the carrier surface of chapter 3733. The endpoint coordinates are the displayed zero and one rows inherited from $\mathsf{Bool}^{\uparrow}$, while the algebraic coordinates are the meet, join, complement, and order rows inherited through the $\mathsf{Lattice}^{\uparrow}$ dependency route.

The Stone-duality handoff can read a Boolean source only after those local Boolean-algebra rows have been exposed. Since the dossier has no coordinate for Stone spaces, ultrafilters, powerset representatives, quotient lattices, or host equality, the outgoing route remains the existing Bool–Lattice–Stone dependency surface. □

The $\mathsf{BooleanAlgebra}^{\uparrow}$ dependency route consumes the $\mathsf{Bool}^{\uparrow}$ endpoint rows of chapter 32 together with the $\mathsf{Lattice}^{\uparrow}$ meet, join, and complement-facing lattice rows of chapter 55 before any $\mathsf{StoneDuality}^{\uparrow}$ handoff in chapter 261 is public.

Theorem 3733.6 (Boolean algebra lattice dependency route)**.** *Every accepted* $\mathsf{BooleanAlgebra}^{\uparrow}$ *read exposes the finite meet, join, complement, endpoint, order, transport, replay, provenance, and local naming rows before any* $\mathsf{Lattice}^{\uparrow}$ *or* $\mathsf{StoneDuality}^{\uparrow}$ *consumer can use the packet. The lattice consumer of chapter 55 reads the meet and join rows together with the complement and endpoint rows as displayed Boolean data, while the Stone-duality consumer of chapter 261 receives the same rows only after that finite lattice surface has been made visible.*

Proof. Project the $\mathsf{BooleanAlgebra}^{\uparrow}$ carrier rows used by the existing lattice and Stone routes. The meet and join rows are already displayed before the complement and endpoint rows can be consumed, and the structural rows only transport and replay that finite packet.

Thus a $\mathsf{Lattice}^{\uparrow}$ consumer reads the lattice part directly from the Boolean carrier. A $\mathsf{StoneDuality}^{\uparrow}$ consumer then uses the same Boolean-source rows as its input side, but no host Boolean algebra, powerset representation, or ambient topology is introduced between the two reads. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraLatticeDependencyRoute`

The $\mathsf{BooleanAlgebra}^{\uparrow}$ carrier consumes the finite meet, join, order, complement, and endpoint rows of chapter 55 before the Boolean source is read by chapter 261. Thus a $\mathsf{StoneDuality}^{\uparrow}$ handoff sees the same displayed $\mathsf{Lattice}^{\uparrow}$ dependency surface already present in the Boolean packet, rather than a host powerset algebra, quotient lattice, ultrafilter selection, or ambient topology.

Theorem 3733.7 (BooleanAlgebra obligation closure package)**.** *The accepted* $\mathsf{BooleanAlgebra}^{\uparrow}$ *packet has an obligation-closure package over the displayed rows*

$$J, M, K, Z, O, R, H, C, P, N.$$

Carrier admission is the finite BHist *surface of Definition 3733.1; complement stability is the pair of endpoint reads* $x \wedge Kx$ *through* Z *and* $x \vee Kx$ *through* O *from Definition 3733.2; finite meet and join laws are consumed through the* $\mathsf{Lattice}^{\uparrow}$ *route of Definition 3733.6; and the Stone-source dependency is exported through Definition 3733.3 and Definition 3733.4. Thus the obligation package contains exactly carrier admission, complement stability, finite meet/join laws, Stone-source route, lattice dependency rows, transport, replay, provenance, and local naming, and no host powerset algebra, ultrafilter selector, quotient lattice, locale carrier, or ambient topology row.*

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier obligation closure package`

Proof. Project the carrier from Definition 3733.1. The rows $J, M, K, Z, O, R, H, C, P, N$ are the complete finite inventory available to a Boolean-algebra consumer.

Use Definition 3733.2 for carrier admission and complement stability. It forces the complement row K to meet the zero endpoint Z and join the one endpoint O inside the displayed route, with transport and replay still attached.

Use Definition 3733.6 for the finite meet and join laws. The lattice dependency reads J and M together with complement, endpoint, order, transport, replay, provenance, and local naming rows before any lattice or Stone-duality consumer can use the packet.

Finally apply Definition 3733.3 and Definition 3733.4. They identify the Stone-source route with the same Boolean rows and prevent divergence through host Boolean algebras, powerset representations, ultrafilter spaces, quotient lattices, locale carriers, or topology bridges. These cited rows are exactly the obligation-closure package. □

Theorem 3733.8 (BooleanAlgebra public NameCert export)**.** *The finite* $\mathsf{BooleanAlgebra}^{\uparrow}$ *NameCert surface exported from Definition 3733.1 is public for* $\mathsf{StoneDuality}^{\uparrow}$ *and* $\mathsf{RegularOpenAlgebra}^{\uparrow}$ *consumers. A public read keeps the* $\mathsf{Bool}^{\uparrow}$ *endpoint rows,* $\mathsf{Poset}^{\uparrow}$ *order row,* $\mathsf{Lattice}^{\uparrow}$ *join and meet rows, complement row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row visible before either downstream consumer may treat the packet as a Boolean source.*

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier public namecert export`

Proof. Project the accepted carrier $B = (J, M, K, Z, O, R, H, C, P, N)$. The rows Z and O are the visible $\mathsf{Bool}^{\uparrow}$ endpoints, R is the $\mathsf{Poset}^{\uparrow}$ order route, and J, M, K are the $\mathsf{Lattice}^{\uparrow}$ join, meet, and complement-facing rows.

Use the local obligation surface and the obligation package. They bind complement endpoint exactness, order-lattice compatibility, transport, replay, provenance, and local naming to the same finite packet, so the public export cannot drop H, C, P, N while retaining a Boolean source.

The outgoing consumers read this same surface in two directions. $\mathsf{StoneDuality}^{\uparrow}$ consumes it as the Boolean-source side of Stone duality, while $\mathsf{RegularOpenAlgebra}^{\uparrow}$ consumes it as the algebraic surface behind regular-open meet, join, and complement. No host Boolean algebra, powerset representation, selected ultrafilter, quotient lattice, locale carrier, or ambient topology row is exported. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraPublicNameCertExport`

The $\mathsf{RegularOpenAlgebra}^{\uparrow}$ consumer of chapter 6835 reads the $\mathsf{BooleanAlgebra}^{\uparrow}$ join, meet, complement, endpoint, order, transport, replay, provenance, and local NameCert rows through topology-facing regularization. The read starts from the finite Boolean-algebra carrier of Definition 3733.1, passes through the regular-open closure and interior rows, and exports no second host Boolean algebra, powerset representation, quotient lattice, or detached topology carrier.

Theorem 3733.9 (BooleanAlgebra Stone-duality handoff)**.** *Every* $\mathsf{StoneDuality}^{\uparrow}$*-facing read of an accepted* $\mathsf{BooleanAlgebra}^{\uparrow}$ *packet first consumes the finite join row* J*, meet row* M*, complement row* K*, endpoint rows* Z, O*, order row* R*, componentwise transport row* H*, replay row* C*, provenance row* P*, and local* NameCert *row* N *of chapter 3733. Only after those rows are exposed may the consumer reach the Boolean-source side of chapter 261.*

The handoff is additive to the local Boolean-algebra carrier: it exports a concrete outgoing dependency edge to $\mathsf{StoneDuality}^{\uparrow}$ *while adding no Stone space, ultrafilter, clopen topology, powerset representation, quotient lattice, or host Boolean-algebra equality row.*

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraStoneDualityHandoff`

Proof. Project the accepted Boolean-algebra carrier from Definition 3733.1. Its visible operation and endpoint surface is exactly J, M, K, Z, O, R, with H, C, P, N carrying transport, replay, provenance, and local naming.

Apply Definition 3733.2. The local certificate requires the operation rows, endpoint exactness rows, and order compatibility rows to be displayed before any downstream packet can treat the carrier as a Boolean source.

The Stone-duality source of chapter 261 consumes a Boolean-algebra source before clopen or topology-facing rows appear. Therefore the Stone-duality-facing read must pass through the BooleanAlgebra rows first, and no absent Stone-space, ultrafilter, clopen-topology, powerset, quotient-lattice, or host-equality coordinate can be exported. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraCarrier stone duality handoff`

The $\mathsf{BooleanAlgebra}^{\uparrow}$ carrier exposes the join, meet, complement, endpoint, order, transport, replay, provenance, and local $\mathsf{NameCert}$ rows that a $\mathsf{StoneDuality}^{\uparrow}$ consumer later reads as its Boolean-source side. Thus the dependency into chapter 261 and the lattice-source handoff of chapter 55 is a finite classifier route through $J, M, K, Z, O, R, H, C, P, N$, not a hidden import of a host Boolean algebra, ultrafilter space, powerset representation, or ambient topology.

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraStoneSourceLatticeForwardConsumer`

The same outgoing route also records the handoff row: after the Stone-source row is read from order and local naming, the provenance row transports it to the concrete downstream handoff row while the forward Stone-source certificate remains available to the same consumer.

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraStoneHandoffForwardConsumer`

The $\mathsf{BooleanAlgebra}^{\uparrow}$ carrier supplies the complemented distributive-lattice source read by chapter 261 and the Boolean endpoint discipline read by chapter 5153. The horizontal route is the same finite join, meet, complement, endpoint, order, transport, replay, provenance, and local $\mathsf{NameCert}$ surface; it does not add a host powerset algebra, selected ultrafilter, ambient locale frame, quotient lattice equality, or topology object outside the displayed Boolean rows.

Theorem 3733.10 (Boolean algebra mature export)**.** *The finite* $\mathsf{BooleanAlgebra}^{\uparrow}$ *rows routed through this hub provide the mature export consumed by the* $\mathsf{Lattice}^{\uparrow}$ *and* $\mathsf{StoneDuality}^{\uparrow}$ *sibling routes. The export consists exactly of the join row* J*, meet row* M*, complement row* K*, endpoint rows* Z, O*, order row* R*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}$ *row* N *of Definition 3733.1. It is the same packet exposed by the lattice dependency route, the Stone-duality handoff, the regular-open forward lattice route, the obligation closure package, and the public NameCert export.*

Proof. Project the carrier of Definition 3733.1. The rows $J, M, K, Z, O, R, H, C, P, N$ are the full finite Boolean-algebra inventory, so every export to a lattice or Stone-facing consumer must use those rows.

Apply Definition 3733.6. It makes the meet and join rows visible together with complement, endpoint, order, transport, replay, provenance, and local naming before any $\mathsf{Lattice}^{\uparrow}$ consumer uses the packet.

Apply Definition 3733.9 and Definition 3733.8. They send the same finite packet to $\mathsf{StoneDuality}^{\uparrow}$ and regular-open consumers after the public obligation surface has been exposed.

Finally use Definition 3733.7. It identifies carrier admission, complement endpoint exactness, finite meet and join laws, Stone-source routing, transport, replay, provenance, and naming as one package. Thus the mature export has no coordinate for a second host Boolean algebra, powerset

representation, selected ultrafilter, quotient lattice equality, detached locale frame, or ambient topology. □

Lean4 ✓ `BEDC.Derived.BooleanalgebraUp.BooleanAlgebraMatureExport`

Chapter 3734

A Concrete Naming Certificate for $\mathsf{CoverageRankAlgebra}^{\uparrow}$

The $\mathsf{CoverageRankAlgebra}^{\uparrow}$ packet realizes the coverage-rank algebra of Definition 9462.1576 as finite BEDC NameCert data. It consumes the six-boundary tile coverage route of chapter 3470, the Boolean trigger lattice of chapter 3704, the window coverage-trigger algebra of chapter 3478, and the finite observation fold of chapter 2236. The packet binds boundary-tile coverage, rank, trigger support, classifier stability, replay, provenance, and local naming rows; it is not a biological code oracle, stochastic transition model, quotient codon space, hidden global support lattice, or infinite trigger search.

Definition 3734.1 (Coverage-rank algebra carrier)**.** *A* $\mathsf{CoverageRankAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, R, T, L, F, Q, H, C, P, N)$$

with the following displayed rows:

1. *B is the consumed* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *row exposing the six boundary-tile coverage coordinates and their visible support faces.*
2. *R is the rank row, recording the finite support-union rank read from the coverage-rank algebra vision.*
3. *T is the boundary-trigger support row, carrying the visible trigger support whose equality or inequality is tested by the classifier.*
4. *L is the consumed* $\mathsf{BooleanTriggerLattice}^{\uparrow}$ *row naming Boolean meet, join, and support-rank comparisons over the same visible boundary supports.*
5. *F is the consumed* $\mathsf{FiniteObservationFold}^{\uparrow}$ *row that bounds every algebra read by a displayed finite observation fold and its omitted-tail ledger.*
6. *Q is the consumed* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *row, carrying the finite closure, blocker, threshold, and residue-facing algebra rows used by downstream trigger consumers.*
7. *H records componentwise* hsame *transport for coverage, rank, trigger support, Boolean lattice, finite fold, trigger algebra, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-trigger coverage request through B, R, T, L, F, Q, H.*

9. *P is the* Pkg *provenance over* $\mathsf{CoverageRankAlgebra}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{BooleanTriggerLattice}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{FiniteObservationFold}^{\uparrow}$, *the source vision of Definition 9462.1576,* BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CoverageRankAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, T, L, F, Q, H, C, P, N$. It has no coordinate for hidden biological semantics, stochastic dynamics, quotient codon equality, global support completion, host rank lattices, or infinite trigger enumeration.

Theorem 3734.2 (Coverage-rank algebra NameCert obligations)**.** *For every accepted* $\mathsf{CoverageRankAlgebra}^{\uparrow}$ *carrier $K = (B, R, T, L, F, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CoverageRankAlgebra}^{\uparrow}}$ *surface consists exactly of boundary-tile coverage through B, rank exposure through R, boundary-trigger support through T, Boolean trigger-lattice comparison through L, finite observation folding through F, coverage-trigger algebra handoff through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

The proposed Lean follow-up for `BEDC.Derived.CoverageRankAlgebraUp` *must provide explicit* Nontrivial $\mathsf{CoverageRankAlgebra}^{\uparrow}$ *and* FieldFaithful $\mathsf{CoverageRankAlgebra}^{\uparrow}$ *instances preserving $B, R, T, L, F, Q, H, C, P, N$ as separate displayed fields.*

Proof. Project the carrier of Definition 3734.1. The rows B, R, T, L, F, Q expose boundary-tile coverage, rank, trigger support, Boolean comparison, finite observation folding, and trigger-algebra handoff before any algebra consumer can read a coverage-rank conclusion.

The classifier is rank-sensitive but support-visible. Equal-rank reads are admitted only through the displayed trigger support row T and the Boolean comparison row L, so a consumer cannot collapse unequal boundary-trigger supports into one stable classifier row.

The finite observation fold F bounds every read, and Q supplies only the already displayed coverage-trigger algebra route. The rows H, C, P, N preserve, replay, source, and name this finite route, leaving hidden biological semantics, stochastic dynamics, quotient codon equality, global support completion, host rank lattices, and infinite trigger enumeration outside the carrier. □

Theorem 3734.3 (Coverage-rank boundary-trigger separation)**.** *Let $K = (B, R, T, L, F, Q, H, C, P, N)$ and $K' = (B', R', T', L', F', Q', H', C', P', N')$ be accepted* $\mathsf{CoverageRankAlgebra}^{\uparrow}$ *packets. If the rank rows R and R' display the same finite rank but the boundary-trigger support rows T and T' expose different support, then a classifier-stable identification of K and K' is refused unless it also supplies a displayed transport row through L, L', F, F', Q, Q' preserving the unequal support evidence. Thus equal rank alone never determines equality of the coverage-rank algebra packet.*

Lean4 ✓ `BEDC.Derived.CoverageRankAlgebraUp.CoverageRankAlgebraBoundaryTriggerSeparation`

Proof. Read the two carriers. The rank rows R, R' and trigger-support rows T, T' are separate coordinates, so equality of rank does not erase the displayed support data.

The Boolean lattice and finite-fold rows L, L', F, F' are the only rows that compare support and bound the observation. A classifier-stable identification must therefore preserve these rows before the trigger-algebra handoff can be read.

Finally $Q, Q', H, H', C, C', P, P', N, N'$ replay and name the same finite route. Since no host rank lattice or hidden global support completion is a carrier coordinate, equal rank with unequal boundary-trigger support remains separated at the packet boundary. □

Falsifiable prediction: Any accepted $\mathsf{CoverageRankAlgebra}^{\uparrow}$ packet that identifies equal rank with unequal boundary-trigger support without displaying the Boolean trigger-lattice, finite observation fold, coverage-trigger algebra, transport, replay, provenance, and local naming rows violates classifier stability.

Independence witness: six-boundary-tile-coverage, boolean-trigger-lattice, window-coverage-trigger-algebra, finite-observation-fold: $\mathsf{CoverageRankAlgebra}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries boundary-tile coverage, rank, boundary-trigger support, Boolean comparison, finite observation fold, coverage-trigger algebra handoff, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CoverageRankAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{CoverageRankAlgebra}^{\uparrow}$ packet is generated from six-boundary tile coverage rows, rank rows, boundary-trigger support rows, Boolean trigger-lattice comparison rows, finite observation fold rows, coverage-trigger algebra rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoverageRankAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3734.1, Definition 3734.2, and Definition 3734.3 seed the finite coverage-rank algebra packet over boundary-tile coverage, rank, trigger support, classifier, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoverageRankAlgebra}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CoverageRankAlgebraUp.CoverageRankAlgebraBoundaryTriggerSeparation`

Bridge status: none

Not claimed: This chapter does not close biological-code truth, stochastic transition laws, quotient codon equality, hidden global support lattices, host rank lattices, infinite trigger search, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rank exposure, boundary-trigger separation, classifier stability, Nontrivial CoverageRankAlgebraUp, and FieldFaithful CoverageRankAlgebraUp for BEDC.Derived.CoverageRankAlgebraUp.

Chapter 3735

A Concrete Naming Certificate for $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ packet records the finite boundary where an ordered Cauchy sequence can be read as a completion-facing real-order object without quotient equality, selected limits, or an ambient completeness primitive. It sits over the ordered sequence route of chapter 3636, the algebra route of chapter 3708, the regular rational handoff of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the complete-metric boundary of chapter 128. The packet names the ordered Cauchy completion boundary as displayed BEDC data; it is not a quotient completion, not a selected representative, and not a host real-order completeness theorem.

Definition 3735.1 (Cauchy sequence order completeness carrier)**.** *A* $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, A, R, S, D, E, M, H, C, P, N)$$

with the following displayed rows:

1. *O is the* ***??*** *row, carrying the finite order-comparison requests and monotone-tail witnesses available to the completion boundary.*
2. *A is the* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *row, carrying the finite algebraic closure operations used by the same tail windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the ordered algebraic Cauchy sequence data.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the inspected sequence entries and comparison windows are read.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, split tolerances, and comparison budgets used by O, A, R, S.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback and dyadic ledger have been displayed.*
7. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row, recording the finite completion-facing metric handoff visible to consumers after O, A, R, S, D, E.*

8. *H stores componentwise* hsame *transport for the order, algebra, regular readback, stream window, dyadic ledger, real seal, complete-metric boundary, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from ordered Cauchy requests through algebraic closure, stream windows, regular rational readback, dyadic comparison, real sealing, and the complete-metric handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$, *??*, $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $O, A, R, S, D, E, M, H, C, P, N$. It contains no coordinate for quotient completion equality, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a bridge-checked standard completion object.*

Theorem 3735.2 (Cauchy sequence order completeness NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ *carrier $K = (O, A, R, S, D, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed order, algebra, regular readback, stream-window, dyadic tolerance, real-seal, complete-metric boundary, transport, replay, provenance, and local naming rows;*
2. *order-algebra compatibility, requiring every completion-facing order comparison to read the same ?? row O and* $\mathsf{CauchySequenceAlgebra}^{\uparrow}$ *row A before any regular rational readback is exposed;*
3. *regular-name handoff, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to be generated from the displayed stream windows S and dyadic tolerance ledger D;*
4. *real-seal and metric-boundary exposure, requiring the* $\mathsf{Real}^{\uparrow}$ *row E and* $\mathsf{CompleteMetric}^{\uparrow}$ *row M to appear only after O, A, R, S, D have been transported through H and replayed through C;*
5. *ledger nonescape, excluding quotient completion equality, selected representatives, countable choice, host real equality, ambient real completeness, and bridge checking from the local carrier.*

Proof. Project the carrier of Definition 3735.1. The accepted inventory is exactly $O, A, R, S, D, E, M, H, C, P, N$, so carrier admission and classifier comparison are finite.

The order and algebra rows are read together. A completion-facing order request cannot inspect the regular rational row until the displayed order row O, algebra row A, stream windows S, and dyadic comparison ledger D have been exposed.

The real seal and complete-metric boundary are downstream. The row E seals the regular rational readback through $\mathsf{Real}^{\uparrow}$, while M records only the finite completion-facing metric handoff after the same route has been transported and replayed.

Finally inspect the excluded coordinates. Since the carrier has no quotient equality, selected representative, countable-choice, host equality, ambient-completeness, or bridge-checking row, the local NameCert cannot export any of those objects. □

Lean4 ✓ `BEDC.Derived.CauchySequenceOrderCompletenessUp.CauchySequenceOrderCompletenessNamecertObligatio`

Theorem 3735.3 (Cauchy sequence order completeness nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ *carrier must traverse the displayed route*

??, $\mathsf{CauchySequenceAlgebra}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame,

before it can expose an ordered completion boundary. The route exports no quotient completion, no selected limit representative, no countable-choice schedule, no host real equality, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no bridge claim.*

Proof. Begin with an accepted carrier $K = (O, A, R, S, D, E, M, H, C, P, N)$. The only order source is O, and the only algebraic closure source is A; both are upstream of the finite stream windows and regular rational readback.

Read S, R, D next. These rows expose finite observations, regular rational data, and dyadic tolerance budgets before any real or metric boundary can be inspected.

The terminal rows E and M are reached only through the componentwise transports H and displayed replay C. The provenance row P and local naming row N source exactly that route.

Since the carrier inventory has no quotient, selector, choice, host equality, ambient completeness, or bridge coordinate, every ordered completion read remains inside the displayed finite BEDC route. □

Falsifiable prediction: Every $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ completion-facing read factors through displayed CauchySequenceOrder, CauchySequenceAlgebra, StreamName, RegSeqRat, DyadicRatCore, RealUp, CompleteMetric, transport, replay, provenance, and local naming rows before exposing an ordered completion boundary.

Independence witness: cauchy-sequence-order, cauchy-sequence-algebra, regseqrat, streamname, dyadicratcore, real, completemetric: $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries ordered tail comparisons, algebraic Cauchy closure, regular rational readback, finite stream windows, dyadic tolerance rows, a Real seal, and a complete-metric handoff in one finite completion-boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}$ packet is generated from CauchySequenceOrder and CauchySequenceAlgebra rows, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, a CompleteMetric boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3735.1, Definition 3735.2, and Definition 3735.3 seed the finite ordered Cauchy completion boundary over order, algebra, regular rational, stream, dyadic, real, and complete-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceOrderCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, order-algebra compatibility, regular-name handoff, real-seal exposure, complete-metric boundary exposure, and ledger nonescape for BEDC.Derived.CauchySequenceOrderCompletenessUp.

Chapter 3736

A Concrete Naming Certificate for $\mathsf{HilleYosida}^{\uparrow}$

Following Hille and Yosida, the $\mathsf{HilleYosida}^{\uparrow}$ packet records the finite BEDC surface by which a densely read linear generator graph is accepted as strongly continuous contraction-semigroup generator data. It consumes the functional-analytic source of chapter 94, the Banach carrier of chapter 90, the linear graph rows of chapter 48, the norm ledgers of chapter 89, and the complete-metric convergence surface of chapter 128. The packet names the generator and resolvent route used by later evolution equations; it is not a spectral theorem, a PDE solver, a selected semigroup object outside the displayed rows, or a global regularity principle.

Definition 3736.1 (Hille–Yosida carrier)**.** *A* $\mathsf{HilleYosida}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (B, A, R, S, N, H, C, P, L)$$

with the following visible rows:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *source row, recording the ambient vector space, normed structure, and complete state classifier in which generator reads are interpreted.*
2. *A is the linear generator graph row, a* $\mathsf{LinMap}^{\uparrow}$*-facing finite graph with its displayed domain row and graph-compatibility observations.*
3. *R is the positive-parameter resolvent ledger, recording the displayed $\lambda > 0$ requests, resolvent graph rows, domain-return rows, and resolvent identity comparisons used by the generator test.*
4. *S is the contraction semigroup row, recording the finite time-parameter observations, identity-at-zero row, composition replay row, and contraction comparisons visible to a strongly continuous semigroup consumer.*
5. *N is the norm-bound ledger, joining the* $\mathsf{Norm}^{\uparrow}$ *contraction bounds for S and the positive-parameter resolvent bounds for R.*
6. *H records componentwise* hsame *transport for the Banach source, generator graph, resolvent ledger, semigroup row, norm bounds, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from finite positive-parameter and finite time requests through*

$$B, A, R, N \longmapsto S, H, P, L.$$

8. *P is the* Pkg *provenance over* HilleYosida$^{\uparrow}$, FunctionalAnalysis$^{\uparrow}$, Banach$^{\uparrow}$, LinMap$^{\uparrow}$, Norm$^{\uparrow}$, CompleteMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* NameCert$_{\text{HilleYosida}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a chosen global semigroup outside S, a spectral calculus, differentiability beyond the displayed graph, maximal PDE regularity, excluded middle, quotient equality, or choice-selected limits.

Lean4 ✓ `BEDC.Derived.HilleYosidaUp.HilleYosidaTasteGate single carrier alignment`

Theorem 3736.2 (Hille–Yosida NameCert obligations)**.** *For an accepted* HilleYosida$^{\uparrow}$ *carrier*

$$Y = (B, A, R, S, N, H, C, P, L),$$

the local NameCert$_{\text{HilleYosida}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, Banach and functional-analysis source compatibility for B, linear generator graph exposure for A, positive-parameter resolvent accounting for R, contraction semigroup visibility for S, norm-bound accounting for N, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through L.*

Proof. Carrier admission is projection from Definition 3736.1. The accepted packet displays the Banach source, generator graph, resolvent ledger, semigroup row, norm ledger, transport row, replay row, provenance row, and local name.

The analytic obligations are read in the displayed order. The source row B fixes the complete normed state space, the generator row A supplies the linear graph, and the resolvent row R records the positive-parameter reads whose estimates are accounted for by N.

The semigroup-facing obligation is then restricted to S. A consumer may read finite time observations, the identity-at-zero row, composition replay, and contraction comparisons, but it cannot import an additional selected semigroup object.

Finally H, C, P, L transport, replay, source, and name exactly the same route. Since no row stores spectral calculus, maximal PDE regularity, quotient equality, excluded middle, or choice-selected limits, those principles are outside the local certificate surface. □

Lean4 ✓ `BEDC.Derived.HilleYosidaUp.HilleYosidaCarrier namecert obligations`

Theorem 3736.3 (Hille–Yosida semigroup generator handoff)**.** *Every strongly continuous semigroup generator read accepted by a* HilleYosida$^{\uparrow}$ *carrier factors through*

FunctionalAnalysis$^{\uparrow}$, Banach$^{\uparrow}$, LinMap$^{\uparrow}$, Norm$^{\uparrow}$, CompleteMetric$^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

Equivalently, an evolution-equation consumer may inspect the Banach source B, generator graph A, positive-parameter resolvent ledger R, contraction semigroup row S, norm-bound ledger N, and structural rows H, C, P, L, but it cannot bypass them by selecting a global semigroup, invoking spectral calculus, or reading a host completion principle not displayed by the packet.

Lean4 ✓ `BEDC.Derived.HilleYosidaUp.HilleYosidaSemigroupGeneratorHandoff`

Proof. Use Definition 3736.2. It exposes a generator-facing read only after B, A, R, S, N have been projected from the finite carrier.

The resolvent side is controlled by R and N. Positive-parameter requests, domain-return rows, identity comparisons, and norm bounds are visible only as finite ledger entries in those coordinates.

The semigroup side is controlled by S. Strong continuity and contraction information are read as the displayed time-row observations and replay rows, not as an external choice of a completed semigroup.

The structural rows H, C, P, L then preserve the same data under transport, replay, provenance, and local naming. Thus a later ODE or PDE evolution packet receives precisely the finite generator handoff and no stronger global regularity or spectral conclusion. □

Falsifiable prediction: Every $\mathsf{HilleYosida}^{\uparrow}$ generator handoff read factors through one Banach and FunctionalAnalysis source row, one linear generator graph row, one positive-parameter resolvent ledger, one contraction semigroup row, one norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: functionalanalysis, banach, linearmap, norm, completemetric: $\mathsf{HilleYosida}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a generator graph, positive-parameter resolvent ledger, contraction semigroup row, norm-bound ledger, and the transport/replay/provenance rows tying them into a semigroup-generator certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HilleYosida}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilleYosida}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3736.1, Definition 3736.2, and Definition 3736.3 seed the finite generator certificate from Banach and functional-analysis source rows through linear graph, resolvent, semigroup, norm-bound, transport, replay, provenance, and local naming data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilleYosida}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral calculus, maximal PDE regularity, a selected global semigroup outside the displayed row, quotient equality, choice principles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, generator graph exposure, resolvent positive-parameter accounting, contraction semigroup visibility, norm-bound stability, complete-metric convergence visibility, transport stability, replay stability, and ledger non-escape for BEDC.Derived.HilleYosidaUp.

Constructive story: A $\mathsf{HilleYosida}^{\uparrow}$ packet is generated from one Banach and FunctionalAnalysis source row, one LinearMap generator graph, one positive-parameter resolvent ledger, one contraction semigroup row, one Norm ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3737

A Concrete Naming Certificate for $\mathsf{CompactUniformOscillation}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Heine–Cantor finite-net route, the CompactUniformOscillatio packet records the finite data by which compact metric source rows and uniform-modulus rows produce bounded target-distance oscillation witnesses. It consumes the compact metric source of chapter 129, the continuous-map graph of chapter 130, the uniform-modulus ledger of chapter 369, and the target distance surface of chapter 57. The packet is a finite oscillation-bound consumer for compact-uniform-continuity routes; it is not an open-cover compactness principle, a selected supremum, host extensionality of functions, or a global image-compactness theorem.

Definition 3737.1 (Compact uniform oscillation carrier)**.** *A* $\mathsf{CompactUniformOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, F, M, D, W, H, C, P, L)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, recording the compact finite-net observations and metric comparison rows on the source space.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, recording the finite graph evaluations and local continuity reads used by the compact-uniform route.*
3. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger, recording tolerance requests, source-radius responses, and the modulus rows obtained from compact finite nets.*
4. *D is the target-distance row, a* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{RealMetric}^{\uparrow}$ *readback ledger for the distances between displayed output observations.*
5. *W is the finite* ProbeBundle *oscillation-witness row, recording source net points, paired source observations within the modulus radius, and the resulting target-distance bounds.*
6. *H records componentwise* hsame *transport for the compact source, continuous graph, uniform modulus, target-distance ledger, oscillation witnesses, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from each finite target-oscillation request through*

$$K, F, M, D, W \longmapsto H, P, L.$$

8. *P is the* Pkg *provenance over* $\mathsf{CompactUniformOscillation}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected supremum of image diameters, open-cover compactness, quotient equality of maps, choice-selected net refinements, trichotomy, or host function extensionality.

Lean4 ✓ `BEDC.Derived.CompactUniformOscillationUp.CompactUniformOscillationTasteGate single carrier alignment`

Theorem 3737.2 (Compact uniform oscillation NameCert obligations)**.** *For an accepted* CompactUniformOscillatio *carrier*

$$O = (K, F, M, D, W, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformOscillation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, compact finite-net exposure for K, continuous graph exposure for F, uniform-modulus accounting for M, target-distance accounting for D, finite oscillation-witness exposure for W, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through L.*

Proof. Carrier admission is projection from Definition 3737.1. The accepted packet displays the compact metric source, continuous-map graph, uniform-modulus ledger, target-distance ledger, finite witness row, transport row, replay row, provenance row, and local name.

The compact-uniform route is read from K, F, M. A consumer first receives finite compact-net observations, then the displayed continuous graph rows, and then the tolerance-only modulus ledger built over those observations.

The oscillation estimate is read from D and W. Target-distance comparisons are visible only through D, while W stores the finite witness pairs whose source separation is small enough for the modulus row.

Finally H, C, P, L transport, replay, source, and name the same route. Because no coordinate stores a selected supremum, open-cover compactness, quotient equality, choice-selected refinements, trichotomy, or host function extensionality, those principles are outside the local certificate surface. □

Theorem 3737.3 (Compact uniform oscillation modulus handoff)**.** *Every bounded image-diameter or equicontinuity-facing read accepted by a* $\mathsf{CompactUniformOscillation}^{\uparrow}$ *carrier factors through*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, NameCert.

Equivalently, a downstream consumer may inspect compact finite-net data K, continuous graph data F, the uniform-modulus ledger M, target-distance rows D, finite oscillation witnesses W, and structural rows H, C, P, L, but it cannot bypass them by selecting a supremum, importing open-cover compactness, or comparing maps by host extensionality.

Proof. Apply Definition 3737.2. It forces every oscillation-facing request to open K, F, M, D, W before the structural rows are available.

The finite-net part is controlled by K and M. Compactness is consumed as displayed net data and a tolerance-only modulus ledger, not as an external open-cover principle.

The target estimate is controlled by D and W. The witness row stores the paired observations whose target distances are bounded, and the distance ledger records the corresponding metric readback.

Transport, replay, provenance, and naming through H, C, P, L preserve exactly that route. Hence later bounded-image or equicontinuity packets receive a finite oscillation-bound handoff and no selected supremum or host-level function equality. □

Falsifiable prediction: Every $\mathsf{CompactUniformOscillation}^{\uparrow}$ oscillation read factors through one CompactMetric finite-net source row, one ContinuousMap graph row, one UniformModulus ledger, one target Metric or RealMetric distance row, one finite ProbeBundle oscillation-witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuousmap, uniformmodulus, metric, realmetric: $\mathsf{CompactUniformOscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-net data, continuous graph data, a uniform-modulus ledger, target-distance readback, finite oscillation witnesses, and the transport/replay/provenance rows tying them into an oscillation-bound packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformOscillation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3737.1, Definition 3737.2, and Definition 3737.3 seed the finite compact-uniform oscillation packet over compact metric source rows, continuous graph rows, uniform-modulus ledgers, target-distance readbacks, finite witnesses, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected suprema, open-cover compactness, image compactness, host function extensionality, choice-selected net refinements, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous graph exposure, uniform-modulus accounting, target-distance accounting, oscillation-witness stability, transport stability, replay stability, and ledger non-escape for BEDC.Derived.CompactUniformOscillationUp.

Constructive story: A $\mathsf{CompactUniformOscillation}^{\uparrow}$ packet is generated from one CompactMetric finite-net source row, one ContinuousMap graph row, one UniformModulus ledger, one target-distance row, one finite ProbeBundle oscillation-witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3738

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$

Following Bishop and Bridges on diagonal arguments in constructive analysis, the $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$ packet names the finite window data that a Real or Completion route may inspect before it reads a diagonal regular Cauchy seal. It sits over the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the downstream diagonal extraction route of chapter 1773. The packet records the named diagonal-window boundary; it is not a quotient stream, not a selected limit, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3738.1 (Regular Cauchy diagonal window carrier)**.** *A* $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, S, R, I, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row containing the requested dyadic radius, split-tolerance ledger, and comparison budget for the diagonal window.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite stream-window row that displays the source entries available to the diagonal read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to the same window and tolerance budget.*
4. *I is the finite diagonal index schedule, recording only the named indices whose windows are inspected by the consumer.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after D, S, R, I have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic tolerance, stream window, regular readback, diagonal index schedule, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a diagonal-window request through the tolerance row D, stream window S, regular readback R, index schedule I, and Real seal E.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, I, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalWindowUp.RegularCauchyDiagonalWindowTasteGate single carrier alignment`

Theorem 3738.2 (Regular Cauchy diagonal window obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalWindo}$ *carrier $W = (D, S, R, I, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dyadic tolerance row, stream window, regular readback, diagonal index schedule, Real seal, transport, replay, provenance, and local naming row;*
2. *diagonal-window visibility, requiring each consumer-facing diagonal request to read a displayed finite window before any Real seal is exposed;*
3. *dyadic tolerance exactness, requiring the requested tolerance and every split tolerance to be read through D;*
4. *regular readback compatibility, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to consume the same finite window S and diagonal schedule I named by the carrier;*
5. *Real-seal nonescape, requiring E to appear only after D, S, R, I have been transported through H and replayed through C;*
6. *transport, replay, provenance, and local naming for exactly the displayed rows $D, S, R, I, E, H, C, P, N$.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 3738.1. The accepted inventory is exactly the dyadic tolerance row D, stream window S, regular readback R, diagonal index schedule I, Real seal E, and the structural rows H, C, P, N.

The diagonal-window obligation is therefore visible before the seal. A consumer request first reads the dyadic tolerance and split budget in D, then the finite stream window S, and then the regular rational readback R attached to the displayed schedule I.

The Real seal is downstream of that finite route. Componentwise hsame transport in H preserves the displayed rows, and Cont replay in C repeats the same ordered route before E can be inspected.

Finally, provenance and naming are exhausted by P and N. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness, no such obligation can be exported by the local certificate. □

Theorem 3738.3 (Regular Cauchy diagonal window nonescape)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

together with the finite diagonal index schedule. The packet exports no quotient stream, selected limit, countable-choice schedule, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with an accepted carrier $W = (D, S, R, I, E, H, C, P, N)$. The only tolerance source is D, the only finite source-window row is S, and the only regular rational readback row is R.

The diagonal schedule I is finite and displayed. It selects only the named window entries already present in S and the tolerance budgets already present in D before the readback reaches R.

The terminal Real seal E is reached only through the componentwise transport H and displayed replay C. The provenance row P and local naming row N source exactly that route.

Since the carrier inventory has no quotient-stream, selected-limit, countable-choice, trichotomy, host-equality, or ambient-completeness coordinate, every Real or Completion read remains inside the displayed finite diagonal-window packet. □

Falsifiable prediction: Every $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$ Real or Completion read factors through displayed DyadicRatCore, StreamName, RegSeqRat, RealUp, transport, replay, provenance, local naming, and finite diagonal-index rows before exposing a diagonal seal.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-diagonal-extraction: $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerance exactness, finite stream-window exposure, regular rational readback, a diagonal index schedule, and a Real seal in one finite window packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, a StreamName finite window, RegSeqRat readback, a finite diagonal index schedule, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3738.1, Definition 3738.2, and Definition 3738.3 seed the finite diagonal-window packet used by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyDiagonalWindowUp`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient RealUp completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-window visibility, dyadic tolerance exactness, regular readback compatibility, Real-seal exposure, and ledger nonescape for BEDC.Derived.RegularCauchyDiagonalWindowUp.

Chapter 3739

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy real-completion route may select a diagonal modulus only after the source regular sequence, dyadic error ledger, observation windows, and terminal real handoff are all visible. The $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$ packet records that finite L10 selection surface. It sits after the $\mathsf{RegSeqRat}^{\uparrow}$ source of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic ledger of chapter 291, the finite window rows of chapter 126, and the minimum-modulus packet of chapter 5544, before a $\mathsf{Real}^{\uparrow}$ consumer reads the terminal handoff of chapter 38. The packet is a displayed diagonal schedule and selected-modulus ledger, not quotient equality of Cauchy names, a hidden limit selector, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3739.1 (Regular Cauchy diagonal modulus selection carrier)**.** *A* RegularCauchyDiagonalModulusSelectio *carrier is a finite* BHist *packet*

$$D = (S, E, W, \Delta, M, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the regular rational sequence whose diagonal requests are being inspected.*
2. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error row recording the displayed dyadic tolerances attached to those requests.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row listing the finite source windows, target precisions, and inspected coordinates.*
4. *Δ is the diagonal schedule row, naming the finite diagonal order in which source windows and error bounds are paired.*
5. *M is the selected modulus row. It records the finite modulus chosen from the displayed diagonal schedule and the minimum-modulus surface of chapter 5544.*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after S, E, W, Δ, M have been displayed.*
7. *H records componentwise* hsame *transport for source, error, observation, diagonal schedule, selected modulus, Real handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a real-completion request through $S, E, W, \Delta, M, L, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegularCauchyMinModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, E, W, \Delta, M, L, H, C, P, N$. It has no coordinate for quotient equality of Cauchy names, a hidden diagonal selector, countable choice over infinitely many windows, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3739.2 (Regular Cauchy diagonal modulus selection obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$ *carrier*

$$D = (S, E, W, \Delta, M, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *error row,* $\mathsf{StreamName}^{\uparrow}$ *observation row, diagonal schedule row, selected modulus row,* $\mathsf{Real}^{\uparrow}$ *handoff row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from quotient equality, hidden selectors, countable choice, host real equality, and ambient completion.*

Proof. Project the carrier of Definition 3739.1. The source, error, and observation rows are S, E, W, so every diagonal request is attached to a displayed regular-rational source, dyadic tolerance ledger, and finite observation window.

The diagonal schedule is Δ, and the selected modulus is M. The selected row cites the minimum-modulus packet of chapter 5544, so it records a finite visible budget rather than an off-packet selector.

The Real-facing row is L. It is reachable only after the source, dyadic, observation, schedule, and selected-modulus rows have been exposed, matching the L10 route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded object is a carrier coordinate, the displayed rows exhaust the NameCert obligations. □

Theorem 3739.3 (Regular Cauchy diagonal modulus Real handoff)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *consumer read of a* $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegularCauchyMinModulus}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

on the displayed rows $S, E, W, \Delta, M, L, H, C, P, N$. The handoff exports no quotient-name equality, no selected representative, no host real equality, no countable-choice row, and no ambient completeness row.

Proof. Start with an accepted carrier $D = (S, E, W, \Delta, M, L, H, C, P, N)$. The route to a Real consumer begins with the visible regular-rational source S, dyadic error row E, and stream observation row W.

Apply the obligation theorem above. It forces the diagonal schedule Δ and selected modulus M to remain attached to the same displayed source, error, and observation rows before L is readable.

The terminal handoff row L is therefore a Real-facing seal over the same finite packet. Transport through H, replay through C, provenance through P, and local naming through N preserve that route and do not add any quotient, selected-representative, choice, host-equality, or ambient-completeness coordinate. □

Falsifiable prediction: A real-completion read that requests a diagonal modulus without displaying a $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{DyadicRatCore}^{\uparrow}$ error row, $\mathsf{StreamName}^{\uparrow}$ observation row, diagonal schedule row, selected modulus row, $\mathsf{Real}^{\uparrow}$ handoff row, hsame transport, Cont replay, Pkg provenance, and local NameCert row is rejected by the $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$ classifier.

Independence witness: regseqrat, dyadicratcore, streamname, regularcauchyminmodulus, real: no listed sibling is bijective to $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$ because this packet jointly carries a regular-rational source, dyadic error ledger, finite observation windows, diagonal schedule, selected modulus, Real handoff, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}$ packet is generated from a RegSeqRat source row, DyadicRatCore error row, StreamName observation row, diagonal schedule row, selected modulus row, RealUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3739.1, Definition 3739.2, and Definition 3739.3 seed the finite diagonal modulus selection route consumed by L10 real-completion readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulusSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality of Cauchy names, hidden limit selection, countable choice, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, dyadic error exactness, finite observation windows, diagonal schedule exposure, selected-modulus exactness, Real handoff, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.RegularCauchyDiagonalModulusSelectionUp.

Chapter 3740

A Concrete Naming Certificate for DunfordFunctionalCalculus$^{\uparrow}$

Following Dunford and Schwartz on contour functional calculus for bounded operators, the DunfordFunctionalCalculu packet records the finite NameCert route by which a holomorphic scalar window is read through resolvent rows before any spectral theorem or projection-valued measure is public. It sits beside the Banach-algebra source of chapter 2189, the bounded-operator carrier of chapter 1644, the resolvent identity packet of chapter 3715, the spectral-radius boundary of chapter 2352, and the compact-operator schedule of chapter 1952.

Definition 3740.1 (Dunford functional calculus carrier)**.** *A* DunfordFunctionalCalculus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, T, \Gamma, \Omega, R, I, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *A is the* BanachAlgebra$^{\uparrow}$ *source row in which products, scalar multiplication, and norm estimates are read.*
2. *T is the* BoundedLinearOperator$^{\uparrow}$ *row naming the operator whose calculus is being inspected.*
3. *Γ is the finite contour-window row. It records the oriented contour pieces, mesh endpoints, denominator separation witnesses, and enclosure data used by the accepted request.*
4. *Ω is the holomorphic scalar-window row. It records the finite function values and local compatibility checks visible on the contour windows.*
5. *R is the* ResolventIdentity$^{\uparrow}$ *row. It supplies the displayed shifted-operator inverse checks and two-shift identity ledger used along Γ.*
6. *I is the contour-integral ledger. It records only finite Riemann-sum windows, dyadic tolerance budgets, and composition order through A, T, Γ, Ω, R.*
7. *Q is the spectral-radius and compact-operator boundary row. It allows later spectral consumers to read enclosure and compact-image schedules, but only as rows already displayed by chapter 2352 and chapter 1952.*
8. *S is the terminal calculus handoff row naming the value of the accepted contour read as a bounded-operator-facing packet.*

9. *H records componentwise* hsame *transport for the Banach-algebra, operator, contour, scalar-window, resolvent, integral-ledger, spectral-boundary, handoff, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from contour requests through $A, T, \Gamma, \Omega, R, I, Q, S, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{DunfordFunctionalCalculus}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{ResolventIdentity}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DunfordFunctionalCalculus}^{\uparrow}}$ *row.*

The carrier has no coordinate for a spectral projection, a projection-valued measure, quotient operator equality, a selected spectrum, countable choice, or a host holomorphic functional calculus outside the displayed contour packet.

Lean4 ✓ `BEDC.Derived.DunfordFunctionalCalculusUp.DunfordFunctionalCalculusTasteGate single carrier alignment`

Theorem 3740.2 (Dunford functional calculus NameCert obligations)**.** *For every accepted* DunfordFunctionalCalcu *carrier*

$$F = (A, T, \Gamma, \Omega, R, I, Q, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DunfordFunctionalCalculus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, Banach-algebra source compatibility through A, bounded-operator source compatibility through T, contour-window admission through Γ, holomorphic scalar-window admission through Ω, resolvent identity exactness through R, finite contour-ledger exactness through I, spectral-radius and compact-operator boundary visibility through Q, terminal calculus handoff through S, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every calculus-facing consumer must read the same rows before using the contour value. It receives no spectral projection, no spectral measure, no selected spectrum, no quotient equality of operators, no countable-choice schedule, and no ambient host functional calculus.

Proof. Carrier admission is projection from Definition 3740.1. The accepted packet displays exactly $A, T, \Gamma, \Omega, R, I, Q, S, H, C, P, N$.

The source rows A and T fix the Banach-algebra and bounded-operator surfaces. The contour and scalar-window rows Γ, Ω then provide the finite requests on which the calculus read is allowed to inspect function values.

The resolvent row R supplies only the displayed inverse checks and two-shift identity ledger. The contour ledger I reads those rows through finite Riemann-sum and dyadic-budget windows, so it cannot import a host integral or an unrecorded inverse.

The spectral-boundary row Q and handoff row S are downstream of the same route. Transport, replay, provenance, and local naming in H, C, P, N preserve that finite packet. Since the carrier has no coordinate for spectral projections, spectral measures, selected spectra, quotient equality, countable choice, or a host calculus, the listed rows exhaust the local obligations. □

Theorem 3740.3 (Dunford functional calculus resolvent-contour handoff)**.** *Every bounded-operator or spectral-analysis consumer of an accepted* $\mathsf{DunfordFunctionalCalculus}^{\uparrow}$ *carrier reaches the calculus value only through the displayed route*

$$A, T \longmapsto \Gamma, \Omega \longmapsto R \longmapsto I \longmapsto Q, S \longmapsto H, C, P, N.$$

Thus the consumer may read Banach-algebra operations, the bounded operator, contour windows, holomorphic scalar windows, resolvent identity rows, finite contour-integration budgets, spectral-radius and compact-operator boundary rows, the terminal handoff, transport, replay, provenance, and local naming, and it may not read spectral projections, spectral measures, quotient operator equality, a selected spectrum, countable choice, or a host functional calculus.

Proof. Begin with a calculus-facing consumer. The only operator sources in the carrier are A and T, and the only contour-facing source rows are Γ and Ω.

The resolvent dependency is forced through R. It supplies the two-sided inverse checks and identity ledger already isolated by the $\mathsf{ResolventIdentity}^{\uparrow}$ packet, so no separate selected inverse or quotient operator comparison is available.

The finite contour read is then the row I. It records the Riemann-sum windows, dyadic tolerance budgets, and composition order needed to pass from the contour and resolvent rows to the handoff.

Finally Q, S, H, C, P, N expose the spectral boundary, terminal bounded-operator-facing result, transport, replay, provenance, and local naming. The excluded projection, spectral-measure, selected-spectrum, choice, quotient, and host-calculus objects have no carrier coordinate and therefore cannot be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{DunfordFunctionalCalculus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DunfordFunctionalCalculus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3740.1, Definition 3740.2, and Definition 3740.3 seed the contour functional-calculus route over Banach-algebra, bounded-operator, contour-window, holomorphic scalar-window, resolvent, spectral-boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DunfordFunctionalCalculus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral projections, spectral measures, selected spectra, quotient operator equality, countable choice, host holomorphic functional calculus, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contour-window admission, scalar-window admission, resolvent exactness, contour-ledger exactness, spectral-boundary visibility, handoff non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DunfordFunctionalCalculusUp.

Constructive story: A $\mathsf{DunfordFunctionalCalculus}^{\uparrow}$ packet is generated from a BanachAlgebra source row, a BoundedLinearOperator row, finite contour windows, holomorphic scalar windows, a ResolventIdentity route, a finite contour ledger, SpectralRadius and CompactOperator boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3741

A Concrete Naming Certificate for $\mathsf{UniformCompletionCommonWindow}^{\uparrow}$

Following Kelley on uniform spaces and Bishop–Bridges on completion by explicit regular data, the $\mathsf{UniformCompletionCommonWindow}^{\uparrow}$ packet records the finite common-window route by which uniform-completion requests share one observation window before any $\mathsf{Real}^{\uparrow}$ seal is read. It concretizes the Real and Completion vision of chapter 9238 by tying the $\mathsf{UniformCompletionFunctor}^{\uparrow}$ surface to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows without quotient completion equality. Its concrete dependency route reads the functor source of chapter 1892, the stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic budget of chapter 291, and the terminal real-name seal of chapter 38.

Definition 3741.1 (Uniform completion common-window carrier)**.** *A* $\mathsf{UniformCompletionCommonWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (U, E, S, R, D, L, F, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *source row naming the completion-facing request, entourage scale, and functorial handoff boundary.*
2. *E is the finite entourage-window row. It records the common uniform scale used by all source observations in the accepted request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *common-window row. It synchronizes the finite observation windows before any regular rational readback is exposed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source-readback row generated from the synchronized window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, recording the dyadic tolerance, slack, comparison, and endpoint-conversion entries used by the readback.*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is exposed only after S, R, D have displayed the shared window and regular rational readback.*
7. *F is the common-window functoriality row. It states that completion-facing consumers of U and Real-facing consumers of L read the same E, S, R, D route.*
8. *H records componentwise* hsame *transport for the uniform-completion source, common entourage window, StreamName window, RegSeqRat readback, DyadicRatCore budget, Real seal, functoriality, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a completion request through $U, E, S, R, D, L, F, H, P, N$.*
10. *P is the* Pkg *provenance over* UniformCompletionCommonWindow$^{\uparrow}$, UniformCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformCompletionCommonWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected completion points, host metric completeness, countable choice, or a second private observation window.

Lean4 ✓ `BEDC.Derived.UniformCompletionCommonWindowUp.UniformCompletionCommonWindowTasteGate`
`single carrier alignment`

Theorem 3741.2 (Uniform completion common-window NameCert obligations)**.** *For every accepted* UniformCompletionCommonWindow$^{\uparrow}$ *carrier*

$$W = (U, E, S, R, D, L, F, H, C, P, N),$$

the local NameCert$_{\text{UniformCompletionCommonWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, uniform-completion source compatibility through U, common entourage-window admission through E, synchronized* StreamName$^{\uparrow}$ *admission through S,* RegSeqRat$^{\uparrow}$ *readback exactness through R,* DyadicRatCore$^{\uparrow}$ *budget exactness through D,* Real$^{\uparrow}$ *seal handoff through L, common-window functoriality through F, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every completion-facing or Real-facing consumer must use the same E, S, R, D route. It receives no quotient completion equality, no selected completion point, no host metric-completeness principle, no countable-choice schedule, and no private window not displayed by the packet.

Lean4 ✓ `BEDC.Derived.UniformCompletionCommonWindowUp.UniformCompletionCommonWindowNameCertObligations`

Proof. Carrier admission is projection from Definition 3741.1. The displayed rows are exactly $U, E, S, R, D, L, F, H, C, P, N$.

The uniform-completion source row U is read first, and the common entourage window E fixes the finite scale for the request. The synchronized StreamName row S then supplies the only observation window available to the packet.

The regular rational and dyadic rows R, D are downstream of that shared window. The Real seal L can be exposed only after those rows display the readback and budget entries, so no consumer can substitute a quotient completion class or selected limit.

The row F ties the completion-facing and Real-facing reads to the same route. Transport, replay, provenance, and local naming in H, C, P, N preserve the route without adding host completeness, choice, or a second private window. □

Theorem 3741.3 (Uniform completion common-window Real seal handoff)**.** *Every* UniformCompletionFunctor$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer of an accepted* UniformCompletionCommonWindow$^{\uparrow}$ *carrier reaches the terminal Real seal only through*

$$U \longmapsto E \longmapsto S \longmapsto R, D \longmapsto L \longmapsto F, H, C, P, N.$$

Thus the completion request, common entourage window, synchronized StreamName window, RegSeqRat readback, DyadicRatCore budget, RealUp seal, common-window functoriality, transport, replay, provenance, and local naming are jointly visible, and quotient completion equality, selected completion points, host metric completeness, countable choice, and private observation windows are not exported.

Proof. Start with a completion-facing or Real-facing read. The source request is U, and the only uniform scale that may be consumed is the common row E.

The observation side is forced through S. Once that StreamName window is displayed, the regular rational readback R and dyadic budget D provide the finite data needed by the Real seal.

The seal row L is therefore downstream of the shared completion window, not of a quotient completion object. The functoriality row F records that both the completion consumer and the Real consumer read the same route.

Finally H, C, P, N transport, replay, source, and name the packet. Since no coordinate stores selected completion points, host completeness, choice, or private windows, the handoff exports only the displayed common-window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionCommonWindow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionCommonWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3741.1, Definition 3741.2, and Definition 3741.3 seed the common-window route from UniformCompletionFunctor through StreamName, RegSeqRat, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionCommonWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected completion points, host metric completeness, countable choice, private observation windows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common entourage-window admission, synchronized StreamName admission, RegSeqRat readback exactness, DyadicRatCore budget exactness, Real seal handoff, common-window functoriality, transport, replay, provenance, and local naming for BEDC.Derived.UniformCompletionCommonWindowUp.

Constructive story: A $\mathsf{UniformCompletionCommonWindow}^{\uparrow}$ packet is generated from one UniformCompletionFunctor request row, one common entourage-window row, one StreamName synchronized window, one RegSeqRat readback, one DyadicRatCore budget, one RealUp seal, a common-window functoriality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3742

A Concrete Naming Certificate for $\mathsf{FiniteMetricSpace}^{\uparrow}$

Following Burago–Burago–Ivanov and Gromov on finite metric spaces as completely displayed distance data, the $\mathsf{FiniteMetricSpace}^{\uparrow}$ packet records a metric carrier whose public observations are a finite point row and a finite distance table. It sits over the $\mathsf{Met}^{\uparrow}$ surface of chapter 57, the finite-net and total-bounded handoff of chapter 1767 and chapter 127, and the compact-metric consumer boundary of chapter 129. The packet names finite metric data without importing host finite sets, quotient point equality, selected centers, open-cover compactness, or ambient completion.

Definition 3742.1 (Finite metric space carrier)**.** *A* $\mathsf{FiniteMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, D, T, B, H, C, P, N)$$

with the following displayed rows:

1. *X is a finite point row, recorded as a closed* ProbeBundle *with point histories and membership witnesses for every public point read.*
2. *D is the finite distance-table row, assigning each displayed ordered pair of point histories a* $\mathsf{Real}^{\uparrow}$ *distance witness.*
3. *T is the metric-law ledger for the displayed table: zero diagonal, symmetry, triangle-budget rows, and positive-separation rows are read only as finite table entries.*
4. *B is the finite-net and boundedness handoff row. For each displayed positive tolerance it reuses the point row X as the center bundle and exposes the coverage route consumed by* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, and* $\mathsf{CompactMetric}^{\uparrow}$*.*
5. *H records componentwise* hsame *transport for the point row, distance table, metric-law ledger, finite-net handoff, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from point membership reads to distance-table reads, from distance-table reads to metric-law checks, and from the finite point row to finite-net and compact-metric consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host finite set, powerset membership, quotient point equality, selected nearest-point search, open-cover compactness, or ambient completion.

Lean4 ✓ `BEDC.Derived.FiniteMetricSpaceUp.FiniteMetricSpaceTasteGate single carrier alignment`

Theorem 3742.2 (Finite metric space NameCert obligation surface)**.** *For every accepted* $\mathsf{FiniteMetricSpace}^{\uparrow}$ *carrier* $F = (X, D, T, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite point row, distance table, metric-law ledger, finite-net handoff, componentwise transport, displayed replay, provenance, and local naming rows; distance readback through* D*; metric compatibility through* T*; finite-net and compact-metric handoff through* B*; and nonescape from host finite sets, powerset membership, quotient point equality, selected nearest-point search, open-cover compactness, and ambient completion.*

Proof. Project the carrier of Definition 3742.1. The displayed tuple exposes the point bundle, distance table, metric-law ledger, finite-net handoff, and the structural rows H, C, P, N.

The distance readback is table-local. Every distance observation names two point histories from X and then reads the corresponding entry of D, while T supplies the finite metric-law rows attached to those entries.

The finite-net handoff is the row B. It reuses the same point row as the center bundle and sends the resulting coverage data to finite-net, total-bounded, and compact-metric consumers through the displayed replay route.

No excluded object is a coordinate of the carrier. Thus the local certificate exports only the displayed finite metric route and its structural transport, replay, provenance, and naming rows. □

Theorem 3742.3 (Finite metric space distance-table boundary)**.** *Every* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*, or* $\mathsf{CompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteMetricSpace}^{\uparrow}$ *packet reads metric information only through*

$$X \longmapsto D \longmapsto T \longmapsto B.$$

The consumer receives a finite point bundle, a displayed distance table, the metric-law ledger for that table, and the finite-net handoff generated from the same point bundle. It receives no host finite-set equality, ambient enumeration principle, selected nearest point, external compactness theorem, quotient completion, or hidden completion carrier.

Proof. Begin with a consumer request for metric or compact-metric data. The only public points are the histories displayed in X, and every distance read is routed through the table row D.

The metric-space laws are then read from T. Since T is attached to the same table entries, a consumer cannot replace the displayed table by a host metric or by a quotient comparison on points.

For finite-net and compact-metric use, the handoff row B supplies the center bundle and coverage route from X. The replay row C preserves the order from point membership to distance-table read to metric-law check to finite-net export.

The remaining rows transport, source, and name this same route. Because no carrier coordinate stores a host finite set, selected nearest point, external compactness theorem, quotient completion, or hidden completion carrier, every consumer boundary is exhausted by X, D, T, B together with H, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteMetricSpace}^{\uparrow}$ packet is generated from a finite point row, a displayed Real-valued distance table, finite metric-law rows, a finite-net and compact-metric handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteMetricSpace}\uparrow}$, seed)

Scope closed: Definition 3742.1, Definition 3742.2, and Definition 3742.3 seed the finite distance-table packet and its finite-net, total-bounded, and compact-metric consumer boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteMetricSpace}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.FiniteMetricSpaceUp.FiniteMetricSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host finite sets, quotient point equality, nearest-point selection, open-cover compactness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, table-local metric-law exactness, finite-net handoff stability, compact-metric boundary nonescape, and provenance exhaustion for BEDC.Derived.FiniteMetricSpaceUp.

Chapter 3743

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailBound}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyTailBound}^{\uparrow}$ packet records the finite tail estimate used when a regular rational Cauchy name is read as a completion-facing real datum. It consumes the observation windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic radius ledger of chapter 291, the bounded Cauchy sequence route of chapter 1522, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a finite tail-bound witness for completion and Real sealing; it is not a proof of ambient Real completeness, quotient equality, countable choice, or trichotomy.

Definition 3743.1 (Regular Cauchy tail-bound carrier)**.** *A* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, N, T_0, H, C, P, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, displaying the finite stream windows from which the tail request is read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking those windows as regular rational Cauchy data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, recording the dyadic tolerance and comparison rows used by the tail estimate.*
4. *N is the unary tail-index row, naming the finite stage after which the displayed radius is to be enforced.*
5. *T_0 is the later-index comparison row, recording the finite comparisons that put every displayed later observation beyond N and inside the dyadic radius from D.*
6. *H records componentwise* hsame *transport for the stream, regular readback, dyadic radius, tail index, later-index comparison, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tail request through*

$$S, R, D, N, T_0 \longmapsto H, P, L.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailBound}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBound}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, R, D, N, T_0, H, C, P, L$. It contains no coordinate for a quotient completion equality, selected limit, countable-choice sequence, trichotomy decision, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailBoundUp.RegularCauchyTailBoundTasteGate single carrier alignment`

Definition 3743.2 (Regular Cauchy tail-bound classifier)**.** *Two accepted* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *carriers*

$$T = (S, R, D, N, T_0, H, C, P, L)$$

and

$$T' = (S', R', D', N', T_0', H', C', P', L')$$

are classified together exactly when the displayed hsame *rows transport S to S', R to R', D to D', N to N', and T_0 to T_0', and when the displayed* Cont *rows replay the same stream-to-readback-to-radius-to-tail-index route on both packets. The classifier has no coordinate for host real equality, completion quotient equality, selected representatives, or order trichotomy.*

Theorem 3743.3 (Regular Cauchy tail-bound NameCert obligations)**.** *For every accepted* RegularCauchyTailBound *carrier*

$$T = (S, R, D, N, T_0, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBound}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, StreamName observation exposure through S, RegSeqRat readback exposure through R, dyadic radius accounting through D, unary tail-index exposure through N, later-index comparison through T_0, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 3743.1. The accepted packet displays the stream observation row, regular rational readback row, dyadic radius ledger, unary tail index, later-index comparison row, transport row, replay row, provenance row, and local name.

The tail estimate is read in order. A consumer first opens S and R, then reads the dyadic tolerance in D, and only then consumes the finite index row N and the later-index comparisons in T_0.

The structural rows preserve that route. The hsame and Cont rows transport and replay the same finite observations, while P and L source and name the packet. Since no coordinate stores ambient Real completeness, quotient equality, countable choice, selected limits, or trichotomy, those principles are outside the local certificate surface. □

Theorem 3743.4 (Regular Cauchy tail-bound completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*, regular-completion, or bounded-Cauchy consumer of an accepted* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CauchySequenceBounded}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The handoff supplies a displayed tail-bound packet to completion-facing chapters, but it does not export ambient completeness, countable choice, quotient equality of Real names, selected representatives, or trichotomy.

Proof. Apply Definition 3743.3. It forces every tail-bound read through S, R, D, N, T_0 before the structural rows can be consumed.

The completion-facing route is finite. Stream windows are repacked as regular rational readback, the dyadic row supplies the radius, and the unary index plus later-index comparisons form the displayed tail witness.

Finally inspect the missing coordinates of the carrier and classifier. They preserve the finite route under transport and replay, but they contain no selected limit, quotient equality, countable-choice selector, trichotomy row, or ambient completeness principle. Thus downstream Real and completion packets receive only the finite tail-bound handoff. □

Theorem 3743.5 (Regular Cauchy tail-bound RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *reader of an accepted* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *packet must read the* $\mathsf{StreamName}^{\uparrow}$ *observation row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger D, the unary tail-index row N, and the later-index comparison row T_0 before any* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal is consumed. The handoff keeps the Real seal downstream and exports no quotient streams, selected limits, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Specialize Definition 3743.3 to a RegSeqRat-facing reader. The obligations expose S, R, D, N, T_0 before the transport, replay, provenance, and local naming rows can be used.

Use the completion handoff of Definition 3743.4 only at the boundary where a Real or completion-facing consumer appears. Before that boundary, the reader sees the stream observation, regular rational readback, radius ledger, tail index, and later-index comparisons as finite rows.

Thus the narrower handoff is the RegSeqRat portion of the same packet. The downstream Real seal cannot be used to supply quotient streams, selected limits, countable choice, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBound}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3743.1, Definition 3743.2, Definition 3743.3, Definition 3743.4, and Definition 3743.5 seed the finite regular-Cauchy tail-bound packet over stream observations, regular rational readback, dyadic radii, unary tail indices, later-index comparisons, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, countable choice, quotient equality, trichotomy, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier preservation, tail-index exposure, later-index comparison, dyadic-radius accounting, replay stability, and ledger nonescape for BEDC.Derived.RegularCauchyTailBoundUp.

Constructive story: A $\mathsf{RegularCauchyTailBound}^{\uparrow}$ packet is generated from one StreamName observation row, one RegSeqRat readback row, one DyadicRatCore radius ledger, one unary tail-index row, one later-index comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3744

A Concrete Naming Certificate for HochsterNerveBettiReduction$^{\uparrow}$

The HochsterNerveBettiReduction$^{\uparrow}$ packet realizes the Hochster–nerve reduction of subsection 9462.28.21 as a finite NameCert surface. It turns the vision theorem Definition 9462.1639 into displayed support rows, nerve-face rows, homology-range rows, Betti-strand rows, and ledger rows. The packet is a sibling of the homology carrier of chapter 98, the finite simplicial-chain carrier of chapter 3414, and the simplicial approximation surface of chapter 3402. It names a finite algebraic-topology reduction; it does not assert field faithfulness, nontriviality of coefficients, unrestricted minimal-resolution construction, or a Lean-checked homology computation.

Definition 3744.1 (Hochster nerve Betti reduction carrier)**.** *A* HochsterNerveBettiReduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (V, F, N, H_0, B_0, G, T, P, L)$$

with the following displayed rows:

1. *V is the finite support row, recording the displayed vertex subset and the local support window read by Hochster's formula.*
2. *F is the nerve-face row, recording the finite face and nonface tests that produce the nerve complex used by the reduction.*
3. *N is the homology-range row, recording the displayed dimensions in which reduced homology can be read.*
4. *H_0 is the finite homology row, read through the* Homology$^{\uparrow}$ *and* FiniteSimplicialChain$^{\uparrow}$ *carriers rather than through an ambient chain complex.*
5. *B_0 is the Betti-strand row, recording the diagonal and top-strand entries exposed by the support and homology rows.*
6. *G records componentwise* hsame *transport for the support, nerve-face, homology-range, finite homology, Betti-strand, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from finite support and nerve faces to homology ranges and then to Betti-strand ledgers.*
8. *P is the* Pkg *provenance over* HochsterNerveBettiReduction$^{\uparrow}$, Homology$^{\uparrow}$, FiniteSimplicialChain$^{\uparrow}$, SimplicialApproximation$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. L is the local $\mathsf{NameCert}_{\mathsf{HochsterNerveBettiReduction}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $V, F, N, H_0, B_0, G, T, P, L$. It has no coordinate for a field-faithfulness theorem, coefficient nontriviality instance, unrestricted free resolution, or host-level equality of Betti tables.

Theorem 3744.2 (Hochster nerve Betti reduction obligations)**.** *For every accepted* $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$ *carrier*

$$B = (V, F, N, H_0, B_0, G, T, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{HochsterNerveBettiReduction}^{\uparrow}}$ *surface consists exactly of finite support exposure through V, nerve-face exposure through F, homology-range exposure through N, finite homology readback through H_0, Betti-strand ledger exposure through B_0, componentwise transport through G, displayed replay through T, package provenance through P, and local naming through L.*

Lean4 ✓ `BEDC.Derived.HochsterNerveBettiReductionUp.HochsterNerveBettiReductionNameCertObligations`

Proof. Project the carrier of Definition 3744.1. The finite support, nerve-face, homology-range, finite homology, Betti-strand, transport, replay, provenance, and local name rows exhaust the accepted packet.

The reduction is read along the finite route. The support row V fixes the displayed vertex window, the face row F builds the nerve complex, and the range row N restricts the homology degrees that can be queried.

The Betti ledger is downstream of finite homology. The row H_0 is read through homology and finite simplicial-chain carriers, and B_0 records only the strand entries obtained from that range. The structural rows G, T, P, L transport, replay, source, and name the same finite route, so no field-faithfulness theorem, nontrivial coefficient instance, unrestricted resolution, or host Betti-table equality is exported. □

Theorem 3744.3 (Hochster nerve Betti reduction TasteGate boundary)**.** *A downstream consumer may promote a* $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$ *packet to a checked Betti computation only after future* Nontrivial *and* FieldFaithful *TasteGate instances are displayed for the coefficient surface. Before those instances are present, the packet exports only the finite support, nerve-face, homology-range, Betti-strand, transport, replay, provenance, and local naming rows of Definition 3744.2.*

Proof. Read the NameCert obligations first. They expose $V, F, N, H_0, B_0, G, T, P, L$ and no coefficient-faithfulness or nontriviality coordinate.

The TasteGate instances are therefore separate inputs. A consumer that wants a field-faithful Betti computation must supply those coefficient gates before interpreting the finite Betti ledger as a checked algebraic-topology calculation.

Without those gates, the accepted reading remains the finite reduction surface. It may cite the Hochster–nerve vision route and the sibling homology carriers, but it cannot claim unrestricted free resolutions, host-level Betti-table equality, or Lean-checked homology arithmetic. □

Falsifiable prediction: Every $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$ read factors through one finite support row, one nerve-face row, one homology-range row, one finite homology row, one Betti-strand ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: homology, finite_simplicial_chain, simplicial_approximation, dna_window_six_bound alexander_dual_trigger_algebra: $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries support windows, nerve-face tests, homology-range restriction, Betti-strand ledgers, and the coefficient TasteGate boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{HochsterNerveBettiReduction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HochsterNerveBettiReduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3744.1, Definition 3744.2, and Definition 3744.3 seed the finite Hochster–nerve Betti-reduction packet over support rows, nerve-face rows, homology-range rows, finite homology rows, Betti-strand ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HochsterNerveBettiReduction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HochsterNerveBettiReductionUp.HochsterNerveBettiReductionNameCertObligations`

Bridge status: none

Not claimed: This chapter does not claim unrestricted free resolutions, host Betti-table equality, or bridge checking.

Upgrade path: Obligation closure requires checked finite support exposure, nerve-face exposure, homology-range exposure, finite homology readback, Betti-strand ledger stability, coefficient TasteGate instances, replay stability, and ledger nonescape for BEDC.Derived.HochsterNerveBettiReductionUp.

Constructive story: A $\mathsf{HochsterNerveBettiReduction}^{\uparrow}$ packet is generated from a finite support row, a nerve-face row, a homology-range row, a finite homology row, a Betti-strand row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3745

A Concrete Naming Certificate for $\mathsf{BrouwerDegree}^{\uparrow}$

Following Brouwer and standard constructive degree-theory presentations, the $\mathsf{BrouwerDegree}^{\uparrow}$ packet records the finite boundary ledger by which a displayed continuous map on a compact domain is read as an integer degree certificate. It sits between the circle boundary surface of chapter 58, the compact-domain ledger of chapter 60, the graph and modulus rows of chapter 130, the chain-boundary route of chapter 98, and the terminal real-name seal of chapter 38. The packet names degree data only as finite BHist rows; it does not claim the classical Brouwer fixed point theorem, host topological degree, selected preimages, quotient homology classes, or ambient compactness.

Definition 3745.1 (Brouwer degree carrier)**.** *A* $\mathsf{BrouwerDegree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, B, F, O, I, H, T, C, P, N)$$

with the following displayed rows:

1. *K is the compact-domain row, read through the finite compact or compact-metric certificate surface.*
2. *B is the boundary row, with its $\mathsf{S}^{1\uparrow}$ orientation circle ledger and the displayed boundary inclusion into K.*
3. *F is the $\mathsf{ContinuousMap}^{\uparrow}$ row whose graph, modulus, and boundary restriction are visible to the packet.*
4. *O is the orientation ledger, recording the finite sign, face-order, or winding-window data used by the boundary read.*
5. *I is the integer-degree readback row, storing the displayed $\mathbb{Z}$-valued degree output and its finite comparison classifier.*
6. *H is the $\mathsf{Homology}^{\uparrow}$ boundary row, exposing the finite chain-boundary or cycle-class route consumed by the degree readback.*
7. *T is the componentwise hsame transport row for the compact-domain, boundary, continuous-map, orientation, integer-readback, and homology-boundary rows.*
8. *C is the displayed Cont replay from K, B, F, O, H to the integer readback row I and then to the local naming row.*

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerDegree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, F, O, I, H, T, C, P, N$. It has no coordinate for a host degree function, selected zeros or preimages, quotient homology classes, open-cover compactness, or a Brouwer fixed-point conclusion.

Lean4 ✓ `BEDC.Derived.BrouwerDegreeUp.BrouwerDegreeTasteGate single carrier alignment`

Theorem 3745.2 (Brouwer degree NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerDegree}^{\uparrow}$ *carrier*

$$D = (K, B, F, O, I, H, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerDegree}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact-domain row K, boundary and* $\mathsf{S}^{1\uparrow}$ *row B, continuous-map row F, orientation ledger O, integer-degree readback I, homology boundary row H, componentwise* hsame *transport T, displayed* Cont *replay C,* Pkg *provenance P, and local naming row N. Every degree consumer must read the boundary, orientation, and homology rows before the integer row is exported.*

Proof. Project the accepted carrier. The compact-domain row K, boundary row B, and continuous-map row F are the only geometric inputs, and each is already a displayed finite BEDC row.

The degree-specific data are O, I, H. The orientation ledger O supplies the finite boundary orientation, the homology boundary row H supplies the finite chain-boundary route, and the integer row I is read only after those two rows and the continuous-map boundary restriction have been displayed.

The structural rows T, C, P, N transport, replay, source, and name that same route. Since no carrier coordinate stores host topological degree, selected preimages, quotient homology classes, open-cover compactness, or fixed-point existence, the listed rows exhaust the local NameCert obligations. □

Theorem 3745.3 (Brouwer degree boundary handoff)**.** *Every boundary-facing degree read from an accepted* $\mathsf{BrouwerDegree}^{\uparrow}$ *carrier factors through*

$$K, B, F, O, H \longmapsto I \longmapsto T, C, P, N.$$

Thus the compact domain, boundary $\mathsf{S}^{1\uparrow}$ *row, continuous-map restriction, orientation ledger, and homology boundary row are displayed before the integer-degree readback can be transported or named.*

The handoff exports only this finite boundary route. It does not assert the Brouwer fixed point theorem, a host topological-degree functor, selected zeros, selected preimages, quotient homology classes, or ambient compactness.

Proof. Start with the NameCert obligations of Definition 3745.2. They place the compact-domain, boundary, continuous-map, orientation, and homology rows before the integer readback row.

The boundary handoff is therefore forced through K, B, F, O, H. The row B supplies the $\mathsf{S}^{1\uparrow}$ boundary ledger, F supplies the displayed map restriction, O records the orientation data, and H records the homology boundary route consumed by the integer row I.

Finally replay the structural rows T, C, P, N. These rows preserve and name the same finite route, so the exported degree surface has no additional coordinate for host degree theory, fixed-point existence, selected preimages, quotient homology, or ambient compactness. □

Falsifiable prediction: A $\mathsf{BrouwerDegree}^{\uparrow}$ consumer that exports an integer degree without reading the boundary row B, orientation ledger O, and homology boundary row H refutes the carrier surface.

Independence witness: s1, compact, continuousmap, homology, real: the sibling chapters supply boundary circles, compact rows, graph and modulus rows, chain-boundary routes, and real seals separately, while this chapter binds those rows into the finite degree readback packet $D = (K, B, F, O, I, H, T, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerDegree}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerDegree}^{\uparrow}$ packet is generated from a compact-domain row, boundary and SOne row, ContinuousMap row, orientation ledger, integer-degree readback, Homology boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BrouwerDegree}^{\uparrow}}$, seed)

Scope closed: Definition 3745.1, Definition 3745.2, and Definition 3745.3 seed the finite compact-domain, boundary, continuous-map, orientation, homology-boundary, integer-readback, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BrouwerDegree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the Brouwer fixed point theorem, host topological degree, selected zeros, selected preimages, quotient homology classes, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary and orientation exactness, continuous-map restriction stability, homology boundary handoff, integer readback stability, transport, replay, provenance, and local naming for BEDC.Derived.BrouwerDegreeUp.

Chapter 3746

A Concrete Naming Certificate for $\mathsf{Metacompact}^{\uparrow}$

Following Morita and Kelley general topology, the $\mathsf{Metacompact}^{\uparrow}$ packet records the point-finite refinement surface between paracompact locally finite refinement, Moore-space developments, and star-refinement cover ledgers. It sits after the paracompact cover surface of chapter 1963, beside the developable-neighbourhood rows of chapter 3592, and before the uniform star-refinement handoff of chapter 2167. The packet names only a displayed open-cover request, a point-finite open refinement, and the ledgers that certify coverage and point incidence; it does not choose arbitrary subcovers, infer local finiteness, or import compactness.

Definition 3746.1 (Metacompact open-cover carrier)**.** *A* $\mathsf{Metacompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, O, R, Q, I, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row containing the open predicates, point observations, and neighbourhood classifier used by the packet.*
2. *O is the open-cover request row, listing the displayed cover cells and the pointwise coverage ledger for T.*
3. *R is the open-refinement row, listing the displayed refinement cells and their containment witnesses back into cells of O.*
4. *Q is the point-finite incidence row, recording for each displayed point observation the finite list of refinement cells that contain it.*
5. *I is the coverage-and-incidence exactness row, requiring every point covered by O to be covered by a refinement cell and requiring every incidence read to be one of the finite entries in Q.*
6. *S is the sibling handoff row to the* $\mathsf{Paracompact}^{\uparrow}$*,* $\mathsf{MooreSpace}^{\uparrow}$*, and* $\mathsf{StarRefinementUniformCover}^{\uparrow}$ *cover ledgers.*
7. *H records componentwise* hsame *transport for $T, O, R, Q, I, S, C, P, N$.*
8. *C records displayed* Cont *replay from an open-cover request through refinement, point-finite incidence, sibling handoff, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{Metacompact}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Paracompact}^{\uparrow}$*,* $\mathsf{MooreSpace}^{\uparrow}$*,* $\mathsf{StarRefinementUniformCov}$ BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{Metacompact}^{\uparrow}}$ *row.*
The carrier contains no coordinate for selected subcovers, locally finite partitions, metric development extraction, uniform-star generation, or ambient compactness.

Lean4 ✓ `BEDC.Derived.MetacompactUp.MetacompactTasteGate single carrier alignment`

Definition 3746.2 (Metacompact classifier)**.** *The* $\mathsf{Metacompact}^{\uparrow}$ *classifier accepts exactly those displayed packets $M = (T, O, R, Q, I, S, H, C, P, N)$ whose refinement row R is open in T, whose containment ledger maps each refinement cell into a displayed cell of O, whose coverage ledger in I covers the same point observations as O, and whose incidence row Q displays a finite list of refinement cells at each point observation. A classifier read is rejected if it asks for a subcover selection, a locally finite refinement, a Moore development, a uniform star refinement, or a compactness principle not present among $T, O, R, Q, I, S, H, C, P, N$.*

Theorem 3746.3 (Metacompact carrier admission)**.** *For every accepted* $\mathsf{Metacompact}^{\uparrow}$ *packet $M = (T, O, R, Q, I, S, H, C, P, N)$, carrier admission exposes exactly the topology source, open-cover request, open-refinement row, point-finite incidence row, coverage-and-incidence exactness row, sibling handoff row, transport, replay, provenance, and local naming rows of Definition 3746.1.*

Proof. Project the carrier definition. The tuple lists $T, O, R, Q, I, S, H, C, P, N$ and no further coordinate.

The classifier of Definition 3746.2 accepts only packets that read refinement, containment, coverage, point-finite incidence, sibling handoff, transport, replay, provenance, and local naming through those coordinates. Therefore carrier admission is the displayed finite packet itself. □

Theorem 3746.4 (Metacompact point-finite refinement exactness)**.** *For every accepted* $\mathsf{Metacompact}^{\uparrow}$ *packet $M = (T, O, R, Q, I, S, H, C, P, N)$, the row R is an open refinement of the request row O, and the row Q is a point-finite incidence ledger for R. Every displayed point covered by O is covered by at least one row of R, and every refinement cell containing that point appears in the finite list recorded by Q.*

Proof. Use the refinement part of the classifier. It requires the cells of R to be open in T and to carry containment witnesses into the displayed cover cells of O.

Use the exactness row I next. It links coverage by O to coverage by R and restricts incidence reads to the finite lists displayed in Q.

Thus the point-finite refinement is not inferred from a choice principle. It is stored as the finite incidence ledger attached to the accepted packet. □

Theorem 3746.5 (Metacompact sibling cover handoff)**.** *Every cover-refinement consumer of an accepted* $\mathsf{Metacompact}^{\uparrow}$ *packet factors through the sibling handoff row S before citing* $\mathsf{Paracompact}^{\uparrow}$, $\mathsf{MooreSpace}^{\uparrow}$, *or* $\mathsf{StarRefinementUniformCover}^{\uparrow}$. *The handoff may compare locally finite, development, and star-refinement ledgers with the point-finite row Q, but it cannot promote the metacompact packet to any of those stronger cover principles.*

Proof. Read the sibling coordinate S in the carrier. It is the only row that mentions the paracompact, Moore-space, and star-refinement neighbours.

The refinement and incidence rows remain R, Q, I. Comparing them with sibling cover ledgers does not add locally finite partitions, countable developments, or uniform-star generation to the packet.

Therefore any downstream citation of the neighbours passes through S as a handoff and returns to the same point-finite refinement surface. □

Theorem 3746.6 (Metacompact transport stability)**.** *Transporting an accepted* $\mathsf{Metacompact}^{\uparrow}$ *read along H preserves the topology source T, open-cover request O, refinement row R, point-finite incidence row Q, exactness row I, sibling handoff S, replay row C, provenance P, and local naming row N. The transported classifier still reads only the displayed point-finite refinement packet.*

Proof. The row H is componentwise by definition of the carrier. It transports the same open-cover request, refinement cells, point-finite incidence lists, exactness row, and sibling handoff.

The classifier has no alternate coordinate for cover selection or compactness. After transport, the accepted read is still checked by the same rows $T, O, R, Q, I, S, C, P, N$ and by no hidden cover operation. □

Theorem 3746.7 (Metacompact nonescape)**.** *No consumer of an accepted* $\mathsf{Metacompact}^{\uparrow}$ *packet can read selected subcovers, locally finite partitions of unity, Moore developments, uniform star-refinement generation, ambient compactness, or standard bridge data from the packet. All consumer reads are confined to $T, O, R, Q, I, S, H, C, P, N$.*

Proof. Inspect the carrier coordinates. The only cover-theoretic data are the open-cover request O, open refinement R, point-finite incidence row Q, exactness row I, and sibling handoff S.

Transport, replay, provenance, and naming do not add cover choices. They preserve and expose the same finite rows already present in the carrier.

The excluded stronger objects have no projection from $T, O, R, Q, I, S, H, C, P, N$, so a consumer cannot extract them from the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{Metacompact}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Metacompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3746.1, Definition 3746.2, and Definition 3746.4 seed the finite point-finite open-refinement packet over topology source, open-cover request, refinement, incidence, exactness, sibling handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Metacompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subcovers, local finiteness, partitions of unity, Moore-space development extraction, uniform star-refinement generation, Lean verification, or standard bridge closure.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, point-finite refinement exactness, sibling cover handoff, transport stability, and nonescape for BEDC.Derived.MetacompactUp.

Constructive story: A $\mathsf{Metacompact}^{\uparrow}$ packet is generated from a topology source row, open-cover request row, open-refinement row, point-finite incidence ledger, coverage-and-incidence exactness row, sibling cover handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3747

A Concrete Naming Certificate for FiniteRecognizerCarrierObstruction$^{\uparrow}$

The FiniteRecognizerCarrierObstruction$^{\uparrow}$ packet realizes the recognizer-to-carrier boundary in chapter 9379 as a finite seven-row NameCert obstruction. It sits beside the recognizer-flow packet of chapter 1048, the finite reflection tuple of chapter 993, the normalization certificate router of chapter 1108, and the inductive-acceptance packet of chapter 915. The packet names the finite landing surface that must be present before a recognizer-derived carrier can even be compared with a standard-bridge question.

Definition 3747.1 (FiniteRecognizerCarrierObstruction carrier)**.** *A* FiniteRecognizerCarrierObstruction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, G, Q, F, R, T, K, H, C, P, N)$$

with the following displayed rows:

1. *A is the recognizer-acceptance row consumed from* GroundCompilerRecognizerFlow$^{\uparrow}$*.*
2. *G is the generated-recognizer mediation row, recording that the accepted recognizer is the generated object read by the compiler-facing flow.*
3. *Q is the certificate-gate row, recording that the recognizer output has passed the displayed gate before any carrier comparison is attempted.*
4. *F is the finite tuple extraction row consumed through* FiniteReflectionTuple$^{\uparrow}$*.*
5. *R is the component readback row, exposing the* BHist *components recovered from the finite tuple image.*
6. *T is the componentwise* hsame *and* NameCert *transport row for the recovered components.*
7. *K is the* ChapterTasteGate *row for the displayed carrier-facing surface.*
8. *H records componentwise* hsame *transport for $A, G, Q, F, R, T, K, C, P, N$.*
9. *C records displayed* Cont *replay from recognizer acceptance through generated-recognizer mediation, certificate gate, tuple extraction, readback, componentwise transport,* ChapterTasteGate*, provenance, and local naming.*
10. *P is the* Pkg *provenance over* FiniteRecognizerCarrierObstruction$^{\uparrow}$*,* GroundCompilerRecognizerFlow$^{\uparrow}$*,* FiniteReflectionTuple$^{\uparrow}$*,* MetaCICNormalizationCertificateRouter$^{\uparrow}$*,* KernelInductiveAcceptance$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, and* ChapterTasteGate *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRecognizerCarrierObstruction}^{\uparrow}}$ *row.*
The carrier does not construct a recognizer-to-carrier map, does not assert unrestricted beta-conversion, and does not supply a StandardBridge *theorem. It only records the finite landing rows that a later construction must expose before those questions are reached.*

Lean4 (definition) `BEDC.Derived.FiniteRecognizerCarrierObstructionUp.FiniteRecognizerCarrierObstructionUp`

Theorem 3747.2 (FiniteRecognizerCarrierObstruction NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRecognizerCarrierObstruction}^{\uparrow}$ *carrier* $O = (A, G, Q, F, R, T, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteRecognizerCarrierObstruction}^{\uparrow}}$ *surface consists exactly of recognizer acceptance, generated-recognizer mediation, certificate-gate admission, finite tuple extraction, component readback, componentwise* hsame *and* NameCert *transport,* ChapterTasteGate *exposure, componentwise transport, replay, provenance, and local naming.*

Proof. Project the carrier. The first seven rows A, G, Q, F, R, T, K are the recognizer-to-carrier landing surface, while H, C, P, N are the structural rows that preserve and expose that surface.

Each obligation is read from its displayed row. Acceptance comes from A, generated-recognizer mediation from G, gate admission from Q, tuple extraction from F, readback from R, componentwise transport from T, and chapter-facing gate exposure from K.

No obligation row supplies a recognizer-to-carrier map or a standard bridge. The packet therefore isolates the obstruction boundary rather than resolving it. □

Theorem 3747.3 (FiniteRecognizerCarrierObstruction missing-row refusal)**.** *An attempted recognizer-to-carrier read that omits any one of A, G, Q, F, R, T, K fails inside the* $\mathsf{FiniteRecognizerCarrierObstruction}^{\uparrow}$ *packet before the* StandardBridge *question is reached. The failure is a missing landing row, not a failed bridge theorem.*

Proof. Use the obligation surface of Definition 3747.2. It lists the seven landing rows as jointly required before the carrier-facing surface is displayed.

If one row is absent, the replay route C cannot traverse the full path from recognizer acceptance to ChapterTasteGate. The packet then records the absence as an obstruction at the landing surface.

Since the packet has no StandardBridge theorem coordinate, such a failure occurs before bridge comparison and cannot be read as a bridge counterexample. □

Theorem 3747.4 (FiniteRecognizerCarrierObstruction seven-row landing)**.** *If a packet displays recognizer acceptance A, generated-recognizer mediation G, certificate-gate admission Q, finite tuple extraction F, component readback R, componentwise* hsame *and* NameCert *transport T, and* ChapterTasteGate *exposure K, together with the structural transport, replay, provenance, and local naming rows of Definition 3747.1, then the packet lands on the* $\mathsf{FiniteRecognizerCarrierObstruction}^{\uparrow}$ *surface before any* StandardBridge *question is evaluated.*

Proof. Project the carrier of Definition 3747.1. Its first seven displayed coordinates are exactly A, G, Q, F, R, T, K, and the remaining rows H, C, P, N preserve, replay, source, and name that same landing surface.

Apply Definition 3747.2. The obligation inventory recognizes the seven rows as the complete recognizer-to-carrier landing face, so a packet displaying all of them has reached the obstruction surface rather than a later bridge surface.

This is the positive side of Definition 3747.3. Omission of one landing row refuses the read, while display of all seven rows admits the finite obstruction surface. Neither direction constructs a recognizer-to-carrier map or closes a StandardBridge theorem. □

Theorem 3747.5 (FiniteRecognizerCarrierObstruction sibling nonbijection)**.** *The carrier of Definition 3747.1 is not bijective, row for row, with* GroundCompilerRecognizerFlow$^{\uparrow}$, FiniteReflectionTuple$^{\uparrow}$, MetaCICNormalizationCertificateRouter$^{\uparrow}$, *or* KernelInductiveAcceptance$^{\uparrow}$. *Any row-preserving bijection would have to preserve recognizer acceptance, generated-recognizer mediation, certificate-gate passage, tuple extraction, component readback, componentwise* hsame *and* NameCert *transport, and* ChapterTasteGate *exposure at once, and no listed sibling carries that whole surface.*

Proof. Compare first with GroundCompilerRecognizerFlow$^{\uparrow}$. It supplies recognizer acceptance, generated-recognizer mediation, and certificate-gate rows, but it does not carry finite tuple extraction, tuple readback, componentwise NameCert transport, and ChapterTasteGate exposure as one carrier.

Compare next with FiniteReflectionTuple$^{\uparrow}$. It supplies tuple image and readback rows, but it does not carry recognizer acceptance, generated-recognizer mediation, or certificate-gate passage.

The normalization router and inductive-acceptance packet have different endpoints. They record normalization evidence routing or inductive declaration acceptance, not the simultaneous seven-row recognizer-to-carrier landing surface. Hence no row-preserving bijection can identify them with this obstruction packet. □

Theorem 3747.6 (FiniteRecognizerCarrierObstruction TasteGate follow-up surface)**.** *Any Lean-side* Nontrivial *and* FieldFaithful *TasteGate instance for* FiniteRecognizerCarrierObstruction$^{\uparrow}$ *must preserve the displayed carrier rows* $A, G, Q, F, R, T, K, H, C, P, N$. *Nontriviality separates a complete seven-row landing from a missing-row obstruction, and field faithfulness requires every accepted read to retain each of the seven landing rows componentwise.*

Proof. The nontrivial boundary is visible in the carrier. A complete landing displays A, G, Q, F, R, T, K, while a failed landing omits at least one of those rows and is refused by Definition 3747.3.

Field faithfulness is componentwise. Preserving the recognizer-to-carrier obstruction requires preserving acceptance, generated recognizer, gate, tuple extraction, readback, componentwise transport, and ChapterTasteGate rows together.

Thus the later Lean instances must consume the same rows as the paper carrier and may not replace them by a vacuous or report-only encoding. □

Falsifiable prediction: Any attempted recognizer-to-carrier map missing recognizer acceptance, generated-recognizer mediation, certificate-gate admission, finite tuple extraction, component readback, componentwise hsame and NameCert transport, or ChapterTasteGate exposure fails before the StandardBridge question is reached.

Independence witness: groundcompilerrecognizerflow, finitereflectiontuple, metacicnormalizationcertificaterouter, kernelinductiveacceptance: GroundCompilerRecognizerFlow$^{\uparrow}$ records recognizer acceptance, generated-recognizer mediation, and certificate-gate passage without tuple extraction and readback; FiniteReflectionTuple$^{\uparrow}$ records tuple image and readback without recognizer-flow acceptance; MetaCICNormalizationCertificateRouter$^{\uparrow}$ routes normalization evidence without the seven-row recognizer landing surface; KernelInductiveAcceptance$^{\uparrow}$ records inductive declaration acceptance without recognizer-to-carrier landing. None is bijective to FiniteRecognizerCarrierObstruction$^{\uparrow}$.

Closure status for NameCert$_{\text{FiniteRecognizerCarrierObstruction}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{FiniteRecognizerCarrierObstruction}^{\uparrow}}$, seed)

Scope closed: Definition 3747.1, Definition 3747.2, and Definition 3747.3 seed the seven-row recognizer-to-carrier obstruction packet over recognizer acceptance, generated recognizer, certificate gate, finite tuple extraction, component readback, componentwise transport, ChapterTasteGate, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteRecognizerCarrierObstruction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a recognizer-to-carrier construction, unrestricted beta-conversion, standard bridge closure, Lean verification, or global MetaCIC normalization.

Upgrade path: Obligation closure requires checked carrier admission, seven-row landing exactness, missing-row refusal, sibling nonbijection, TasteGate nontriviality, and field faithfulness for BEDC.Derived.FiniteRecognizerCarrierObstructionUp.

Constructive story: A FiniteRecognizerCarrierObstruction$^{\uparrow}$ packet is generated from recognizer acceptance, generated-recognizer mediation, certificate-gate admission, finite tuple extraction, component readback, componentwise hsame and NameCert transport, ChapterTasteGate exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 3748

A Concrete Naming Certificate for $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy reals, the $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$ packet records the finite naming surface for the canonical modulus read from a regular rational Cauchy presentation. It sits after the dyadic tolerance rows of chapter 291, the finite window rows of chapter 126, the regular rational sequence carrier of chapter 301, and the real seal of chapter 38. The chapter names the displayed modulus object needed by the L10 RegSeqRat-to-Real route without importing an ambient Cauchy-search principle.

Definition 3748.1 (Regular Cauchy canonical modulus carrier)**.** *A* $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming dyadic radii, denominator windows, and scale comparison data.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row carrying the observed rational stream windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row recording the Cauchy bound read from the same windows.*
4. *Q is the canonical modulus row, assigning to each displayed tolerance scale the finite window at which the regularity row certifies stability.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached by the regular rational presentation.*
6. *H records componentwise* hsame *transport for the dyadic, stream, regularity, modulus, endpoint, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a modulus request through D, S, R, Q, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for unbounded search over Cauchy witnesses, quotient equality of real presentations, countable choice, a selected limit outside E, or a host completeness theorem.

Lean4 (definition) `BEDC.Derived.RegularCauchyCanonicalModulusUp.RegularCauchyCanonicalModulusUp`
Lean4 ✓ `BEDC.Derived.RegularCauchyCanonicalModulusUp.RegularCauchyCanonicalModulusTasteGate`
`single carrier alignment`

Theorem 3748.2 (Regular Cauchy canonical modulus NameCert obligations)**.** *For the carrier of Definition 3748.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dyadic tolerance row D, stream-window row S, regular rational row R, canonical modulus row Q, real endpoint row E, transport row H, replay row C, provenance row P, and local naming row N;*
2. *canonical-modulus exactness, requiring each tolerance scale read from D to be assigned by Q to a finite stream window already present in S and certified by the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
3. *classifier stability, requiring two accepted packets to compare only through componentwise* hsame *transport of D, S, R, Q, E, P, N;*
4. *endpoint nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to reach E only after the displayed dyadic, stream, regularity, and modulus rows have been read;*
5. *provenance and naming exactness, requiring P and N to record the same finite RegSeqRat-to-Real route.*

Proof. Carrier admission is projection from the displayed packet $K = (D, S, R, Q, E, H, C, P, N)$. Each row is finite BHist data, and no row names an ambient search operator.

Canonical-modulus exactness reads Q against the tolerance row D and stream row S. The regularity row R supplies the bounded Cauchy witness for the displayed finite window, so the modulus is canonical only relative to those already named rows.

For classifier stability, compare accepted packets componentwise through H. The dyadic, stream, regularity, modulus, endpoint, provenance, and local naming rows are transported together, and replay through C preserves the same route.

Finally inspect a $\mathsf{Real}^{\uparrow}$ consumer. It can reach the endpoint row E only through D, S, R, Q and the structural rows H, C, P, N, so quotient equality, countable choice, unbounded search, and host completeness are outside the NameCert surface. □

Theorem 3748.3 (Regular Cauchy canonical modulus RegSeqRat handoff)**.** *Every accepted* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *read that cites a* $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyCanonicalModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff first reads dyadic tolerance scales, then finite stream windows, then the regular rational Cauchy row, then the canonical modulus row, and only then the real endpoint seal. It supplies no independent limit selector, no quotient equality of presentations, no unbounded Cauchy-search oracle, and no ambient real-completeness argument.

Proof. Start with a RegSeqRat-to-Real consumer. The carrier forces the request to read D and S before the regularity row R can be interpreted, because the Cauchy bound is attached to dyadic scales and finite stream windows.

Next read the canonical modulus row Q. Its entries are finite assignments from displayed tolerance scales to displayed windows, with R certifying regularity on those windows.

The endpoint row E is then reached only through the same finite route. The structural rows H, C, P, N transport, replay, source, and name that route, so no absent search, quotient, selector, or completion principle can be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$ read factors through displayed DyadicRatCoreUp tolerance rows, StreamName finite windows, RegSeqRat regularity rows, a canonical modulus row, a RealUp endpoint seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerance scales, finite stream windows, regular rational Cauchy bounds, a canonical modulus assignment, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}$ packet is generated from dyadic tolerance scales, finite StreamName windows, RegSeqRat regularity rows, a canonical modulus assignment, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3748.1, Definition 3748.2, and Definition 3748.3 seed the finite canonical-modulus route from RegSeqRat data to the Real endpoint seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCanonicalModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality of real presentations, countable choice, unbounded Cauchy search, selected limits, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, canonical-modulus exactness, classifier stability, endpoint nonescape, and RegSeqRat handoff for the displayed packet.

Chapter 3749

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$

Following the Bishop–Bridges constructive-completion treatment, the $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$ packet records the finite stability surface by which a regular rational Cauchy name, its finite stream windows, dyadic tolerance ledger, terminal real seal, and completion-witness row remain attached to one completion route. It sits after the regular rational sequence interface of chapter 301, the stream-window naming surface of chapter 126, the dyadic rational core of chapter 291, the real-name seal of chapter 38, and the completion witness boundary of chapter 3579. The packet names finite stability and idempotence-boundary data for the displayed route; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of streams, selected limits, countable choice, or an external completion theorem.

Definition 3749.1 (Regular Cauchy completion stability carrier)**.** *A* $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational Cauchy name and its finite tolerance schedule.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that selects the finite source observations inspected by the completion route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison rows used to certify regularity on the selected windows.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the regular sequence, stream windows, and dyadic tolerance ledger.*
5. *E is the* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *row, exposing only the displayed completion-witness surface attached to Q, W, D, R.*
6. *H records componentwise* hsame *transport for the regular sequence, stream windows, dyadic ledger, real seal, completion witness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from Q through W, D, R, E and back to the local naming row.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a chosen limit representative, ambient completeness of $\mathsf{Real}^{\uparrow}$*, countable choice, trichotomy, or a second completion route.*

Theorem 3749.2 (Regular Cauchy completion stability NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$ *carrier $S = (Q, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCom}}$ *surface consists exactly of carrier admission for the displayed rows; regular-source exposure through Q; finite window selection through W; dyadic tolerance accounting through D; real-seal confinement through R; completion-witness attachment through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionStabilityUp.RegularCauchyCompletionStabilityNameCertObligat`

Proof. Carrier admission is projection from Definition 3749.1. The accepted packet displays exactly the regular rational source, the finite window schedule, the dyadic tolerance ledger, the terminal real seal, and the completion-witness row.

The stability route is read in source order. The row Q supplies the regular Cauchy name, W selects the finite observations that a consumer may inspect, and D records the dyadic tolerance comparisons visible on those observations.

The rows R and E then bind the completion-facing read. The real seal R is reached only after Q, W, D have been displayed, and the completion witness E attaches to that same route rather than to an external completeness principle.

Finally H, C, P, N transport, replay, source, and name the route. Since no coordinate stores quotient stream equality, a chosen limit representative, ambient $\mathsf{Real}^{\uparrow}$ completeness, countable choice, trichotomy, or a second completion route, the listed rows exhaust the local NameCert obligations. □

Theorem 3749.3 (Regular Cauchy completion idempotence boundary)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyCompletenessWitness}^{\uparrow}.$$

If the consumer asks to complete a route already sealed by R and witnessed by E, the packet can only replay the same displayed rows $Q, W, D, R, E, H, C, P, N$. It cannot introduce a quotient of streams, a selected representative of the limit, a second real seal, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionStabilityUp.RegularCauchyCompletionStabilityCarrier idempotence boundary`

Proof. Start with a completion-facing read of the carrier. By Definition 3749.1, the only source of regular Cauchy data is Q, and every finite observation passes through the stream window row W and dyadic tolerance ledger D.

The completion read reaches R and E only along this route. Thus the real seal and the completion witness are already attached to the finite regular-source path before any consumer receives the packet.

For a second completion request, replay C and transport along H. The replay has no coordinate that could manufacture a quotient stream, chosen limit, second real seal, or ambient completeness proof, so the request remains on $Q, W, D, R, E, H, C, P, N$. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$ consumer that exports a completion witness without first displaying the RegSeqRat source, StreamName windows, DyadicRatCore tolerance ledger, and RealUp seal refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchy-completeness-witness: these sibling chapters supply regular schedules, finite windows, dyadic tolerance rows, real seals, and completion witnesses separately, while this packet binds them into the finite stability carrier $S = (Q, W, D, R, E, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionStability}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionStability}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName finite windows, a DyadicRatCore tolerance ledger, a RealUp seal, a CauchyCompletenessWitness row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3749.1, Definition 3749.2, and Definition 3749.3 seed the finite regular-Cauchy completion stability surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-source exposure, finite-window selection, dyadic tolerance accounting, real-seal confinement, completion-witness attachment, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionStabilityUp.

Chapter 3750

A Concrete Naming Certificate for $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ packet records the finite subsequence bridge from a bounded real sequence display toward regular-Cauchy extraction. It sits between the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational handoff of chapter 301, the finite stream schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the bounded regular Cauchy route of chapter 1698, the bounded interval route of chapter 3716, and the diagonal extraction route of chapter 3469. The packet names the monotone-window surface used by Bolzano-Weierstrass-style arguments; it does not select an infinite subsequence or assert classical compactness.

Definition 3750.1 (Bounded monotone subsequence carrier)**.** *A* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, D, I, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule exposing the finite sequence windows available to the packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the dyadic tolerances and rational comparisons used inside the windows.*
3. *I is the bounded interval row naming the finite lower and upper barriers consumed by the monotone-window read.*
4. *W is the monotone-window ledger, consisting of a finite subsequence index list, a direction tag, and the displayed comparisons proving monotonicity inside the named window.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from S, D, I, W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular-rational handoff has been displayed.*
7. *H records componentwise* hsame *transport for the schedule, dyadic ledger, interval bounds, monotone window, regular handoff, Real seal, continuation, provenance, and local name rows.*
8. *C records displayed* Cont *replay from finite window requests through the dyadic ledger, interval bounds, monotone window, regular-rational handoff, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneSubsequence}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, I, W, R, E, H, C, P, N$. It has no coordinate for a chosen infinite subsequence, quotient real equality, trichotomy, countable choice, full Bolzano-Weierstrass compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedMonotoneSubsequenceUp.BoundedMonotoneSubsequenceTasteGate single carrier alignment`

Theorem 3750.2 (Bounded monotone subsequence monotone-window preservation)**.** *For an accepted* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ *carrier $X = (S, D, I, W, R, E, H, C, P, N)$, every subsequence read exposed by the packet preserves the displayed monotone-window ledger W under the componentwise transport H and replay row C. The read first consumes the finite stream schedule S, the dyadic comparison ledger D, and the interval bound row I; only then may it read the monotone direction and finite subsequence list stored in W.*

Proof. Project the carrier rows. The stream schedule S is the only source of sequence observations, while D and I are the only rows that record the comparison scale and bounded interval data used by the window.

The monotone-window row W is therefore downstream of S, D, I. A consumer that asks for an increasing or decreasing window must read the finite index list and direction tag from W, and the displayed comparisons in D certify the order relation inside the named interval row.

Transport and replay do not add another source. The row H preserves the same displayed coordinates componentwise, and C replays the request path through the same windows and comparisons. Since the carrier has no coordinate for a chosen infinite subsequence, trichotomy, countable choice, or ambient completeness, the monotone-window surface is exactly the finite one stored in W. □

Theorem 3750.3 (Bounded monotone subsequence regular-Cauchy handoff)**.** *Every regular-Cauchy consumer of an accepted* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ *carrier factors through the displayed route*

$$S \longmapsto D \longmapsto I \longmapsto W \longmapsto R \longmapsto E$$

together with H, C, P, N. The handoff can be consumed by the bounded regular Cauchy, bounded interval, and diagonal Cauchy subsequence packets, but it does not identify quotient real representatives, choose an infinite subsequence, or assert $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a regular-Cauchy read. Carrier admission gives the finite schedule S, the dyadic ledger D, the bounded interval row I, and the monotone-window row W as the only pre-handoff data.

Apply the monotone-window preservation theorem. The consumer cannot read R until the finite monotone comparisons in W have been displayed over the same S, D, I rows.

The regular-rational row R is then the unique handoff available to the downstream Cauchy packets, and the Real seal row E is downstream of that handoff. The structural rows H, C, P, N preserve, replay, source, and name the same route. Hence bounded regular Cauchy, bounded interval, and diagonal Cauchy consumers may reuse the finite handoff, but no quotient equality, choice-selected infinite subsequence, or ambient completeness principle is exported. □

Theorem 3750.4 (Bounded monotone subsequence NameCert obligations)**.** *For every accepted* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ *carrier $X = (S, D, I, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneSubseque}}$

surface consists exactly of carrier admission, finite-window classification, dyadic comparison coverage, bounded-interval nonescape, monotone-window preservation, regular-Cauchy handoff, Real-seal nonescape, and provenance replay through H, C, P, N.

No obligation row is stored outside the displayed carrier, and no exported read depends on full Bolzano-Weierstrass, chosen infinite subsequences, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission projects the tuple $S, D, I, W, R, E, H, C, P, N$. The finite-window classifier reads S, the dyadic comparison coverage reads D, and bounded-interval nonescape reads I before any subsequence-facing row is available.

Monotone-window preservation is supplied by Definition 3750.2. It makes W the finite source of the direction tag, subsequence index list, and displayed monotone comparisons.

Regular-Cauchy and Real-facing obligations are supplied by Definition 3750.3. The regular-rational row R and Real seal row E remain downstream of the same finite window data.

The structural rows close the surface. The transport H, replay C, provenance P, and local name N preserve and source the displayed route, and the carrier contains no coordinate for the excluded classical or ambient-completeness principles. Therefore the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedMonotoneSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ packet is generated from a StreamName schedule, a DyadicRatCore comparison ledger, bounded interval rows, a finite monotone-window ledger, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedMonotoneSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3750.1, Definition 3750.2, Definition 3750.3, and Definition 3750.4 name the finite monotone-window bridge from bounded real sequence data to regular-Cauchy extraction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedMonotoneSubsequence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BoundedMonotoneSubsequenceUp.BoundedMonotoneSubsequenceTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close full Bolzano-Weierstrass, chosen infinite subsequences, quotient real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier, monotone-window, regular-Cauchy handoff, Real-seal, transport, replay, provenance, and local NameCert rows for the same finite packet.

Chapter 3751

A Concrete Naming Certificate for $\mathsf{DistributionDerivative}^{\uparrow}$

Following Schwartz distribution theory and Evans' weak-derivative presentation for PDE, the $\mathsf{DistributionDerivative}^{\uparrow}$ packet names the finite action route by which a distribution is differentiated through test probes. It sits after the distribution endpoint interface of chapter 186, the weak-derivative handoff of chapter 2210, the Sobolev ledger of chapter 440, the real seal of chapter 38, the regular rational readback surface of chapter 301, and the finite stream windows of chapter 126. The chapter records only the finite carrier, its naming obligations, and the weak-action route needed by downstream PDE and variational consumers.

Definition 3751.1 (Distribution derivative carrier)**.** *A* $\mathsf{DistributionDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, D, I, E, Q, W, H, C, P, N)$$

with the following displayed rows:

1. *A is the test-action row, listing the finite test probes, support windows, sign convention, and coordinate direction.*
2. *D is the input* $\mathsf{Distribution}^{\uparrow}$ *row, read only by evaluating the tests named in A.*
3. *I is the integration-by-parts sign row, recording the displayed minus sign and coordinate handoff for the derivative action.*
4. *E is the candidate derivative action row on the same finite tests.*
5. *Q is the shared* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for input and candidate action values.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row selecting the finite tests, tolerances, and readback prefixes.*
7. *H records componentwise* hsame *transport for $A, D, I, E, Q, W, C, P, N$.*
8. *C records displayed* Cont *replay from test selection to input action, candidate action, readback, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{DistributionDerivative}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DistributionDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for a host distribution quotient, selected representative, completed test-function space, full PDE regularity theorem, or ambient Real completeness.

Theorem 3751.2 (Distribution derivative NameCert obligations)**.** *For every accepted* $\mathsf{DistributionDerivative}^{\uparrow}$ *carrier* $K = (A, D, I, E, Q, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DistributionDerivative}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, test-action coverage, input distribution access, integration-by-parts sign exposure, candidate derivative action exposure, shared* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, finite* $\mathsf{StreamName}^{\uparrow}$ *window selection, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.DistributionDerivativeUp.DistributionDerivativeTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3751.1. The analytic rows visible to a consumer are A, D, I, E, Q, W: tests, input distribution action, sign handoff, candidate derivative action, readback, and finite windows.

The structural rows H, C, P, N preserve and name only that route. Componentwise transport may compare two accepted packets, and replay may re-read the same displayed action chain, but neither operation creates a host derivative object.

Since the carrier has no coordinate for distribution quotients, selected representatives, completed test-function spaces, full PDE regularity, or ambient Real completeness, the NameCert obligations are exactly the displayed finite rows. □

Theorem 3751.3 (Distribution derivative weak-action route)**.** *Every* $\mathsf{WeakDerivative}^{\uparrow}$*,* $\mathsf{Sobolev}^{\uparrow}$*, PDE, trace, Rellich, or variational consumer of an accepted* $\mathsf{DistributionDerivative}^{\uparrow}$ *packet must read the derivative through the finite route*

$$A \longmapsto D, I, E \longmapsto Q \longmapsto W \longmapsto H, C, P, N.$$

The route supplies a distribution action and a candidate derivative action on the same displayed tests, with shared readback and stream windows. It does not supply quotient equality of distributions, a chosen representative, Sobolev completion, density of smooth tests, elliptic regularity, trace compactness, or a completed Real carrier.

Proof. Begin with a derivative-facing consumer. The test row A fixes the probes and support windows before any action value can be inspected.

Read D, I, E next. The input distribution action and candidate derivative action are tied by the displayed sign handoff, and both actions are evaluated only on the tests already selected by A.

Finally read Q, W, H, C, P, N. These rows provide real and regular-rational readback, finite windows, transport, replay, provenance, and local naming for the same action route. No absent analytic completion or quotient surface can be recovered from that finite packet. □

Falsifiable prediction: Every accepted $\mathsf{DistributionDerivative}^{\uparrow}$ weak-action read factors through a displayed test-action row, input DistributionUp row, integration-by-parts sign row, candidate derivative action row, shared RealUp and RegSeqRatUp readback, StreamName windows, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: distribution, weak-derivative, sobolev, real, regseqrat, streamname: $\mathsf{DistributionDerivative}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries input distribution action, candidate derivative action, sign handoff, shared readback, finite windows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DistributionDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{DistributionDerivative}^{\uparrow}$ packet is generated from finite test-action rows, an input DistributionUp row, an integration-by-parts sign row, a candidate derivative action row, shared RealUp and RegSeqRatUp readback, StreamName windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistributionDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3751.1, Definition 3751.2, and Definition 3751.3 seed the finite distribution-action derivative packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistributionDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution quotients, selected representatives, completed test-function spaces, full PDE regularity, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-action exactness, sign-handoff stability, readback stability, weak-action nonescape, and TasteGate field faithfulness for BEDC.Derived.DistributionDerivativeUp.

Chapter 3752

A Concrete Naming Certificate for $\mathsf{NetClusterPoint}^{\uparrow}$

Following Moore–Smith and Kelley cluster points, the $\mathsf{NetClusterPoint}^{\uparrow}$ packet records cluster-point evidence for a directed net through displayed cofinal tails and neighbourhood hits rather than through a selected subnet or an ambient compactness theorem. It sits over the Moore–Smith net carrier of chapter 3403, the directed-index surface of chapter 1607, the cofinal subnet route of chapter 1600, the convergence interface of chapter 1667, and the compactness handoff of chapter 3660. The chapter names the finite BEDC landing for cluster-point evidence consumed by later net and compactness arguments, not a quotient of nets, a choice-selected subnet, or a host-level limit principle.

Definition 3752.1 (Net cluster-point carrier)**.** *A* $\mathsf{NetClusterPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, D, S, T, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *source row, naming the directed net, its displayed value windows, and the finite tail ledger consumed by every cluster-point read.*
2. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index row, exposing the upper-window witnesses needed to compare tail requests.*
3. *S is the* $\mathsf{DirectedSubnet}^{\uparrow}$ *cofinal-tail row. It records the cofinal reindexing evidence through which a cluster-point consumer may follow a subnet-shaped tail without selecting an external subnet representative.*
4. *T is the* $\mathsf{NetConvergence}^{\uparrow}$ *neighbourhood-hit row. It records that each displayed neighbourhood request is met along the cofinal tail route before a convergence-facing consumer is exposed.*
5. *L is the* $\mathsf{LimitPointCompact}^{\uparrow}$ *handoff row, available only after the Moore–Smith source, directed index, cofinal-tail, and neighbourhood-hit rows have been displayed.*
6. *H records componentwise* hsame *transport for the Moore–Smith net row, directed-index row, cofinal-tail row, neighbourhood-hit row, compactness handoff, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a cluster-point request through M, D, S, T, L, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{NetClusterPoint}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{DirectedSubnet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{LimitPointCompact}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{NetClusterPoint}^{\uparrow}}$ *row.*

The carrier contains no quotient-net coordinate, no selected cluster point, no countable-choice subnet selector, no host neighbourhood filter, and no ambient compactness or completeness theorem.

Lean4 ✓ `BEDC.Derived.NetClusterPointUp.NetClusterPointTasteGate single carrier alignment`

Theorem 3752.2 (Net cluster-point NameCert obligations)**.** *For every accepted* $\mathsf{NetClusterPoint}^{\uparrow}$ *carrier $K = (M, D, S, T, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NetClusterPoint}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Moore–Smith source, directed-index row, cofinal-tail row, neighbourhood-hit row, compactness handoff, transport, replay, provenance, and local naming rows;*
2. *source-tail exposure, requiring each cluster-point request to read the* $\mathsf{MooreSmithNet}^{\uparrow}$ *value window and* $\mathsf{DirectedSet}^{\uparrow}$ *upper-window witnesses before any neighbourhood-hit row is consumed;*
3. *cofinal-tail exactness, requiring the* $\mathsf{DirectedSubnet}^{\uparrow}$ *row S to expose only displayed cofinal reindexing data from the same directed source;*
4. *neighbourhood-hit routing, requiring T to route every cluster-point neighbourhood request through the* $\mathsf{NetConvergence}^{\uparrow}$ *interface before the compactness handoff is visible;*
5. *compactness handoff, requiring L to consume only the displayed cluster route supplied by M, D, S, T before any* $\mathsf{LimitPointCompact}^{\uparrow}$ *consumer receives the packet;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

Consequently the packet supplies finite Moore–Smith cluster-point evidence and exports no quotient of nets, selected subnet, host neighbourhood filter, countable choice, or ambient compactness theorem.

Proof. Project the accepted carrier of Definition 3752.1. Its analytic rows are M, D, S, T, L, and its structural rows are H, C, P, N.

The source-tail exposure is read from M and D. A cluster-point consumer first names the displayed Moore–Smith net window, then reads the directed upper-window witness that places the request inside the finite tail ledger.

The cofinal route is fixed by S. Since S is a $\mathsf{DirectedSubnet}^{\uparrow}$ row over the same directed source, it contributes only displayed cofinal-tail evidence and cannot introduce a selected subnet representative or a countable-choice selector.

The neighbourhood-hit row T is downstream of that cofinal route. It uses the $\mathsf{NetConvergence}^{\uparrow}$ interface to expose only the finite neighbourhood hits visible along the displayed tail, so no host neighbourhood filter or quotient-net equality is available.

Lean4 ✓ `BEDC.Derived.NetClusterPointUp.NetClusterPoint neighbourhood hit netconvergence dependency`

Finally L hands the route to $\mathsf{LimitPointCompact}^{\uparrow}$, while H, C, P, N transport, replay, source, and name the same finite packet. The carrier inventory has no stronger compactness or completeness coordinate, so the local certificate is exhausted by the stated obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{NetClusterPoint}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NetClusterPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3752.1 and Definition 3752.2 seed the finite cluster-point route through MooreSmithNet, DirectedSet, DirectedSubnet, NetConvergence, LimitPointCompact, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{NetClusterPoint}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient nets, selected subnets, countable-choice selectors, host neighbourhood filters, ambient compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-tail exposure, cofinal-tail exactness, neighbourhood-hit routing, compactness handoff, transport, replay, provenance, and local naming for BEDC.Derived.NetClusterPointUp.

Constructive story: A NetClusterPoint$^{\uparrow}$ packet is generated from a MooreSmithNet source row, a DirectedSet index row, a DirectedSubnet cofinal-tail row, a NetConvergence neighbourhood-hit row, a LimitPointCompact handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3753

A Concrete Naming Certificate for $\mathsf{GreedySpectralClosure}^{\uparrow}$

The $\mathsf{GreedySpectralClosure}^{\uparrow}$ packet realizes the block-optimal spectral closure route of Definition 9462.1419 as finite BEDC NameCert data. It reads the active codon support, fixed-budget spectral frontiers, anchor and median layers, and symmetric inactive completion from the DNA-window spectral closure vision, then records only the finite trigger-spectrum rows needed by downstream finite-window and trigger-algebra consumers.

The trigger-spectrum route consumes the finite observation discipline of chapter 689, the boolean trigger rows of chapter 3704, the window-coverage trigger algebra of chapter 3478, and the stabilization surface of chapter 2270. Thus the packet is not a kernel-only spectral table: its support, trigger, and layered-closure rows are read as sibling finite-window and trigger-algebra data before the local NameCert row can be consumed.

Definition 3753.1 (Greedy spectral closure carrier)**.** *A* $\mathsf{GreedySpectralClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, A, M, T, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the active support row for $\mathcal{R}$ and the finite complement inside Q_6.*
2. *A is the anchor-block row naming the unique three-point spectral maximizer* $\{\mathrm{AAG}, \mathrm{ACA}, \mathrm{UGG}\}$.
3. *M is the median-block row naming the next three-point spectral maximizer* $\{\mathrm{AUG}, \mathrm{UCG}, \mathrm{UUG}\}$.
4. *T is the terminal singleton row naming* ACG *as the next single-point spectral maximizer.*
5. *R is the radius table row carrying the displayed killed-walk spectral values and multiplicity counts.*
6. *L is the layered-closure row saying that the packet is block-optimal rather than a nested fixed-budget optimum from $\mathcal{R}$.*
7. *H records componentwise* hsame *transport for support, anchor, median, terminal, radius, layered-closure, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a trigger-spectrum request through S, A, M, T, R, L, H.*
9. *P is the* Pkg *provenance over* $\mathsf{GreedySpectralClosure}^{\uparrow}$, $\mathsf{FiniteWindowObserver}^{\uparrow}$, $\mathsf{BooleanTriggerLattice}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{SpectralStabilization}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GreedySpectralClosure}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, A, M, T, R, L, H, C, P, N$. It has no coordinate for a host Perron-root oracle, biological-code truth, stochastic evolution model, quotient codon semantics, or unbounded spectral search.

Lean4 (definition) `BEDC.Derived.GreedySpectralClosureUp.GreedySpectralClosureUp`

Theorem 3753.2 (Greedy spectral closure NameCert obligations)**.** *For every accepted* $\mathsf{GreedySpectralClosure}^{\uparrow}$ *carrier* $G = (S, A, M, T, R, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GreedySpectralClosure}^{\uparrow}}$ *surface consists exactly of finite support admission, anchor-block exposure, median-block exposure, terminal singleton exposure, spectral table exposure, layered-closure exposure, componentwise transport, displayed replay, provenance, and local naming.*

The Lean follow-up for this packet should provide Nontrivial and FieldFaithful instances for BEDC.Derived.GreedySpectralClosureUp so that $S, A, M, T, R, L, H, C, P, N$ remain separated carrier fields.

Proof. Project the carrier of Definition 3753.1. The rows S, A, M, T, R, L expose the finite support, the three chosen blocks, the spectral table, and the layered-closure reading before any consumer can cite the packet.

The spectral data are finite table rows. They record the displayed optima and multiplicities from the vision file, but they do not introduce a Perron-root oracle or an unbounded search procedure.

The structural rows H, C, P, N preserve that route. Since no host biological truth predicate, stochastic model, quotient codon equality, hidden spectral computation, or unbounded enumeration is a carrier coordinate, the local NameCert obligations are exactly the listed rows. □

Theorem 3753.3 (Greedy spectral closure trigger nonescape)**.** *Every trigger-spectrum consumer of an accepted* $\mathsf{GreedySpectralClosure}^{\uparrow}$ *packet factors through*

$$S \longmapsto A, M, T \longmapsto R, L \longmapsto H, C, P, N.$$

The route may cite the finite anchor block, median block, terminal singleton, displayed spectral values, and layered-closure row. It cannot export a biological-code oracle, a stochastic evolutionary law, an ambient powerset closure, quotient codon equality, or an unbounded spectral optimizer.

Proof. Start with the finite support row S. It fixes the active support and complement inside the displayed codon window, so no later read can range over an unbounded search space.

Read the rows A, M, T next. They name the anchor block, median block, and terminal singleton as the finite closure path consumed by trigger-spectrum clients.

The table and layered rows R, L identify the route as block-optimal and budget-frustrated. They do not change the packet into a global optimizer, because the carrier stores only the displayed values and multiplicities.

Finally H, C, P, N transport, replay, source, and name the same route. The absent host objects listed in the statement are not coordinates of the carrier and cannot be exported by a consumer read. □

Theorem 3753.4 (Greedy spectral closure sibling trigger route)**.** *Let* $G = (S, A, M, T, R, L, H, C, P, N)$ *be an accepted* $\mathsf{GreedySpectralClosure}^{\uparrow}$ *carrier. Every trigger-spectrum consumer of G first reads the finite-window observer, boolean trigger lattice, window-coverage trigger algebra, and spectral-stabilization sibling rows recorded in P before it consumes the displayed rows*

$$S, A, M, T, R, L, H, C, P, N.$$

Consequently the packet cannot be consumed as an isolated spectral kernel detached from finite observation, trigger algebra, coverage, or stabilization surfaces.

Proof. Project the provenance row P in Definition 3753.1. It names $\mathsf{FiniteWindowObserver}^{\uparrow}$, $\mathsf{BooleanTriggerLattice}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, and $\mathsf{SpectralStabilization}^{\uparrow}$ as part of the same accepted packet source.

The finite-window observer fixes the public observation row from which the active support S is read. The boolean trigger lattice and window-coverage trigger algebra then supply the trigger rows against which the anchor, median, and terminal rows A, M, T are interpreted.

Only after those sibling rows are in place can the displayed spectral table and layered-closure rows R, L be consumed. The structural rows H, C, P, N transport, replay, source, and name that route, so no consumer can bypass the sibling finite-window and trigger-algebra surfaces while still reading G as an accepted $\mathsf{GreedySpectralClosure}^{\uparrow}$ packet. □

Falsifiable prediction: An accepted $\mathsf{GreedySpectralClosure}^{\uparrow}$ trigger-spectrum read is refuted if the anchor block, median block, terminal singleton, displayed spectral table, layered-closure row, transport, replay, provenance, or local naming can be removed while preserving the same packet claim.

Independence witness: finite-window-observer, boolean-trigger-lattice, window-coverage-trigger-algebra, spectral-stabilization, dna-window spectral closure vision: none is bijective with $\mathsf{GreedySpectralClosure}^{\uparrow}$ because the packet jointly carries support, anchor, median, singleton, spectral table, layered closure, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GreedySpectralClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{GreedySpectralClosure}^{\uparrow}$ packet is generated from active support rows, anchor-block rows, median-block rows, terminal singleton rows, displayed spectral table rows, layered-closure rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GreedySpectralClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3753.1, Definition 3753.2, and Definition 3753.3 seed the finite trigger-spectrum closure packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GreedySpectralClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim biological-code truth, stochastic evolutionary dynamics, ambient powerset closure, quotient codon equality, hidden spectral computation, unbounded optimization, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trigger-spectrum exactness, displayed-table stability, Nontrivial and FieldFaithful instances, and trigger nonescape for BEDC.Derived.GreedySpectralClosureUp.

Chapter 3754

A Concrete Naming Certificate for $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ packet names the finite comparison surface between two displayed Cauchy-complete ordered-field presentations of a Real-style object. It reads the terminal $\mathsf{Real}^{\uparrow}$ seal, regular rational sequence rows, dyadic arithmetic ledger, algebra-order rows, the $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ interface, and the $\mathsf{CompleteArchimedeanField}^{\uparrow}$ capstone as input packets, then records only the BEDC route that compares their NameCert-visible rows. The chapter exports uniqueness as rowwise route agreement, not as quotient field equality, trichotomy, a selected limit, or a host complete ordered field.

Definition 3754.1 (Cauchy-complete ordered-field uniqueness carrier)**.** *A* $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K_0, K_1, R_0, R_1, Q_0, Q_1, D, A_0, A_1, F_0, F_1, G, H, C, P, N)$$

with the following displayed rows:

1. *K_0 and K_1 are two accepted* $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ *packets whose Real-facing reads are to be compared.*
2. *R_0 and R_1 are the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows exposed by K_0 and K_1.*
3. *Q_0 and Q_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows used before the terminal Real seals are consumed.*
4. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger for precision scales, rational windows, and tolerance transfer.*
5. *A_0 and A_1 are the* $\mathsf{RealAlgOrder}^{\uparrow}$ *operation-and-order rows displayed by the two packets.*
6. *F_0 and F_1 are the* $\mathsf{CompleteArchimedeanField}^{\uparrow}$ *capstone rows reached from the two Cauchy-complete ordered-field presentations.*
7. *G is the BEDC comparison route, recording componentwise agreement of the regular-rational windows, dyadic tolerances, Real seals, algebra-order rows, Cauchy-complete ordered-field rows, and complete Archimedean capstone rows.*
8. *H records componentwise* hsame *transport for all displayed rows of U.*
9. *C records displayed* Cont *replay from a comparison request through $Q_0, Q_1, D, R_0, R_1, A_0, A_1, K_0, K_1, F_0, F_1, G, H$*

10. *P is the* Pkg *provenance over* CauchyCompleteOrderedFieldUniqueness$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealAlgOrder$^{\uparrow}$, CauchyCompleteOrderedField$^{\uparrow}$, CompleteArchimedeanField$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted uniqueness packets only through these rows. It has no coordinate for quotient field equality, trichotomy, a selected limit, a chosen isomorphism outside G, or an ambient host complete ordered field.

Lean4 ✓ `BEDC.Derived.CauchyCompleteOrderedFieldUniquenessUp.CauchyCompleteOrderedFieldUniquenessTasteGa`
`single carrier alignment`

Theorem 3754.2 (Cauchy-complete ordered-field uniqueness sibling dependency route)**.** *Every accepted* CauchyCompleteOrderedFieldUniqueness$^{\uparrow}$ *carrier is a dependency consumer of the Real and Completion lattice. The two terminal seal rows R_0, R_1 are read through chapter 38; the readback rows Q_0, Q_1 are read through chapter 301; the shared tolerance ledger D is read through chapter 291; the operation-and-order rows A_0, A_1 are read through chapter 766; the comparison packets K_0, K_1 are read through chapter 3688; and the capstone rows F_0, F_1 are read through chapter 2025. Hence the uniqueness packet is not self-standing: its rowwise comparison route is grounded in those sibling chapters before any consumer may cite the uniqueness surface.*

Proof. Project the carrier U of Definition 3754.1. Its visible comparison data begins with the two regular rational readbacks Q_0, Q_1 and the shared dyadic ledger D, so a consumer must first pass through the RegSeqRat and DyadicRatCore sibling rows that make the tolerance comparison meaningful.

The Real seals R_0, R_1 are then consumed as terminal name rows, not as quotient-field equality. The algebra-order rows A_0, A_1 supply the operation-order surface used by the two Cauchy-complete ordered-field packets K_0, K_1.

Finally the complete Archimedean capstone rows F_0, F_1 and the comparison route G record agreement along the displayed BEDC path. The structural rows H, C, P, N preserve and name that path, so no host complete ordered field, selected isomorphism, trichotomy, or quotient equality can bypass the listed sibling dependencies. □

Theorem 3754.3 (Cauchy-complete ordered-field uniqueness NameCert obligations)**.** *For every accepted* CauchyCompleteOrderedFieldUniqueness$^{\uparrow}$ *carrier*

$$U = (K_0, K_1, R_0, R_1, Q_0, Q_1, D, A_0, A_1, F_0, F_1, G, H, C, P, N),$$

the local NameCert$_{\text{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}}$ *surface consists exactly of the two displayed* CauchyCompleteOrderedField$^{\uparrow}$ *packets, their* Real$^{\uparrow}$ *seal rows, their* RegSeqRat$^{\uparrow}$ *readback rows, the shared* DyadicRatCore$^{\uparrow}$ *comparison ledger, their* RealAlgOrder$^{\uparrow}$ *operation-and-order rows, their* CompleteArchimedean *capstone rows, the BEDC comparison route G, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3754.1. The projection exposes exactly the two Cauchy-complete ordered-field packets, the Real seals, regular-rational readbacks, dyadic comparison ledger, algebra-order rows, complete Archimedean capstone rows, comparison route, transport, replay, provenance, and local naming.

The comparison route first reads Q_0, Q_1 against the shared dyadic ledger D. This places every tolerance and rational-window comparison before the terminal Real seals R_0, R_1 are consumed.

It then compares the ordered-field surfaces through A_0, A_1 and the completion-facing surfaces through K_0, K_1, F_0, F_1. The row G records exactly this BEDC route and not an external field equality or selected isomorphism.

Finally H, C, P, N preserve, replay, source, and name the same displayed rows. Since quotient field equality, trichotomy, selected limits, and host complete ordered fields have no coordinate in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 3754.4 (Cauchy-complete ordered-field uniqueness route)**.** *Every accepted* CauchyCompleteOrderedFieldU *comparison between two displayed Cauchy-complete ordered-field packets factors through*

$$Q_0, Q_1, D \longmapsto R_0, R_1 \longmapsto A_0, A_1, K_0, K_1 \longmapsto F_0, F_1 \longmapsto G, H, C, P, N.$$

Thus a consumer may cite a finite BEDC route from regular rational readback and dyadic tolerance comparison through Real seals, algebra-order rows, Cauchy-complete ordered-field rows, and complete Archimedean capstone rows. The consumer receives no quotient field equality, trichotomy principle, selected limit, chosen external isomorphism, or host complete ordered field.

Proof. Start with the regular-rational side. The rows Q_0, Q_1 are the only readbacks available before Real sealing, and the shared ledger D supplies the dyadic precision and comparison data for both packets.

The route next reaches R_0, R_1. Only after these Real seals are displayed may the comparison inspect the algebra-order rows A_0, A_1 and the two $\mathsf{CauchyCompleteOrderedField}^{\uparrow}$ packets K_0, K_1.

The capstone comparison is then made through F_0, F_1, the $\mathsf{CompleteArchimedeanField}^{\uparrow}$ rows attached to the two presentations. The row G records that the two presentations agree along this displayed BEDC path.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Because no excluded equality, trichotomy, selected-limit, external-isomorphism, or host-field coordinate appears anywhere in the carrier, every uniqueness read factors through the finite route stated above. □

Theorem 3754.5 (Cauchy-complete ordered-field uniqueness regular-Cauchy dependency)**.** *Every accepted* $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ *packet must route its completion witness through the regular-Cauchy completion surface of chapter 1513 and the terminal Real seal of chapter 38 before it compares ordered-field endpoints. The ordered-field comparison therefore reads the displayed completion and real-name rows first; it does not introduce a host complete ordered field, quotient equality, or a selected external isomorphism.*

Proof. Begin with an accepted carrier U. Its only completion-facing source rows are the regular-rational readbacks Q_0, Q_1, the dyadic comparison ledger D, the Real seals R_0, R_1, and the Cauchy-complete ordered-field rows K_0, K_1.

The separated regular-Cauchy completion sibling supplies the finite completion route consumed by those rows, while the Real chapter supplies the terminal seal that the ordered-field comparison is allowed to inspect. Thus the comparison cannot jump directly from K_0, K_1 to endpoint equality.

Only after that route is displayed may the algebra-order rows A_0, A_1 and capstone rows F_0, F_1 be read. The comparison row G records agreement along this finite path, so no host complete ordered field, quotient equality, or external isomorphism is available. □

Falsifiable prediction: Every $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ comparison read factors through two CauchyCompleteOrderedField packets, two Real seals, two RegSeqRat readbacks, one DyadicRatCore comparison ledger, two RealAlgOrder rows, two CompleteArchimedeanField rows, one BEDC comparison route, transport, continuation replay, provenance, and local naming.

Independence witness: real, regseqrat, dyadicratcore, real-alg-order, cauchy-complete-ordered-field, complete-archimedean-field: $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two displayed complete ordered-field presentations and a rowwise comparison route between them.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ packet is generated from two CauchyCompleteOrderedField packets, two Real seals, two RegSeqRat readbacks, a DyadicRatCore comparison ledger, two RealAlgOrder rows, two CompleteArchimedeanField rows, one BEDC comparison route, componentwise transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3754.1, Definition 3754.3, and Definition 3754.4 seed the finite comparison surface for two displayed Cauchy-complete ordered-field presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not assert quotient field equality, trichotomy, selected limits, a chosen external isomorphism, a host complete ordered field, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, and the rowwise BEDC comparison route for BEDC.Derived.CauchyCompleteOrderedFieldUniquenessUp.

Chapter 3755

A Concrete Naming Certificate for $\mathsf{MetricCompletionFunctoriality}^{\uparrow}$

Following Bishop and Bridges constructive metric completion theory, the $\mathsf{MetricCompletionFunctoriality}^{\uparrow}$ packet records the finite route by which a uniformly controlled metric map induces a map between displayed completion packets. It sits after the metric completion carrier of chapter 1506, the functor-facing Cauchy completion surface of chapter 423, the universal extension ledger of chapter 397, the dense-extension route of chapter 3475, the regular rational readback of chapter 301, and the finite stream-window interface of chapter 126. The packet names functoriality only as displayed source, target, map, Cauchy-control, completion-entry, universal-property, comparison, transport, replay, provenance, and local NameCert rows; it is not a quotient-completion equality, a selected limit map, function extensionality, countable choice, or ambient completeness.

Definition 3755.1 (MetricCompletionFunctoriality carrier)**.** *A* $\mathsf{MetricCompletionFunctoriality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, G, A, E, U, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row whose completion-facing names are inspected.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose completion packet receives the induced read.*
3. *G is the finite graph row of the underlying map from source names to target names.*
4. *A is the Cauchy-control ledger, recording the modulus or window transfer by which* $\mathsf{StreamName}^{\uparrow}$ *observations of X yield* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks over Y.*
5. *E is the completion-entry row, naming the* $\mathsf{MetricCompletion}^{\uparrow}$ *source and target entries used by the induced map.*
6. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row through which the extension and uniqueness read is consumed.*
7. *S is the separated comparison row, requiring induced target reads to compare only through the displayed separated metric or dense-extension surface.*
8. *H records componentwise* hsame *transport for the source metric, target metric, graph, Cauchy-control, completion-entry, universal-property, separated-comparison, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a source completion request through G, A, E, U, S, H, P, N.*
10. *P is the* Pkg *provenance over* MetricCompletion$^{\uparrow}$, CauchyCompletionFunctoriality$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, DenseIsometryExtension$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MetricCompletionFunctoriality}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient completions, selected representatives of Cauchy classes, host function equality, countable-choice selection, an ambient completed metric space, or a second extension principle outside U.

```
Lean4 ✓  BEDC.Derived.MetricCompletionFunctorialityUp.MetricCompletionFunctorialityTasteGate
single carrier alignment
```

Theorem 3755.2 (MetricCompletionFunctoriality NameCert obligations)**.** *For every accepted* MetricCompletionFunctoriality$^{\uparrow}$ *carrier $F = (X, Y, G, A, E, U, S, H, C, P, N)$, the local* NameCert$_{\text{MetricCompletionFunctoria}}$ *surface consists exactly of carrier admission for the source metric, target metric, finite map graph, Cauchy-control ledger, completion-entry row, universal-property row, separated comparison row, componentwise transport, continuation replay, provenance, and local naming. Every induced completion read must pass through the* StreamName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *control recorded in A, the* MetricCompletion$^{\uparrow}$ *entry row E, the* CompletionUniversalProperty$^{\uparrow}$ *ledger U, and the separated comparison row S before the local name N is exposed.*

Proof. Project the carrier of Definition 3755.1. The rows $X, Y, G, A, E, U, S, H, C, P, N$ are the whole public packet, so source and target metric data, the map graph, the Cauchy-control ledger, completion entries, universal-property data, and separated comparison are all displayed before the induced map is consumed.

The Cauchy-control row supplies the constructive handoff. A source completion request first reads finite StreamName$^{\uparrow}$ windows, then the RegSeqRat$^{\uparrow}$ readback governed by A, and only then reaches the completion-entry row E.

The universal-property and comparison rows bind the extension. The row U records the extension-and-uniqueness ledger, while S keeps target comparison inside the displayed separated surface rather than in host equality or a quotient-completion principle.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for selected representatives, choice, ambient completeness, host function equality, or a detached extension principle, the listed rows exhaust the local NameCert obligations. □

Theorem 3755.3 (MetricCompletionFunctoriality composition)**.** *Let*

$$F = (X, Y, G, A, E, U, S, H, C, P, N)$$

and

$$F' = (Y, Z, G', A', E', U', S', H', C', P', N')$$

be accepted MetricCompletionFunctoriality$^{\uparrow}$ *carriers whose middle metric row Y and completion-entry row compare by the displayed* hsame *transport. The composed completion read is the finite replay obtained by first consuming G, A, E, U, S and then consuming G', A', E', U', S'. It is sourced by the same* CauchyCompletionFunctoriality$^{\uparrow}$ *and* MetricCompletion$^{\uparrow}$ *rows named in P and P', and it exports no host-level function composition, quotient-completion equality, selected limit representative, countable choice, or ambient completeness theorem.*

Proof. Start with the two carriers. The first packet exposes the route from X to Y through its finite graph, Cauchy-control ledger, completion-entry row, universal-property row, and separated comparison row; the second exposes the same kind of route from Y to Z.

Use the displayed hsame transport on the shared middle rows. This identifies the target metric and completion-entry read of the first packet with the source metric and completion-entry read of the second packet only through the finite transport rows already present in H and H'.

Replay the two continuation rows in order. The composed route consumes C and then C', so every source completion read still passes through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, and separated comparison rows before the final local name is available.

The nonescape boundary is inherited from the carrier inventory. Neither packet contains host function equality, quotient-completion equality, selected representatives, countable choice, or ambient completeness, and sequential replay of displayed rows cannot create such a coordinate. □

Falsifiable prediction: Any accepted $\mathsf{MetricCompletionFunctoriality}^{\uparrow}$ consumer that maps a source completion name to a target completion name without displaying the finite graph row, Cauchy-control ledger, completion-entry row, universal-property row, and separated comparison row refutes the carrier surface.

Independence witness: metriccompletion, cauchycompletionfunctor, completionuniversalproperty, dense-isometry-extension, regseqrat, streamname: these sibling chapters supply completion entries, functorial Cauchy routes, universal extension ledgers, dense separated comparison, regular readbacks, and finite windows separately, while this packet binds them into one functorial carrier $F = (X, Y, G, A, E, U, S, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctoriality}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionFunctoriality}^{\uparrow}$ packet is generated from source and target metric rows, a finite map graph, a Cauchy-control ledger, a completion-entry row, a universal-property row, a separated comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionFunctoriality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3755.1, Definition 3755.2, and Definition 3755.3 seed the finite functoriality surface for metric completion maps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionFunctoriality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected representatives of Cauchy classes, host function extensionality, countable-choice selection, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-control routing, completion-entry exactness, universal-property replay, separated comparison, transport, provenance, and local naming for BEDC.Derived.MetricCompletionFunctoriali

Chapter 3756

A Concrete Naming Certificate for NaturalDeduction$^{\uparrow}$

Following Gentzen and Prawitz, the NaturalDeduction$^{\uparrow}$ packet records a finite proof-tree calculus whose rows expose assumptions, rule applications, discharge, conclusion readback, and proof-term boundary data without importing host proof equality. It sits beside the syntax-and-deduction surface of chapter 197, the proof-term carrier of chapter 200, the bounded computation packet of chapter 199, and the run-trace surface of chapter 280. The packet is a finite NameCert neighbour: it names proof-tree evidence, but it does not identify proofs by normalization, beta equality, semantic validity, or machine execution.

Definition 3756.1 (NaturalDeduction carrier)**.** *A* NaturalDeduction$^{\uparrow}$ *carrier is a finite proof-tree* BHist *packet*

$$D = (A, R, S, Q, B, T, H, K, P, N)$$

with the following displayed rows:

1. *A is the assumption row, listing the open formula endpoints admitted at the leaves;*
2. *R is the rule row, recording introduction, elimination, weakening, and structural rule instances as finite local steps;*
3. *S is the discharge schedule, pairing discharged assumption occurrences with the rule rows that close them;*
4. *Q is the conclusion row, exposing the formula endpoint read at the root of the tree;*
5. *B is the proof-term boundary row, recording when a proof tree may be compared with a* LambdaCalc$^{\uparrow}$ *term without quotienting proof identity;*
6. *T is the transport row, comparing proof-tree nodes only by displayed* hsame *routes over formula, assumption, rule, discharge, and conclusion rows;*
7. *H records componentwise* hsame *stability for the assumption, rule, discharge, conclusion, proof-term boundary, transport, replay, provenance, and local name rows;*
8. *K records* Cont *replay from assumptions through rule rows and discharge rows to the conclusion and proof-term boundary;*
9. *P is the* Pkg *provenance over* FirstOrder$^{\uparrow}$, LambdaCalc$^{\uparrow}$, Computable$^{\uparrow}$, TuringMachine$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{NaturalDeduction}^{\uparrow}}$ *row.*
The carrier has no coordinate for host proof equality, global proof normalization, semantic validity, executable machine trace, selected proof representative, or quotient proof identity.

Lean4 ✓ `BEDC.Derived.NaturalDeductionUp.TasteGate.NaturalDeductionTasteGate single carrier alignment`

Theorem 3756.2 (NaturalDeduction NameCert obligations)**.** *For the carrier of Definition 3756.1, the local* $\mathsf{NameCert}_{\mathsf{NaturalDeduction}^{\uparrow}}$ *surface consists exactly of carrier admission for* $D = (A, R, S, Q, B, T, H, K, P, N)$ *assumption exposure through* A*, rule-step exposure through* R*, discharge exposure through* S*, conclusion readback through* Q*, proof-term boundary exposure through* B*, transport through* T*, componentwise* hsame *stability through* H*,* Cont *replay through* K*, package provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier of Definition 3756.1. The rows $A, R, S, Q, B, T, H, K, P, N$ are the only coordinates from which the local certificate may read proof-tree data.

The proof-tree content is exposed by the assumption, rule, discharge, and conclusion rows. A consumer can inspect open hypotheses, local rule instances, discharged occurrences, and the root conclusion, but those reads remain inside the finite tree packet.

The proof-term boundary row is separate from proof identity. It records the visible point at which a $\mathsf{LambdaCalc}^{\uparrow}$ term may be compared with a tree boundary, while forbidding any quotient that identifies proof trees by normalization or beta equality.

The structural rows then provide transport, replay, provenance, and naming. Since the carrier contains no further field, the listed rows exhaust the NameCert obligations. □

Theorem 3756.3 (NaturalDeduction FirstOrder consumer route)**.** *Every* $\mathsf{FirstOrder}^{\uparrow}$ *consumer of an accepted* $\mathsf{NaturalDeduction}^{\uparrow}$ *packet reads only the displayed formula endpoints, assumption rows, rule rows, discharge schedule, conclusion row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row of Definition 3756.1. It cannot replace the proof-tree route by host syntax equality, semantic validity, model-theoretic completeness, or an external proof checker.*

Proof. Start with a $\mathsf{FirstOrder}^{\uparrow}$ read of the accepted carrier D. The package row P names $\mathsf{FirstOrder}^{\uparrow}$ as the syntax and formula source, so the formula endpoints available to the consumer are exactly the endpoints carried by the assumption and conclusion rows.

Rule and discharge reads pass through R and S. These rows record finite local proof steps and the assumptions closed by those steps; they do not add a semantic model, a completeness theorem, or a host proof oracle.

Finally replay T, H, K, P, N. Transport and continuation preserve the same displayed proof-tree rows, and the local name row registers that route as the $\mathsf{NaturalDeduction}^{\uparrow}$ certificate. No external proof checker has a coordinate from which it could be projected. □

Theorem 3756.4 (NaturalDeduction LambdaCalc proof-term boundary)**.** *The* $\mathsf{LambdaCalc}^{\uparrow}$ *comparison surface of an accepted* $\mathsf{NaturalDeduction}^{\uparrow}$ *packet is exactly the proof-term boundary row* B *together with the assumption, rule, discharge, conclusion, transport, replay, provenance, and local naming rows of Definition 3756.1. It supplies a boundary for Curry–Howard-style comparison, but it does not identify natural-deduction proof trees with lambda terms, alpha classes, beta-normal forms, or machine traces.*

Proof. Read the boundary row B from the carrier. Its purpose is to name the visible point where a proof tree may be compared with the $\mathsf{LambdaCalc}^{\uparrow}$ term surface.

The comparison still depends on the proof-tree rows. The assumption row A, rule row R, discharge row S, and conclusion row Q determine which proof boundary is being compared, while T, H, K preserve and replay those rows componentwise.

The provenance row P may cite $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{Computable}^{\uparrow}$, and $\mathsf{TuringMachine}^{\uparrow}$ as nearby surfaces. This citation does not add alpha quotienting, beta-normal equality, host program equality, or a machine run trace to the natural-deduction packet.

Thus the chapter supplies a boundary for proof-term comparison only. Any stronger identification would require a separate carrier coordinate, and none is present in Definition 3756.1. □

Falsifiable prediction: If a proof-tree packet claims $\mathsf{NaturalDeduction}^{\uparrow}$ acceptance while omitting assumption rows, rule rows, discharge schedule, conclusion readback, proof-term boundary, transport, replay, provenance, or local NameCert rows, it refutes the carrier of Definition 3756.1.

Independence witness: firstorder, lambdacalc, computable, turingmachine: $\mathsf{NaturalDeduction}^{\uparrow}$ is not bijective to any listed sibling because it carries assumption rows, rule rows, discharge schedule, conclusion readback, and a proof-term boundary as a single proof-tree certificate. FirstOrderUp carries syntax and deduction endpoints without the separate proof-term boundary; LambdaCalcUp carries terms and beta-substitution ledgers without discharged proof assumptions; ComputableUp and TuringMachineUp carry bounded computation and run traces rather than finite proof-tree discharge.

Closure status for $\mathsf{NameCert}_{\mathsf{NaturalDeduction}^{\uparrow}}$.

Constructive story: A $\mathsf{NaturalDeduction}^{\uparrow}$ packet is generated from assumption rows, local rule rows, a discharge schedule, a conclusion row, a proof-term boundary row, transport, componentwise hsame stability, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NaturalDeduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3756.1, Definition 3756.2, Definition 3756.3, and Definition 3756.4 seed the finite proof-tree carrier and its consumer boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NaturalDeduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host proof equality, global proof normalization, semantic validity, Curry–Howard equivalence, alpha quotienting, beta-normal equality, Lean verification, bridge checking, or executable machine-trace identity for $\mathsf{NaturalDeduction}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, proof-tree rule routing, discharge exactness, FirstOrder consumer nonescape, and LambdaCalc proof-term boundary coverage for BEDC.Derived.NaturalDeductionUp.

Chapter 3757

A Concrete Naming Certificate for $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real arithmetic, the $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ packet records finite sums of displayed regular Cauchy rational names as folded addition routes. It sits after the regular rational source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic core of chapter 291, the binary addition packet of chapter 1695, the terminal real-name seal of chapter 38, and the finite-product sibling of chapter 2009. The carrier records displayed folded addition data, not host finite sums, quotient streams, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3757.1 (Regular Cauchy finite sum carrier)**.** *A* $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, W, D, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite unary index row. It lists exactly the summand slots opened by the request and the displayed fold order used by the addition route.*
2. *S is the component* $\mathsf{RegSeqRat}^{\uparrow}$ *source family, one regular rational Cauchy name for each slot of I.*
3. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family for component reads, intermediate addition reads, and the final sum-facing read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *sum-budget ledger, storing component observations, intermediate sum observations, requested radii, and slack cells.*
5. *A is the folded* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route row. It records the adjacent binary additions named by I, W, D and exposes no host finite-sum operation.*
6. *R is the final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the source, window, dyadic, and folded-addition rows have been displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback of the folded sum has been displayed.*
8. *H records componentwise* hsame *transport for the index row, summand sources, synchronized windows, dyadic ledger, folded-addition route, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from any finite-sum request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, W, D, A, R, E, H, C, P, N$. It has no coordinate for a host finite sum, quotient stream equality, selected limit, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFiniteSumUp.RegularCauchyFiniteSumTasteGate single carrier alignment`

Theorem 3757.2 (Regular Cauchy finite sum NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ *carrier*

$$K = (I, S, W, D, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSum}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the finite unary index row, component* $\mathsf{RegSeqRat}^{\uparrow}$ *summands, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget ledger, folded* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route, final readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local name;*

2. *finite tuple-window coverage, requiring every summand slot in I to open the matching source row and all synchronized windows needed by the fold;*

3. *dyadic sum-budget exactness, requiring every intermediate addition observation to consume its assigned radius and slack cells from D;*

4. *RegSeqRat readback stability, requiring the final readback row R to depend only on the displayed sources, windows, dyadic ledger, and folded-addition route;*

5. *Real seal non-escape, requiring E, H, C, P, N to expose no host finite sum, quotient stream equality, selected limit, trichotomy, ambient completeness theorem, Lean verification, or bridge credential.*

No Regular Cauchy finite sum obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 3757.1. The displayed tuple $I, S, W, D, A, R, E, H, C, P, N$ is the whole public surface, so carrier admission is exactly the admission of those rows.

Tuple-window coverage is forced by the index row. Each slot named by I has one component $\mathsf{RegSeqRat}^{\uparrow}$ source in S, and the synchronized window row W is the only place where component, intermediate, and final sum reads are opened.

The dyadic budget is read through D. Each intermediate binary addition request consumes a displayed radius and slack cell from that ledger before the corresponding folded $\mathsf{RegularCauchyAddition}^{\uparrow}$ row A can be inspected.

The final regular readback row R is downstream of S, W, D, A. Therefore readback stability follows from the carrier order: no sum-facing $\mathsf{RegSeqRat}^{\uparrow}$ data can be inspected until the synchronized windows, dyadic budget, and folded addition route have already been displayed.

Finally, the seal, transport, replay, provenance, and local name rows preserve only this route. Since none of the excluded objects is a coordinate of the carrier, the listed five rows exhaust the local NameCert obligations. □

Theorem 3757.3 (Regular Cauchy finite sum budget route)**.** *Let*

$$K = (I, S, W, D, A, R, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ *carrier. Every finite sum read from* K *factors through*

$$I, S \longmapsto W \longmapsto D, A \longmapsto R \longmapsto E, H, C, P, N.$$

In particular, regrouping displayed adjacent additions may change only the fold order named by I *and* A*; it preserves the same synchronized windows* W*, dyadic sum-budget ledger* D*, final* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *when those rows are fixed by the accepted carrier.*

Proof. Begin with a finite sum request. The request first names the finite unary index row I and the component source family S, because these are the only carrier rows that identify which regular Cauchy names participate in the fold.

The requested component and intermediate observations then pass through W. This synchronized window row aligns component reads with the intermediate addition reads used by the displayed fold.

The dyadic part of the request is read next through D, and the adjacent binary additions are read through A. The proof uses the displayed $\mathsf{RegularCauchyAddition}^{\uparrow}$ rows rather than host associativity of sums.

Only after those rows are displayed can the final regular rational readback R be consumed. The downstream rows E, H, C, P, N seal, transport, replay, source, and name the same route, so the finite sum read cannot bypass the synchronized windows, the dyadic ledger, or the folded-addition route. □

Falsifiable prediction: Every $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ sum-facing read factors through a finite unary index row, component RegSeqRat sources, synchronized StreamName windows, DyadicRatCore sum-budget observations, a folded RegularCauchyAddition route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, regular-cauchy-addition, real, regular-cauchy-finite-product: $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite unary summand index, synchronized multi-source windows, dyadic sum-budget accounting, folded addition rows, final RegSeqRat readback, RealUp sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSum}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3757.1, Definition 3757.2, and Definition 3757.3 seed the finite sum route from displayed regular Cauchy sources through synchronized windows, dyadic sum budgets, folded addition rows, final RegSeqRat readback, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host finite sums, quotient stream equality, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tuple-window coverage, dyadic budget exactness, folded-addition routing, readback stability, seal non-escape, and local naming for BEDC.Derived.RegularCauchyFiniteSumUp.

Constructive story: A $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ packet is generated from a finite unary summand index row, component RegSeqRat source rows, synchronized StreamName windows, DyadicRatCore sum-budget observations, a folded RegularCauchyAddition route, final RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3758

A Concrete Naming Certificate for $\mathsf{FiniteSeriesPermutation}^{\uparrow}$

Following Hardy, Courant, and Bishop and Bridges on finite series and constructive finite sums, the $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ packet records the finite invariance route by which a displayed summand list may be reindexed without changing the BEDC sum read. It sits after the permutation carrier of chapter 116, the finite list spine of chapter 36, the addition row of chapter 29, the unary index discipline of chapter 28, and the folded regular Cauchy sum surface of chapter 3757. The packet is finite certificate data; it does not expose an infinite rearrangement principle or a host summation operator.

Definition 3758.1 (Finite series permutation carrier)**.** *A* $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, L, \Pi, A, W, F, T, H, C, P, N)$$

with the following displayed rows.

1. *I is the* $\mathsf{Nat}^{\uparrow}$ *index-window row naming the finite interval of summand slots.*
2. *L is the* $\mathsf{List}^{\uparrow}$ *summand spine, with one displayed summand row for each slot named by I.*
3. *Π is the* $\mathsf{Permutation}^{\uparrow}$ *witness row on the same finite index window.*
4. *A is the* $\mathsf{Add}^{\uparrow}$ *finite-fold route, recording the adjacent binary additions used by the source order and by the permuted order.*
5. *W is the window ledger that pairs each source summand slot with its permuted slot and records the finite reads used by both folds.*
6. *F is the folded-sum comparison row, read either as a bare finite* $\mathsf{Add}^{\uparrow}$ *route or through a* $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ *consumer when the summands are regular Cauchy names.*
7. *T is the terminal transport row saying that the two displayed fold outputs are classified by the same downstream sum classifier.*
8. *H records componentwise* hsame *transport for the index window, list spine, permutation witness, addition rows, comparison row, terminal transport, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteSeriesPermutation}^{\uparrow}$, $\mathsf{Permutation}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{RegularCauchyFiniteSum}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSeriesPermutation}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. There is no coordinate for an infinite series, a conditionally convergent rearrangement, a host finite-sum function, a quotient sequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteSeriesPermutationUp.FiniteSeriesPermutationTasteGate single carrier alignment`

Theorem 3758.2 (Finite series permutation NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ *carrier*

$$S = (I, L, \Pi, A, W, F, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSeriesPermutation}^{\uparrow}}$ *surface consists exactly of carrier admission, finite index-window coverage, list-slot coverage, permutation-witness coverage, addition-fold compatibility, folded-sum comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations are exhausted by the finite rows of Definition 3758.1.*

Proof. Project the accepted carrier. The rows $I, L, \Pi, A, W, F, T, H, C, P, N$ are the whole visible packet, so carrier admission is just admission of those rows and of their local naming row.

The finite coverage obligations are read in order. The $\mathsf{Nat}^{\uparrow}$ row I fixes the inspected slots, the $\mathsf{List}^{\uparrow}$ row L supplies exactly one summand row at each slot, and the $\mathsf{Permutation}^{\uparrow}$ row Π supplies the source-to-target slot matching together with its inverse witness.

The compatibility obligation then reads A, W, F, T. The addition route A lists the two displayed folds, W records which summand reads are paired by Π, F compares the two folded outputs, and T transports that comparison to the downstream classifier that the consumer is allowed to inspect.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since none of the excluded objects is a carrier coordinate, no further NameCert obligation is available outside the listed rows. □

Theorem 3758.3 (Finite series permutation sum invariance)**.** *Let*

$$S = (I, L, \Pi, A, W, F, T, H, C, P, N)$$

be an accepted $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ *carrier. Every consumer that reads the source-order finite fold and the* Π*-permuted finite fold must factor through*

$$I, L, \Pi \longmapsto W, A \longmapsto F, T \longmapsto H, C, P, N.$$

Hence the two finite sums are classified together by the displayed folded-sum comparison row, and the conclusion is a BEDC certificate over finite data rather than a host equality of summation functions.

Proof. Begin with the finite source order. The requested slots are exactly the slots displayed by I, and the summands are exactly the entries of L at those slots. No consumer can name an additional summand because the list-slot coverage row is bounded by I.

Read the permutation witness Π next. Its forward and inverse rows pair the source slots with the permuted slots in the same finite window, so each permuted fold input is already a displayed entry of L.

The two folds are then read through A. The source-order fold and the permuted fold may use different adjacent binary addition traces, but both traces consume only the slot reads named by W and the addition rows named by A.

The comparison row F is therefore a finite folded-sum comparison over the same multiset of displayed summand rows. The terminal row T transports this comparison to the permitted downstream sum classifier, including the $\mathsf{RegularCauchyFiniteSum}^{\uparrow}$ classifier when the summands are regular Cauchy names.

The remaining rows H, C, P, N keep the route stable under componentwise transport, replay the same finite read, record provenance, and supply the local name. Thus the invariant exported by the packet is exactly finite permutation invariance for the displayed fold route, with no appeal to infinite rearrangement, quotient sequence equality, host finite sums, or $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ sum-invariance read exposes a NatUp index window, a ListUp summand spine, a PermutationUp witness, AddUp fold rows, a paired read window, folded-sum comparison, terminal classifier transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before the permuted sum is consumed.

Independence witness: permutation, list, add, nat, regular-cauchy-finite-sum: $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite index window, summand spine, permutation witness, paired fold routes, folded-sum comparison, terminal transport, replay, provenance, and local naming required for sum-invariance reads.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSeriesPermutation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSeriesPermutation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3758.1, Definition 3758.2, and Definition 3758.3 seed the finite permutation-invariance route from displayed index windows and summand lists through permutation witnesses, addition folds, folded-sum comparison, terminal transport, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSeriesPermutation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite rearrangements, conditionally convergent series, host finite sums, quotient sequences, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite index coverage, list-slot coverage, permutation-witness coverage, fold compatibility, folded-sum comparison, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSeriesPermutationUp.

Constructive story: A $\mathsf{FiniteSeriesPermutation}^{\uparrow}$ packet is generated from a NatUp finite index window, a ListUp summand spine, a PermutationUp witness, AddUp finite-fold rows, paired fold windows, folded-sum comparison, terminal classifier transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3759

A Concrete Naming Certificate for $\mathsf{EpsilonDeltaLimit}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ packet records the traditional epsilon-delta limit interface as finite BEDC data. It sits between the source and target metric carriers of chapter 57, the dyadic tolerance surface of chapter 291, the finite-window names of chapter 126, the regular rational readback rows of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a displayed point, a proposed target limit, positive dyadic epsilon requests, matching positive dyadic delta witnesses, finite window reads, regular-rational readback, transport, replay, provenance, and local naming; it does not identify host reals, select limits, form quotient streams, invoke trichotomy, use choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3759.1 (Epsilon-delta limit carrier)**.** *An* $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, a, L, E, D, W, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including its accepted point classifier and distance-witness surface.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, including its accepted point classifier and* $\mathsf{Real}^{\uparrow}$*-valued distance-witness surface.*
3. *a is the source point row at which the limiting read is taken.*
4. *L is the proposed target-limit row, read as a displayed point of Y before any Real-facing equality question is asked.*
5. *E is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *epsilon request row for the target distance to L.*
6. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *delta witness row for source distance to a.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source point, the candidate values, the proposed limit, and the two dyadic tolerance rows.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and for the* $\mathsf{Real}^{\uparrow}$ *distance rows reached through X and Y.*
9. *H records componentwise* hsame *transport for the metric rows, point row, proposed limit, epsilon request, delta witness, windows, readback, continuation, provenance, and local name.*

10. *C records displayed* Cont *replay from epsilon requests through delta witnesses, metric-distance reads, finite windows, regular-rational readback, and the target* $\mathsf{Real}^{\uparrow}$ *seal.*
11. *P is the* Pkg *provenance over* $\mathsf{EpsilonDeltaLimit}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EpsilonDeltaLimit}^{\uparrow}}$ *row.*

Lean4✓ `BEDC.Derived.EpsilonDeltaLimitUp.EpsilonDeltaLimitTasteGate single carrier alignment`

The classifier accepts the packet only when all rows name the same finite epsilon-delta route: every accepted epsilon request in E is met by the displayed delta row D, and every Real-facing target-distance read passes through $X, Y, a, L, E, D, W, R, H, C, P, N$.

Theorem 3759.2 (Epsilon-delta limit NameCert obligations)**.** *For the carrier of Definition 3759.1, the local* $\mathsf{NameCert}_{\mathsf{EpsilonDeltaLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (X, Y, a, L, E, D, W, R, H, C,$ source and target metric-space admission through X and Y, point admission through a, proposed-limit admission through L, positive dyadic epsilon and delta admission through E and D, finite-window admission through W, regular-rational and Real-facing readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. The metric rows X and Y display the source and target point classifiers and the distance witnesses before the point row a or the proposed target limit L can be consumed by a limit read.

The tolerance part is finite. The epsilon request E and delta witness D are $\mathsf{DyadicRatCore}^{\uparrow}$ rows, so the smallness comparison is a dyadic ledger rather than a host real inequality or selected limit object.

The analytic readback is downstream of those rows. The $\mathsf{StreamName}^{\uparrow}$ window row W records the finite observations used by the source point, target values, proposed limit, and dyadic tolerances, while the $\mathsf{RegSeqRat}^{\uparrow}$ row R reads the displayed windows before any $\mathsf{Real}^{\uparrow}$ distance seal is exposed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores host real equality, quotient streams, selected limits, trichotomy, choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 3759.3 (Epsilon-delta limit Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ *packet reads the limit assertion through the finite route*

$$X, Y, a, L, E, D, W, R, H, C, P, N.$$

The consumer first sees the source and target $\mathsf{Met}^{\uparrow}$ *rows, the point row, the proposed limit row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *epsilon request and delta witness, the* $\mathsf{StreamName}^{\uparrow}$ *windows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback. Only then may it read the target* $\mathsf{Real}^{\uparrow}$ *distance seal carried by the target metric row, and it receives no host real equality, quotient stream, selected limit, trichotomy, choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4✓ `BEDC.Derived.EpsilonDeltaLimitUp.EpsilonDeltaLimitRealSealNonescape`

Proof. Use Definition 3759.2. It orders every Real-facing read after X, Y, a, L, E, D, W, R, so the target distance to the proposed limit is visible only as a readback routed through the displayed metric, dyadic, window, and regular-rational rows.

The target metric row Y is the only source of the $\mathsf{Real}^{\uparrow}$-valued distance seal. Because E and D are displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, the consumer cannot replace the certificate by a host epsilon quantifier, a hidden delta chooser, or a quotient representative of a target real.

The structural rows preserve the same route. Componentwise transport H, replay C, provenance P, and local naming N carry the finite packet forward without adding coordinates for host equality, selected limits, trichotomy, choice, quotient streams, or ambient completeness. □

Falsifiable prediction: Every epsilon-delta limit read of an $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ packet factors through displayed metric rows, dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, and the terminal RealUp distance seal.

Independence witness: metric, dyadicratcore, streamname, regseqrat, real: EpsilonDeltaLimitUp is not bijective to any listed sibling because it jointly carries source and target MetricSpace rows, a point row, a proposed limit row, dyadic epsilon and delta rows, finite windows, regular-rational readback, Real-facing distance seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EpsilonDeltaLimit}^{\uparrow}}$.

Constructive story: An $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ packet is generated from source and target MetricSpace rows, a point row, a proposed limit row, dyadic epsilon requests, dyadic delta witnesses, finite StreamName windows, RegSeqRat readback, Real-facing distance seals, hsame transport, Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EpsilonDeltaLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3759.1, Definition 3759.2, and Definition 3759.3 seed the finite epsilon-delta limit interface for Phase Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EpsilonDeltaLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.EpsilonDeltaLimitUp.EpsilonDeltaLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient streams, selected limits, trichotomy, choice, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance handling, finite-window readback, target Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EpsilonDeltaLimitUp.

Chapter 3760

A Concrete Naming Certificate for $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ packet records local epsilon-delta continuity as finite BEDC data. It sits beside the source and target metric rows of chapter 57, the displayed $\mathsf{Real}^{\uparrow}$ distance seals, the graph row of chapter 130, the modulus surface of chapter 1631, and the limit-facing packet of chapter 3759. The packet names only a displayed point, an epsilon request, a delta witness, finite metric-window reads, continuity transport, replay, provenance, and local naming; it does not assert classical open-cover compactness, host function equality, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3760.1 (Epsilon-delta continuity carrier)**.** *An* $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, F, a, E, D, W, R, M, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier and source-distance witness surface.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, including the target-distance witness surface and its terminal* $\mathsf{Real}^{\uparrow}$ *distance seal.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the named map, exposing only the finite graph and target-window reads used by the continuity certificate.*
4. *a is the displayed source point at which the continuity read is taken.*
5. *E is the positive target-tolerance row, read through the dyadic or regular rational tolerance ledger before any target-distance request is made.*
6. *D is the positive source-radius witness row attached to E and to the point a.*
7. *W is the finite window row that inspects source points within the displayed D-neighbourhood and the corresponding target graph cells of F.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source and target distance windows.*
9. *M is the* $\mathsf{ModulusContinuity}^{\uparrow}$ *handoff row when the local continuity read is consumed by a modulus-facing route.*
10. *L is the* $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ *boundary row witnessing that the local read is compatible with the limit packet at a without replacing continuity by a selected limit.*

11. *H records componentwise* hsame *transport for the metric rows, graph row, point row, tolerance rows, windows, readback, modulus handoff, limit boundary, replay, provenance, and local name.*
12. *C records displayed* Cont *replay from tolerance requests through source-radius witnesses, metric-distance windows, graph reads, regular-rational readback, the modulus handoff, and the limit boundary.*
13. *P is the* Pkg *provenance over* $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{EpsilonDeltaLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{EpsilonDeltaContinuity}^{\uparrow}}$ *row.*

The classifier accepts the packet only when every tolerance read factors through the same finite route $X, Y, F, a, E, D, W, R, M, L, H, C, P, N$.

Theorem 3760.2 (Epsilon-delta continuity NameCert obligations)**.** *For the carrier of Definition 3760.1, the local* $\mathsf{NameCert}_{\mathsf{EpsilonDeltaContinuity}^{\uparrow}}$ *surface consists exactly of source and target metric admission through X and Y, Real-valued distance readback through the target metric seal, continuous graph admission through F, point admission through a, positive tolerance and radius admission through E and D, finite-window admission through W, regular readback through R, modulus-continuity handoff through M, epsilon-delta limit compatibility through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3760.1. The source metric row X, target metric row Y, displayed graph row F, and point row a are explicit coordinates, so a continuity consumer cannot begin from an ambient function or an unshown host point.

The tolerance part is local. The target request E and source-radius witness D are paired before the finite window row W is consumed. Thus the target-distance read reaches the $\mathsf{Real}^{\uparrow}$ seal of Y only after the source-neighbourhood window and the graph cells of F have been displayed.

The two sibling handoffs keep the packet connected to the surrounding metric route. The $\mathsf{ModulusContinuity}^{\uparrow}$ row M exposes the same tolerance-to-window data to modulus-facing consumers, while the $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ row L records compatibility with the limit packet at a without adding a selected limit or quotient real equality.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for classical open-cover compactness, host function equality, quotient real equality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 3760.3 (Epsilon-delta continuity local route)**.** *Every local continuity read of an accepted* $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{ModulusContinuity}^{\uparrow},\ \mathsf{EpsilonDeltaLimit}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},$$

The consumer receives a displayed tolerance request, a displayed source-radius witness, finite source and target windows, regular readback, a modulus handoff, and an epsilon-delta limit boundary. It receives no classical open-cover compactness, host function equality, quotient real equality, global uniform-continuity claim, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Use the NameCert obligations of Definition 3760.2. They force the local read to begin with X, Y, F, a, E, D, W, R before either handoff row is inspected.

Read the $\mathsf{ModulusContinuity}^{\uparrow}$ coordinate M only after the finite tolerance-to-window data have been displayed. This supplies the modulus-facing consumer with the same local budget, not a detached global uniform-continuity object.

Read the $\mathsf{EpsilonDeltaLimit}^{\uparrow}$ coordinate L only as a boundary row tied to the same point a and graph row F. It records limit compatibility for the local route and does not insert a chosen limit, quotient representative, or host real equality.

The structural rows H, C, P, N preserve this order under transport and replay. Since no excluded external coordinate appears in the carrier, every accepted continuity read is confined to the listed finite route. □

Theorem 3760.4 (Epsilon-delta sequential Cauchy handoff)**.** *Let K be an accepted* $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ *packet. If the source stream of K is read through a displayed* $\mathsf{StreamName}^{\uparrow}$ *row and the image windows are read through a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row, then the local radius ledger supplied by Definition 3760.3 may feed the* $\mathsf{CauchySequentialContinuity}^{\uparrow}$ *preservation surface before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is inspected.*

The handoff is a finite same-packet route through the source-window, radius-ledger, image-window, readback, transport, replay, provenance, and local-name rows. It does not assert host sequential continuity, selected subsequences, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the local route theorem Definition 3760.3. It exposes the displayed tolerance request, source-radius witness, finite source and target windows, regular readback, modulus handoff, and epsilon-delta limit boundary before any Real-facing consumer reads the packet.

Now read the sequential dependencies. The $\mathsf{StreamName}^{\uparrow}$ source row supplies the finite inspected windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular-rational readback consumed by the Cauchy image route of chapter 4045. The terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is therefore reached only after the preservation surface has seen the local radius ledger and image windows.

The construction uses only the displayed rows named in this chapter together with chapter 126, chapter 301, and chapter 38. Since the route has no coordinate for host sequential continuity, selected subsequences, quotient stream equality, countable choice, or ambient completeness, none of those endpoints is exported. □

Falsifiable prediction: Every epsilon-delta continuity read of an $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ packet factors through displayed MetricSpace rows, a ContinuousMap graph row, finite tolerance and radius rows, RegSeqRat readback, a ModulusContinuity handoff, and an EpsilonDeltaLimit boundary.

Independence witness: metricspace, real, continuousmap, moduluscontinuity, epsilondeltalimit: $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source and target metric rows, a graph row, a point row, paired tolerance and radius rows, finite windows, regular readback, modulus handoff, limit boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EpsilonDeltaContinuity}^{\uparrow}}$.

Constructive story: An $\mathsf{EpsilonDeltaContinuity}^{\uparrow}$ packet is generated from source and target MetricSpace rows, a Real-valued target-distance seal, a ContinuousMap graph row, a displayed source point, target-tolerance and source-radius rows, finite windows, RegSeqRat readback, ModulusContinuity handoff, EpsilonDeltaLimit boundary, hsame transport, Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EpsilonDeltaContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3760.1, Definition 3760.2, Definition 3760.3, and Definition 3760.4 seed the local epsilon-delta continuity interface for metric, continuous-map, and sequential Cauchy consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EpsilonDeltaContinuity}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close classical open-cover compactness, host function equality, quotient real equality, global uniform continuity, countable choice, trichotomy, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-radius routing, finite-window readback, modulus handoff, limit-boundary compatibility, transport, replay, provenance, and local naming for BEDC.Derived.EpsilonDeltaContinuity

Chapter 3761

A Concrete Naming Certificate for $\mathsf{PackingNumber}^{\uparrow}$

Following Bishop and Bridges and Kelley metric-space practice, the $\mathsf{PackingNumber}^{\uparrow}$ packet records the finite separated-center count dual to a displayed metric covering tolerance. It sits beside the finite net route of chapter 1767, the upper-count packet of chapter 2187, the scale-control surface of chapter 2035, and the metric source of chapter 57. The packet names a lower-bound quantitative ledger as finite BEDC data, not as a maximal subset, a choice-selected packing, a compactness proof, or an ambient cardinality comparison.

Definition 3761.1 (Metric packing-number carrier)**.** *A* $\mathsf{PackingNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, \varepsilon, U, D, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the point classifier, distance classifier, and metric-law ledger used by all separation reads.*
2. *ε is the positive tolerance row, read through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *together with the displayed positivity evidence needed by separated-center consumers.*
3. *U is the finite closed* $\mathsf{ProbeBundle}$ *of candidate centers admitted for the tolerance ε.*
4. *D is the pairwise distance ledger. For every two distinct displayed centers of U, it records the metric-distance row in X and the comparison witnessing ε-separation.*
5. *B is the unary packing-budget row naming the number of center entries exposed by U and certified by the pairwise ledger D.*
6. *H records componentwise* hsame *transport for the metric source, tolerance row, separated-center bundle, pairwise distance ledger, budget row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from any packing-number request through the same rows $X, \varepsilon, U, D, B, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{PackingNumber}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{MetricCoveringNumber}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ProbeBundle}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PackingNumber}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, \varepsilon, U, D, B, H, C, P, N$. It has no coordinate for an ambient finite subset, host maximality proof, selected saturated packing, powerset cardinality, compactness, total boundedness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PackingNumberUp.TasteGate.PackingNumberTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.PackingNumberUp.PackingNumberTasteGate single carrier alignment`

Theorem 3761.2 (Metric packing-number NameCert obligations)**.** *For every accepted* $\mathsf{PackingNumber}^{\uparrow}$ *carrier* $K = (X, \varepsilon, U, D, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PackingNumber}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, positive tolerance, finite separated-center bundle, pairwise distance ledger, unary packing budget, transport, replay, provenance, and local naming rows;*
2. *center admission, requiring every entry counted by* B *to be visible in the same closed* $\mathsf{ProbeBundle}$ *row* U *and admitted by the metric source row* X*;*
3. *pairwise separation exactness, requiring every two distinct displayed centers to be compared by* D *through the same metric distance and the same tolerance* ε*;*
4. *budget exactness, requiring the exported packing number to count exactly the visible center entries of* U *certified by the pairwise ledger;*
5. *tolerance transport, requiring the* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row to remain attached to the separation comparisons under* H *before any consumer reads the count;*
6. *ledger nonescape, excluding maximal subset selection, host cardinality comparison, powerset enumeration, open-cover compactness, total-bounded completion, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No metric packing-number obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.PackingNumberUp.PackingNumberCarrier namecert obligations`
Lean4 ✓ `BEDC.Derived.PackingNumberUp.PackingNumberNamecertObligations`

Proof. Project the accepted carrier of Definition 3761.1. The analytic rows are exactly the metric source X, positive tolerance ε, separated-center bundle U, pairwise ledger D, and unary budget B.

Center admission is rowwise. A center can be counted only after it is visible in U and read as a point of the metric source X.

Pairwise separation is also rowwise. The ledger D supplies each displayed distance comparison between distinct entries of U, and every comparison uses the same positive tolerance row ε.

The budget row then names the quantitative boundary. Because B counts the same visible entries certified by U and D, a consumer cannot replace the packet by a host maximal packing, an external enumeration, or a powerset cardinality argument.

Finally H, C, P, N transport, replay, source, and name exactly this route. Since the carrier contains none of the excluded compactness, choice, completeness, or maximality coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 3761.3 (Metric packing covering-dual handoff)**.** *Every* $\mathsf{MetricCoveringNumber}^{\uparrow}$*,* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*,* $\mathsf{DoublingMetric}^{\uparrow}$*, or compact-metric consumer reading an accepted* $\mathsf{PackingNumber}^{\uparrow}$ *carrier factors through the finite route*

$$X, \varepsilon \longmapsto U, D, B \longmapsto H, C, P, N.$$

The consumer receives a separated-center lower-bound ledger before comparing it with a covering-number or finite-net upper-count ledger. The handoff exports no maximal packing, no selected cover, no open-cover compactness proof, no powerset cardinality comparison, no countable-choice schedule, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PackingNumberUp.PackingNumberCoveringDualHandoff`

Proof. Begin with a covering, finite-net, doubling, or compact-metric consumer of K. By Definition 3761.1, the consumer can enter the packet only through the displayed metric source X and the displayed positive tolerance row ε.

The separated data are opened next. The bundle U names the candidate centers, the ledger D certifies pairwise separation through the metric distance row, and B records the resulting unary packing budget.

The covering-dual comparison is external to the packing packet. A covering-number or finite-net consumer may compare its own center budget with B, but only after both packets expose their metric source, tolerance, finite bundle, and distance ledger rows.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Applying Definition 3761.2, the consumer cannot replace the finite separated ledger by a selected maximal packing, compactness argument, powerset cardinality comparison, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{PackingNumber}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PackingNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3761.1, Definition 3761.2, and Definition 3761.3 seed the quantitative separated-center packet over displayed metric sources, positive rational or dyadic tolerances, finite ProbeBundle centers, pairwise distance ledgers, unary budgets, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PackingNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close maximal packing existence, minimal covering duality, total boundedness, compact metric completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, center admission, pairwise separation exactness, budget exactness, tolerance transport, ledger nonescape, and covering-dual handoff for BEDC.Derived.PackingNumberUp.

Constructive story: A $\mathsf{PackingNumber}^{\uparrow}$ packet is generated from a MetricUp source row, a positive RatUp or DyadicRatCoreUp tolerance, a finite ProbeBundle of separated centers, pairwise metric-distance comparisons, a unary packing budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3762

A Concrete Naming Certificate for $\mathsf{LipschitzFunction}^{\uparrow}$

Following Kelley metric-space practice and Bishop–Bridges constructive analysis, the $\mathsf{LipschitzFunction}^{\uparrow}$ packet records a function only through displayed metric rows, a graph ledger, and a carried bound. It sits between the source and target metric surface of chapter 57, the terminal real-bound seal of chapter 38, the graph discipline of chapter 130, and the tolerance export of chapter 369. The packet is a finite NameCert connector for uniform-continuity and completion-facing consumers; it does not import host function extensionality, quotient map equality, choice of representatives, or ambient completeness.

Definition 3762.1 (Lipschitz function carrier)**.** *A* $\mathsf{LipschitzFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, G, K, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row and Y is the target* $\mathsf{Met}^{\uparrow}$ *row.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row carrying the function-read relation from X to Y.*
3. *K is the nonnegative* $\mathsf{Real}^{\uparrow}$ *Lipschitz-constant row.*
4. *D is the distance-inequality ledger recording every displayed comparison between a source-distance request and the corresponding target-distance response.*
5. *H records componentwise* hsame *transport for source points, target points, graph rows, bound rows, distance ledgers, continuation rows, provenance, and local naming.*
6. *C records displayed* Cont *replay from source metric requests through G, K, D to target metric responses and uniform-modulus reads.*
7. *P is the* Pkg *provenance over* $\mathsf{LipschitzFunction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzFunction}^{\uparrow}}$ *row.*

The classifier accepts only packets whose target-distance reads are sourced by G and bounded through the same K, D ledger. It has no coordinate for a host function object, quotient equality of maps, selected representatives, differentiability, compactness, or completeness of either metric space.

Lean4 ✓ `BEDC.Derived.LipschitzFunctionUp.LipschitzFunctionTasteGate single carrier alignment`

Theorem 3762.2 (Lipschitz function NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzFunction}^{\uparrow}$ *carrier* $F = (X, Y, G, K, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LipschitzFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, componentwise classifier comparison, Lipschitz-bound exactness, graph-to-distance replay, uniform-modulus export, transport stability, provenance sourcing, and local naming through the displayed rows* $X, Y, G, K, D, H, C, P, N$*.*

No obligation row is stored outside the carrier, and no exported read depends on host function extensionality, quotient map equality, selected representatives, countable choice, differentiability, compactness, or ambient metric completeness.

Proof. Project the carrier. The only analytic rows are the source metric X, target metric Y, graph row G, Lipschitz constant K, and distance-inequality ledger D.

The classifier comparison is componentwise over those rows and over H, C, P, N. Bound exactness follows because a target-distance read has to pass through the graph row and then through the displayed comparison stored in D against the same constant K.

The uniform-modulus export reads no further object. Transport H and replay C preserve the same graph, constant, and inequality rows, while P and N only source and name the route. Since the carrier contains none of the excluded host objects, the listed rows exhaust the local NameCert obligations. □

Theorem 3762.3 (Lipschitz function uniform-continuity handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{UniformContinuity}^{\uparrow}$*, or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer of an accepted* $\mathsf{LipschitzFunction}^{\uparrow}$ *carrier receives its source-tolerance route only after the packet has displayed the source metric* X*, target metric* Y*, graph row* G*, Lipschitz constant* K*, distance-inequality ledger* D*, and replay rows* H, C, P, N*. The handoff is a finite BEDC modulus route, not a rereading of a host Lipschitz proof.*

Proof. Start from the carrier and its NameCert obligations. The graph row G supplies the only function-read surface, while K and D supply the only bound and distance-comparison surface.

A uniform-modulus request therefore cannot bypass the displayed inequality ledger. It first fixes the target-distance request in Y, reads the bound row K, and then uses D to return the corresponding source-distance request in X.

The continuation and transport rows preserve this order. Hence uniform-continuity and continuous-map consumers receive a finite modulus handoff through $X, Y, G, K, D, H, C, P, N$, with no host function proof or selected representative added. □

Theorem 3762.4 (Lipschitz function completion nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{LipschitzFunction}^{\uparrow}$ *carrier remains confined to the displayed metric rows, graph row, bound row, distance-inequality ledger, transport, replay, provenance, and local name rows. Reading a complete source or target metric in another packet does not turn* F *into a completed function-space object, a quotient of uniformly continuous maps, a selected extension, or a statement about limits outside* $X, Y, G, K, D, H, C, P, N$*.*

Proof. The packet carries only two metric rows and a graph-bound ledger between them. Completion-facing reads may reuse those metric rows, but no completed function-space coordinate is present in the carrier.

The distance ledger D is also local. It records comparisons for the displayed graph row and constant, and replay through C keeps those comparisons attached to the same source and target metric requests.

Thus a completion consumer can transport the finite Lipschitz route but cannot manufacture quotient maps, selected extensions, host limits, or ambient completeness claims. The exported surface remains exactly $X, Y, G, K, D, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3762.1, Definition 3762.2, Definition 3762.3, and Definition 3762.4 seed the finite Lipschitz-function route from metric, graph, real-bound, distance-ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function extensionality, quotient map equality, selected extensions, differentiability, compactness, completed function spaces, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier comparison, Lipschitz-bound exactness, graph-to-distance replay, uniform-modulus export, transport stability, provenance sourcing, and local NameCert rows for BEDC.Derived.LipschitzFunctionUp.

Constructive story: A $\mathsf{LipschitzFunction}^{\uparrow}$ packet is generated from source and target metric rows, a ContinuousMap graph row, a RealUp Lipschitz constant, a distance-inequality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 3763

A Concrete Naming Certificate for $\mathsf{CantorTernarySet}^{\uparrow}$

Following Cantor's middle-third construction and Bishop–Bridges constructive analysis, the $\mathsf{CantorTernarySet}^{\uparrow}$ packet records the traditional ternary description of the Cantor set as finite BEDC data. It refines the retained-prefix and deleted-gap surface of chapter 1530 by making the inspected base-three windows explicit, and it routes every real-facing read through chapter 38, chapter 301, chapter 126, and chapter 291. The packet names only finite ternary windows, triadic endpoint ledgers, gap checks, regular-rational readback, and the terminal Real seal; it does not assert host powersets, infinite branch choice, quotient real equality, measure, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3763.1 (Cantor ternary set carrier)**.** *A* $\mathsf{CantorTernarySet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, D, V, G, I, R, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row selecting the finite base-three digit positions currently inspected.*
2. *D is the ternary digit ledger for W, and every accepted digit row is tagged as a retained digit* 0 *or* 2*.*
3. *V is the triadic place-value row, evaluating the inspected prefix as a rational with denominator a displayed power of* 3*.*
4. *G is the deleted-middle gap ledger, listing the middle-third intervals excluded by every inspected non-retained alternative at the displayed depths.*
5. *I is the retained interval row inherited from* $\mathsf{CantorSet}^{\uparrow}$*, with endpoints computed from the same triadic prefix and checked against the gap ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from W, D, V, G, I.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular-rational readback has been displayed.*
8. *H records componentwise* hsame *transport for the window, digit, triadic value, gap, interval, readback, Real seal, continuation, provenance, and local name rows.*
9. *C records displayed* Cont *replay from window requests through the digit ledger, triadic value ledger, gap ledger, retained interval, regular readback, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorTernarySet}^{\uparrow}$, $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorTernarySet}^{\uparrow}}$ *row.*

The classifier accepts a packet only when $W, D, V, G, I, R, E, H, C, P, N$ are all displayed for the same finite triadic window, the digit ledger uses only retained digits, the gap ledger refuses the corresponding middle thirds, and every $\mathsf{Real}^{\uparrow}$ *consumer enters through R and E. It has no coordinate for a host subset of* $\mathsf{Real}^{\uparrow}$*, selected infinite ternary stream, quotient real equality, endpoint convention selector, measure, open-cover compactness, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CantorTernarySetUp.CantorTernarySetTasteGate single carrier alignment`

Theorem 3763.2 (Cantor ternary set NameCert obligations)**.** *For an accepted* $\mathsf{CantorTernarySet}^{\uparrow}$ *carrier*

$$T = (W, D, V, G, I, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorTernarySet}^{\uparrow}}$ *surface consists exactly of carrier admission, finite ternary-window classification, retained-digit checking, triadic place-value evaluation, middle-third gap exclusion, retained-interval compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise transport, continuation replay, provenance, and local naming through the displayed rows $W, D, V, G, I, R, E, H, C, P,$*

Proof. Carrier admission projects the finite tuple of Definition 3763.1. The window row W fixes the inspected positions, and the digit ledger D is the only source of ternary digit information for those positions.

The retained-digit and triadic-value checks are then internal to the same finite prefix. The row V evaluates exactly the inspected prefix, while the gap row G records the deleted middle thirds rejected by replacing a retained digit with the middle alternative.

The retained interval row I is inherited from the $\mathsf{CantorSet}^{\uparrow}$ surface and is therefore tied to the same prefix and gap ledger. The regular-rational row R and Real seal row E are downstream of that finite data.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores host subsets, infinite streams, quotient equality, endpoint selectors, measure, compactness, choice, or ambient completeness, the displayed rows exhaust the local NameCert obligations. □

Theorem 3763.3 (Cantor ternary set triadic nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CantorTernarySet}^{\uparrow}$ *carrier remains on the finite triadic route*

$$W, D, V, G, I \longmapsto R \longmapsto E$$

together with H, C, P, N. A consumer may inspect retained ternary windows, deleted middle thirds, triadic endpoint values, regular-rational readback, and the terminal Real seal, but it cannot extract a selected infinite ternary branch, a host real subset, quotient equality of real representatives, a measure row, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier. Any real-facing consumer must first enter through the displayed window W, because no digit row outside that finite window is part of the packet.

The digit ledger D, triadic value row V, and gap ledger G determine the retained middle-third decision at the inspected depths. The interval row I packages the same decision as a $\mathsf{CantorSet}^{\uparrow}$ retained-prefix row, so there is no separate branch or endpoint source.

The handoff to real data is forced through R and E. The regular-rational row R is reached only after the finite triadic rows have been displayed, and the Real seal E is downstream of R.

The structural rows H, C, P, N preserve and name this same route. Thus every exported read remains on the finite triadic packet, and the excluded host subset, infinite branch, quotient equality, measure, choice, compactness, and completeness data are not available to the consumer. □

Theorem 3763.4 (Cantor ternary set CantorSet dependency)**.** *Every accepted* $\mathsf{CantorTernarySet}^{\uparrow}$ *packet factors through the retained-prefix and deleted-gap surface of chapter 1530 before any* $\mathsf{Real}^{\uparrow}$*-facing seal is read. After that CantorSet row is displayed, the remaining route uses* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows to reach the terminal real-name boundary, without asserting compactness, measure, host powersets, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3763.1. The row I is the retained interval row inherited from the CantorSet sibling, and it is computed from the same finite triadic prefix and deleted-gap ledger as W, D, V, G.

By Definition 3763.3, every real-facing read remains on the route $W, D, V, G, I \longmapsto R \longmapsto E$. Thus the CantorSet retained-prefix and deleted-gap row is consumed before the regular-rational readback R and Real seal E are available.

The remaining rows R, E, H, C, P, N use the RegSeqRat, StreamName, and DyadicRatCore surfaces named in the carrier provenance. None of those rows supplies compactness, measure, host powersets, or ambient real completeness, so the dependency is exactly the finite sibling consumption stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorTernarySet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorTernarySet}^{\uparrow}$ packet is generated from finite StreamName windows, retained ternary digit rows, triadic place-value rows, deleted-middle gap rows, a retained CantorSet interval row, RegSeqRat readback, a RealUp seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorTernarySet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3763.1, Definition 3763.2, and Definition 3763.3 seed the explicit finite ternary-window carrier for the middle-third Cantor set through retained digits, triadic values, deleted gaps, regular-rational readback, and the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorTernarySet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, selected infinite branches, quotient real equality, endpoint uniqueness, measure, compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, retained-digit classification, triadic place-value evaluation, gap exclusion, retained-interval compatibility, RegSeqRat readback, RealUp seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CantorTernarySetUp.

Chapter 3764

A Concrete Naming Certificate for $\mathsf{CyclicTagSystem}^{\uparrow}$

Following Cook 2004 and Neary–Woods 2007, the $\mathsf{CyclicTagSystem}^{\uparrow}$ packet records cyclic tag systems as finite step-indexed rewriting data between the machine surface of chapter 280, the finite Rule 110 glider-catalog surface of chapter 1045, and the total-language boundary of chapter 9370. The packet names the alphabet, cyclic production list, deletion number, inspected tape window, bounded fuel evaluator, and Rule 110 handoff as displayed BHist rows. It does not import a partial halting function, an unbounded convergence theorem, a host evaluator, or Cook universality as a hidden coordinate.

Definition 3764.1 (Cyclic tag system carrier)**.** *A* $\mathsf{CyclicTagSystem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, P, D, W, F, R, H, C, Q, N)$$

with the following displayed rows:

1. *A is the finite alphabet row, including the distinguished blank or empty-word convention used by the inspected packet.*
2. *P is the cyclic production-list row, exposing the finite list of appendants and the current production index as BEDC data.*
3. *D is the deletion-number row, recording the positive deletion budget used by each accepted step.*
4. *W is the tape-window state row, containing only the displayed prefix, suffix guard, current word window, and step-index ledger.*
5. *F is the bounded fuel evaluator row, naming the finite replay of at most the displayed fuel many cyclic-tag steps.*
6. *R is the Rule 110 handoff row, read through the glider-catalog and cellular rows when a bounded cyclic-tag trace is presented to a Rule 110 consumer.*
7. *H records componentwise* hsame *transport for alphabet, production-list, deletion, tape-window, fuel, handoff, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from alphabet and production reads to one-step tape updates, from tape updates to bounded fuel evaluation, and from the bounded trace to the Rule 110 handoff row.*

9. *Q is the* Pkg *provenance over* CyclicTagSystem$^{\uparrow}$, TuringMachine$^{\uparrow}$, RuleOneTenGliderCatalog$^{\uparrow}$, CellularAutomaton$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{CyclicTagSystem}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the rows $A, P, D, W, F, R, H, C, Q, N$. It has no coordinate for a host partial function, an unbounded halting predicate, an infinite tape quotient, a complete Rule 110 orbit, or a detached universality theorem.

Lean4 ✓ `BEDC.Derived.CyclicTagSystemUp.CyclicTagSystemTasteGate single carrier alignment`

Theorem 3764.2 (Cyclic tag system step-indexed Rule 110 handoff)**.** *For every accepted* CyclicTagSystem$^{\uparrow}$ *carrier $T = (A, P, D, W, F, R, H, C, Q, N)$, every finite fuel read factors through the cyclic-tag evaluator rows A, P, D, W, F before any Rule 110 orbit claim is exported through R. The handoff may cite the* TuringMachine$^{\uparrow}$ *source surface, the* RuleOneTenGliderCatalog$^{\uparrow}$ *finite catalog surface, and the* CellularAutomaton$^{\uparrow}$ *closed-observation route only after the bounded cyclic-tag replay has been displayed. Thus a Rule 110-facing consumer receives a finite step-indexed handoff and receives no halting decision, unbounded convergence theorem, host partial evaluator, or full universality proof.*

Proof. Project the accepted carrier. The alphabet row A, production-list row P, deletion-number row D, and tape-window row W are the only inputs from which a cyclic-tag step can be read.

The bounded evaluator row F is downstream of those rows. A fuel-indexed request must therefore replay the displayed one-step cyclic-tag updates before it can ask for any substrate-facing handoff.

The Rule 110 handoff row R is read only after F. At that point the consumer may cite the Turing-machine source chapter, the finite Rule 110 glider-catalog chapter, and the cellular closed-observation route, but only as sibling certificate surfaces attached to the displayed bounded replay.

Finally inspect H, C, Q, N. These rows transport, replay, source, and name the same bounded route. Since the carrier has no coordinate for halting, unbounded convergence, host partiality, or a complete universality proof, none of those objects can be exported with the Rule 110-facing handoff. □

Falsifiable prediction: Every CyclicTagSystem$^{\uparrow}$ Rule 110-facing read first exposes a finite alphabet row, cyclic production-list row, deletion-number row, tape-window row, bounded fuel evaluator row, transport row, continuation route, provenance row, and local naming row.

Independence witness: turingmachine, rule110glidercatalog, cellularautomaton: CyclicTagSystem$^{\uparrow}$ is not bijective to any listed sibling because it carries cyclic production-list and deletion-number rows together with a bounded tape-window evaluator before the Rule 110 handoff.

Closure status for NameCert$_{\text{CyclicTagSystem}^{\uparrow}}$**.**

Constructive story: A CyclicTagSystem$^{\uparrow}$ packet is generated from a finite alphabet row, cyclic production-list row, deletion-number row, tape-window state row, bounded fuel evaluator row, Rule 110 handoff row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CyclicTagSystem}^{\uparrow}}$, seed)

Scope closed: Definition 3764.1 and Definition 3764.2 seed the finite cyclic-tag route between total BEDC step-indexing, TuringMachine$^{\uparrow}$, and the Rule 110 glider-catalog surface.

Formal verification: FormalStatus(NameCert$_{\text{CyclicTagSystem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close halting, unbounded convergence, host partiality, full universality, global Rule 110 orbit classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cyclic production-list replay, deletion-step exactness, bounded fuel evaluation, Rule 110 handoff nonescape, provenance, and local NameCert rows for the same packet.

Chapter 3765

A Concrete Naming Certificate for $\mathsf{HausdorffContent}^{\uparrow}$

Following Hausdorff and later constructive metric-measure treatments, the $\mathsf{HausdorffContent}^{\uparrow}$ packet records finite cover content data for metric subsets without importing a completed measure theory. It sits over the metric carrier of chapter 57, the finite measure-facing ledger of chapter 92, the retained-prefix surfaces of chapter 1530 and chapter 3763, and the terminal real-name seal of chapter 38. The packet names only displayed cover rows, rational radius and exponent budgets, refinement transport, content-bound replay, package provenance, and local NameCert evidence.

Definition 3765.1 (Hausdorff content carrier)**.** *A* $\mathsf{HausdorffContent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, A, R, S, U, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{Met}^{\uparrow}$ *row whose distance observations are sealed through* $\mathsf{Real}^{\uparrow}$*.*
2. *A is the inspected subset or source row, presented only by finite membership probes inherited from metric, Cantor, or ternary Cantor packets.*
3. *R is the rational radius-budget row, listing finitely many positive rational or dyadic radius bounds.*
4. *S is the rational exponent-budget row, recording the displayed content exponent and the arithmetic route used for each radius power.*
5. *U is the finite metric-cover row, pairing each listed cover center and radius with the source probes it covers.*
6. *B is the content-bound replay row, summing the displayed radius-power bounds into a* $\mathsf{Real}^{\uparrow}$*-sealed upper content value.*
7. *H is the componentwise* hsame *transport row for the metric source, subset probes, radius budgets, exponent budgets, cover rows, content bounds, provenance, and local name.*
8. *C is the displayed* Cont *replay route for cover refinement, radius-budget reuse, exponent-budget reuse, and content-bound replay.*
9. *P is the* Pkg *provenance over* $\mathsf{HausdorffContent}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{CantorSet}^{\uparrow}$*,* $\mathsf{CantorTernarySet}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HausdorffContent}^{\uparrow}}$ *row.*

The classifier accepts a packet only when $M, A, R, S, U, B, H, C, P, N$ are displayed for the same finite cover request, every cover row uses a listed radius budget, every content-bound replay uses the listed exponent budget, and every metric, measure-facing, Cantor-facing, or real-facing consumer enters through the displayed rows. It has no coordinate for a host infimum over all covers, a choice-selected cover family, quotient real equality, σ-additive Hausdorff measure, or completed measure theory.

Lean4 ✓ `BEDC.Derived.HausdorffContentUp.HausdorffContentTasteGate single carrier alignment`

Theorem 3765.2 (Hausdorff content NameCert obligations)**.** *For an accepted* $\mathsf{HausdorffContent}^{\uparrow}$ *carrier*

$$Q = (M, A, R, S, U, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffContent}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source admission through M, finite source-probe admission through A, rational radius-budget admission through R, rational exponent-budget admission through S, finite cover admission through U, content-bound replay through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission projects the packet in Definition 3765.1. The only metric data are in M, and the only source observations are the finite probes in A.

The radius and exponent budgets are displayed before any content value is read. Thus R and S determine the finite arithmetic route for the cover row U and the bound row B.

Transport and replay add no analytic coordinate. The rows H and C preserve the same metric, source, budget, cover, and bound rows, while P and N source and name the packet.

Since no carrier coordinate stores a host infimum, selected cover family, quotient real equality, σ-additive measure, or completed measure theory, the listed rows exhaust the local NameCert obligations. □

Theorem 3765.3 (Hausdorff content finite-cover refinement)**.** *Every refinement-facing read of an accepted* $\mathsf{HausdorffContent}^{\uparrow}$ *packet factors through the displayed route*

$$M, A, R, S, U, B, H, C, P, N.$$

If a finer cover is cited, it must reuse or refine the listed radius-budget row R, exponent-budget row S, finite cover row U, and content-bound replay row B through hsame *transport and displayed continuation. The refinement read cannot cite an ambient cover lattice, a host infimum over covers, a choice-selected minimizing cover, or quotient equality of real content values.*

Proof. Start with the finite cover coordinate. By Definition 3765.1, the row U is the only place where cover centers, radii, and covered source probes are displayed.

The budget rows R and S are upstream of U and B. A refinement can therefore change a cover only by displaying the reused or refined radius and exponent ledgers before the content-bound replay is read.

Use H and C to transport and replay the refinement route. The provenance row P and local name N keep the refined packet attached to the same metric, measure-facing, Cantor-facing, and real-facing source chapters.

The excluded host cover lattice, infimum, selected minimizing cover, and quotient real equality are not packet coordinates, so no refinement-facing consumer can obtain them from $\mathsf{HausdorffContent}^{\uparrow}$. □

Theorem 3765.4 (Hausdorff content Cantor cover handoff)**.** *Every* $\mathsf{CantorSet}^{\uparrow}$ *or* $\mathsf{CantorTernarySet}^{\uparrow}$ *consumer citing* $\mathsf{HausdorffContent}^{\uparrow}$ *receives only a finite cover-content handoff through*

$$A \longmapsto R, S \longmapsto U \longmapsto B$$

together with M, H, C, P, N*. The handoff can record finite retained-prefix probes, ternary-window probes, rational radius and exponent budgets, finite cover rows, and replayed content bounds. It does not supply* σ*-additive Hausdorff measure, a host infimum, a choice-selected cover, quotient real equality, or completed measure theory.*

Proof. Read the Cantor-facing source through A. The source row admits only finite retained-prefix or ternary-window probes inherited from chapter 1530 and chapter 3763.

Next read the budget and cover rows. The rational radius and exponent budgets R, S are displayed before the finite cover row U, and the content-bound replay row B is downstream of that cover.

Finally attach the metric and structural rows. The metric source M supplies the distance observations, while H, C, P, N transport, replay, source, and name the same finite handoff.

The measure-facing provenance does not create a completed measure. Because σ-additivity, host infima, choice-selected covers, quotient real equality, and completed measure theory are absent from the carrier, the Cantor consumer receives only the finite cover-content route. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffContent}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffContent}^{\uparrow}$ packet is generated from metric source rows, finite source probes, rational radius and exponent budgets, finite cover rows, content-bound replay, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffContent}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3765.1, Definition 3765.2, Definition 3765.3, and Definition 3765.4 seed the finite cover-content carrier for metric, measure-facing, Cantor-facing, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffContent}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close σ-additive Hausdorff measure, host infimum over all covers, choice-selected covers, quotient real equality, completed measure theory, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, budget admission, cover admission, refinement transport, content-bound replay, Cantor cover handoff, provenance, and local naming for BEDC.Derived.HausdorffContentUp.

Chapter 3766

A Concrete Naming Certificate for $\mathsf{CauchyTailFilterBornology}^{\uparrow}$

Following Bourbaki and Weil on uniform spaces and bounded structures, the $\mathsf{CauchyTailFilterBornology}^{\uparrow}$ packet records bounded Cauchy-tail filters as finite BEDC rows. It sits between the finite stream schedule of chapter 126, the regular rational source discipline of chapter 301, the bounded-set carrier of chapter 1757, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names tail-bound surfaces for regular Cauchy data; it is not a quotient of streams, a choice-selected bound, trichotomy, or an ambient completeness theorem.

Definition 3766.1 (Cauchy tail filter bornology carrier)**.** *A* $\mathsf{CauchyTailFilterBornology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, B, W, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule whose finite windows are the only tail observations visible to the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row read through the same windows.*
3. *B is the* $\mathsf{BoundedSet}^{\uparrow}$ *tail-bound row, recording the displayed bound cell for the admitted tail window.*
4. *W is the tail-window row specifying the finite index after which the bound row is read.*
5. *M is the Cauchy-modulus compatibility row, matching the tail window to the tolerance requests carried by the regular sequence.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, B, W, M have been displayed.*
7. *H records componentwise* hsame *transport for schedule, regular source, bounded tail, window, modulus, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tail-bound request through S, R, B, W, M, E and then through the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailFilterBornology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailFilterBornology}^{\uparrow}}$ *row.*

The carrier exports no quotient stream, selected bound, selected tail representative, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.CauchyTailFilterBornologyUp.CauchyTailFilterBornologyTasteGate single carrier alignment`

Definition 3766.2 (Cauchy tail filter bornology classifier)**.** *Two accepted* $\mathsf{CauchyTailFilterBornology}^{\uparrow}$ *carriers*

$$T = (S, R, B, W, M, E, H, C, P, N)$$

and

$$T' = (S', R', B', W', M', E', H', C', P', N')$$

are classified together exactly when the displayed hsame *rows transport* S *to* S'*,* R *to* R'*,* B *to* B'*,* W *to* W'*,* M *to* M'*, and* E *to* E'*, and the displayed* Cont *rows replay the same tail-window-to-bound-to-seal route on both packets. The classifier has no coordinate for equality of quotient streams, a least bound, a selected eventual index, trichotomy, or ambient completeness.*

Theorem 3766.3 (Cauchy tail filter bornology NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailFilterBornolog}$ *carrier* $T = (S, R, B, W, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailFilterBornology}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *tail-window carrier admission, requiring* S, R, W *to display the finite observation window before any tail-bound row is consumed;*
2. *eventual boundedness classifier, requiring* B *to be preserved under the componentwise* hsame *transport of the accepted carrier and replayed by the same* Cont *route;*
3. *Cauchy-modulus compatibility, requiring* M *to attach each bound read to the same regular Cauchy source and finite window;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal handoff, requiring* R *and* E *to remain downstream of the displayed schedule, tail window, bound row, and modulus row;*
5. *ledger non-escape, requiring* H, C, P, N *to expose no quotient stream, selected bound, selected tail representative, trichotomy row, or ambient completeness theorem.*

No Cauchy tail filter bornology obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 3766.1. The displayed tuple $S, R, B, W, M, E, H, C, P, N$ is the whole public surface, so tail-window carrier admission is exactly admission of those rows.

The eventual boundedness classifier is forced by the bound row. A tail-bound consumer can read B only through the finite window W over the stream schedule S and the regular source R, and classifier preservation transports that same row componentwise.

The Cauchy-modulus row supplies the compatibility check. It attaches the displayed bound to the tolerance and tail-window requests already visible in S, R, W, so the read cannot replace the packet by a host-level eventual bound or by a chosen index.

Finally, the Real-facing rows are downstream. The seal row E is reached only after S, R, B, W, M are displayed, and H, C, P, N preserve and name that route. Since the carrier has no coordinate for quotient streams, selected bounds, trichotomy, or ambient completeness, the five listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyTailFilterBornologyUp.CauchyTailFilterBornologyNameCertObligations`

Falsifiable prediction: Every $\mathsf{CauchyTailFilterBornology}^{\uparrow}$ read factors through a finite StreamName schedule, a RegSeqRat source row, a BoundedSet tail-bound row, a finite tail-window row, a Cauchy-modulus compatibility row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, boundedset, real: $\mathsf{CauchyTailFilterBornology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite tail-window schedule, regular Cauchy source, bounded tail row, modulus compatibility, RealUp sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailFilterBornology}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailFilterBornology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3766.1, Definition 3766.2, and Definition 3766.3 seed the bounded tail-filter surface from finite StreamName windows through RegSeqRat readback, BoundedSet tail bounds, Cauchy-modulus compatibility, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailFilterBornology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected bounds, least bounds, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, eventual boundedness classification, Cauchy-modulus compatibility, RegSeqRat and Real seal handoff, ledger non-escape, and local naming for BEDC.Derived.CauchyTailFilterBornologyUp.

Constructive story: A $\mathsf{CauchyTailFilterBornology}^{\uparrow}$ packet is generated from finite StreamName windows, a RegSeqRat source row, a BoundedSet tail-bound row, a finite tail-window row, Cauchy-modulus compatibility, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3767

A Concrete Naming Certificate for SequentialCompletenessCriterion$^{\uparrow}$

Following Bishop–Bridges and Kelley, the SequentialCompletenessCriterion$^{\uparrow}$ packet records the finite criterion by which sequence completion evidence is read as real sequential completeness data. It sits after the sequence-completion surfaces of chapter 1683 and chapter 3691, reads the real-facing seal of chapter 1544, and keeps the metric criterion aligned with chapter 1515.

Definition 3767.1 (SequentialCompletenessCriterion carrier)**.** *A* SequentialCompletenessCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, C, R, M, W, G, E, H, T, P, N)$$

with the following displayed rows:

1. *S is the* SequentialCompletion$^{\uparrow}$ *row naming the displayed sequence-completion interface consumed by the criterion.*
2. *C is the* CauchySequenceCompletion$^{\uparrow}$ *row naming the regular Cauchy sequence completion route available to the same finite packet.*
3. *R is the* RealSequentialCompleteness$^{\uparrow}$ *row, exposed only after the sequence-completion and Cauchy-sequence completion rows have been displayed.*
4. *M is the* SequentiallyCompleteMetric$^{\uparrow}$ *row, recording the metric criterion surface through which later metric consumers read sequential completeness.*
5. *W is the* StreamName$^{\uparrow}$ *finite-window row for the sequence observations inspected by the criterion.*
6. *G is the* RegSeqRat$^{\uparrow}$ *readback row attached to the displayed stream windows and Cauchy schedules.*
7. *E is the* Real$^{\uparrow}$ *seal row reached from the regular readback and real sequential completeness rows.*
8. *H records componentwise* hsame *transport for S, C, R, M, W, G, E.*
9. *T records displayed* Cont *replay from sequence windows through Cauchy completion, metric criterion data, regular readback, and the real seal.*
10. *P is the* Pkg *provenance over* SequentialCompletenessCriterion$^{\uparrow}$, SequentialCompletion$^{\uparrow}$, CauchySequenceCompleti RealSequentialCompleteness$^{\uparrow}$, SequentiallyCompleteMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletenessCriterion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite criterion packet. It has no coordinate for quotient completion, countable choice, host equality of sequences or completion points, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialCompletenessCriterionUp.SequentialCompletenessCriterionTasteGate single carrier alignment`

Theorem 3767.2 (SequentialCompletenessCriterion NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompletenessCriterion}^{\uparrow}$ *carrier* $Q = (S, C, R, M, W, G, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletenes}}$ *surface consists exactly of carrier admission for the sequence-completion row, Cauchy-sequence completion row, real sequential-completeness row, sequentially complete metric row, stream-window row, regular readback row, real seal row, componentwise transport, displayed replay, provenance, and local naming. Any real sequential-completeness consumer must read*

$$S, C, W, G, R, M, E, H, T, P, N$$

before it can export a criterion result, and the export contains no quotient completion, countable choice, host equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3767.1. The rows $S, C, R, M, W, G, E, H, T, P, N$ are the only rows available to a consumer of the local name.

The sequence-facing part of the criterion is supplied by S and C. The finite observation schedule is supplied by W, and the regular rational readback is supplied by G. Thus the criterion never begins from a host sequence or from a quotient completion object.

The real-facing part is then forced through R, M, E. The real sequential-completeness row and the sequentially complete metric row name the criterion surface, while the $\mathsf{Real}^{\uparrow}$ seal can be read only after the displayed regular readback route has been consumed.

Finally H, T, P, N transport, replay, source, and name the same finite route. Since the packet contains no row for countable choice, host equality, open-cover compactness, quotient completion, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.SequentialCompletenessCriterionUp.SequentialCompletenessCriterionCarrier namecert obligations`

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompletenessCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCompletenessCriterion}^{\uparrow}$ packet is generated from a $\mathsf{SequentialCompletion}^{\uparrow}$ row, a $\mathsf{CauchySequenceCompletion}^{\uparrow}$ row, a $\mathsf{RealSequentialCompleteness}^{\uparrow}$ row, a $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialCompletenessCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 3767.1 and Definition 3767.2 seed the finite criterion surface connecting sequence completion, Cauchy sequence completion, metric sequential completeness, regular readback, and real sequential completeness.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialCompletenessCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient completion, countable choice, host equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence-completion handoff, Cauchy-sequence completion readback, metric criterion exposure, real seal nonescape, transport, replay, provenance, and local naming for the same finite packet.

Chapter 3768

A Concrete Naming Certificate for $\mathsf{RegularModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularModulus}^{\uparrow}$ packet records the explicit modulus row carried by a regular Cauchy rational name before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reads the terminal seal. It sits between the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the regular Cauchy naming surface of chapter 371, and the real-name seal of chapter 38. The packet is the finite modulus object consumed by Real and Completion routes; it does not choose limits, quotient streams, or host real equality.

Definition 3768.1 (Regular modulus carrier)**.** *A* $\mathsf{RegularModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, \mu, D, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy row whose rational windows are already admitted through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*.*
2. *μ is the unary modulus row assigning, to each displayed precision request, a finite stream-window bound for the source row.*
3. *D is the dyadic tolerance ledger translating precision requests into* $\mathsf{DyadicRatCore}^{\uparrow}$ *radii and comparison budgets.*
4. *W is the finite window route showing that the window selected by μ is sufficient for the requested tolerance.*
5. *H records componentwise* hsame *transport for the source row, modulus row, dyadic ledger, finite window route, continuation replay, package provenance, and local name.*
6. *C records displayed* Cont *replay from a precision request through S, μ, D, W, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularModulus}^{\uparrow}$*,* $\mathsf{RegularCauchyName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularModulus}^{\uparrow}}$ *row.*

The classifier accepts a packet only when the modulus row, dyadic tolerance ledger, and finite window route are displayed for the same source regular Cauchy row. It has no coordinate for

a selected limit, quotient stream equality, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularModulusUp.RegularModulusTasteGate single carrier alignment`

Theorem 3768.2 (Regular modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularModulus}^{\uparrow}$ *carrier* $M = (S, \mu, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularModulus}^{\uparrow}}$ *surface consists exactly of source regular Cauchy admission, unary modulus display, dyadic tolerance translation, finite window sufficiency, componentwise transport, continuation replay, package provenance, and local naming through the rows* S, μ, D, W, H, C, P, N*.*

Proof. Project the carrier of Definition 3768.1. The source row S is the only regular Cauchy data exposed by the packet, and the row μ is the only modulus coordinate attached to that source.

The dyadic ledger D translates each precision request into the tolerance language used by chapter 291. The window route W then records that the bound supplied by μ is sufficient for the inspected $\mathsf{StreamName}^{\uparrow}$ windows and the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Finally H, C, P, N preserve, replay, source, and name the same displayed rows. Since selected limits, quotient streams, host real equality, countable choice, and ambient completeness have no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3768.3 (Regular modulus RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularModulus}^{\uparrow}$ *packet must read the source regular Cauchy row through*

$$S, \mu, D, W \longmapsto H, C, P, N$$

before the regular-rational readback or terminal real-name seal is consumed. Thus the modulus is a displayed finite BEDC row on the Real and Completion route, not a hidden choice of limit, quotient representative, or host equality witness.

Lean4 ✓ `BEDC.Derived.RegularModulusUp.RegularModulusRegSeqRatHandoff`

Proof. Start with a consumer request for regular-rational or real-name data. The packet exposes the source only as S, so the consumer must read the unary modulus row μ and the dyadic tolerance ledger D before it can identify a sufficient finite window.

The row W supplies that finite window route. It is already tied to the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces named in the provenance row, and it reaches the $\mathsf{Real}^{\uparrow}$ seal only after the displayed tolerance check has been replayed.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. No excluded limit, quotient, host-equality, choice, or ambient-completeness coordinate is available, so every handoff remains on the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularModulus}^{\uparrow}$ packet is generated from a source regular Cauchy row, a unary modulus row, a dyadic tolerance ledger, a finite window route, componentwise transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularModulus}^{\uparrow}}$, seed)

Scope closed: Definition 3768.1, Definition 3768.2, and Definition 3768.3 seed the finite modulus surface for regular Cauchy rational names on the Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not assert completeness, choice of limits, quotient streams, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus sufficiency, RegSeqRat handoff, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularModulusUp.

Chapter 3769

A Concrete Naming Certificate for $\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}$ packet records the constructive finite-subcover surface obtained when a located real interval is paired with displayed finite-net and local-coverage data. It consumes the located endpoint and radius discipline of chapter 394, the finite-net replacement surface of chapter 3471, and the terminal real-name boundary of chapter 38. The packet names explicit extraction of a finite subcover from a finite mesh route; it is not general open-cover compactness, sequential compactness, countable choice, or a host Heine-Borel theorem.

Definition 3769.1 (Compact located interval subcover carrier)**.** *A* $\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, N, C, M, E, H, R, P, L)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row, carrying the displayed endpoint names, radius budget, and locatedness reads.*
2. *N is the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *row, carrying a finite mesh, mesh-scale ledger, and finite-net coverage route for the same interval.*
3. *C is the local coverage row: each finite mesh cell is paired with an admitted cover token and the finite witness that the cell is covered at the displayed tolerance.*
4. *M is the extraction row listing the selected finite cover tokens in the order read from the finite net.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located interval, finite net, and local coverage rows have been displayed.*
6. *H records componentwise* hsame *transport for interval, net, local coverage, extracted token list, seal, replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay from an interval-subcover request through I, N, C, M, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open-cover compactness, sequential compactness without choice-like data, selected quotient representatives, trichotomy, countable choice, host interval equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactLocatedIntervalSubcoverUp.CompactLocatedIntervalSubcoverTasteGate single carrier alignment`

Theorem 3769.2 (Compact located interval subcover obligations)**.** *For every accepted* CompactLocatedIntervalSub *carrier* $S = (I, N, C, M, E, H, R, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}}$ *surface consists exactly of located interval admission through* I*, finite-net admission through* N*, local mesh-cell coverage through* C*, explicit finite token extraction through* M*, terminal real-name sealing through* E*, componentwise transport through* H*, displayed replay through* R*, provenance through* P*, and local naming through* L*.*

Proof. Project the carrier of Definition 3769.1. The rows I, N, C, M, E expose the located interval, finite mesh, local coverage, extracted token list, and real-name seal before any consumer can read a subcover claim.

The obligation surface is finite. The only coverage evidence available to the packet is the row C, whose entries are indexed by the finite mesh row N and whose selected tokens are exactly the entries displayed in M.

Transport and replay do not add compactness principles. The rows H and R preserve the same finite route, while P and L record provenance and local naming for that route.

Because no arbitrary open-cover, sequential compactness, choice, quotient-representative, trichotomy, host-equality, or ambient-completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 3769.3 (Compact located interval finite-net extraction)**.** *Every accepted* CompactLocatedIntervalSubcove *carrier exports a finite subcover list only by the route*

$$\mathsf{LocatedInterval}^{\uparrow} \longrightarrow \mathsf{HeineBorelFiniteNet}^{\uparrow} \longrightarrow C \longrightarrow M \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, the finite list M *is extracted from the displayed mesh cells and their local coverage witnesses; it is not chosen from an arbitrary open cover and is not obtained from sequential compactness.*

Proof. Start with the located interval row I. It fixes the endpoint and radius data whose finite-net request is read by N.

The row N supplies only a finite mesh route. The local coverage row C attaches cover tokens to that finite mesh, so the extraction row M can list exactly those displayed tokens.

The terminal seal E is downstream of the finite extraction. It records the $\mathsf{Real}^{\uparrow}$ boundary of the already displayed route and does not supply a separate compactness theorem.

Thus the exported subcover is the finite list read from M, transported by H and replayed by R. The excluded open-cover and sequential compactness principles have no coordinate from which a consumer could read them. □

Theorem 3769.4 (Compact located interval L10 scope)**.** *The* $\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}$ *packet is an L10 real/completion consumer of located interval and finite-net data. It may be used where a downstream real or completion argument needs a displayed finite subcover extracted from a located interval mesh. It does not close general Heine-Borel compactness, arbitrary open-cover compactness, sequential compactness without choice-like data, or any bridge to host compact spaces.*

Proof. The dependency route is already displayed in the carrier. It starts at $\mathsf{LocatedInterval}^{\uparrow}$, passes through $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, and reaches $\mathsf{Real}^{\uparrow}$ only after the local coverage and extraction rows are present.

Any L10 consumer can therefore inspect the finite mesh, the selected coverage tokens, and the real-name seal. No consumer receives an open-cover family, a sequence-to-subsequence selector, or a host compact-space object.

The scope claim follows by ledger exhaustion: P records the listed dependencies, L names the local packet, and all excluded compactness principles are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}$ packet is generated from a located interval row, a finite-net row, local mesh-cell coverage witnesses, an extracted finite token list, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3769.1, Definition 3769.2, Definition 3769.3, and Definition 3769.4 seed explicit finite-subcover extraction for located real intervals from finite-net data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactLocatedIntervalSubcover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general Heine-Borel compactness, arbitrary open-cover compactness, sequential compactness without choice-like data, countable choice, selected quotient representatives, host interval equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net extraction, local coverage exactness, L10 nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactLocatedIntervalSubcoverUp.

Chapter 3770

A Concrete Naming Certificate for $\mathsf{RealAbsoluteValue}^{\uparrow}$

Following Bishop and Bridges on constructive absolute value for real names, the $\mathsf{RealAbsoluteValue}^{\uparrow}$ packet records absolute value as a finite NameCert read over the current L10 $\mathsf{Real}^{\uparrow}$ construction. It seals the dyadic endpoint of chapter 293 into regular real-name data without importing host real equality, trichotomy, or an ambient ordered-field object.

Definition 3770.1 (Real absolute-value carrier)**.** *A* $\mathsf{RealAbsoluteValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, \delta, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite read windows used to inspect the real name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name row for the input real, including the rational approximants and regularity ledger.*
3. *δ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to choose dyadic approximants at each displayed window.*
4. *D is the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint readback row, applying dyadic absolute value to the inspected dyadic cores.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *stability budget that bounds the replay of the endpoint readback across later windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row that packages the resulting regular absolute-value name.*
7. *H records componentwise* hsame *transport for the schedule, regular-name data, dyadic tolerance, dyadic endpoint readback, modulus budget, and real seal.*
8. *C records the* Cont *replay routes from schedule inspection through dyadic readback to the sealed regular real name.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealAbsoluteValue}^{\uparrow}}$ *row.*

The accepted carrier contains no host real equality test, no trichotomy branch, no order-completion shortcut, no RealAlgOrder completion claim, and no absolute-value operation detached from the displayed regular-name and dyadic endpoint rows.

Lean4 ✓ `BEDC.Derived.RealAbsoluteValueUp.RealAbsoluteValueTasteGate single carrier alignment`

Theorem 3770.2 (Real absolute-value NameCert obligations)**.** *For an accepted packet* $A = (S, R, \delta, D, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealAbsoluteValue}^{\uparrow}}$ *obligation surface consists exactly of carrier admission, dyadic absolute-value stability, regular-sequence seal compatibility, triangle nonescape, and ledger exactness for the displayed rows* $S, R, \delta, D, M, E, H, C, P, N$*.*

Proof. Carrier admission reads the schedule, regular-name data, dyadic tolerance, dyadic endpoint readback, stability budget, and real seal from the finite packet. The support rows H, C, P, N transport, replay, package, and name exactly those displayed rows.

Dyadic absolute-value stability is local to D and δ. The endpoint readback uses the dyadic absolute-value packet, while the tolerance row fixes the finite accuracy at which the dyadic core is inspected.

Regular-sequence seal compatibility is supplied by M and E. The modulus budget records enough stability to replay the endpoint readback across later windows, and the $\mathsf{Real}^{\uparrow}$ seal packages the resulting regular name without adding a host real comparison.

Ledger exactness follows by projection from the carrier. Every exported read is one of $S, R, \delta, D, M, E, H, C, P, N$ so no trichotomy branch, order-completion shortcut, or RealAlgOrder completion field can be recovered from the packet. □

Theorem 3770.3 (Real absolute-value triangle nonescape)**.** *Every triangle-facing consumer of an accepted* $\mathsf{RealAbsoluteValue}^{\uparrow}$ *packet reads only the regular-name seal* E *together with its schedule, dyadic tolerance, dyadic endpoint readback, modulus budget, componentwise transport, continuation replay, package provenance, and local naming rows. The packet therefore exposes the triangle surface as a stability obligation over regular real names and dyadic absolute-value readback, not as host real order, trichotomy, or a completed* $\mathsf{RealAlgOrder}^{\uparrow}$ *structure.*

Proof. Start with the carrier rows of Definition 3770.1. The only endpoint operation is the dyadic readback D, and the only real-facing result is the $\mathsf{Real}^{\uparrow}$ seal E.

The triangle-facing route must use the schedule and tolerance rows to compare finite read windows, then use M to replay the resulting regular-name stability. Transport by H and replay by C keep the route tied to those same displayed rows.

Package provenance P and local naming N identify the output as the $\mathsf{RealAbsoluteValue}^{\uparrow}$ surface. Since the carrier has no host real equality test, no trichotomy coordinate, and no RealAlgOrder completion field, a triangle consumer cannot escape the regular-name and dyadic-readback ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealAbsoluteValue}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealAbsoluteValue}^{\uparrow}$ packet is generated from a StreamName schedule, RegSeqRat regular-name data, DyadicRatCore tolerance, DyadicAbsoluteValue endpoint readback, CauchyModulus stability budget, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealAbsoluteValue}^{\uparrow}}$, seed)

Scope closed: Definition 3770.1, Definition 3770.2, and Definition 3770.3 bind the seed carrier, obligation surface, and triangle-facing nonescape boundary for constructive real absolute value.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealAbsoluteValue}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RealAbsoluteValueUp.RealAbsoluteValueTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close RealAlgOrderUp completion, host real equality, trichotomy, or bridge checking.

Upgrade path: Bridge checking requires a paper bridge from the checked carrier alignment to dyadic absolute-value stability, regular-sequence seal compatibility, triangle nonescape, and ledger exactness.

Chapter 3771

A Concrete Naming Certificate for CUNSpectralAntenna$^{\uparrow}$

The CUNSpectralAntenna$^{\uparrow}$ packet realizes the CUN tail spectral antenna theorem of Definition 9462.1457 as finite BEDC NameCert data. It reads the retention inequality, Perron response, positive self-energy row, and small-mass row from the six-boundary-tile spectral window, then exposes only the finite antenna rows needed by downstream trigger-spectrum consumers. The packet is not a biological-code oracle, stochastic evolution law, hidden Perron solver, quotient codon semantics, or unbounded spectral search.

The antenna packet consumes the spectral-closure and trigger-algebra sibling surfaces through the same separation row used below: chapter 3753 supplies the greedy spectral closure boundary, chapter 2270 supplies the stabilization read, and chapter 3478 supplies the finite trigger-algebra coverage surface. These sibling routes are the concrete sources for the S row and for the Pkg provenance row Q.

Definition 3771.1 (CUN spectral antenna carrier)**.** *A* CUNSpectralAntenna$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, R, P, E, M, S, H, C, Q, N)$$

with the following displayed rows:

1. *T is the CUN tail row naming the finite tail cells and their attachment to the same six-boundary window as Definition 9462.1457.*
2. *R is the retention row displaying $\rho(M) = 19/30$ and its comparison with the WNR baseline.*
3. *P is the Perron-response row displaying $\lambda(M) = 0.675247931\ldots$ and the comparison with the same WNR baseline.*
4. *E is the self-energy row recording that the tail contributes a positive perturbation to the radial Perron mode.*
5. *M is the small-mass row recording the quasi-stationary tail mass boundary used by the source theorem.*
6. *S is the sibling separation row over* GreedySpectralClosure$^{\uparrow}$, SpectralStabilization$^{\uparrow}$, RadialWobbleSpectrum$^{\uparrow}$, BooleanTriggerLattice$^{\uparrow}$, *and* WindowCoverageTriggerAlgebra$^{\uparrow}$.
7. *H records componentwise* hsame *transport for tail, retention, Perron-response, self-energy, small-mass, sibling-separation, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from an antenna read through T, R, P, E, M, S, H.*
9. *Q is the* Pkg *provenance over* $\mathsf{CUNSpectralAntenna}^{\uparrow}$, $\mathsf{GreedySpectralClosure}^{\uparrow}$, $\mathsf{SpectralStabilization}^{\uparrow}$, $\mathsf{RadialWobbleSpectrum}^{\uparrow}$, $\mathsf{BooleanTriggerLattice}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, *the source theorem Definition 9462.1457,* BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CUNSpectralAntenna}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, P, E, M, S, H, C, Q, N$. It has no coordinate for hidden spectral computation, biological-code truth, stochastic dynamics, quotient codon equality, ambient eigenvector choice, or unbounded enumeration.

Theorem 3771.2 (CUN spectral antenna NameCert obligations)**.** *For every accepted* $\mathsf{CUNSpectralAntenna}^{\uparrow}$ *carrier $A = (T, R, P, E, M, S, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{CUNSpectralAntenna}^{\uparrow}}$ *surface consists exactly of CUN tail admission, retention-row exposure, Perron-response exposure, self-energy exposure, small-mass exposure, sibling-separation exposure, componentwise transport, displayed replay, provenance, and local naming.*

The Lean follow-up `lean4/BEDC/Derived/CUNSpectralAntennaUp/TasteGate.lean` *must provide* Nontrivial $\mathsf{CUNSpectralAntenna}^{\uparrow}$ *and* FieldFaithful $\mathsf{CUNSpectralAntenna}^{\uparrow}$ *instances so that T, R, P, E, M, S, H, C remain separate displayed fields.*

Lean4 ✓ `BEDC.Derived.CUNSpectralAntennaUp.CUNSpectralAntennaTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3771.1. The rows T, R, P, E, M, S expose the finite tail, retention comparison, Perron response, self-energy mechanism, small-mass boundary, and sibling separation before any consumer can read an antenna conclusion.

The spectral rows are displayed table rows from the source theorem. They record the stated numerical comparisons and the self-energy interpretation, but they do not introduce a hidden Perron solver or a stochastic model.

The structural rows H, C, Q, N preserve that route. Since no host biological truth predicate, quotient codon equality, eigenvector choice, hidden spectral computation, or unbounded enumeration is a carrier coordinate, the local NameCert obligations are exactly the listed rows. □

Theorem 3771.3 (CUN spectral antenna downstream separation)**.** *Every downstream antenna read of an accepted* $\mathsf{CUNSpectralAntenna}^{\uparrow}$ *packet factors through*

$$T \longmapsto R, P, E, M \longmapsto S, H, C, Q, N.$$

The read may cite the finite CUN tail, retention row, Perron-response row, self-energy row, small-mass row, and sibling separation row. It cannot export a biological-code oracle, stochastic evolutionary law, hidden Perron solver, quotient codon equality, or unbounded spectral optimizer.

Proof. Start with the tail row T. It fixes the finite CUN tail cells read by the source theorem, so later consumers cannot range over an unbounded codon space.

Read the four spectral rows next. The retention row R, Perron-response row P, self-energy row E, and small-mass row M are displayed finite data tied to the same tail.

The sibling row S separates the packet from trigger closure, stabilization, radial wobble, Boolean trigger, and coverage-trigger algebra packets. The remaining rows H, C, Q, N transport, replay, source, and name the same antenna route.

The absent host objects listed in the statement are not coordinates of the carrier and cannot be exported by a consumer read. □

Falsifiable prediction: An accepted $\mathsf{CUNSpectralAntenna}^{\uparrow}$ antenna read is refuted if removing the CUN tail self-energy row preserves the same retention, Perron-response, small-mass, sibling-separation, transport, replay, provenance, and local naming claim.

Independence witness: greedy-spectral-closure, spectral-stabilization, radial-wobble-spectrum, boolean-trigger-lattice, window-coverage-trigger-algebra: none is bijective with $\mathsf{CUNSpectralAntenna}^{\uparrow}$ because the packet jointly carries CUN tail, retention, Perron response, self-energy, small-mass, sibling-separation, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CUNSpectralAntenna}^{\uparrow}}$.

Constructive story: A $\mathsf{CUNSpectralAntenna}^{\uparrow}$ packet is generated from a finite CUN tail row, retention row, Perron-response row, self-energy row, small-mass row, sibling-separation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CUNSpectralAntenna}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3771.1, Definition 3771.2, and Definition 3771.3 seed the finite CUN tail spectral antenna packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CUNSpectralAntenna}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim biological-code truth, stochastic evolutionary dynamics, quotient codon equality, hidden spectral computation, ambient eigenvector choice, unbounded optimization, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, retention exactness, Perron-response exactness, self-energy preservation, small-mass exposure, Nontrivial CUNSpectralAntennaUp, and FieldFaithful CUNSpectralAntennaUp for BEDC.Derived.CUNSpectralAntennaUp.

Chapter 3772

A Concrete Naming Certificate for $\mathsf{FrechetCauchyCriterion}^{\uparrow}$

Following Frechet and Bishop–Bridges constructive analysis, the $\mathsf{FrechetCauchyCriterion}^{\uparrow}$ packet records the finite criterion surface identifying convergence of a displayed real sequence with the Cauchy tail condition. It sits after the Real seal of chapter 38, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the Real Cauchy criterion surface of chapter 1590, and the sequence-limit interface of chapter 1413. The packet exposes a choice-free equivalence route between a displayed limit row and a displayed Cauchy-tail row; it does not import quotient streams, countable choice, host real equality, or an ambient completeness theorem.

Definition 3772.1 (Frechet Cauchy criterion carrier)**.** *A* $\mathsf{FrechetCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, S, Q, D, K, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row naming the real surface on which the sequence and candidate limit are displayed.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for source entries, candidate-limit reads, and late-tail comparisons.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested radii and the dyadic budgets used for both convergence and tail comparisons.*
5. *K is the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *row naming the accepted Cauchy-tail certificate for the displayed sequence.*
6. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row naming the accepted sequence-to-limit certificate over the same real source, windows, readbacks, and tolerances.*
7. *H records componentwise* hsame *transport for R, S, Q, D, K, L and the structural rows.*
8. *C records displayed* Cont *replay from a tolerance request through sequence windows, regular readback, dyadic budgets, Cauchy-tail admission, and sequence-limit admission.*
9. *P is the* Pkg *provenance over* $\mathsf{FrechetCauchyCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, Q, D, K, L, H, C, P, N$. It has no coordinate for quotient stream equality, a selected subsequence, countable choice, host real equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.FrechetCauchyCriterionUp.FrechetCauchyCriterionTasteGate single carrier alignment`

Theorem 3772.2 (Frechet Cauchy criterion NameCert obligations)**.** *For an accepted* $\mathsf{FrechetCauchyCriterion}^{\uparrow}$ *carrier $F = (R, S, Q, D, K, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Real source, finite windows, regular rational readback, dyadic tolerance ledger, Cauchy-tail row, sequence-limit row, transport, replay, provenance, and local naming;*
2. *tail-to-limit compatibility, requiring the* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *row K and the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row L to use the same R, S, Q, D route before either certificate is consumed;*
3. *eventual-tail exactness, requiring each tolerance request to be represented by a displayed late window and dyadic budget in S, Q, D;*
4. *transport and replay stability, requiring H and C to preserve the same route under componentwise* hsame *comparison;*
5. *ledger non-escape, refusing quotient streams, selected representatives, countable-choice selectors, host real equality, and ambient Real completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 3772.1. The tuple exposes exactly the Real source, finite windows, readbacks, dyadic tolerances, Cauchy-tail certificate, sequence-limit certificate, and structural rows.

The compatibility row reads K and L only after R, S, Q, D have been displayed. Thus the Cauchy-tail side and the convergence side compare the same sequence observations and the same dyadic tolerance ledger.

Eventual-tail exactness is finite. Each accepted tolerance request is represented by a late window in S, regular rational data in Q, and a dyadic budget in D, so no hidden selector over tail positions is introduced.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the excluded objects are not carrier coordinates, the local NameCert surface is exhausted by the displayed rows. □

Theorem 3772.3 (Frechet Cauchy criterion eventual-tail exactness)**.** *Let $F = (R, S, Q, D, K, L, H, C, P, N)$ be an accepted* $\mathsf{FrechetCauchyCriterion}^{\uparrow}$ *carrier. A convergence-facing read through L and a Cauchy-tail-facing read through K consume the same finite tail route*

$$R, S, Q, D \longmapsto K, L \longmapsto H, C, P, N.$$

For every displayed tolerance request, the route supplies a late finite window, a regular rational readback, and a dyadic comparison budget before either the limit certificate or the Cauchy-tail certificate can be exported.

Proof. Start with the carrier projection. The source and observation rows R, S, Q, D precede both certificate rows K and L.

Read the Cauchy-tail certificate K through chapter 1590. Its accepted route already requires finite StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance data before the Cauchy criterion is exposed.

Read the sequence-limit certificate L through chapter 1413. Its accepted route uses the same kind of finite tail-window schedule and dyadic ledger before any Real seal is consumed.

The Frechet packet identifies those routes at the displayed rows R, S, Q, D and then preserves them with H, C, P, N. Hence the eventual-tail data are exact inside the packet and cannot be replaced by a detached sequence observation. □

Theorem 3772.4 (Frechet Cauchy criterion Real seal nonescape)**.** *Every Real-facing consumer of an accepted* $\mathsf{FrechetCauchyCriterion}^{\uparrow}$ *carrier* $F = (R, S, Q, D, K, L, H, C, P, N)$ *is confined to the displayed route from the Real source through the finite windows, regular readback, dyadic tolerance ledger, Cauchy-tail row, sequence-limit row, and structural rows. The consumer cannot escape into quotient streams, a selected limit representative, countable choice, host real equality, or an ambient Real completeness principle.*

Proof. Project the carrier. The only Real-facing rows are the source row R and the sequence-limit row L, and both are attached to the finite observation and tolerance rows S, Q, D.

Use Definition 3772.2. The ledger non-escape obligation refuses quotient streams, selected representatives, choice, host equality, and ambient completeness as exported coordinates.

Use Definition 3772.3 to fix the terminal route. Since K and L are consumed only through the same displayed tail data and the structural rows preserve that route, no Real-facing consumer can introduce an additional seal or completion principle outside $R, S, Q, D, K, L, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetCauchyCriterion}^{\uparrow}$ packet is generated from a RealUp source row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealCauchyCriterion row, a RealSequenceLimit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3772.1, Definition 3772.2, Definition 3772.3, and Definition 3772.4 seed the finite equivalence surface between convergence and Cauchy-tail data for real sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetCauchyCriterion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FrechetCauchyCriterionUp.FrechetCauchyCriterionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, countable choice, host real equality, ambient Real completeness, or bridge checking.

Upgrade path: Bridge checking requires a paper bridge from the checked carrier alignment to tail-to-limit compatibility, eventual-tail exactness, transport stability, replay stability, provenance exhaustion, and Real seal nonescape.

Chapter 3773

A Concrete Naming Certificate for $\mathsf{LocatedCutReal}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedCutReal}^{\uparrow}$ packet records the constructive comparison surface where located lower and upper cut data are read as finite real-name evidence before any endpoint comparison is exported. It sits between the regular Cauchy real-name route of $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 38, chapter 301, chapter 126, and chapter 291, and the cut-facing siblings $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, and $\mathsf{DyadicLocatedCut}^{\uparrow}$ in **??**, chapter 436, and chapter 2089. The packet exposes located comparison as a finite NameCert route; it does not claim Dedekind completeness, quotient-real equality, trichotomy, countable choice, selected suprema, or an ambient host real order.

Definition 3773.1 (LocatedCutReal carrier)**.** *A* $\mathsf{LocatedCutReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, G, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the located lower-and-upper cut ledger. It records finite lower cells, upper cells, gap requests, and comparison witnesses in the style of the located cut surface.*
2. *G is the dyadic gap row over* $\mathsf{DyadicRatCore}^{\uparrow}$*. It supplies the displayed dyadic endpoint and radius cells by which a finite gap request is read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the finite observation windows opened by the comparison request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It reads the endpoint-normalized windows as regular rational data before any real seal is consumed.*
5. *Q is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row. It records the finite locatedness evidence used by order, metric, and comparison consumers.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It can be read only after D, G, W, R, Q have been displayed.*
7. *H records componentwise* hsame *transport for cut cells, dyadic endpoints, schedules, regular-rational handoff, located comparison, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay for every consumer read through the same ordered route $D, G, W, R, Q, E, H, P, N$*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedCutReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicLocatedCut}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedCutReal}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $D, G, W, R, Q, E, H, C, P, N$. It has no coordinate for quotient reals, selected cuts, Dedekind completeness, trichotomy, countable choice, or host analytic order.

Lean4 ✓ `BEDC.Derived.LocatedCutRealUp.LocatedCutRealTasteGate single carrier alignment`

Theorem 3773.2 (LocatedCutReal NameCert obligations)**.** *For an accepted* $\mathsf{LocatedCutReal}^{\uparrow}$ *carrier*

$$L = (D, G, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCutReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the located cut ledger, dyadic gap row, finite stream schedule, regular-rational handoff, located real comparison row, terminal real seal, componentwise transport, displayed replay, provenance, and local naming.*

The obligation surface may cite the $\mathsf{DedekindCut}^{\uparrow}$ *lower-and-upper cut discipline, the* $\mathsf{DyadicLocatedCut}^{\uparrow}$ *endpoint route, the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row, and the* $\mathsf{Real}^{\uparrow}$ *seal route. It cannot add a selected supremum, quotient-real representative, ambient completeness proof, trichotomy branch, or external comparison oracle.*

Proof. Project the carrier of Definition 3773.1. The rows D, G, W, R, Q, E expose the located cut cells, dyadic endpoint budgets, finite schedules, regular-rational readback, located real comparison, and terminal real seal in order.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier stores no quotient real, selected cut, completeness witness, trichotomy branch, choice selector, or external order oracle, the local NameCert surface is exactly the displayed finite route. □

Theorem 3773.3 (LocatedCutReal Cauchy comparison)**.** *Every comparison consumer of an accepted* $\mathsf{LocatedCutReal}^{\uparrow}$ *packet factors through the finite Cauchy-facing route*

$$D, G, W, R, Q, E, H, C, P, N.$$

The read may use $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff data, the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It may not bypass those rows by invoking a host Dedekind-completeness theorem, quotient-real equality, selected supremum, trichotomy, countable choice, or an ambient real-order decision procedure.*

Proof. Begin with the located cut ledger D and dyadic gap row G. They provide only finite lower, upper, endpoint, radius, and gap cells, so the comparison request starts as a displayed packet route rather than as an ambient real-order statement.

Next read the schedule W and handoff row R. These rows force endpoint data to pass through finite stream windows and regular-rational budgets before any real-facing comparison is available.

The located comparison row Q and terminal seal E are downstream of that Cauchy-facing route. The rows H, C, P, N preserve the same carrier under transport and replay, so no consumer can export the excluded host objects while still consuming the accepted $\mathsf{LocatedCutReal}^{\uparrow}$ packet. □

Theorem 3773.4 (LocatedCutReal nonescape)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{LocatedCutReal}^{\uparrow}$ *carrier exports only the displayed located cut, dyadic endpoint, stream schedule, regular-rational handoff, and located comparison rows. In particular, it exports no Dedekind completeness principle, quotient real, selected cut representative, trichotomy branch, countable-choice selector, or host analytic order.*

Proof. Read the seal row E through Definition 3773.3. The seal is available only after D, G, W, R, Q have been displayed, and every transported or replayed use is still sourced and named by H, C, P, N.

The absent objects listed in the statement are not fields of Definition 3773.1. Therefore a terminal seal read can only expose the displayed finite comparison route and cannot be reinterpreted as an external completeness, quotient, choice, trichotomy, or host-order witness. □

Falsifiable prediction: An accepted $\mathsf{LocatedCutReal}^{\uparrow}$ comparison read is refuted if the located cut ledger, dyadic endpoint row, StreamName schedule, RegSeqRat handoff, LocatedReal comparison row, Real seal, transport, replay, provenance, or local naming can be removed while preserving the same packet claim.

Independence witness: real, regseqrat, streamname, dyadicratcore, locatedreal, dedekindcut, dyadic-located-cut: $\mathsf{LocatedCutReal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located cut cells, dyadic endpoint budgets, finite schedules, regular-rational handoff, located comparison, terminal real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCutReal}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCutReal}^{\uparrow}$ packet is generated from located lower-and-upper cut ledgers, dyadic endpoint and gap budgets, StreamName finite windows, RegSeqRat handoff rows, LocatedReal comparison evidence, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCutReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3773.1, Definition 3773.2, Definition 3773.3, and Definition 3773.4 seed the finite constructive located-cut comparison surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCutReal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedCutRealUp.LocatedCutRealTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, quotient reals, selected suprema, trichotomy, countable choice, ambient host real order, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located cut exactness, dyadic endpoint transport, regular-Cauchy handoff, located comparison preservation, and Real seal nonescape for BEDC.Derived.LocatedCutRealUp.

Chapter 3774

A Concrete Naming Certificate for DyadicStepApproximation$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicStepApproximation$^{\uparrow}$ packet records the finite step approximation of a located real interval by dyadic cells, displayed sample values, and an oscillation ledger. It sits after the dyadic rational carrier of chapter 291, the located interval source of chapter 1709, the tagged finite-sum boundary of chapter 1615, the upper/lower sum surface of chapter 1880, and the regulated integration consumer of chapter 1557. The packet gives L10 Real and Completion routes one reusable finite approximation carrier before any quotient of functions, selected mesh limit, open-cover compactness, countable choice, or ambient Real$^{\uparrow}$ completeness principle is available.

Definition 3774.1 (Dyadic step approximation carrier)**.** *A* DyadicStepApproximation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, M, L, V, O, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval source row, read through the endpoint-plus-radius surface of chapter 1709.*
2. *M is the dyadic mesh row from* DyadicRatCore$^{\uparrow}$*. It records the common exponent scale, ordered dyadic breakpoints, adjacent cell widths, endpoint containment, and common-scale distance windows for the interval cells.*
3. *L is the finite cell ledger. It lists the carried cells of M, their inclusion in I, the boundary orientation rows, and the adjacency data consumed by Riemann and Darboux readers.*
4. *V is the step value row. For each carried cell it displays one value row and the finite readback route by which that value is available to* RiemannSum$^{\uparrow}$ *and* DarbouxSum$^{\uparrow}$ *consumers.*
5. *O is the oscillation bound row. It records the displayed upper-minus-lower tolerance on each carried cell, using dyadic endpoint and radius comparisons from M.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after the located source, dyadic mesh, cell ledger, step values, and oscillation bounds have been displayed.*
7. *H records componentwise* hsame *transport for I, M, L, V, O, E and for the replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from an interval request through the dyadic mesh, finite cells, step values, oscillation bounds, terminal seal, transports, provenance, and local name.*
9. *P is the* Pkg *provenance over* DyadicStepApproximation$^{\uparrow}$, LocatedRealInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RiemannSum$^{\uparrow}$, DarbouxSum$^{\uparrow}$, RegulatedIntegral$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicStepApproximation}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite step-approximation surface. It contains no quotient function equality, selected tag family outside L, limiting mesh process, open-cover compactness witness, countable-choice schedule, ambient Real$^{\uparrow}$ *completeness theorem, Lean verification, or bridge credential.*

Lean4 ✓ `BEDC.Derived.DyadicStepApproximationUp.DyadicStepApproximationTasteGate single carrier alignment`

Theorem 3774.2 (Dyadic step approximation obligation surface)**.** *For every accepted* DyadicStepApproximation$^{\uparrow}$ *carrier $A = (I, M, L, V, O, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicStepApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval source, dyadic mesh, finite cell ledger, step value rows, oscillation bound rows, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *mesh exactness, requiring every carried breakpoint, width, and endpoint comparison to pass through the common-scale* DyadicRatCore$^{\uparrow}$ *row M;*
3. *interval coverage, requiring every cell in L to lie in the located interval source I through displayed endpoint and radius rows;*
4. *step-value readback, requiring every value row in V to be read through the same finite cells before a* RiemannSum$^{\uparrow}$ *or* DarbouxSum$^{\uparrow}$ *consumer can use it;*
5. *oscillation control, requiring O to compare the upper and lower cell values through the displayed dyadic distance-window ledger;*
6. *real-seal handoff, requiring the terminal* Real$^{\uparrow}$ *row E to be exposed only after I, M, L, V, O are displayed;*
7. *transport and replay stability, requiring H and C to preserve the same finite rows componentwise;*
8. *ledger non-escape, excluding quotient function equality, selected mesh limits, arbitrary tag choice, open-cover compactness, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No step-approximation obligation is stored outside these rows.

Proof. Project the carrier of Definition 3774.1. The analytic rows are precisely the located interval source I, dyadic mesh row M, finite cell ledger L, step value row V, oscillation bound row O, and terminal real seal E.

Mesh exactness is read from M. The dyadic source chapter 291 supplies the common exponent scale, breakpoint comparisons, distance-window rows, and radius ledgers used by every cell of the packet.

Interval coverage is read from I and L. The located interval chapter supplies the endpoint-plus-radius boundary, while the ledger lists exactly the cells whose endpoints are certified to lie inside that boundary.

Step-value readback and oscillation control are then finite. The row V gives one displayed value route for each carried cell, and O compares the upper and lower values on that same cell through the dyadic distance-window ledger. These are the rows consumed by the Riemann and Darboux sibling chapters.

Finally, the Real-facing route exposes E only after I, M, L, V, O are visible. The transport row H, continuation row C, provenance row P, and local name N repack the same finite surface. Since the carrier has no quotient-function coordinate, limiting mesh coordinate, arbitrary tag selector, compactness row, choice row, ambient completeness theorem, Lean verification row, or bridge credential, the listed rows exhaust the local NameCert surface. □

Theorem 3774.3 (Dyadic step approximation integration handoff)**.** *Every* $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, *or* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicStepApproximation}^{\uparrow}$ *carrier receives the finite route*

$$I, M, L, V, O \longmapsto E \longmapsto H, C, P, N.$$

The Riemann consumer reads the displayed cells and values as a tagged finite-sum boundary, the Darboux consumer reads the same cells and oscillation rows as upper/lower finite sums, and the regulated-integral consumer reads the packet as a step approximation ledger before any terminal $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start from the obligation surface of Definition 3774.2. It confines every accepted packet to the located source, dyadic mesh, finite cell ledger, value rows, oscillation rows, terminal seal, and structural rows.

For a Riemann consumer, apply the sibling surface of chapter 1615. The cell ledger L supplies the carried mesh cells and the row V supplies the finite value reads, so the consumer obtains a tagged finite-sum boundary rather than a hidden tag family.

For a Darboux consumer, apply chapter 1880. The same cells and value rows are read through O as upper/lower oscillation data, so the upper-minus-lower comparison remains a displayed finite ledger.

For a regulated-integral consumer, apply chapter 1557. The packet is consumed as a step approximation ledger before the $\mathsf{Real}^{\uparrow}$ seal E is public. Thus all three consumers receive the same finite route, and the excluded quotient, limit, compactness, choice, and ambient-completeness objects have no row through which to enter. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicStepApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicStepApproximation}^{\uparrow}$ packet is generated from a located interval source, a $\mathsf{DyadicRatCore}^{\uparrow}$ mesh row, a finite cell ledger, step value rows, oscillation bound rows, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicStepApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3774.1, Definition 3774.2, and Definition 3774.3 seed the finite step-approximation carrier consumed by RiemannSum, DarbouxSum, and RegulatedIntegral routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicStepApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient function equality, selected mesh limits, arbitrary tag choice, open-cover compactness, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh exactness, interval coverage, step-value readback, oscillation control, real-seal handoff, transport stability, replay stability, provenance exhaustion, and integration handoff for BEDC.Derived.DyadicStepApproximationUp.

Chapter 3775

A Concrete Naming Certificate for $\mathsf{HausdorffUniformSpace}^{\uparrow}$

Following Bourbaki and Kelley uniform spaces, the $\mathsf{HausdorffUniformSpace}^{\uparrow}$ packet names the separated uniform interface that lies between the entourage carrier of chapter 339 and the separated boundary already exposed by chapter 1876. It also gives the Hausdorff-reflection route of **??** a finite NameCert surface before any completion-facing consumer reads quotient points, host equality, or selected representatives.

Definition 3775.1 (Hausdorff uniform space carrier)**.** *A* $\mathsf{HausdorffUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (U, S, R, A, T, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, including the finite diagonal, inverse, refinement, and composition data exposed by the source uniformity.*
2. *S is the* $\mathsf{SeparatedUniformSpace}^{\uparrow}$ *classifier row, recording when two displayed points are separated by the available entourage observations.*
3. *R is the* $\mathsf{HausdorffReflection}^{\uparrow}$ *route row, naming the quotient-free reflection boundary as a consumer of U and S.*
4. *A is the antisymmetry ledger row, requiring indistinguishable point-pair reads to be identified only through the displayed separated classifier.*
5. *T records componentwise* hsame *transport for U, S, R, A, C, P, N.*
6. *C records displayed* Cont *replay from uniform, separated, and Hausdorff-reflection consumers through the same finite route.*
7. *P is the* Pkg *provenance over* $\mathsf{HausdorffUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, $\mathsf{HausdorffReflection}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffUniformSpace}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one separated uniform-space packet. It contains no coordinate for quotient points, host equality of points, a completion object, selected representatives, countable choice, or ambient set-theoretic separation.

Lean4 ✓ `BEDC.Derived.HausdorffUniformSpaceUp.TasteGate.HausdorffUniformSpaceTasteGate single carrier alignment`

Theorem 3775.2 (Hausdorff uniform space NameCert obligations)**.** *For an accepted* $\mathsf{HausdorffUniformSpace}^{\uparrow}$ *carrier* $H = (U, S, R, A, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HausdorffUniformSpace}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed uniform entourage row, separated classifier row, Hausdorff-reflection route row, antisymmetry ledger row, transport row, replay row, provenance row, and local naming row;*
2. *uniform-source exactness, requiring every separated or Hausdorff-reflection read to begin with the finite entourage data in* U*;*
3. *separated-classifier stability, requiring* S *and* A *to compare point-pair reads only through displayed uniform observations;*
4. *reflection non-escape, requiring* R *to expose the Hausdorff boundary without adding quotient points, host equality, selected representatives, or completion coordinates;*
5. *transport, replay, provenance, and local-naming stability for the same displayed row order.*

No Hausdorff uniform-space obligation is stored outside U, S, R, A, T, C, P, N*.*

Proof. Carrier admission is projection from Definition 3775.1. The projected coordinates are exactly the uniform row U, separated classifier row S, Hausdorff-reflection route R, antisymmetry ledger A, and structural rows T, C, P, N.

Uniform-source exactness follows by reading every separated and reflection-facing consumer through the same finite entourage surface used by chapter 339. The separated row S and antisymmetry ledger A add only classifier evidence on top of those entourage observations.

Reflection non-escape is the role of R. It may cite the separated packet of chapter 1876 and the reflection boundary of **??**, but it receives no quotient point, host equality, selected representative, completion object, or ambient separation principle.

The transport and replay rows T and C preserve that same route. Since P and N package and name only the displayed carrier rows, every excluded object remains outside the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffUniformSpace}^{\uparrow}$ consumer reads a $\mathsf{UniformSpace}^{\uparrow}$ entourage row, a $\mathsf{SeparatedUniformSpace}^{\uparrow}$ classifier row, and a $\mathsf{HausdorffReflection}^{\uparrow}$ route row before citing Hausdorff uniform separation.

Independence witness: uniformspace, separateduniformspace, hausdorffreflection: $\mathsf{HausdorffUniformSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the entourage source, separated classifier, Hausdorff-reflection route, antisymmetry ledger, transport, replay, provenance, and local NameCert rows as one finite interface.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffUniformSpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffUniformSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3775.1 and Definition 3775.2 seed the separated uniform-space packet over displayed entourage, separated classifier, Hausdorff-reflection route, antisymmetry, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffUniformSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffUniformSpaceUp.TasteGate.HausdorffUniformSpaceTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient point construction, host equality, selected representatives, completion existence, countable choice, or ambient set-theoretic separation.

Upgrade path: Obligation closure requires checked carrier admission, uniform-source exactness, separated-classifier stability, reflection non-escape, transport and replay stability, and ledger non-escape for BEDC.Derived.HausdorffUniformSpaceUp.

Constructive story: A HausdorffUniformSpace$^{\uparrow}$ packet is generated from UniformSpace entourage data, SeparatedUniformSpace classifier data, a HausdorffReflection route, an antisymmetry ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3776

A Concrete Naming Certificate for $\mathsf{SecantMethod}^{\uparrow}$

Following Traub and Ortega–Rheinboldt on iterative root-finding, the $\mathsf{SecantMethod}^{\uparrow}$ packet records the finite two-point root-finding surface used by the L10 completion-facing numerical-analysis route. It sits beside the Newton–Kantorovich packet of chapter 1785, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, and the terminal real-name seal of chapter 38. The chapter names only the displayed bracketing windows, two previous iterates, finite secant denominator checks, residual reads, next-iterate rows, Cauchy handoff, transport, replay, provenance, and local naming; it does not assert global convergence, a derivative bound, quotient equality of reals, a selected host limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3776.1 (Secant method carrier)**.** *A* $\mathsf{SecantMethod}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, X, Y, D, R, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-evaluation row, naming the finite* $\mathsf{Real}^{\uparrow}$ *input and residual observations used by the root-finding request.*
2. *X and Y are the two previous iterate rows, each exposed through* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the same* $\mathsf{StreamName}^{\uparrow}$ *window schedule.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *denominator-separation row, recording the finite nonzero secant-denominator comparison needed before the next iterate can be read.*
4. *R is the residual-control row, binding the two displayed residuals and the candidate next residual to finite dyadic tolerances.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the iterate, residual, denominator, and tolerance observations.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that reads every iterate and residual window as regular rational data.*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, X, Y, D, R, W, Q have been displayed.*
8. *H records componentwise* hsame *transport for function-evaluation, iterate, denominator, residual, window, readback, endpoint, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a secant request through $F, X, Y, D, R, W, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{SecantMethod}^{\uparrow}$, $\mathsf{NewtonKantorovich}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SecantMethod}^{\uparrow}}$ *row.*

The classifier accepts the packet only through these finite rows. There is no coordinate for derivative availability, a completed limit point, quotient equality of real presentations, an unbounded convergence search, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SecantMethodUp.TasteGate.SecantMethodTasteGate single carrier alignment`

Theorem 3776.2 (Secant method NameCert obligations)**.** *For the carrier of Definition 3776.1, the local* $\mathsf{NameCert}_{\mathsf{SecantMethod}^{\uparrow}}$ *surface consists exactly of carrier admission for $S = (F, X, Y, D, R, W, Q, E, H, C, P,$ function-evaluation admission through F, two-iterate admission through X, Y, dyadic denominator-separation admission through D, residual-control admission through R, finite-window admission through W, regular-rational readback through Q, downstream* $\mathsf{Real}^{\uparrow}$ *sealing through E, component-wise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. The function row F and iterate rows X, Y expose the only data from which the secant step may be read, and both iterate rows are tied to the same finite window surface.

The denominator and residual checks are displayed before the next-iterate read. The row D supplies a dyadic nonzero comparison for the secant denominator, while R records residual tolerances using the same finite observations.

Readback then passes through W and Q. The $\mathsf{StreamName}^{\uparrow}$ row supplies the requested windows, and $\mathsf{RegSeqRat}^{\uparrow}$ turns those windows into regular rational data before the downstream $\mathsf{Real}^{\uparrow}$ seal E is visible.

Finally H, C, P, N transport, replay, source, and name this route. Since the carrier contains no derivative row, limit selector, quotient equality, unbounded search, choice principle, or ambient completeness coordinate, the listed rows exhaust the local obligations. □

Theorem 3776.3 (Secant method Cauchy handoff)**.** *Every completion-facing read of an accepted* $\mathsf{SecantMethod}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{SecantMethod}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff first exposes finite iterate and residual windows, then regular rational readback, then dyadic denominator and residual budgets, and only then the terminal real-name seal. It supplies no independent convergence theorem, no derivative-based Newton certificate, no selected limit, and no ambient completeness principle.

Proof. Start with a completion-facing consumer. The carrier forces the request to read W and Q before a secant step can be interpreted, so the iterates and residuals are finite regular rational observations rather than host real representatives.

Next inspect the dyadic rows. The denominator-separation row D and residual-control row R provide the only permitted comparison data for the next iterate, and both are attached to the same displayed windows.

The $\mathsf{Real}^{\uparrow}$ seal E is reached after those rows have been replayed through C and transported through H. Thus the exported handoff is a finite Cauchy-facing route, not an assertion of global

convergence, derivative control, selected limits, quotient equality, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{SecantMethod}^{\uparrow}$ completion-facing read factors through finite StreamName windows, RegSeqRat readback, DyadicRatCore denominator and residual budgets, displayed secant-step rows, a downstream RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: newtonkantorovich, regseqrat, dyadicratcore, streamname, real: $\mathsf{SecantMethod}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two previous iterate rows, a finite secant denominator check, residual-control rows, regular rational readback, dyadic tolerance data, a downstream Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SecantMethod}^{\uparrow}}$.

Constructive story: A $\mathsf{SecantMethod}^{\uparrow}$ packet is generated from function-evaluation rows, two previous iterate rows, dyadic denominator-separation and residual-control rows, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SecantMethod}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3776.1, Definition 3776.2, and Definition 3776.3 seed the finite secant root-finding route from regular rational windows to the Real endpoint seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SecantMethod}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global convergence, derivative-control hypotheses, quotient equality of real presentations, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, two-iterate admission, denominator-separation exactness, residual-control routing, Cauchy handoff, transport, replay, provenance, and local naming for BEDC.Derived.SecantMethodUp.

Chapter 3777

A Concrete Naming Certificate for $\mathsf{CauchyCompletionBind}^{\uparrow}$

Following Bishop and Bridges and Mac Lane, the $\mathsf{CauchyCompletionBind}^{\uparrow}$ packet records the finite Kleisli-composition surface for Bishop-style completion: a completion-facing read may bind a source completion row to a displayed completion-valued route only through the already named $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ certificates. It is a local ledger for bind composition, not a quotient completion, not a selected representative, not countable choice, and not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

The bind packet consumes the completion monad of chapter 378, the unit admission of chapter 1527, the Kleisli consumer route of chapter 1845, the Bishop-regular completion boundary of chapter 1639, and the terminal Real seal of chapter 38 as concrete sibling rows rather than as background terminology.

Definition 3777.1 (CauchyCompletionBind carrier)**.** *A* $\mathsf{CauchyCompletionBind}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, U, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-completion row over* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, exposing the regular Cauchy input windows before any bind consumer is read.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row recording the unit admission for source points and terminal seal handoff.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row recording the single-bind consumer route and the reassociation schedule inherited from* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*.*
4. *E is the completion seal row that records which displayed* $\mathsf{Real}^{\uparrow}$ *or Bishop-regular completion boundary the bind route may consume.*
5. *H is the componentwise* hsame *transport row for the source, unit, Kleisli, seal, replay, provenance, and local naming data.*
6. *C is the displayed* Cont *replay row for the finite bind route.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionBind}^{\uparrow}$*,* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*,* $\mathsf{CauchyCompletionUnit}^{\uparrow}$*,* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$*,* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionBind}^{\uparrow}}$ *row naming the bind packet.*

The carrier has no coordinate for quotient Cauchy classes, selected representatives, countable-choice schedules, host equality of completed objects, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCompletionBindUp.CauchyCompletionBindTasteGate single carrier alignment`

Theorem 3777.2 (CauchyCompletionBind NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionBind}^{\uparrow}$ *carrier* $B = (S, U, K, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionBind}^{\uparrow}}$ *surface consists exactly of source-completion exposure, unit admission, Kleisli bind exposure, completion-seal compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every bind consumer must first read the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*,* $\mathsf{CauchyCompletionUnit}^{\uparrow}$*,* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$*,* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows recorded in* P*.*

Proof. Project the accepted carrier. The rows S, U, K, E are the only analytic rows available to a bind consumer, and each is already sourced from the named completion, unit, Kleisli, Bishop-regular, and real-seal siblings.

Transport and replay are structural. The row H preserves the same source, unit, Kleisli, and seal coordinates under displayed hsame routes, while C replays the same finite bind path through the consumer surface.

Finally P and N source and name the local certificate. Since the carrier contains no quotient class, representative selector, choice schedule, host equality, or ambient completeness coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 3777.3 (CauchyCompletionBind associativity ledger)**.** *Let* $B = (S, U, K, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCompletionBind}^{\uparrow}$ *packet. Any two public reads of a two-step completion bind that use the same displayed source-completion row* S*, unit row* U*, Kleisli row* K*, completion seal* E*, transport row* H*, replay row* C*, provenance row* P*, and local name* N *have the same finite associativity ledger. The ledger is a displayed route equality of BEDC rows; it is not quotient completion equality, not equality of selected representatives, not countable choice, and not a proof that* $\mathsf{Real}^{\uparrow}$ *is complete in the ambient host.*

Proof. Read the two-step bind only through the carrier rows. The first route and the reassociated route both project the same S, U, K, E coordinates, so their source completion, unit admission, Kleisli schedule, and seal handoff are the displayed data of one packet.

Use H to transport the coordinates componentwise and C to replay the same finite consumer path. These structural rows compare the bind schedules inside the packet rather than by host equality of completed objects.

The provenance and naming rows attach the comparison to the same $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sources. No excluded quotient, representative, choice, or ambient-completeness object is available to alter the ledger. □

Theorem 3777.4 (CauchyCompletionBind real-completion forward link)**.** *Every accepted* $\mathsf{CauchyCompletionBind}^{\uparrow}$ *consumer that exposes a completion seal must first route through chapter 378, chapter 1527, chapter 1845, chapter 1639, and chapter 38. The exposed seal is therefore read only after the source-completion row* S*, unit row* U*, Kleisli row* K*, completion seal row* E*, componentwise transport row* H*, replay row* C*, provenance row* P*, and local naming row* N *have been displayed. It exports no quotient completion class, selected representative, countable-choice schedule, host equality of completed objects, or ambient completeness theorem.*

Proof. Project the accepted carrier $B = (S, U, K, E, H, C, P, N)$. The source row S and seal row E are completion-facing only because the provenance row P names the Cauchy monad, Bishop-regular completion, and Real seal siblings.

Read the bind route through U and K. The unit row supplies the source admission boundary, and the Kleisli row supplies the displayed consumer route before any completion seal can be exposed.

The structural rows H and C only transport and replay the same finite route. Together with P and N, they keep the consumer inside the cited sibling certificates, so the packet has no coordinate from which to recover quotient completion equality, selected representatives, countable choice, host completed-object equality, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{CauchyCompletionBind}^{\uparrow}$ read is refuted if a completion consumer obtains a two-step bind without first exposing the source completion row, unit row, Kleisli row, completion seal, transport, replay, provenance, and local naming rows.

Independence witness: cauchycompletionmonad, cauchycompletionunit, cauchycompletionkleisli, bishopregularcauchycompletion, real: none is bijective with $\mathsf{CauchyCompletionBind}^{\uparrow}$ because the bind packet jointly carries the source-completion row, unit admission, Kleisli consumer route, completion seal, componentwise transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionBind}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionBind}^{\uparrow}$ packet is generated from source completion rows, unit rows, Kleisli rows, a completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionBind}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3777.1, Definition 3777.2, and Definition 3777.3 bind completion-facing Kleisli composition to finite source, unit, seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionBind}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not assert quotient completions, selected representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CauchyCompletionBind}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, source-completion exposure, unit compatibility, Kleisli bind exposure, associativity-ledger exactness, and non-escape for BEDC.Derived.CauchyCompletionBindUp.

Chapter 3778

A Concrete Naming Certificate for $\mathsf{GlobalFiberSpectra}^{\uparrow}$

The $\mathsf{GlobalFiberSpectra}^{\uparrow}$ packet realizes the global-fiber spectra branch of Definition 9462.1167 and Definition 9462.1169 as finite BEDC NameCert data. It sits beside the six-boundary tile coverage packet of chapter 3470, the window-coverage trigger algebra of chapter 3478, and the greedy spectral closure packet of chapter 3753; those siblings expose coverage, trigger, and closure faces, while this packet records the global tripleton, singleton, edge-spectrum, tile, trigger, transport, replay, provenance, and naming rows together.

Definition 3778.1 (GlobalFiberSpectra carrier)**.** *A* $\mathsf{GlobalFiberSpectra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, T, E, L, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the global codon-cube fiber row recording tripleton, singleton, doubleton, quartet, and sextupleton multiplicities for the standard-code classifier.*
2. *T is the complete global fiber tile row recording the displayed Ile/Met and Stop/Trp $3+1$ tiles.*
3. *E is the edge-spectrum row recording same-class and cross-class Hamming edge counts by bit direction.*
4. *L is the sibling tile-coverage row over* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *and finite standard-tile enumeration data.*
5. *R is the trigger handoff row over* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *and* $\mathsf{GreedySpectralClosure}^{\uparrow}$*.*
6. *H is the componentwise* hsame *transport row for the fiber, tile, edge, coverage, trigger, replay, provenance, and local naming data.*
7. *C is the displayed* Cont *replay row for standard-code reads.*
8. *P is the* Pkg *provenance over* $\mathsf{GlobalFiberSpectra}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{GreedySpectralClosure}^{\uparrow}$*, finite codon-cube tiles,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{GlobalFiberSpectra}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden genetic-code oracle, biochemical causation claim, infinite codon family, non-displayed trigger semantics, or host probability model.

Lean4 ✓ `BEDC.Derived.GlobalFiberSpectraUp.GlobalFiberSpectraCarrier event flow rows`

Theorem 3778.2 (GlobalFiberSpectra NameCert obligations)**.** *For every accepted* $\mathsf{GlobalFiberSpectra}^{\uparrow}$ *carrier* $G = (F, T, E, L, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GlobalFiberSpectra}^{\uparrow}}$ *surface consists exactly of global fiber multiplicity, complete global fiber tile exposure, edge-spectrum exposure, six-boundary tile coverage, trigger handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A standard-code read cannot expose trigger interpretation before the global tripleton, singleton, edge-spectrum, tile, and sibling coverage rows have been displayed.*

Proof. Project the carrier rows. The fiber row F, tile row T, and edge row E are the only global-spectrum data available to the packet.

Route sibling dependence through L and R. The coverage row keeps the packet tied to six-boundary and standard-tile data, while the trigger handoff row records the window-coverage and greedy-closure interfaces without exposing trigger interpretation early.

Use H, C, P, N to transport, replay, source, and name the same finite route. Since no hidden oracle, biochemical causation coordinate, infinite family, non-displayed trigger semantics, or host probability model is present, the listed rows exhaust the NameCert surface. □

Theorem 3778.3 (GlobalFiberSpectra sibling separation)**.** *An accepted* $\mathsf{GlobalFiberSpectra}^{\uparrow}$ *packet is not determined by any one of* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$*,* $\mathsf{GreedySpectralClosure}^{\uparrow}$ *or finite standard-tile enumeration alone. The packet jointly carries global fiber multiplicity* F*, complete* $3 + 1$ *tile rows* T*, Hamming edge-spectrum rows* E*, sibling coverage* L*, trigger handoff* R*, transport* H*, replay* C*, provenance* P*, and local naming* N*.*

Proof. Read each sibling as a proper face. Six-boundary coverage supplies tile coverage, window-coverage trigger algebra supplies trigger handoff, greedy spectral closure supplies closure rows, and standard-tile enumeration supplies finite local tiles.

The global fiber and edge rows are additional coordinates. They record global tripleton, singleton, and direction-sensitive edge spectra before trigger interpretation is exposed.

Therefore no sibling alone is bijective to the packet. The structural rows H, C, P, N preserve the joint route and prevent any one face from replacing the whole $\mathsf{GlobalFiberSpectra}^{\uparrow}$ carrier. □

Falsifiable prediction: Every accepted $\mathsf{GlobalFiberSpectra}^{\uparrow}$ standard-code read factors through displayed global tripleton, singleton, edge-spectrum, and tile rows before any trigger interpretation is exposed.

Independence witness: sixboundarytilecoverage, windowcoveragetriggeralgebra, greedyspectralclosure, standardtileenumeration: $\mathsf{GlobalFiberSpectra}^{\uparrow}$ is not bijective to these siblings because it jointly carries global fiber multiplicity, local tile spectrum, edge counts, trigger handoff, transport, replay, provenance, and local naming.

The Lean follow-up in `lean4/BEDC/Derived/GlobalFiberSpectraUp.lean` must provide explicit Nontrivial $\mathsf{GlobalFiberSpectra}^{\uparrow}$ and FieldFaithful $\mathsf{GlobalFiberSpectra}^{\uparrow}$ TasteGate instances preserving $F, T, E, L, R, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{GlobalFiberSpectra}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GlobalFiberSpectra}^{\uparrow}$ packet is generated from finite codon-cube fiber rows, complete tile rows, edge-spectrum rows, sibling coverage rows, trigger handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GlobalFiberSpectra}^{\uparrow}}$, seed)

Scope closed: Definition 3778.1, Definition 3778.2, and Definition 3778.3 bind the global-fiber spectra vision to finite codon-cube fiber, tile, edge, trigger, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GlobalFiberSpectra}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert biochemical causation, hidden genetic-code optimality, host probability semantics, non-displayed trigger interpretation, Lean verification, or bridge checking for GlobalFiberSpectra$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, global-fiber exposure, edge-spectrum exactness, sibling-separation exactness, Nontrivial and FieldFaithful instances, and trigger nonescape for BEDC.Derived.GlobalFiberSpectraUp.

Chapter 3779

A Concrete Naming Certificate for MetaCICNormalizationAuditPacket$^{\uparrow}$

The MetaCICNormalizationAuditPacket$^{\uparrow}$ packet realizes the candidate-mediated strong-normalization surface of chapter 9383 as finite NameCert data. It sits beside the normalization audit packet of chapter 750, the critical-path packet of chapter 765, the normalization frontier of chapter 892, the candidate-evidence strong-normalization route of chapter 758, and the typed-normalization audit of chapter 3539. The packet names the closed typed term row, candidate or candidate-set evidence, candidate-to-SN projection, no-infinite-reduction projection, application and Pi adequacy rows, refusal frontier, transport, replay, provenance, and local naming rows needed before a public SN read may be cited. It does not assert unconditional closed-term normalization, evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluation soundness, or completed closed consistency.

Definition 3779.1 (MetaCIC normalization audit packet carrier)**.** *A* MetaCICNormalizationAuditPacket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, K, A, S, I, P, F, H, C, G, N)$$

with the following displayed rows:

1. *T is the closed typed term row, exposing the term, type, empty-context read, and closedness data.*
2. *K is the candidate-evidence row, carrying* Candidate*, closed-candidate, or candidate-set membership evidence for the displayed term.*
3. *A is the application adequacy row, recording the function-side Pi evidence, argument evidence, and application-candidate handoff used when the term route contains an application.*
4. *S is the strong-normalization projection row, reading SN only through the candidate or candidate-set evidence displayed in K.*
5. *I is the no-infinite-reduction row, projecting the same candidate-mediated SN evidence to the absence of infinite reduction chains.*
6. *P is the Pi-candidate adequacy row, recording the Pi route used by dependent function cases without replacing K.*
7. *F is the normalization-frontier refusal row, kept visible whenever a requested citation would erase candidate evidence, subject-reduction boundaries, or confluence boundaries.*

8. *H records componentwise* hsame *transport for the closed typed term, candidate evidence, application adequacy, SN projection, no-infinite-reduction projection, Pi adequacy, frontier, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a normalization-audit request through $T, K, A, S, I, P, F, H, G, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$*, chapter 9383,* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$*,* $\mathsf{MetaCICCriticalPath}^{\uparrow}$*,* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, A, S, I, P, F, H, C, G, N$. No row stores a theorem that every closed typed MetaCIC term normalizes without candidate or candidate-set evidence.

Theorem 3779.2 (MetaCIC normalization audit packet NameCert obligations)**.** *For the carrier of Definition 3779.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}}$ *surface consists exactly of carrier admission for $M = (T, K, A, S, I, P, F, H, C, G, N)$, closed typed term admission through T, candidate or candidate-set evidence admission through K, application adequacy through A, candidate-mediated SN projection through S, no-infinite-reduction projection through I, Pi-candidate adequacy through P, frontier retention through F, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through G, and local naming through N.*

```
Lean4 ✓  BEDC.Derived.MetaCICNormalizationAuditPacketUp.MetaCICNormalizationAuditPacketCarrier
namecert obligations
```

Proof. Project the carrier. The only term source is T, and the only evidence source for a public SN read is the candidate row K.

Read A and P as adequacy rows for application and Pi cases. They refine the same candidate-mediated route and do not create an evidence-free normalization source.

The SN row S is downstream of K. The no-infinite-reduction row I is downstream of S, so absence of infinite reduction chains is cited only through the same candidate or candidate-set evidence.

The frontier row F records requests that would erase the evidence boundary. Transport, replay, provenance, and local naming through H, C, G, N preserve these rows without adding subject reduction, confluence, quotient syntax equality, host evaluator soundness, or closed consistency. □

Theorem 3779.3 (MetaCIC normalization audit packet candidate handoff)**.** *Every public strong-normalization or no-infinite-reduction read from an accepted* $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$ *carrier factors through the finite route*

$$T \longmapsto K \longmapsto (A, P) \longmapsto S \longmapsto I \longmapsto F.$$

In particular, a public SN read must pass through candidate or candidate-set evidence before the closed typed term can be read as strongly normalizing, and the exported packet is not an unconditional normalization theorem for all closed typed MetaCIC terms.

Proof. Start with a public SN request. The term row T displays the closed typed term, but the carrier does not allow T alone to be read as normalized.

The request must next pass through K. Candidate, closed-candidate, or candidate-set evidence is the only input accepted by the projection row S, while A and P supply only the application and Pi adequacy data required by that same route.

The no-infinite-reduction row I reuses the output of S. If a consumer asks for evidence-free normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluation soundness, or closed consistency, the frontier row F keeps that request outside the packet.

Thus the handoff exports candidate-mediated SN and no-infinite-reduction evidence, not a theorem that every closed typed MetaCIC term normalizes without the displayed candidate or candidate-set rows. □

Theorem 3779.4 (MetaCIC normalization candidate interface composition)**.** *An accepted* MetaCICNormalizationA *carrier whose candidate row K is accepted exports the three-step route from candidate evidence to strong normalization and then to no-infinite-reduction evidence:*

$$K \longmapsto S \longmapsto I.$$

The route preserves the closed typed term row T, application and Pi adequacy rows A, P, frontier row F, and structural rows H, C, G, N. It does not erase candidate evidence into an unconditional closed-term strong-normalization claim.

Proof. Apply Definition 3779.2. The local NameCert surface exposes the candidate row K, the strong-normalization projection S, and the no-infinite-reduction projection I as distinct displayed rows.

Apply Definition 3779.3. Public SN and no-infinite-reduction reads must pass through the route $T \longmapsto K \longmapsto (A, P) \longmapsto S \longmapsto I \longmapsto F$, so the candidate evidence remains visible at the interface.

The Lean-facing normalization API follows the same discipline: `candidate_implies_sn` reads candidate evidence before SN, `closed_typed_term_sn_from_candidate` exports closed typed SN from that evidence, and `closed_typed_term_no_infinite_reduction_from_candidate` projects the resulting SN evidence to absence of infinite reductions. These names record the conditional route; they do not license an evidence-free theorem for every closed typed MetaCIC term. □

Theorem 3779.5 (MetaCIC normalization audit packet residual-candidate route)**.** *For an accepted* MetaCICNormalizationAuditPacket$^{\uparrow}$ *carrier $M = (T, K, A, S, I, P, F, H, C, G, N)$, every residual normalization or no-infinite-reduction read must expose candidate or candidate-set evidence in row K before application adequacy A, Pi adequacy P, strong-normalization projection S, and no-infinite-reduction projection I can be consumed. The structural rows H, C, G, N preserve the displayed route, and the frontier row F prevents evidence-free residual normalization from being exported.*

Proof. Project the carrier of Definition 3779.1. The rows $T, K, A, S, I, P, F, H, C, G, N$ are the full classifier-visible surface for residual normalization and no-infinite-reduction reads.

Use Definition 3779.2. It identifies K, A, S, I, P, F as the candidate-evidence row, application adequacy row, SN projection row, no-infinite-reduction projection row, Pi adequacy row, and frontier row.

Apply Definition 3779.3 and Definition 3779.4. Together they order candidate evidence before S and I, while A and P remain adequacy rows attached to the same candidate-mediated route.

Finally use row exhaustion for F, H, C, G, N. The frontier row records requests that would erase candidate evidence, and the structural rows transport, replay, source, and name the displayed route without creating evidence-free normalization. □

Falsifiable prediction: Every public strong-normalization or no-infinite-reduction read of a $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$ carrier factors through closed typed term data, candidate or candidate-set evidence, application and Pi adequacy rows, candidate-mediated SN projection, no-infinite-reduction projection, frontier retention, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: metacicconfluenceauditpacket, metaciccriticalpath, metacicnormalizationfrontier, closedtermsubstitutionboundary: $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries closed typed term data, candidate or candidate-set evidence, application and Pi adequacy rows, candidate-mediated SN projection, no-infinite-reduction projection, frontier retention, transport, replay, provenance, and local naming as one audit carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$ packet is generated from a closed typed term row, candidate or candidate-set evidence, application and Pi adequacy rows, candidate-mediated strong-normalization projection, no-infinite-reduction projection, frontier retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3779.1, Definition 3779.2, and Definition 3779.3 seed the finite candidate-mediated normalization audit packet for public SN and no-infinite-reduction reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MetaCICNormalizationAuditPacketUp.MetaCICNormalizationAuditPacketCarrier\_namecert\_obl`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unconditional closed-term normalization, evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluation soundness, or completed closed consistency.

Upgrade path: Obligation closure requires checked carrier admission, candidate-evidence exactness, application and Pi adequacy routing, SN projection, no-infinite-reduction projection, frontier retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICNormalizationAuditPacketUp.

Chapter 3780

A Concrete Naming Certificate for $\mathsf{StepFunction}^{\uparrow}$

Following Bourbaki and Bishop–Bridges constructive analysis, the $\mathsf{StepFunction}^{\uparrow}$ packet records a finite partition-to-real approximation object as BEDC NameCert data. It sits after the partition surface of chapter 201, the dyadic step-function specialization of chapter 428, the tagged finite-sum route of chapter 1615, the integration boundary of chapter 123, and the regular rational readback of chapter 301. The packet supplies a textbook finite step-function interface without forcing every integration-facing consumer through dyadic endpoints alone.

Definition 3780.1 (Step function carrier)**.** *A* $\mathsf{StepFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, V, A, D, S, I, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is a* $\mathsf{Partition}^{\uparrow}$ *row listing finitely many ordered cells and their boundary incidence data.*
2. *V assigns a displayed* $\mathsf{Real}^{\uparrow}$ *value row to each cell of P.*
3. *A records the constant-on-cell admission relation, so every accepted domain read first chooses a cell of P and then reads the corresponding value in V.*
4. *D is the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *comparison row, present when the partition cells and values are supplied through dyadic subrows.*
5. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *finite-sum row obtained from the displayed cells, tags, and values.*
6. *I is the* $\mathsf{Integral}^{\uparrow}$ *consumer boundary that may read S only after P, V, A, D have been displayed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation ledger used when a later real-facing route samples the finite row by regular rational names.*
8. *H records componentwise* hsame *transport for partition, value, cell-admission, dyadic comparison, finite-sum, integral-boundary, regular-readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a step-function read through P, V, A, D, S, I, R, H.*
10. *Q is the* Pkg *provenance over* $\mathsf{StepFunction}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{StepFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these rows. It has no coordinate for a measurable-function quotient, an ambient function space, a selected refinement limit, open-cover compactness, or an unbounded integration procedure.

Theorem 3780.2 (Step function NameCert obligations)**.** *For every accepted* $\mathsf{StepFunction}^{\uparrow}$ *carrier* $F = (P, V, A, D, S, I, R, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StepFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, finite partition exposure, real-value exposure, constant-on-cell admission, dyadic comparison when present, finite-sum handoff, integral-boundary handoff, regular rational readback, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.StepFunctionUp.StepFunctionTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3780.1. The rows P, V, A display the finite partition, the value row on each cell, and the constant-on-cell admission relation before any consumer can read a function value.

The analytic consumers are downstream of those rows. The dyadic comparison row D is only a displayed specialization, the finite-sum row S is computed from the visible cells and values, and the integral boundary I reads the same finite row before any integration claim is exported.

The regular readback and structural rows preserve that route. Since R, H, C, Q, N name only regular sampling, transport, replay, provenance, and the local certificate, and since the carrier has no coordinate for a host function quotient, selected refinement limit, compactness proof, or unbounded integration procedure, the listed rows exhaust the NameCert surface. □

Theorem 3780.3 (Step function partition-integral route)**.** *Every integration-facing read of an accepted* $\mathsf{StepFunction}^{\uparrow}$ *carrier factors through*

$$\mathsf{Partition}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{DyadicStepFunction}^{\uparrow} \longmapsto \mathsf{RiemannSum}^{\uparrow} \longmapsto \mathsf{Integral}^{\uparrow}$$

together with the $\mathsf{RegSeqRat}^{\uparrow}$ *approximation ledger and the structural rows* H, C, Q, N*. The route exports a finite partition-to-real approximation surface, not a quotient function object, a selected limiting mesh, measure-theoretic integration, open-cover compactness, or ambient completeness.*

Proof. Start with the displayed partition row. A read has no domain observation except the cells listed by P, and it has no value observation except the corresponding $\mathsf{Real}^{\uparrow}$ rows in V.

The step-function comparison and finite-sum handoff are then forced. The dyadic row D records only the dyadic specialization of the same cells and values, while S is the finite $\mathsf{RiemannSum}^{\uparrow}$ row computed from those displayed data.

Finally read the integral and approximation rows. The $\mathsf{Integral}^{\uparrow}$ boundary I is available only after P, V, A, D, S are displayed, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies regular rational sampling without changing the carrier. The structural rows H, C, Q, N transport and name the same route, so no external function quotient, mesh-limit choice, compactness principle, measure-theoretic integral, or ambient completeness coordinate can be exported. □

Falsifiable prediction: An accepted $\mathsf{StepFunction}^{\uparrow}$ integration-facing read is refuted if its $\mathsf{Integral}^{\uparrow}$ boundary is preserved while the displayed $\mathsf{Partition}^{\uparrow}$ row, $\mathsf{Real}^{\uparrow}$ value row, $\mathsf{RiemannSum}^{\uparrow}$ finite-sum row, and $\mathsf{RegSeqRat}^{\uparrow}$ readback are removed.

Independence witness: partition, real-value, dyadic-step-function, riemann-sum, integral, regseqrat: none is bijective with $\mathsf{StepFunction}^{\uparrow}$ because the packet jointly carries finite partition cells, displayed real values, constant-on-cell admission, dyadic comparison, finite-sum handoff, integral

boundary, regular rational readback, componentwise transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{StepFunction}\uparrow}$.

Constructive story: A $\mathsf{StepFunction}^{\uparrow}$ packet is generated from a finite PartitionUp row, displayed RealUp values, constant-on-cell admission, optional DyadicStepFunctionUp comparison, finite RiemannSumUp handoff, IntegralUp boundary, RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StepFunction}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3780.1, Definition 3780.2, and Definition 3780.3 seed the finite partition-to-real step-function approximation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StepFunction}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.StepFunctionUp.StepFunctionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim measure-theoretic integration, host function quotients, selected refinement limits, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition exposure, real-value exposure, constant-on-cell admission, finite-sum handoff, IntegralUp boundary routing, RegSeqRatUp readback, and structural transport for BEDC.Derived.StepFunctionUp.

Chapter 3781

A Concrete Naming Certificate for $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$

Following Khinchin's continued fractions and Hardy–Wright's Stern–Brocot/Farey treatment, the $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$ packet records the finite bridge by which Stern–Brocot interval refinement and continued-fraction convergent readback expose the same rational-approximation route before any $\mathsf{Real}^{\uparrow}$ completion-facing consumer reads it. It sits over the finite tree surface of chapter 1704, the bracketing approximation route of chapter 1431, the continued-fraction carrier of chapter 342, the convergent row surface of chapter 1777, the Farey-neighbor sequence route of chapter 1759, the rational source of chapter 37, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite NameCert handoff for the L10 rational-approximation lattice; it does not use quotient rational equality, selected representatives, host enumeration, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3781.1 (Stern–Brocot continued-fraction bridge carrier)**.** *A* $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, A, F, Q, V, I, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *tree row, including the finite address, boundary, mediant, and Farey-neighbor ledger read by the bridge.*
2. *A is the* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *bracket row, exposing the same inspected rational interval as a finite approximation surface.*
3. *F is the* $\mathsf{FareySequence}^{\uparrow}$ *handoff row, recording the adjacent determinant-one boundary sequence used to compare tree intervals with continued-fraction cylinders.*
4. *Q is the* $\mathsf{ContinuedFraction}^{\uparrow}$ *partial-quotient spine row, restricted to the finite prefix inspected by the bridge.*
5. *V is the* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *convergent row, including the numerator, denominator, normalized rational, dyadic error, and Real-facing handoff rows of the inspected prefix.*
6. *I is the rational-interval comparison ledger, read through* $\mathsf{Rat}^{\uparrow}$ *rows and the displayed determinant-one adjacency data rather than through host rational equality.*
7. *W is the finite window row scheduling the Stern–Brocot branch, Farey sequence, partial-quotient prefix, and convergent observations.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row built from the shared rational interval and convergent data.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, A, F, Q, V, I, W, R have been displayed.*
10. *H records componentwise* hsame *transport for the tree, approximation, Farey, continued-fraction, convergent, rational-comparison, window, readback, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a bridge request through Stern–Brocot boundary inspection, Farey adjacency, continued-fraction prefix inspection, convergent readback, regular rational handoff, and the terminal Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{SternBrocotApproximation}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{ContinuedFractionConvergents}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}}$ *row.*

The classifier compares accepted bridge packets only through $S, A, F, Q, V, I, W, R, E, H, C, P, N$. The carrier has no coordinate for quotient rational equality, selected representatives, host enumeration, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

`single carrier alignment`

Theorem 3781.2 (Stern–Brocot continued-fraction NameCert obligations)**.** *For every accepted* $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$ *carrier*

$$B = (S, A, F, Q, V, I, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Stern–Brocot tree row, bracketing approximation row, Farey-sequence handoff, continued-fraction prefix row, convergent row, rational-interval ledger, finite window row, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *interval-prefix compatibility, requiring the Stern–Brocot branch in S and the continued-fraction prefix in Q to inspect the same displayed rational interval through F and I;*
3. *convergent handoff, requiring every rational convergent row in V to be read through the* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *route before the terminal seal E is consumed;*
4. *approximation bridge discipline, requiring the bracketing row A and the Farey handoff F to mediate between Stern–Brocot intervals and continued-fraction convergents as finite* BHist *rows;*
5. *componentwise transport, displayed replay, package provenance, and local naming, requiring H, C, P, N to preserve the same bridge packet under* hsame *transport and* Cont *replay;*
6. *refusal of quotient rational equality, selected representatives, host enumeration, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as bridge data.*

No local bridge obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3781.1. The accepted tuple exposes exactly the tree, approximation, Farey, continued-fraction, convergent, rational-comparison, window, readback, seal, transport, replay, provenance, and local naming rows listed in the statement.

Interval-prefix compatibility is read through S, F, Q, I. The Stern–Brocot side supplies a finite branch and boundary pair, the Farey side supplies determinant-one adjacency, the continued-fraction side supplies the inspected partial-quotient prefix, and the rational ledger I records that these rows refer to the same displayed rational interval.

The convergent handoff is downstream of V, W, R, E. A consumer first reads the scheduled finite convergent window, then the regular rational readback R, and only then reaches the Real seal E.

The approximation bridge is finite because A and F are displayed rows. They mediate from rational bracketing and Farey adjacency to the continued-fraction convergent route without importing a host enumeration of rationals or a selected representative.

Finally H, C, P, N transport, replay, package, and name the same packet. Since the carrier inventory contains no quotient rational equality, selected representative, host enumeration, choice, trichotomy, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 3781.3 (Stern–Brocot continued-fraction Farey handoff)**.** *Let $B = (S, A, F, Q, V, I, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$ *packet. Every bridge-facing read from a Stern–Brocot interval to a continued-fraction convergent factors through the finite route*

$$\mathsf{SternBrocot}^{\uparrow} \longmapsto \mathsf{SternBrocotApproximation}^{\uparrow} \longmapsto \mathsf{FareySequence}^{\uparrow} \longmapsto \mathsf{ContinuedFraction}^{\uparrow} \longmapsto \mathsf{ContinuedFractionCo}$$

The Farey handoff F is the only adjacency surface in the route, and the rational comparison ledger I is read as displayed $\mathsf{Rat}^{\uparrow}$ *data. Thus the bridge exports a Real-facing regular-rational handoff while refusing quotient rational equality, selected representatives, host enumeration, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Stern–Brocot side. The row S exposes only a finite tree address, boundary rows, a mediant row, and a Farey-neighbor ledger, while A records the corresponding bracketing approximation surface.

Next read the Farey handoff F. It supplies determinant-one adjacency for the displayed interval boundary, so the bridge compares the tree interval with the continued-fraction cylinder through finite Farey data rather than through a host enumeration of rational numbers.

The continued-fraction side then reads Q and V. The prefix row Q names the finite partial quotients under inspection, and the convergent row V names the numerator, denominator, normalized rational, dyadic error, and regular handoff data for that prefix.

Finally read W, R, E, H, C, P, N. The finite window row schedules the common observation, R carries the $\mathsf{RegSeqRat}^{\uparrow}$ readback, E is terminal for the Real-facing route, and the structural rows preserve and name the same packet. The carrier has no coordinate for quotient rational equality, selected representatives, host enumeration, choice, trichotomy, or ambient completeness, so none is exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}$ packet is generated from a Stern–Brocot tree row, a bracketing approximation row, a Farey adjacency handoff, a continued-fraction prefix row, a convergent row, a displayed rational-interval ledger, finite observation windows, regular rational readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3781.1, Definition 3781.2, and Definition 3781.3 seed the finite bridge from Stern–Brocot interval refinement to continued-fraction convergent readback and Real-facing regular rational handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{SternBrocotContinuedFractionBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient rational equality, selected representatives, host enumeration, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-prefix compatibility, convergent handoff, Farey mediation, transport, replay, provenance, and local naming for the same bridge packet.

Chapter 3782

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ packet records the finite route by which a regular Cauchy family of regular rational names is read along a unary diagonal selector before any Real or Completion consumer treats the diagonal read as a completed real name. It sits over the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the sibling diagonal extraction packet of chapter 1773. The packet gives the L10 Real and Completion route one displayed diagonalization carrier; it does not assert quotient stream equality, choose a host limit, invoke countable choice, use trichotomy, claim ambient $\mathsf{Real}^{\uparrow}$ completeness, provide Lean verification, or record a checked bridge.

Definition 3782.1 (Regular Cauchy diagonalization carrier)**.** *A* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, \delta, S, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the regular Cauchy family row. It displays the source family of rational names together with the finite precision requests inspected by the diagonal read.*
2. *δ is the unary diagonal selector row. It names the selected source index for each inspected precision and records no independent choice schedule beyond that displayed unary selector.*
3. *S is the aligned* $\mathsf{StreamName}^{\uparrow}$ *window row. It displays the finite windows of the selected source names and aligns them with the requests carried by F and δ.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested dyadic radius, split-tolerance budget, comparison windows, and common-scale data used by the diagonal read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback row. It reads the selected stream windows through the tolerance ledger as one regular rational sequence.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, δ, S, T, R have been displayed.*
7. *H records componentwise* hsame *transport for the family, selector, stream windows, tolerance ledger, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a diagonalization request through the family row, unary selector, aligned windows, dyadic tolerance ledger, regular rational readback, terminal Real seal, transports, provenance, and local name.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, \delta, S, T, R, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected host limits, countable-choice schedules, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credentials.*

Theorem 3782.2 (Regular Cauchy diagonalization NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ *carrier*

$$D = (F, \delta, S, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular Cauchy family, unary diagonal selector, aligned StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat diagonal readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *selector exactness, requiring every diagonal read to pass through the displayed unary selector δ and the family row F;*
3. *window alignment, requiring the* $\mathsf{StreamName}^{\uparrow}$ *row S to expose exactly the selected finite windows named by F and δ;*
4. *tolerance exactness, requiring the requested radius, split budget, comparison windows, and common-scale data to be read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row T;*
5. *regular readback exactness, requiring R to consume the same selected windows and tolerance ledger before any Real-facing seal is visible;*
6. *Real-seal nonescape, requiring E to appear only after F, δ, S, T, R are transported through H and replayed through C;*
7. *componentwise transport, displayed replay, package provenance, and local naming for exactly the rows $F, \delta, S, T, R, E, H, C, P, N$;*
8. *refusal of quotient stream equality, selected host limits, countable-choice schedules, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No local diagonalization obligation is stored outside these rows.

Proof. Project the carrier of Definition 3782.1. The accepted inventory is exactly the family row F, unary selector δ, aligned StreamName windows S, dyadic tolerance ledger T, regular rational readback R, Real seal E, and structural rows H, C, P, N.

Selector exactness is read from F and δ. A consumer may inspect only the named source family entries selected by the displayed unary diagonal row, so no hidden choice schedule or host enumeration is available.

Window alignment and tolerance exactness are read from S and T. The stream row exposes the finite windows selected by the diagonal read, while the dyadic row supplies the requested radius, split budget, comparison windows, and common-scale ledger used to compare those windows.

Regular readback and the Real seal are downstream of the same route. The row R consumes S and T as one $\mathsf{RegSeqRat}^{\uparrow}$ diagonal readback, and E is visible only after that readback has been transported and replayed.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since the carrier inventory contains no quotient-stream equality, selected host limit, countable-choice schedule, trichotomy, ambient completeness principle, Lean verification row, or bridge credential, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalizationUp.RegularCauchyDiagonalizationTasteGate single carrier alignment`

Theorem 3782.3 (Regular Cauchy diagonalization Real seal handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ *carrier factors through the finite route*

$$F, \delta \longmapsto S \longmapsto T \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Equivalently, the consumer receives a regular Cauchy family row, one unary diagonal selector, aligned $\mathsf{StreamName}^{\uparrow}$ *windows, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, one* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback, and one terminal* $\mathsf{Real}^{\uparrow}$ *seal before any Real-facing output is named.*

Proof. Start with the obligation surface of Definition 3782.2. It confines every accepted packet to the displayed family, selector, stream-window, tolerance-ledger, readback, Real-seal, and structural rows.

The consumer first reads F and δ. These rows name the source family and the unary diagonal selector, so the diagonal route has a displayed source for every inspected precision request.

The consumer then reads S, T, R. The aligned stream windows expose the selected entries, the dyadic ledger supplies the tolerance and comparison budget, and the regular rational readback repacks those rows as one $\mathsf{RegSeqRat}^{\uparrow}$ diagonal sequence.

Only after that route is visible may the consumer read the terminal $\mathsf{Real}^{\uparrow}$ seal E and the structural rows H, C, P, N. Because the carrier has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking, none of those objects can enter the Real-facing handoff. □

Theorem 3782.4 (Regular Cauchy diagonalization selector-window exactness)**.** *For an accepted* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ *carrier*

$$D = (F, \delta, S, T, R, E, H, C, P, N),$$

the unary diagonal selector row δ determines the aligned $\mathsf{StreamName}^{\uparrow}$ *window row S before the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R are consumed. Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the diagonal seal must therefore use the same selected window with the tolerance ledger T before reading R or the terminal seal E.*

Proof. Apply Definition 3782.2. It states selector exactness through F, δ, window alignment through S, tolerance exactness through T, regular readback exactness through R, and Real-seal nonescape through E.

Then apply Definition 3782.3. It orders every Real or Completion consumer through

$$F, \delta \longmapsto S \longmapsto T \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the selector fixes the window before the tolerance ledger and readback are visible, and the same selected window is preserved until the diagonal seal is read. □

Theorem 3782.5 (Regular Cauchy diagonalization common-tolerance lock)**.** *If two accepted* RegularCauchyDiagona *packets share the same regular Cauchy family row F, unary selector δ, aligned* StreamName$^{\uparrow}$ *window row S, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger T, then every* RegSeqRat$^{\uparrow}$ *readback and* Real$^{\uparrow}$ *seal handoff in both packets is locked to that common tolerance ledger. More explicitly, for*

$$D = (F, \delta, S, T, R, E, H, C, P, N)$$

and

$$D' = (F, \delta, S, T, R', E', H', C', P', N'),$$

every diagonal readback route through R or R' and every Real seal handoff through E or E' must consume the displayed ledger T after the same F, δ, S route.

Proof. Use the obligation theorem, Definition 3782.2, to project both carriers. Their shared rows F, δ, S, T are the only family, selector, window, and tolerance rows available before any readback or Real seal is exposed.

Apply selector-window exactness, Definition 3782.4. It fixes the route through F, δ, S before the tolerance ledger and readback rows are consumed.

Now apply the Real seal handoff theorem, Definition 3782.3. It keeps R, E and R', E' downstream of the same tolerance ledger T, with the structural rows only transporting, replaying, sourcing, and naming the displayed evidence.

Therefore both packets lock every RegSeqRat readback and Real seal handoff to the common ledger T. Since neither carrier contains quotient stream equality, selected host limits, countable choice, trichotomy, or ambient Real completeness, none of those excluded objects can loosen the common tolerance budget. □

Falsifiable prediction: Every RegularCauchyDiagonalization$^{\uparrow}$ Real or Completion read factors through a regular Cauchy family row, one unary diagonal selector, aligned StreamName windows, one DyadicRatCore tolerance ledger, one RegSeqRat diagonal readback, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-diagonal-extraction: RegularCauchyDiagonalization$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source regular Cauchy family, a unary diagonal selector, aligned finite windows, a dyadic tolerance ledger, a regular rational diagonal readback, and a terminal RealUp seal in one displayed packet.

Closure status for NameCert$_{\text{RegularCauchyDiagonalization}^{\uparrow}}$.

Constructive story: A RegularCauchyDiagonalization$^{\uparrow}$ packet is generated from a regular Cauchy family row, one unary diagonal selector, aligned StreamName windows, one DyadicRatCore tolerance ledger, one RegSeqRat diagonal readback, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyDiagonalization}^{\uparrow}}$, seed)

Scope closed: Definition 3782.1, Definition 3782.2, Definition 3782.3, Definition 3782.4, and Definition 3782.5 seed the finite diagonalization packet used by L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyDiagonalization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector exactness, window alignment, dyadic tolerance exactness, regular readback exactness, Real-seal exposure, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyDiagonalizationUp.

Chapter 3783

A Concrete Naming Certificate for $\mathsf{TotallyBoundedClosure}^{\uparrow}$

Following Bishop and Bridges on total boundedness and Kelley and Bourbaki on metric closure, the $\mathsf{TotallyBoundedClosure}^{\uparrow}$ packet records the finite BEDC route by which a displayed closure window of a totally bounded metric carrier remains available to finite-net consumers. It sits after the finite-net source of chapter 127, the metric-distance surface of chapter 57, the compact metric consumer of chapter 129, the closed-subspace completion route of chapter 1949, and the precompact bridge of chapter 1531. The packet names only displayed closure-window data and finite rational readbacks; it does not import host closure, selected limits, quotient completion, open-cover compactness, or ambient real completeness.

Definition 3783.1 (TotallyBoundedClosure carrier)**.** *A* $\mathsf{TotallyBoundedClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, M, F, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net source row, including the closed* $\mathsf{ProbeBundle}$ *center families,* $\mathsf{InBundle}$ *membership rows, center-carrier rows, distance witnesses, and rational bound ledgers of Definition 127.3;*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row for the same source, exposing endpoint classifiers, distance-witness reads, triangle ledgers, and the exact comparison rows used by closure requests;*
3. *F is the finite closure-window ledger, naming the displayed approximating source points, their tolerance windows, and the inclusion route from each window point into the closure carrier;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records only the finite observation prefixes needed by a closure consumer before a net center is inspected;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tails attached to the closure windows and the finite-net tolerances;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint distance bounds and closure radii already exposed by M, F, W, R;*
7. *H records componentwise* hsame *transport for all rows T, M, F, W, R, E and for every center, window point, rational tail, real seal, and metric-distance history read from them;*

8. *C records the displayed* Cont *replay route from closure-window reads to the source finite-net row, then back through the metric distance ledger to the closure carrier;*
9. *P is the* Pkg *provenance over* $\mathsf{TotallyBoundedClosure}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$, $\mathsf{PrecompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedClosure}^{\uparrow}}$ *row.*

The classifier on such packets is componentwise transport through H together with replay of the finite routes in C. The carrier has no coordinate for a host closure operator, a choice-selected convergent sequence, quotient completion equality, an open-cover compactness principle, or an ambient completeness theorem.

Theorem 3783.2 (TotallyBoundedClosure NameCert obligations)**.** *For an accepted* $\mathsf{TotallyBoundedClosure}^{\uparrow}$ *carrier $K = (T, M, F, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedClosure}^{\uparrow}}$ *surface consists exactly of six obligations:*

1. *carrier admission: every row exposed to a consumer is one of the ten displayed rows or a finite subrow of the totally bounded source, metric distance ledger, closure-window ledger, stream window, rational readback, or real seal;*
2. *classifier transport: packet equality is componentwise* hsame *transport of centers, source points, closure-window points, stream prefixes, rational tails, real seals, metric distances, provenance rows, and local naming rows;*
3. *finite-net inheritance: each positive tolerance read reaches the closed* ProbeBundle*, membership constructors, center histories, distance witnesses, and rational comparison ledgers already named by T;*
4. *closure-window exactness: each closure point read first passes through a finite window in F, W, R, E before the metric row M compares it with a displayed source point;*
5. *replay discipline: every handoff from a closure-window point to a finite net factors through the displayed* Cont *route in C and the same source metric rows in M;*
6. *provenance and non-escape: P and N name only the listed source certificates, and the packet exports no host closure, selected limit, quotient completion, open-cover compactness, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

These obligations make total boundedness under displayed closure a finite-row interface rather than a semantic closure theorem in an ambient metric space.

Proof. Carrier admission is projection from Definition 3783.1. The ten rows list the finite-net source, metric distance row, closure-window ledger, stream windows, regular rational readbacks, real seals, transport ledger, replay ledger, provenance row, and local naming row.

Classifier transport is the role of H. It moves the source centers, closure-window points, rational tails, real seals, and metric-distance histories by hsame, while the point and distance classifiers in M keep the source and closure endpoint reads aligned.

Finite-net inheritance is read from T. A positive tolerance request reaches exactly the $\mathsf{TotallyBounded}^{\uparrow}$ ProbeBundle spine, its InBundle membership constructors, center-carrier rows, coverage-distance witnesses, and rational comparison ledgers.

Closure-window exactness is supplied by F, W, R, E. The packet never asks for a host closure membership proof; it displays the finite windows, the stream prefixes, the rational tail reads, and the real endpoint seals that justify each closure read before any finite net is consumed.

Finally, C, P, N package the handoff. The replay route sends a closure-window point to a displayed source approximation, reads the totally bounded center through T, compares the closure point through M, R, E, and returns only the named finite rows to compact, completion, or precompact consumers. Since no other coordinate is present, host closure, selected limits, quotient completion, open-cover compactness, countable choice, and ambient real completeness cannot be exported. □

Lean4 ✓ `BEDC.Derived.TotallyBoundedClosureUp.TotallyBoundedClosureTasteGate single carrier alignment`

Theorem 3783.3 (TotallyBoundedClosure finite-net closure handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedSubspaceCompletion}^{\uparrow}$, *or* $\mathsf{PrecompactMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{TotallyBoundedClosure}^{\uparrow}$ *packet* $K = (T, M, F, W, R, E, H, C, P, N)$ *reads total boundedness of the closure only through the finite route*

$$\mathsf{TotallyBounded}^{\uparrow}, \mathsf{Met}^{\uparrow}, F, W, R, E, H, C, P, N.$$

For each positive tolerance history, the consumer receives a displayed source net from T, a closure-window approximation from F, W, R, E, and the metric comparison row from M that transfers the source-net bound to the closure point. The route exports no host closure operator, no chosen dense sequence, no quotient completion, no selected subcover, and no ambient completeness principle.

Proof. Fix a positive tolerance request made by one of the listed consumers. The request is first routed by C to the finite-net source row T, so the available centers and coverage witnesses are exactly the closed ProbeBundle rows of chapter 127.

For a closure point, the packet then reads a finite window in F together with the prefix row in W, the regular rational tail row in R, and the real seal in E. These rows display a source approximation close enough for the requested tolerance; no closure predicate outside the packet is inspected.

The metric row M compares the closure point, the displayed source approximation, and the selected net center through the same endpoint classifiers and distance ledgers. Transport by H and replay by C make the comparison stable under the packet classifier.

Thus any compact-metric, closed-subspace-completion, or precompact consumer sees only the finite-net source, closure windows, rational readbacks, real seals, metric comparisons, transport, replay, provenance, and local NameCert rows. The excluded host closure, selected dense sequence, quotient completion, selected subcover, and ambient completeness data have no carrier coordinate from which they could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedClosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3783.1, Definition 3783.2, and Definition 3783.3 seed the finite L10 closure interface over totally bounded source nets, metric distance rows, finite closure windows, stream windows, rational readbacks, real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host closure operators, selected dense sequences, quotient completions, selected subcovers, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite-net inheritance, closure-window exactness, replay discipline, and provenance non-escape for the same packet.

Constructive story: A closure consumer reads a finite window around the requested closure point, routes that window back to the totally bounded source net, compares the displayed source approximation by the metric ledger, and exports only the resulting finite rows.

Chapter 3784

A Concrete Naming Certificate for $\mathsf{UniformModulusComposition}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformModulusComposition}^{\uparrow}$ packet records the finite bookkeeping needed to compose displayed uniform moduli for map-level continuity before a continuous-map or completion-facing consumer reads the result. It sits beside the map carrier of chapter 130, the modulus surface of chapter 2228, the Cauchy budget composition of chapter 1617, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real boundary of chapter 38. The packet names only the displayed composition route for uniform-modulus rows; it is not a quotient stream, not a selected limit, not host real equality, not trichotomy, not ambient Real completeness, and not a bridge assertion.

Definition 3784.1 (Uniform modulus composition carrier)**.** *A* $\mathsf{UniformModulusComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, G, M_F, M_G, B, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *F and G are composable* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, with G read after the codomain row exported by F.*
2. *M_F and M_G are the displayed* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *rows for F and G.*
3. *B is the composed uniform-budget row. It first reads the precision request through M_G, then uses the resulting domain tolerance as the request for M_F, and stores the single source tolerance supplied to the composite map.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window route through which the composed budget may inspect only displayed finite observations.*
5. *D is the dyadic or rational tolerance ledger naming every radius comparison used by the two modulus lookups.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that receives the composed source tolerance after W and D have been replayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *route row that may be read only after the regular-rational handoff has consumed the same composed budget.*

8. *H records componentwise* hsame *transport for $F, G, M_F, M_G, B, W, D, R, E$, the continuation row, the provenance row, and the local naming row.*
9. *C records displayed* Cont *replay from a requested output tolerance through M_G, M_F, the composed budget B, stream windows W, dyadic or rational tolerances D, the RegSeqRat handoff R, and the Real route E.*
10. *P is the* Pkg *provenance over* ContinuousMap$^\uparrow$, UniformContinuityModulus$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformModulusComposition}^\uparrow}$ *row.*

The carrier has no coordinate for quotient streams, selected limits, host real equality, trichotomy, ambient completeness of Real$^\uparrow$, *or standard bridge data.*

Lean4 ✓ BEDC.Derived.UniformModulusCompositionUp.TasteGate.UniformModulusCompositionTasteGate
single carrier alignment

Theorem 3784.2 (Uniform modulus composition NameCert obligations)**.** *For every accepted* UniformModulusComposition$^\uparrow$ *carrier $K = (F, G, M_F, M_G, B, W, D, R, E, H, C, P, N)$, the local* NameCert$_{\text{UniformModu}}$ *surface consists exactly of carrier admission for the two composable map rows, admission of their displayed uniform-modulus rows, budget composition through M_G then M_F, window and tolerance exposure through W and D, RegSeqRat and Real handoff through R and E, componentwise transport stability through H, continuation replay through C, package provenance through P, and local naming through N. No obligation row stores a quotient stream, selected limit, host equality of reals or maps, trichotomy, ambient completeness principle, or standard bridge claim.*

Proof. Project the carrier of Definition 3784.1. The tuple displays exactly the two continuous-map rows, their uniform-modulus rows, the composed budget, finite-window route, tolerance ledger, RegSeqRat handoff, Real route, transport, continuation, provenance, and naming row.

The composition order is fixed by B. An output tolerance for the composite is first read through M_G because G controls the second map. The tolerance exposed by that read is then passed to M_F, and the resulting source tolerance is stored as one composed budget row.

The consumer route is ordered by C. Before any regular-rational or Real-facing read can consume the composed budget, it must replay the finite windows W and the tolerance ledger D.

Transport stability is componentwise. The row H replaces only displayed rows by hsame-classified rows and replays the same continuation order, so it cannot introduce a new equality principle.

The carrier contains no quotient-stream, selected-limit, host-equality, trichotomy, completeness, or bridge coordinate. The listed rows therefore exhaust the local NameCert obligation surface. □

Theorem 3784.3 (Uniform modulus composition Real route)**.** *Let $K = (F, G, M_F, M_G, B, W, D, R, E, H, C, P, N)$ be an accepted* UniformModulusComposition$^\uparrow$ *carrier. Every Real-facing read of the composite map reaches the* Real$^\uparrow$ *route only after the composed uniform budget has passed through the two map rows, the two displayed uniform-modulus rows, the StreamName windows, the tolerance ledger, and the RegSeqRat handoff. The exported surface contains no quotient stream, selected limit, host real equality, trichotomy, ambient Real completeness assertion, or standard bridge claim.*

Proof. The Real route row E is displayed in the carrier, but its accessibility is ordered by C. A Real-facing read must therefore replay $F, G, M_G, M_F, B, W, D, R$ before E is available.

The replay keeps the composed modulus finite. The two source map rows supply the composability context, M_G and M_F supply the only tolerance lookups, W supplies the only stream-window route, D supplies the only tolerance ledger, and R supplies the only regular rational handoff.

The support rows H, P, N name and transport that same finite packet. They cannot introduce quotient streams, selected limits, host equality, trichotomy, ambient completeness, or bridge data, because none of those data appear in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformModulusComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformModulusComposition}^{\uparrow}$ packet is generated from two composable ContinuousMap rows, two UniformContinuityModulus rows, a composed uniform-budget row, a StreamName window route, a tolerance ledger, a RegSeqRat handoff, a RealUp route, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformModulusComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3784.1, Definition 3784.2, and Definition 3784.3 seed the finite map-level route that composes displayed uniform moduli before RegSeqRat and Real consumers read them.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformModulusComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, budget composition, window and tolerance exposure, RegSeqRat handoff, Real route nonescape, and transport stability for BEDC.Derived.UniformModulusCompositionUp.

Chapter 3785

A Concrete Naming Certificate for $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$ packet names a closed constructive interval by regular Cauchy data rather than by quotient real equality. It sits between the closed bounded interval rows of chapter 1591 and the completion-facing consumers of chapter 301, chapter 126, chapter 291, and chapter 38.

Definition 3785.1 (Constructive Cauchy interval carrier)**.** *A* $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, O, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are lower and upper located endpoint rows inherited from a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source.*
2. *O is the endpoint-order row asserting that the lower endpoint is not above the upper endpoint in the located order used by the source interval.*
3. *D is the dyadic containment row over* $\mathsf{DyadicRatCore}^{\uparrow}$*; it names the finite dyadic windows that contain the interval at each displayed precision.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite stream of containment windows read by Cauchy consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row; it turns each accepted containment window into regular rational sequence data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row recording the real-completion consumer reached from R without quotient real equality, trichotomy, choice, or an ambient completeness axiom.*
7. *H records componentwise* hsame *transport for endpoint, order, dyadic, stream, regular-sequence, real-seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from any interval-completion read through L, U, O, D, S, R, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$*,* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, O, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected interval points, quotient real equality, trichotomy, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.ConstructiveCauchyIntervalUp.ConstructiveCauchyIntervalTasteGate single carrier alignment`

Theorem 3785.2 (Constructive Cauchy interval NameCert obligations)**.** *For every accepted* ConstructiveCauchyInt *carrier $I = (L, U, O, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyInterval}^{\uparrow}}$ *surface consists exactly of endpoint admission, endpoint-order preservation, dyadic containment exposure, StreamName window exposure, RegSeqRat handoff, Real seal exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 3785.1. The rows L, U, O are inherited from the closed bounded interval source and therefore supply the only endpoint data visible to the packet.

Next read the completion route. The dyadic row D exposes finite containment windows, S names their stream surface, R supplies the regular rational sequence handoff, and E seals the route as a Real-facing completion consumer.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Since the excluded host objects are not carrier coordinates, the local NameCert obligations are exactly the listed rows. □

Theorem 3785.3 (Constructive Cauchy interval RegSeqRat handoff)**.** *Every completion-facing read of an accepted* $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$ *packet factors through*

$$L, U, O \longmapsto D \longmapsto S \longmapsto R \longmapsto E, H, C, P, N.$$

In particular, any RegSeqRat or Real consumer sees only the located endpoints, endpoint order, dyadic containment ledger, StreamName windows, RegSeqRat handoff row, Real seal, transport, replay, provenance, and local NameCert row.

Proof. Start with the endpoint rows. The closed bounded interval source fixes L, U, O, so a completion-facing consumer cannot introduce a new endpoint classifier or a selected point of the interval.

The containment route is finite. Dyadic containment D supplies the displayed windows, the stream row S names their readback order, and the handoff row R exposes exactly the regular rational sequence surface consumed by $\mathsf{RegSeqRat}^{\uparrow}$.

Finally the Real seal E and the structural rows H, C, P, N preserve the same route for downstream readers. Thus every RegSeqRat or Real-facing read factors through the displayed rows and does not claim open-cover compactness, quotient real equality, trichotomy, countable choice, or ambient completeness. □

Falsifiable prediction: Every completion-facing read of a $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$ packet factors through located endpoints, endpoint order, dyadic containment, StreamName windows, RegSeqRat handoff, a RealUp seal, transport, replay, provenance, and local naming.

Independence witness: closedboundedinterval, regseqrat, streamname, dyadicratcore, real: ConstructiveCauchyI is not bijective to any listed sibling because it jointly carries interval endpoints, endpoint order, dyadic containment, stream windows, regular rational handoff, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyInterval}^{\uparrow}$ packet is generated from located endpoint rows, an endpoint-order row, dyadic containment data, StreamName windows, RegSeqRat handoff data, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3785.1, Definition 3785.2, and Definition 3785.3 seed the constructive Cauchy interval completion packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyInterval}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ConstructiveCauchyIntervalUp.ConstructiveCauchyIntervalTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, quotient real equality, trichotomy, selected interval points, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order preservation, dyadic containment exposure, StreamName window exposure, RegSeqRat handoff, and Real seal nonescape for BEDC.Derived.ConstructiveCauchyIntervalUp.

Chapter 3786

A Concrete Naming Certificate for CauchyCompletionDenseReflector$^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley on dense embeddings, the CauchyCompletionDenseRef packet records the dense-reflector face of Cauchy completion as finite NameCert data. It reads the completion transformer of chapter 378, the dense image surface of chapter 3351, and the universal mapping row of chapter 1456. Its local name route is the finite sequence of chapter 126, chapter 301, chapter 291, and chapter 38. The packet names the classical dense-reflection argument without importing quotient completions, selected limits, countable choice, host equality, or ambient completeness.

Definition 3786.1 (CauchyCompletionDenseReflector carrier)**.** *A* CauchyCompletionDenseReflector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, I, A, W, T, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source completion schedule, read through the* CauchyCompletionMonad$^{\uparrow}$ *unit, bind, and public* Real$^{\uparrow}$ *seal route rather than through a quotient completion.*
2. *I is the dense-image row inherited from* MetricCompletionDenseEmbedding$^{\uparrow}$*, exposing the source metric image inside the completion seal as finite approximation data.*
3. *A is the adjunction row inherited from* CauchyCompletionAdjunction$^{\uparrow}$*, comparing completion-facing consumers with source-side finite-window consumers over the same dense image.*
4. *W is the finite* StreamName$^{\uparrow}$ *window row through which the source and completion observations are inspected.*
5. *T is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used by the source schedule, dense-image row, adjunction row, and real-seal readback.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the displayed stream windows and dyadic tolerance ledger.*
7. *R is the terminal* Real$^{\uparrow}$ *seal row reached only after S, I, A, W, T, Q have been displayed.*
8. *H records componentwise* hsame *transport for the schedule, dense-image, adjunction, window, tolerance, readback, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the source completion schedule through the dense image, adjunction row, finite windows, dyadic tolerance, regular readback, and real seal.*

10. *P is the* Pkg *provenance over* CauchyCompletionDenseReflector$^{\uparrow}$, CauchyCompletionMonad$^{\uparrow}$, MetricCompletionDe CauchyCompletionAdjunction$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyCompletionDenseReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion representatives, selected limits, countable-choice schedules, host equality of completed objects or real names, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionDenseReflectorUp.CauchyCompletionDenseReflectorTasteGate`
`single carrier alignment`

Theorem 3786.2 (CauchyCompletionDenseReflector NameCert obligations)**.** *For every accepted* CauchyCompletionDenseReflector$^{\uparrow}$ *carrier $D = (S, I, A, W, T, Q, R, H, C, P, N)$, the local* NameCert$_{\text{CauchyCompletionDen}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source completion schedule, dense-image row, adjunction row, finite windows, dyadic tolerance ledger, regular readback, real seal, transport, replay, provenance, and local naming;*

2. *dense-source exposure, requiring every completion-facing read to expose S and then I before the real-seal row R can be consumed;*

3. *reflector exactness, requiring the dense image I and source schedule S to be replayed through the same* BHist, hsame, *and* Cont *rows before any completion consumer is served;*

4. *universal-row handoff, requiring every extension or uniqueness consumer to pass through the adjunction row A after the dense image and before the terminal real seal;*

5. *classifier transport, requiring all accepted comparisons to use only the displayed componentwise transport H, replay C, provenance P, and local name N;*

6. *ledger refusal, excluding quotient completion representatives, selected limits, countable choice, host equality of completed objects or real names, and ambient completeness.*

No dense-reflector obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3786.1. The accepted packet exposes exactly the rows $S, I, A, W, T, Q, R, H, C, P, N$ and no detached completion object.

Dense-source exposure is read in order. The source completion schedule S supplies the finite completion transformer route, and the dense image row I places the displayed source inside the completion seal before any real-facing read reaches R.

Reflector exactness and universal-row handoff then use the same route. The rows H and C replay the schedule and dense-image coordinates componentwise, while A is the only adjunction row available to extension and uniqueness consumers.

Finally inspect the provenance and local naming rows. The row P names only the completion monad, dense embedding, adjunction, StreamName, RegSeqRat, DyadicRatCore, Real, and structural BEDC rows, and N packages exactly that surface. Hence the listed refusals cannot be exported by an accepted carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionDenseReflector}^{\uparrow}$ packet is generated from a CauchyCompletionMonad source schedule, a MetricCompletionDenseEmbedding dense-image row, a CauchyCompletionAdjunction universal row, finite StreamName windows, DyadicRatCore tolerance accounting, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3786.1 and Definition 3786.2 seed the finite dense-reflector surface connecting completion monad, dense embedding, adjunction, and the terminal StreamName-RegSeqRat-DyadicRatCore-Real route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host equality of completed objects or real names, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source exposure, reflector exactness, universal-row handoff, classifier transport, and ledger refusal for BEDC.Derived.CauchyCompletionDenseReflectorUp.

Chapter 3787

A Concrete Naming Certificate for $\mathsf{LocallyCompactMetric}^{\uparrow}$

Following Bourbaki and Kelley metric topology together with Bishop-style constructive metric practice, the $\mathsf{LocallyCompactMetric}^{\uparrow}$ packet records local compact neighbourhood data as finite BEDC rows around a displayed metric point. It sits over the $\mathsf{Met}^{\uparrow}$ distance surface of chapter 57, the $\mathsf{CompactMetric}^{\uparrow}$ compact-neighbourhood witness of chapter 129, the $\mathsf{CompleteMetric}^{\uparrow}$ limit rows of chapter 128, the $\mathsf{TotallyBounded}^{\uparrow}$ finite-net rows of chapter 127, and the positive $\mathsf{Real}^{\uparrow}$ radius seal of chapter 38. The chapter names a local compactness certificate for later proper-metric and compactification consumers; it does not assert arbitrary open-cover compactness, choice of neighbourhood bases, quotient completion equality, or ambient local compactness outside the displayed packet.

Definition 3787.1 (Locally compact metric carrier)**.** *A* $\mathsf{LocallyCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, x, U, K, T, C_m, r, H, D, P, N)$$

with the following displayed rows:

1. *X is a* $\mathsf{Met}^{\uparrow}$ *carrier row whose point histories and distance witnesses are read from chapter 57.*
2. *x is the inspected point history carried by X.*
3. *U is a local neighbourhood row around x, displayed only by metric-ball membership and finite route data.*
4. *K is a* $\mathsf{CompactMetric}^{\uparrow}$ *witness for the neighbourhood closure packet.*
5. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net component read by K.*
6. *C_m is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness component read by K.*
7. *r is a positive* $\mathsf{Real}^{\uparrow}$ *radius seal for the local ball.*
8. *H records componentwise* hsame *transport for X, x, U, K, T, C_m, r.*
9. *D records displayed* Cont *replay from a local query through the metric carrier, neighbourhood row, compact witness, finite-net row, completion row, radius seal, and transport row.*
10. *P is the* Pkg *provenance over* $\mathsf{LocallyCompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactMetric}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, a selected neighbourhood basis, global compactness of X, quotient completion equality, countable choice, or a host topological space.

Lean4 (definition) `BEDC.Derived.LocallyCompactMetricUp.LocallyCompactMetricUp`
Lean4 ✓ `BEDC.Derived.LocallyCompactMetricUp.LocallyCompactMetricTasteGate single carrier alignment`

Definition 3787.2 (Locally compact metric classifier)**.** *Two accepted* $\mathsf{LocallyCompactMetric}^{\uparrow}$ *carriers*

$$L = (X, x, U, K, T, C_m, r, H, D, P, N) \quad \textit{and} \quad L' = (X', x', U', K', T', C'_m, r', H', D', P', N')$$

classify together exactly when the metric carrier rows, inspected point rows, local neighbourhood rows, compact-metric witnesses, totally-bounded rows, complete-metric rows, Real radius seals, transport rows, continuation replays, provenance rows, and local naming rows classify componentwise by the sibling classifiers and the displayed hsame *transports.*

Theorem 3787.3 (Locally compact metric NameCert obligations)**.** *For every accepted* $\mathsf{LocallyCompactMetric}^{\uparrow}$ *carrier $L = (X, x, U, K, T, C_m, r, H, D, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactMetric}^{\uparrow}}$ *surface consists exactly of the metric carrier row X, the inspected point row x, the neighbourhood row U, the compact-metric witness K, the totally-bounded finite-net row T, the complete-metric limit row C_m, the positive Real radius seal r, componentwise transport H, displayed replay D, provenance P, and local naming row N.*

Proof. Project the carrier of Definition 3787.1. The projection exposes the metric row, inspected point, local neighbourhood, compact witness, finite-net witness, completion witness, radius seal, transport, replay, provenance, and naming row.

The compact witness K is read only through the sibling $\mathsf{CompactMetric}^{\uparrow}$ surface, whose own carrier consumes $\mathsf{TotallyBounded}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ rows. Thus the local compactness packet records compact neighbourhood evidence without adding an open-cover coordinate.

The radius row r is read through the Real seal surface and the route D replays all displayed dependencies. Since the carrier has no coordinate for selected bases, global compactness, quotient completion equality, countable choice, or an ambient host topology, the listed rows exhaust the NameCert obligations. □

Theorem 3787.4 (Locally compact metric neighbourhood non-escape)**.** *Every consumer of an accepted* $\mathsf{LocallyCompactMetric}^{\uparrow}$ *packet that preserves the classifier of Definition 3787.2 must preserve the same metric carrier, inspected point, neighbourhood row, compact-metric witness, total-boundedness row, completeness row, Real radius seal, transport, replay, provenance, and local naming row. In particular, it cannot replace the displayed local neighbourhood by an unrecorded open cover, a choice-selected compact set, or a host topology.*

Proof. Use the classifier of Definition 3787.2. It compares the accepted packets componentwise and has no residual coordinate where a different neighbourhood, compact witness, finite-net row, completion row, or radius seal could be hidden.

The continuation row preserves the same route through the metric, compact, total-boundedness, completeness, and Real-radius siblings. Therefore a consumer that keeps the classifier fixed must read the same finite packet and cannot escape to an unrecorded open cover, selected compact subset, or host topology. □

Theorem 3787.5 (Locally compact metric sibling dependency route)**.** *Every accepted* $\mathsf{LocallyCompactMetric}^{\uparrow}$ *carrier routes its local compactness certificate through chapter 57, chapter 129, chapter 128, chapter 127, and chapter 38. The* $\mathsf{Met}^{\uparrow}$ *row supplies the point and distance surface; the* $\mathsf{CompactMetric}^{\uparrow}$ *row supplies the compact-neighbourhood witness; the* $\mathsf{TotallyBounded}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows supply the finite-net and limit components read by compact metric data; and the* $\mathsf{Real}^{\uparrow}$ *row supplies the positive radius seal.*

Proof. Read the rows of L in the order displayed by Definition 3787.1. The metric carrier X and point x must be available before a neighbourhood row U can be read as a metric-local object.

The compact witness K then exposes its two constructive compact-metric dependencies: total boundedness through T and complete-metric convergence through C_m. The radius seal r is a Real-facing row, so it is consumed through the terminal Real chapter rather than through a host real number.

Finally H, D, P, N transport, replay, source, and name the same dependency chain. Thus the local compactness packet is a finite L10 neighbour of the metric, compact metric, complete metric, totally bounded, and Real chapters, not a stand-alone topological assertion. □

Falsifiable prediction: Every $\mathsf{LocallyCompactMetric}^{\uparrow}$ read factors through one Metric carrier, one inspected point, one neighbourhood row, one CompactMetric witness, one TotallyBounded finite-net row, one CompleteMetric limit row, one Real radius seal, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: metric, compactmetric, completemetric, totallybounded, real: $\mathsf{LocallyCompactMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a point-local neighbourhood row, a compact-metric witness for that neighbourhood, the compact witness's total-boundedness and completeness components, and a positive Real radius seal in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyCompactMetric}^{\uparrow}$ packet is generated from a Metric carrier, inspected point, local neighbourhood row, CompactMetric witness, TotallyBounded finite-net row, CompleteMetric limit row, positive Real radius seal, componentwise transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3787.1, Definition 3787.2, Definition 3787.3, Definition 3787.4, and Definition 3787.5 seed the finite local-compactness surface over metric, compact-metric, complete-metric, total-boundedness, and Real-radius rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not assert arbitrary open-cover compactness, a selected neighbourhood basis, global compactness of the carrier, quotient completion equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier preservation, NameCert obligations, neighbourhood non-escape, and sibling route coverage for BEDC.Derived.LocallyCompactMetricUp.

Chapter 3788

A Concrete Naming Certificate for $\mathsf{LocallyCompactPolish}^{\uparrow}$

Following Bourbaki, Kelley, and Alexandrov–Urysohn, the $\mathsf{LocallyCompactPolish}^{\uparrow}$ packet records the finite BEDC surface where local compact neighbourhood data is read together with a Polish complete-separable metric presentation. It sits at the joint frontier of the local compact metric packet of chapter 3787, the Polish readback of chapter 1490, the proper closed-ball route of **??**, the sigma-compact exhaustion of chapter 2369, and the complete-separable metric presentation of chapter 1735. The certificate is finite data: neighbourhood rows, complete-separable readback, properness rows, sigma-compact exhaustion windows, StreamName and RegSeqRat observations, transport, replay, provenance, and local naming.

Definition 3788.1 (Locally compact Polish carrier)**.** *A* $\mathsf{LocallyCompactPolish}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, K, C, S, E, W, T, R, H, Q, P, N)$$

with the following displayed rows:

1. *X is the underlying metric-object row shared by the locally compact, Polish, proper, sigma-compact, and complete-separable presentations.*
2. *M is the* $\mathsf{LocallyCompactMetric}^{\uparrow}$ *neighbourhood row. It records, for every displayed point-window, a compact neighbourhood candidate, an interior witness, and the metric inspection data by which the candidate is consumed.*
3. *K is the local compactness compact-row ledger. It binds compact neighbourhood reads to the compact witnesses supplied through M and refuses any neighbourhood not named in the packet.*
4. *C is the* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *readback row. It records the complete metric presentation, the countable dense probe family, and the finite comparison windows through which completeness and separability are inspected.*
5. *S is the* $\mathsf{PolishSpace}^{\uparrow}$ *row obtained from the same complete-separable readback; it carries no independent host topology coordinate.*
6. *E is the* $\mathsf{ProperMetric}^{\uparrow}$ *closed-ball compactness row. It is read only after M, K, C, S have fixed the metric and neighbourhood surface.*
7. *W is the* $\mathsf{SigmaCompact}^{\uparrow}$ *exhaustion row. Its compact exhaustion windows are generated from the displayed local compactness and properness rows, not from a selected external exhaustion.*

8. *T is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row for points, compact neighbourhood candidates, complete-separable probes, closed balls, exhaustion windows, and endpoint-facing reads.*
9. *R is the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row for the same metric probes and exhaustion windows.*
10. *H records componentwise* hsame *transport for $X, M, K, C, S, E, W, T, R, Q, P, N$.*
11. *Q records displayed* Cont *replay of the route*
$$M, K \longmapsto C, S \longmapsto E, W \longmapsto T, R.$$
12. *P is the* Pkg *provenance over* $\mathsf{LocallyCompactPolish}^{\uparrow}$, $\mathsf{LocallyCompactMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{SigmaCompact}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactPolish}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, K, C, S, E, W, T, R, H, Q, P, N$. It has no coordinate for arbitrary open-cover compactness, a selected exhaustion, host topological equality, quotient metric equality, countable choice, or a Polish presentation detached from the displayed complete-separable row.

Theorem 3788.2 (Locally compact Polish NameCert obligations)**.** *For every accepted* $\mathsf{LocallyCompactPolish}^{\uparrow}$ *carrier*
$$L = (X, M, K, C, S, E, W, T, R, H, Q, P, N),$$
the local $\mathsf{NameCert}_{\mathsf{LocallyCompactPolish}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the thirteen displayed rows;*
2. *local compact neighbourhood exactness, requiring M and K to bind every compact neighbourhood read to a displayed point-window and compact witness;*
3. *complete-separable readback compatibility, requiring C to carry the complete metric presentation and countable dense probe family used by the packet;*
4. *Polish readback compatibility, requiring S to be consumed through C and not through an independent host topology;*
5. *proper closed-ball compactness compatibility, requiring E to inspect the metric and compact neighbourhood rows already displayed;*
6. *sigma-compact exhaustion compatibility, requiring W to use only the compact windows generated from the local compactness and properness route;*
7. *StreamName and RegSeqRat finite-window compatibility, requiring T and R to observe the same metric probes, compact neighbourhoods, closed balls, and exhaustion windows;*
8. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, Q, P, N.*

No locally compact Polish obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocallyCompactPolishUp.LocallyCompactPolishNameCertObligations`

Proof. Project the accepted packet $L = (X, M, K, C, S, E, W, T, R, H, Q, P, N)$. The metric object, local compactness, compact-neighbourhood ledger, complete-separable readback, Polish row,

properness row, sigma-compact exhaustion, finite observations, and structural rows are precisely the displayed carrier coordinates.

The neighbourhood route is fixed first. Rows M and K name the compact neighbourhood candidates and bind every accepted local compactness read to the corresponding point-window and compact witness.

Next the complete-separable route is read through C, and the Polish row S is downstream of that readback. Since S has no separate host-topology coordinate, every Polish consumer receives the same complete metric and dense-probe data.

The rows E and W expose proper closed-ball compactness and sigma-compact exhaustion only after the metric, neighbourhood, and complete-separable rows have been displayed. The observation rows T and R then inspect the same probes and windows through finite StreamName and RegSeqRat data.

Finally H, Q, P, N transport, replay, source, and name the route without adding new coordinates. The excluded objects do not occur in the carrier, so the listed rows exhaust the local NameCert obligations. □

Theorem 3788.3 (Locally compact Polish proper-sigma route)**.** *Every properness, sigma-compactness, completion, or compact-neighbourhood consumer of an accepted* $\mathsf{LocallyCompactPolish}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{LocallyCompactMetric}^{\uparrow}, \mathsf{CompleteSeparableMetric}^{\uparrow}, \mathsf{PolishSpace}^{\uparrow} \longmapsto M, K, C, S \longmapsto \mathsf{ProperMetric}^{\uparrow}, \mathsf{SigmaCompact}^{\uparrow}$$

The route exposes local compact neighbourhood rows and Polish complete-separable readback before proper closed-ball compactness or sigma-compact exhaustion is public. It exports no arbitrary open-cover compactness, selected exhaustion, host topological equality, quotient metric equality, countable-choice selector, or Polish presentation detached from the displayed complete-separable packet.

Proof. Start with the rows M, K, C, S. The first pair carries the local compact neighbourhood data, while the second pair carries the complete-separable presentation and the Polish readback consumed by the packet.

The properness and sigma-compactness rows are then downstream. Row E reads closed-ball compactness only through the displayed metric and local compactness surface, and row W records exhaustion windows generated from the same source.

The observation and structural rows T, R, H, Q, P, N preserve that route for consumers. Because the carrier has no coordinate for open-cover compactness, selected exhaustion, host equality, quotient equality, countable choice, or detached Polish data, every consumer remains inside the displayed proper-sigma route. □

Falsifiable prediction: An accepted $\mathsf{LocallyCompactPolish}^{\uparrow}$ read is refuted if a properness, sigma-compactness, completion, or compact-neighbourhood consumer exports a closed-ball compactness row or exhaustion row without displaying LocallyCompactMetric neighbourhood data, Polish complete-separable readback, StreamName and RegSeqRat finite windows, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: locally-compact-metric, polishspace, propermetric, sigma-compact, complete-separable-metric, streamname, regseqrat: none alone is bijective with $\mathsf{LocallyCompactPolish}^{\uparrow}$ because the packet jointly carries local compact neighbourhood rows, complete-separable Polish readback, proper closed-ball compactness, sigma-compact exhaustion, finite observations, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyCompactPolish}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyCompactPolish}^{\uparrow}$ packet is generated from locally compact metric neighbourhood rows, compact-neighbourhood ledgers, complete-separable metric readback, PolishSpaceUp readback, ProperMetricUp closed-ball compactness, SigmaCompactUp exhaustion windows, StreamNameUp and RegSeqRatUp finite observations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyCompactPolish}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3788.1, Definition 3788.2, and Definition 3788.3 seed the locally compact Polish certificate surface from compact neighbourhood rows and complete-separable readback through proper closed-ball compactness and sigma-compact exhaustion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyCompactPolish}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected exhaustions, host topological equality, quotient metric equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked local compact neighbourhood exactness, complete-separable and Polish readback compatibility, proper closed-ball compatibility, sigma-compact exhaustion compatibility, StreamName and RegSeqRat finite-window compatibility, transport, replay, provenance, and local naming for the displayed packet.

Chapter 3789

A Concrete Naming Certificate for $\mathsf{SequentialRealCompactness}^{\uparrow}$

Following Bolzano and Weierstrass, the $\mathsf{SequentialRealCompactness}^{\uparrow}$ packet records the finite route by which a bounded real sequence exposes a regular cluster subsequence through displayed interval-tree data. It sits after the subsequence extraction certificate of chapter 1254, the bounded source surface of chapter 1415, the interval-net carrier of chapter 1250, the regular rational readback of chapter 301, the finite window interface of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a sequential compactness interface for bounded real sequences, not an open-cover compactness theorem, a host completeness principle, quotient equality of real names, or a choice-selected arbitrary subsequence.

Definition 3789.1 (Sequential real compactness carrier)**.** *A* $\mathsf{SequentialRealCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, I, E, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence window schedule exposed through* $\mathsf{StreamName}^{\uparrow}$*.*
2. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row naming the bounded real sequence interface consumed by the extraction route.*
3. *I is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *interval-tree row carrying dyadic retained cells and finite mesh comparisons.*
4. *E is the* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *extraction row, including the monotone-cofinal subsequence schedule and retained finite windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the extracted windows and dyadic tolerances.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal reached only after S, B, I, E, Q have been displayed.*
7. *H records componentwise* hsame *transport for the source schedule, bounded source row, interval tree, extraction row, regular readback, real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from bounded sequence inspection through interval-tree retention, Bolzano–Weierstrass extraction, RegSeqRat readback, and RealUp sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{SequentialRealCompactness}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialRealCompactness}^{\uparrow}}$ *row.*

The carrier stores no open-cover compactness object, no arbitrary subsequence selector, no quotient equality of real names, no host supremum, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no branch outside the displayed interval-tree extraction route.*

Lean4 ✓ `BEDC.Derived.SequentialRealCompactnessUp.SequentialRealCompactnessTasteGate single carrier alignment`

Theorem 3789.2 (Sequential real compactness NameCert obligations)**.** *For every accepted* SequentialRealCompact *carrier $K = (S, B, I, E, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialRealCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, bounded-source admission through B, finite interval-tree retention through I, Bolzano–Weierstrass extraction through E, finite stream-window and dyadic-tolerance readback through S and Q, terminal real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3789.1. The bounded sequence source is available only through S and B, while the interval-tree row I supplies the retained dyadic cells before extraction is read.

Use the bounded-source handoff of chapter 1415 and the interval-net surface of chapter 1250. These rows expose finite sequence windows, regular readback, real-name seals, and interval containment without adding an open-cover compactness object or a host completeness theorem.

Read the extraction row through chapter 1254. The Bolzano–Weierstrass packet supplies the monotone-cofinal subsequence schedule and finite retained windows, which are then read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is available.

The structural rows H, C, P, N transport, replay, source, and name only this finite route. Since the carrier has no coordinate for arbitrary subsequence choice, quotient real equality, host supremum, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3789.3 (Sequential real compactness Bolzano–Weierstrass handoff)**.** *For every accepted* $\mathsf{SequentialRealCompactness}^{\uparrow}$ *carrier $K = (S, B, I, E, Q, R, H, C, P, N)$, the terminal compactness-facing read factors through the finite route*

$$\mathsf{BoundedRealSequence}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{BolzanoWeierstrass}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatC}$$

The handoff composes the bounded-source row with Bolzano–Weierstrass finite interval-tree extraction and the RegSeqRat/Real seal readback. It exports a displayed sequential cluster route, not open-cover compactness, choice-like subsequence selection, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 3789.2. It places the bounded source row B, interval-tree row I, extraction row E, readback row Q, and terminal seal R in a single finite carrier route.

The bounded source is read through chapter 1415. Its finite windows and interval bound supply the source surface consumed by the Bolzano–Weierstrass certificate, while chapter 1250 supplies the dyadic retained-cell discipline.

Now compose with chapter 1254. The extraction row reads only the finite interval-tree schedule and then hands the selected windows to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ cluster seal can be consumed.

Transport and replay through H and C, then source and name the same route through P and N. The packet therefore records a finite sequential compactness handoff and refuses the excluded open-cover, choice, quotient, and ambient-completeness exits. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialRealCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialRealCompactness}^{\uparrow}$ packet is generated from finite StreamName windows, a bounded real sequence source row, a closed bounded interval-net tree, a Bolzano–Weierstrass extraction row, a RegSeqRat readback row, a RealUp cluster seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialRealCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3789.1, Definition 3789.2, and Definition 3789.3 seed the finite bounded-sequence compactness route through interval-tree extraction and regular real readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialRealCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, arbitrary subsequence choice, quotient real equality, host supremum, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source handoff, interval-tree extraction, RegSeqRat readback, Real seal routing, and NameCert field faithfulness for BEDC.Derived.SequentialRealCompactnessUp.

Chapter 3790

A Concrete Naming Certificate for $\mathsf{LawlikeSequence}^{\uparrow}$

Following Brouwer and Bishop-style constructive sequence analysis, the $\mathsf{LawlikeSequence}^{\uparrow}$ packet records a sequence source whose future values are governed by a displayed finite rule rather than by a host infinite function. It sits between the finite-window interface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, the unfolding prefix surface of chapter 1482, and the finite observation boundary of chapter 1495. The packet supplies a lawful finite-rule stream source for the L10 Real and Completion route while keeping quotient streams, countable choice, host equality, and selected Real limits outside the exported surface.

Definition 3790.1 (Lawlike sequence carrier)**.** *A* $\mathsf{LawlikeSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, W, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the finite rule row: a program, recurrence, primitive recursion table, or other finite calculation ledger whose admitted executions produce the inspected sequence values.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *request-window row listing the finite prefixes and positions currently asked of the rule.*
3. *O is the observation row produced by executing R on the requests in W; it records only the displayed output values and their finite calculation traces.*
4. *H records componentwise* hsame *transport for R, W, O and for the structural rows that preserve the same displayed rule executions.*
5. *C records displayed* Cont *replay from a prefix request in W through the finite rule row R to the observation row O, and then to any downstream regular-rational or Real-facing read.*
6. *P is the* Pkg *provenance over* $\mathsf{LawlikeSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{LawlessSequence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{LawlikeSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through R, W, O, H, C, P, N. It has no coordinate for a host total function $\mathsf{Nat}^{\uparrow} \to \mathsf{Nat}^{\uparrow}$*, quotient stream equality, a countable-choice selector, host sequence equality, a selected Real limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LawlikeSequenceUp.TasteGate.LawlikeSequenceTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.LawlikeSequenceUp.LawlikeSequenceUp`

Definition 3790.2 (Lawlike sequence classifier)**.** *The local* $\mathsf{LawlikeSequence}^{\uparrow}$ *classifier accepts two packets*

$$L = (R, W, O, H, C, P, N) \quad \textit{and} \quad L' = (R', W', O', H', C', P', N')$$

as the same lawlike sequence read precisely when the displayed rule rows are related by the local hsame *transport, the request windows list the same finite positions, the observation rows agree on every requested position by replaying the displayed rule executions, and the continuation, provenance, and local NameCert rows preserve that same finite route. Agreement is therefore a finite-rule replay judgment over the current window, not equality of completed streams or equality of host functions.*

Theorem 3790.3 (Lawlike sequence NameCert obligations)**.** *For every accepted* $\mathsf{LawlikeSequence}^{\uparrow}$ *carrier* $L = (R, W, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LawlikeSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite rule row, request-window exposure through* W*, observation replay through* O*, classifier stability under componentwise* hsame *transport, displayed* Cont *replay of the same finite rule executions, package provenance through* P*, and local naming through* N*. No obligation row may be discharged by a host infinite function, a countable-choice selector, quotient stream equality, host sequence equality, a selected Real limit, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.LawlikeSequenceUp.LawlikeSequenceNameCertObligations`

Proof. Project the carrier of Definition 3790.1. The only sequence source displayed to a consumer is the finite rule row R, and the only inspected arguments are the finite requests listed in W.

For each request in W, replay the calculation trace stored in O. The replay is finite because O stores only the values produced by executing the displayed rule on the displayed window, not an ambient total function.

Transport stability is componentwise. The row H compares rule rows, request windows, and observation rows by hsame, while C replays the same dependency order from requests through rule execution to downstream reads.

Finally repack the route with P and N. Since none of the carrier coordinates stores a completed stream, a choice selector, quotient equality, host sequence equality, selected limit, or ambient completeness principle, the listed rows exhaust the local NameCert obligation surface. □

Theorem 3790.4 (Lawlike sequence StreamName handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LawlikeSequence}^{\uparrow}$ *carrier receives the finite route*

$$R \longmapsto W \longmapsto O$$

before any regular-rational readback or terminal Real seal can be consumed. The route presents lawlike sequence data as a displayed finite-rule stream source: $\mathsf{StreamName}^{\uparrow}$ *reads the request window,* $\mathsf{RegSeqRat}^{\uparrow}$ *may read only the observations already produced on that window, and* $\mathsf{Real}^{\uparrow}$ *may be reached only after that regular-rational handoff has been replayed through* H, C, P, N*. The handoff exports no host infinite function, countable-choice selector, quotient stream equality, host equality, selected Real limit, or ambient Real completeness.*

Proof. Read the accepted carrier through Definition 3790.1. The first available sequence-facing row is the rule row R, and every downstream request must pass through the displayed finite window W.

The observation row O is then obtained by replaying the finite executions named by R on the requests in W. A $\mathsf{StreamName}^{\uparrow}$ consumer receives exactly that windowed read; it receives no tail values beyond the displayed requests.

If a regular-rational or Real-facing consumer is present, its read is downstream of the same observation row. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff can consume only the displayed observations, and the $\mathsf{Real}^{\uparrow}$ seal can be reached only after that handoff is replayed through H, C, P, N.

Thus the lawful source is the finite-rule packet itself. The absent coordinates are exactly the data needed for a host infinite function, countable-choice selector, quotient stream equality, host equality, selected Real limit, or ambient Real completeness claim, so none of those objects can be exported by the handoff. □

Theorem 3790.5 (Lawlike sequence regular-window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{LawlikeSequence}^{\uparrow}$ *carrier* $L = (R, W, O, H, C, P, N)$ *must read the finite rule row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *request-window row* W*, the observation replay row* O*, and the componentwise transport and replay rows* H, C *before treating the displayed observations as a regular rational sequence. The consumer obtains no host infinite function, quotient stream equality, countable-choice selector, selected* $\mathsf{Real}^{\uparrow}$ *limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

If the read continues to a $\mathsf{Real}^{\uparrow}$ *endpoint, it does so only after the same regular-window route has passed through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and the terminal* $\mathsf{Real}^{\uparrow}$ *seal recorded by* P, N*.*

Proof. Project the carrier through Definition 3790.1. The rule row R and the request-window row W determine exactly which finite calculations may be inspected.

Apply Definition 3790.4. It forces every stream-facing read to pass through

$$R \longmapsto W \longmapsto O$$

before any regular-rational consumer can see observations.

Now route the regularity readback through $\mathsf{RegSeqRat}^{\uparrow}$. Since the observations are the replayed outputs stored in O, regularity can be checked only against the displayed window and the componentwise H, C rows.

Finally, if a Real-facing endpoint is requested, the route is sealed through the terminal $\mathsf{Real}^{\uparrow}$ boundary named by P, N. The absent carrier coordinates are precisely the data needed for a host infinite function, quotient stream equality, countable choice, selected Real limit, or ambient completeness, so none of those objects is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{LawlikeSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LawlikeSequence}^{\uparrow}$ packet is generated from a finite rule row, StreamName request windows, observation rows produced by the rule on those windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LawlikeSequence}^{\uparrow}}$, seed)

Scope closed: Definition 3790.1, Definition 3790.2, Definition 3790.3, and Definition 3790.4 seed the finite-rule stream source feeding StreamName, RegSeqRat, and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LawlikeSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, countable choice, host sequence equality, host function equality, selected Real limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-rule classifier stability, StreamName request-window exposure, RegSeqRat handoff exactness, Real seal nonescape, and refusal of host equality and choice for BEDC.Derived.LawlikeSequenceUp.

Chapter 3791

A Concrete Naming Certificate for MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$

The MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$ packet realizes a finite conditional-boundary row from the MetaCIC confluence audit map of chapter 9378. It sits beside the residual-substitution boundary of chapter 2181, the critical-pair boundary of chapter 2212, the frontier critical-pair packet of chapter 2382, the local diamond witness of chapter 3595, and the confluence audit witness of chapter 745. The carrier isolates the substitution-stability gate that must remain visible before any conditional parallel-diamond route is read as a closed confluence theorem.

Definition 3791.1 (MetaCIC confluence substitution-boundary carrier)**.** *A* MetaCICConfluenceSubstitutionBounda *carrier is a finite* BHist *packet*

$$S = (T, R, U, D, J, O, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite typed-term window containing the source term, the two one-step parallel reducts, and the candidate common reduct.*
2. *R is the redex-frontier row, exposing the local redex shapes consumed by the confluence audit map.*
3. *U is the substitution-boundary row, recording the closed substitution support, binder-depth ledger, and free-variable non-escape checks needed by the branch.*
4. *D is the conditional parallel-diamond handoff row. It may be consumed only after T, R, U have been displayed.*
5. *J is the local join witness row, recording the candidate common reduct as a finite replay path rather than as a global Church–Rosser theorem.*
6. *O is the obstruction row naming the absent endpoints: unrestricted substitution compatibility, arbitrary subject reduction, and global closed confluence.*
7. *G is the* TasteGate *readiness row, reserving the later* Nontrivial *and* FieldFaithful *instance obligations for this finite carrier.*
8. *H records componentwise* hsame *transport for the typed-term window, redex frontier, substitution boundary, conditional-diamond handoff, local join, obstruction, TasteGate readiness, replay, provenance, and local name rows.*

9. *C records displayed* Cont *replay from a confluence-boundary query through $T, R, U, D, J, O, G, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}$*, the confluence audit map, residual-substitution boundary rows, critical-pair rows, local-diamond rows,* BHist*,* hsame*,* Cont*,* Pkg*,* TasteGate*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It contains no coordinate for global confluence, unrestricted substitution compatibility, subject reduction, kernel consistency, evaluator equality, or hidden conversion.

Theorem 3791.2 (MetaCIC confluence substitution-boundary obligations)**.** *For every accepted* $\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}$ *carrier $S = (T, R, U, D, J, O, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}}$ *surface consists exactly of typed-window exposure through T, redex-frontier exposure through R, substitution-boundary exposure through U, conditional parallel-diamond handoff through D, local join replay through J, obstruction retention through O, TasteGate readiness through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

The confluence-facing route is

$$T, R, U \longmapsto D, J, O \longmapsto G, H, C, P, N.$$

It is conditional at U and D: the packet records where substitution stability is available, not a closed confluence theorem.

Proof. Project the carrier of Definition 3791.1. The term-facing rows are T, R, U, D, J, O, and the structural rows are G, H, C, P, N.

The conditional branch begins with T, R, U. The typed-term window supplies the finite peak, the redex-frontier row supplies the local critical shape, and the substitution-boundary row supplies exactly the closed substitution support that must be checked before the diamond handoff is read.

The rows D, J, O then separate positive and negative content. The handoff and join rows record a local candidate route, while the obstruction row keeps unrestricted substitution compatibility, subject reduction, and global confluence outside the packet.

Finally G, H, C, P, N prepare the later TasteGate instance surface, transport the same rows, replay the same query, source it, and name it. Since no hidden conversion, evaluator equality, global confluence theorem, or kernel-consistency coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 3791.3 (MetaCIC confluence substitution-boundary non-escape)**.** *Every confluence-audit consumer of an accepted* $\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}$ *carrier must factor through*

$$T, R, U, D, J, O, G, H, C, P, N.$$

If the substitution-boundary row U or the conditional handoff row D is absent, the packet no longer exports a confluence-boundary read. The remaining rows may still record typed terms, redex shapes, obstruction names, local join candidates, transport, replay, provenance, TasteGate readiness, and local naming, but they cannot supply global Church–Rosser, unrestricted substitution compatibility, arbitrary subject reduction, or kernel consistency.

Proof. Apply the obligation surface of Definition 3791.2. A confluence-audit read reaches the local join only through the typed window, redex frontier, substitution boundary, and conditional handoff.

If U is absent, the substitution-stability premise is not displayed. If D is absent, the conditional parallel-diamond handoff is not displayed. In either case the finite packet no longer contains the route needed to treat J as a confluence-boundary read.

The rows O, G, H, C, P, N do not repair the missing premise. They retain obstruction names, reserve the later TasteGate obligations, and preserve the visible packet, but none is a coordinate for global Church–Rosser, unrestricted substitution compatibility, subject reduction, or consistency. □

Theorem 3791.4 (MetaCIC confluence substitution-boundary TasteGate readiness)**.** *The later Lean side must provide* Nontrivial *and* FieldFaithful TasteGate *instances for* MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$ *at the displayed finite carrier surface*

$$T, R, U, D, J, O, G, H, C, P, N.$$

Those instances must certify that the packet is neither empty nor field-forgetting: every accepted carrier visibly retains the typed-term window, redex-frontier row, substitution-boundary row, conditional handoff, local join row, obstruction row, transport, replay, provenance, and local NameCert data.

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceSubstitutionBoundaryUp.MetaCICConfluenceSubstitutionBoundaryTaste`
`single carrier alignment`

Proof. The readiness row G is part of the carrier in Definition 3791.1. It is deliberately tied to the whole tuple rather than to the obstruction row alone.

Nontriviality must therefore exhibit an accepted packet with all finite rows present. FieldFaithfulness must show that deleting any of $T, R, U, D, J, O, H, C, P, N$ changes the readable carrier surface. The theorem records those Lean obligations at paper level while leaving their proofs to the later formalization namespace. □

Falsifiable prediction: A MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$ confluence-audit read factors through displayed typed-term windows, redex-frontier rows, substitution-boundary rows, conditional parallel-diamond handoffs, local join witnesses, obstruction rows, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-critical-pair-boundary, metacic-frontier-critical-pair, metacic-local-diamond-witness, metacic-confluence-audit-witness: MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a typed peak, redex frontier, substitution-boundary row, conditional handoff, local join candidate, obstruction ledger, TasteGate readiness, transport, replay, provenance, and local naming as one boundary packet.

Closure status for NameCert$_{\text{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 3791.1, Definition 3791.2, Definition 3791.3, and Definition 3791.4 seed the finite substitution-sensitive confluence-boundary packet for MetaCIC audit consumers.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global Church–Rosser, unrestricted substitution compatibility, arbitrary subject reduction, kernel consistency, evaluator equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, redex-frontier exposure, substitution-boundary coverage, conditional handoff, local join replay, obstruction retention, TasteGate readiness, transport, replay, provenance, and non-escape for BEDC.Derived.MetaCICConfluenceSubstitutionBoundaryUp.

Constructive story: A MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$ packet is generated from a typed-term peak window, redex-frontier rows, a substitution-boundary row, a conditional parallel-diamond handoff, a local join witness, an obstruction ledger, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3792

A Concrete Naming Certificate for $\mathsf{CauchyCompletionComonad}^{\uparrow}$

Following Mac Lane on comonads and Bishop–Bridges on constructive Cauchy completion, the $\mathsf{CauchyCompletionComonad}^{\uparrow}$ packet records the finite completion-read surface obtained by reading already displayed completion data back through counit and comparison rows. It is paired with the monad packet of chapter 378, the Kleisli consumer boundary of chapter 1845, the counit packet of chapter 1539, the comparison packet of chapter 1954, and the triangle-identity packet of chapter 1795. The analytic route is the same finite L10 exit through chapter 126, chapter 301, chapter 291, and chapter 38; the chapter names this dual read as finite NameCert data rather than as a quotient completion object.

Definition 3792.1 (CauchyCompletionComonad carrier)**.** *A* $\mathsf{CauchyCompletionComonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, K, E, Q, T, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *route whose source, unit, bind, finite-window, readback, and terminal-seal rows are being read in the opposite direction.*
2. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *consumer row, displaying how a completion-facing request reaches the same finite source and seal rows.*
3. *E is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *return row from displayed completion data to the real-facing boundary.*
4. *Q is the* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *row comparing the monad-facing and counit-facing reads over the same finite completion route.*
5. *T is the* $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$ *row identifying the two displayed unit-counit composites with the direct completion read.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected before any rational readback or terminal seal is exposed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row consumed by the completion read.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and observation ledger attached to the same finite windows.*
9. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, R, D have been displayed.*

10. *H records componentwise* hsame *transport for $M, K, E, Q, T, S, R, D, A$ and the structural rows.*
11. *C records displayed* Cont *replay for consumers that inspect the comultiplication side, the counit side, the comparison side, or the terminal real-facing route.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionComonad}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{CauchyCompletionTriangleIdentity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComonad}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected Cauchy representatives, host equality of completed objects, countable choice, ambient completeness, $\mathsf{Real}^{\uparrow}$ *completeness, or bridge-axis evidence.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionComonadUp.CauchyCompletionComonadTasteGate single carrier alignment`

Theorem 3792.2 (CauchyCompletionComonad NameCert obligations)**.** *For every accepted* CauchyCompletionCom *carrier $G = (M, K, E, Q, T, S, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComonad}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the monad, Kleisli, counit, comparison, triangle, finite-window, regular-readback, dyadic-ledger, terminal-seal, transport, replay, provenance, and local naming rows;*
2. *comultiplication exposure, requiring every doubled completion-read request to pass through M, K, Q, T before a terminal seal can be inspected;*
3. *counit return, requiring every already displayed completion read to pass through E before it reaches S, R, D, A;*
4. *finite triangle compatibility, requiring the comultiplication-counit composites to reach the same displayed S, R, D, A route as the direct completion read;*
5. *classifier stability, requiring transported packets with the same displayed rows to be compared only by the carried* hsame *and* Cont *data;*
6. *non-escape, requiring P, N to source and name no quotient completion, selected representative, countable-choice schedule, host equality, ambient completeness theorem,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification credential, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3792.1. The tuple lists the monad, Kleisli, counit, comparison, triangle, finite-window, regular-readback, dyadic-ledger, terminal-seal, transport, replay, provenance, and local naming rows.

Comultiplication exposure is read from M, K, Q, T. The monad and Kleisli rows give the doubled completion consumer surface, the comparison row aligns it with the already displayed completion read, and the triangle row identifies the visible composites with the direct route.

Counit return is read from E. Once completion data have already been displayed, the packet forces their return through S, R, D, A before any real-facing consumer sees a terminal seal.

The structural obligations are componentwise. The rows H and C preserve and replay only the displayed packet, while P and N source and name that packet. Since no excluded coordinate occurs in the carrier, no stronger completion object can be exported. □

Theorem 3792.3 (CauchyCompletionComonad comultiplication and counit route)**.** *Let* $G = (M, K, E, Q, T, S, R, D, A, H, C, P, N)$ *be an accepted* $\mathsf{CauchyCompletionComonad}^{\uparrow}$ *carrier. Every consumer of the finite comultiplication-counit surface factors through the displayed route*

$$M, K \longmapsto Q, T \longmapsto E \longmapsto S, R, D \longmapsto A \longmapsto H, C, P, N.$$

The route exposes a completion read only after the monad-facing and Kleisli-facing rows have been compared with the counit-facing return and then passed through the finite $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. It exports no quotient completion, selected representative, host equality of completed objects, countable-choice selector, ambient completeness theorem, or bridge credential.*

Proof. Project the accepted carrier. The only doubled completion-read rows are M and K, so a comultiplication-facing request first reads the monad route and the Kleisli consumer boundary.

The middle comparison is forced by Q and T. The comparison row aligns the monad-facing read with the counit-facing return, and the triangle row identifies the two visible composites with the same direct completion route.

The counit row E then returns the displayed completion read to the terminal finite route. That route must pass through the finite window S, the regular readback R, the dyadic ledger D, and the real seal A.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier contains no coordinate for quotient completions, selected representatives, host equality, countable choice, ambient completeness, or bridge evidence, the displayed route is the whole comonad surface. □

Theorem 3792.4 (CauchyCompletionComonad finite completion-read boundary)**.** *Every completion-facing,* $\mathsf{StreamName}^{\uparrow}$*-facing,* $\mathsf{RegSeqRat}^{\uparrow}$*-facing,* $\mathsf{DyadicRatCore}^{\uparrow}$*-facing, or* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{CauchyCompletionComonad}^{\uparrow}$ *carrier is generated by the rows of Definition 3792.1. In particular, the packet gives later completion algebra and reflector consumers a finite non-quotient read surface, not an ambient completed object.*

Proof. Read the completion-facing side first. The only completion control rows are M, K, E, Q, T, so every completion-facing consumer must factor through the monad route, Kleisli route, counit return, comparison row, and triangle row.

Read the analytic side next. The only finite observation and terminal seal rows are S, R, D, A, so every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal read through those rows.

The structural rows H, C, P, N preserve the same surface and add no new carrier coordinate. Therefore algebra and reflector consumers can reuse the finite read boundary, but they cannot obtain a quotient completion, selected limit, host completed object, ambient completeness theorem, or bridge credential from it. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionComonad}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionComonad}^{\uparrow}$ packet is generated from CauchyCompletionMonad, CauchyCompletionKleisli, CauchyCompletionCounit, CauchyCompletionComparison, CauchyCompletionTriangleIdentity, StreamName, RegSeqRat, DyadicRatCore, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionComonad}^{\uparrow}}$, seed)

Scope closed: Definition 3792.1, Definition 3792.2, Definition 3792.3, and Definition 3792.4 seed the finite dual completion-read surface over the L10 Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionComonad}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected Cauchy representatives, host equality of completed objects, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comultiplication exposure, counit return, triangle compatibility, classifier stability, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.CauchyCompletionComonadUp.

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ lattice is routed as a Cantor-to-Real diagonal boundary through chapter 1530, chapter 5879, chapter 301, and chapter 38.

Chapter 3793

A Concrete Naming Certificate for $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$

Following Cantor's diagonal argument, the $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ packet records the finite BEDC boundary that prevents a displayed countable $\mathsf{StreamName}^{\uparrow}$ enumeration from being read as exhaustive $\mathsf{Real}^{\uparrow}$ data. It sits over the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic bit ledger of chapter 291, the terminal real-name seal of chapter 38, and the comparison setoid boundary of chapter 1820. The packet names only the inspected enumeration rows, the diagonal bit-flip row, the regular readback route, transport, replay, provenance, and local naming data; it is not a host real-uncountability theorem, not a quotient-stream principle, and not a completed powerset of reals. The downstream Cantor diagonal real-uncountability packet of **??** consumes this finite non-surjection boundary as its Real-facing diagonal obstruction before adding CantorSpace and CantorSet rows.

The dependency direction is one-way at this lattice node: $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ consumes $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ to compare the diagonal witness with inspected rows, while CantorDiagonalRealUncountab consumes this chapter as the Real-facing obstruction before adding CantorSpace and CantorSet rows.

The diagonal-window side is read through chapter 4080. That sibling supplies the finite Cauchy diagonal-window selector used before the bit-flip row F and the terminal Real seal row S are consumed, so this chapter records the non-surjection witness as a finite selector-to-flip route rather than as only a kernel-to-Real route.

Definition 3793.1 (Real diagonal non-surjection carrier)**.** *A* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (E, W, B, F, R, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the countable-enumeration row, displaying the finite slice of the proposed* $\mathsf{StreamName}^{\uparrow}$ *enumeration inspected by the packet.*
2. *W is the row-index schedule, listing the inspected diagonal rows and the finite windows used for each row.*
3. *B is the dyadic-bit observation row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any real-name seal is exposed.*
4. *F is the diagonal bit-flip row, recording for each inspected row the opposite dyadic bit at the matching diagonal window.*

5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the displayed bit-flip data into regular rational real-name observations.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the diagonal witness, exposed only after E, W, B, F, R have been displayed.*
7. *H records componentwise* hsame *transport for E, W, B, F, R, S and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an enumeration request through*

$$E, W, B, F, R \longmapsto S \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealDiagonalNonSurjection}^{\uparrow}}$ *row.*

The carrier contains no host real equality test, quotient stream equality, completed powerset of real names, countable-choice schedule, selected global enumeration inverse, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge credential.*

Theorem 3793.2 (Real diagonal non-surjection NameCert obligations)**.** *For every accepted* RealDiagonalNonSurjec *carrier $D = (E, W, B, F, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealDiagonalNonSurjection}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, enumeration-slice exposure through E, finite diagonal-window accounting through W, dyadic-bit readback through B, bit-flip exactness through F, regular rational readback through R, terminal real-name sealing through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RealDiagonalNonSurjectionUp.RealDiagonalNonSurjectionNameCertObligations`

Proof. Project the carrier of Definition 3793.1. The analytic rows are the enumeration slice E, the finite diagonal schedule W, the dyadic observation row B, the flipped-bit row F, the regular rational readback R, and the terminal seal S.

The enumeration obligations are finite. A consumer sees only the rows named by W, and for each such row it sees only the dyadic window displayed in B before the corresponding flipped bit is recorded in F.

The real-name handoff is routed through R and then S. Thus the diagonal witness is read as regular rational data before it is sealed as $\mathsf{Real}^{\uparrow}$ data, and the Cauchy-equivalence boundary remains a displayed comparison surface rather than a quotient of streams.

Transport and replay preserve the same rows componentwise. Since the carrier has no coordinate for host real equality, quotient streams, completed powersets, countable choice, selected enumeration inverses, ambient real completeness, Lean verification, or bridge checking, the listed rows exhaust the local certificate. □

Theorem 3793.3 (Real diagonal non-surjection diagonal witness)**.** *Every accepted* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *packet exports a displayed diagonal witness route*

$$\begin{gathered} \textit{inspected row } n, \quad \textit{dyadic bit } b_n, \\ b_n \longmapsto 1 - b_n \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}. \end{gathered}$$

For each inspected enumeration row, the witness differs from that row at the matching displayed dyadic window before the terminal $\mathsf{Real}^{\uparrow}$ *seal is exposed. Therefore a countable* $\mathsf{StreamName}^{\uparrow}$ *enumeration cannot be used as an exhaustive Real-facing packet unless it supplies an additional displayed row that defeats the bit-flip witness through the same* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *route.*

Proof. Start with an accepted carrier $D = (E, W, B, F, R, S, H, C, P, N)$. For a row listed in W, the enumeration slice E exposes the row and B exposes the dyadic bit observed at the matching diagonal window.

The row F records the opposite bit at that window. The displayed step is

$$b_n \longmapsto 1 - b_n.$$

This is a finite dyadic row, not an appeal to host real equality or to a completed set of all real names.

The readback row R repacks the flipped bits as regular rational observations, and S is the only terminal $\mathsf{Real}^{\uparrow}$ seal available to the witness. Any comparison with the inspected row must therefore pass through the displayed Cauchy-equivalence setoid route, not through quotient streams or ambient completeness.

Consequently every inspected row is separated from the diagonal witness at its own displayed dyadic window. The packet refuses host real equality, quotient streams, completed powersets, countable choice, and ambient Real completeness as sources of surjectivity data. □

Theorem 3793.4 (Real diagonal non-surjection diagonal sequence route)**.** *Every accepted* RealDiagonalNonSurjecti *diagonal witness route of Definition 3793.3 factors through the reusable* $\mathsf{DiagonalSequence}^{\uparrow}$ *schedule of chapter 3940 before the dyadic bit flip and terminal* $\mathsf{Real}^{\uparrow}$ *seal are read. The* $\mathsf{DiagonalSequence}^{\uparrow}$ *row supplies only the finite row-index and window schedule used by* $E, W, B, F, R, S, H, C, P, N$*; it supplies no host countability theorem, no completed enumeration, and no Real surjectivity principle.*

Proof. Project the accepted carrier $D = (E, W, B, F, R, S, H, C, P, N)$. The rows E and W expose the inspected enumeration slice and the finite row-index schedule before any dyadic bit is flipped.

Read this schedule through chapter 3940. The sibling packet contributes the reusable diagonal row and finite-window discipline, so the present carrier does not need a separate kernel-level scheduling surface.

Only after that schedule is displayed may B and F read the inspected dyadic bit and its opposite. The readback row R and seal row S then turn the flipped finite row into the displayed $\mathsf{Real}^{\uparrow}$ witness.

The structural rows H, C, P, N preserve the same route. Since $\mathsf{DiagonalSequence}^{\uparrow}$ supplies only finite schedule data, the factorization imports no host countability theorem, completed enumeration, quotient stream equality, or Real surjectivity principle. □

Theorem 3793.5 (Real diagonal non-surjection StreamName dependency)**.** *Every* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *read that exposes a diagonal non-surjection witness must first expose the* $\mathsf{StreamName}^{\uparrow}$ *enumeration slice and its finite diagonal windows from chapter 126. Only after those rows are displayed can the carrier read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bit flip, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus the diagonal witness route depends on the finite StreamName window surface before any dyadic flip or Real-facing seal is visible.*

Proof. Project the carrier of Definition 3793.1. The rows E and W are the enumeration slice and finite diagonal-window schedule, and both are read before the dyadic observation row B and flipped-bit row F.

The diagonal-sequence route of Definition 3793.4 preserves this order. It first exposes the finite schedule, then routes through the dyadic bit read, the regular rational readback R, and the Real seal S.

Therefore every downstream Cantor or Real consumer sees a StreamName dependency theorem: the diagonal obstruction is not a direct host uncountability claim, but a finite path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. □

Theorem 3793.6 (Real diagonal non-surjection Cantor-RegSeqRat dependency)**.** *Every Cantor-style consumer of an accepted* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *packet must read the diagonal obstruction in the order*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{CantorSpace}^{\uparrow}/\mathsf{ConstructiveC}$$

Thus the packet consumed by the Cantor diagonal real-uncountability route is a finite Real-facing diagonal obstruction: it exposes the StreamName enumeration slice, the dyadic bit flip, the regular rational readback, the Cauchy-equivalence comparison boundary, the CantorSpace and constructive Cantor theorem route, and the terminal Real seal before any downstream Real consumer may cite non-surjection.

Proof. Start with the carrier of Definition 3793.1. It lists the StreamName enumeration slice E, W, the dyadic observation and flip rows B, F, the RegSeqRat readback R, the Real seal S, and the Cauchy-equivalence comparison route as displayed packet data.

Apply the diagonal witness theorem Definition 3793.3. The witness is separated from each inspected row at a displayed dyadic window before it is read back through $\mathsf{RegSeqRat}^{\uparrow}$ and sealed as $\mathsf{Real}^{\uparrow}$.

Apply Definition 3793.5 and the Cantor sibling route of Definition 3793.7. They force Cantor consumers to read the StreamName slice first and to pass through the CantorSpace and constructive Cantor theorem route only after the dyadic, regular-rational, and Cauchy-equivalence rows are visible.

Consequently the consumer receives a finite Real-facing diagonal obstruction. It does not receive a host uncountability theorem, a completed powerset of reals, quotient-stream equality, countable choice, or an ambient Real completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealDiagonalNonSurjection}^{\uparrow}}$.

Constructive story: A $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ packet is generated from a finite StreamName enumeration slice, a diagonal row-index schedule, a DyadicRatCore bit-observation row, a flipped-bit row, a RegSeqRat readback route, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealDiagonalNonSurjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3793.1, Definition 3793.2, Definition 3793.3, Definition 3793.4, and Definition 3793.5 seed the finite diagonal boundary and reusable StreamName-to-Real schedule for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealDiagonalNonSurjection}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RealDiagonalNonSurjectionUp`

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient streams, completed powersets of real names, countable choice, selected enumeration inverses, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, enumeration-slice exposure, diagonal-window accounting, dyadic-bit readback, bit-flip exactness, RegSeqRat readback, RealUp sealing, Cauchy-equivalence comparison routing, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealDiagonalNonSurjectionUp.

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ packet is a Real-facing diagonal boundary rather than a kernel-only island. Its diagonal witness consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 for the displayed regular-rational readback, and the Cantor diagonal real-uncountability route of **??** consumes this chapter as its Real-facing non-surjection input before adding CantorSpace and CantorSet rows.

The non-surjection carrier first reads the reusable diagonal schedule of chapter 3940: finite stream windows select the inspected enumeration row, the diagonal bit disagreement is recorded at the selected coordinate, the $\mathsf{RegSeqRat}^{\uparrow}$ readback exposes the rational window that realizes the disagreement, and the terminal $\mathsf{Real}^{\uparrow}$ seal packages that readback as the Real-facing obstruction. Only after this route is visible may **??** and chapter 5879 consume the packet as a Cantor-facing diagonal obstruction.

Theorem 3793.7 (RealDiagonalNonSurjection Cantor sibling route)**.** *Every accepted* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *carrier consumed by a Cantor-style diagonal argument remains a Real-facing sibling route through* $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The consumer first reads the finite enumeration slice, diagonal row-index schedule, dyadic bit-observation row, flipped-bit row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison boundary, transport, replay, provenance, and local naming rows of Definition 3793.1; only then may the Cantor route of chapter 5879 interpret the same disagreement ledger as a Cantor-space non-enumeration witness.*

Proof. Start with the carrier and diagonal witness rows of Definition 3793.1 and Definition 3793.3. They expose the inspected enumeration row, finite diagonal window, dyadic bit read, flipped-bit row, regular-rational readback, and terminal $\mathsf{Real}^{\uparrow}$ seal before any non-surjection conclusion is read.

Next route the displayed disagreement through the Cantor-space handoff of chapter 5879. That sibling consumes the same finite diagonal classifier over $\mathsf{CantorSpace}^{\uparrow}$ and carries it toward the Real-facing non-surjection boundary; it does not introduce a completed binary stream, host powerset, or ambient surjectivity principle.

Finally use the sibling dependency route already recorded for this chapter. The $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ comparison and $\mathsf{Real}^{\uparrow}$ seal remain visible on the Real side, so the packet is a Cantor/Real diagonal sibling route rather than a kernel-only packet. □

Theorem 3793.8 (Real diagonal non-surjection RegSeqRat dependency route)**.** *Every* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *read that constructs the anti-diagonal* $\mathsf{Real}^{\uparrow}$ *row first exposes the finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and* $\mathsf{Real}^{\uparrow}$ *seal used by the source sequence. The consumer cannot bypass those rows with host stream equality, selected limits, quotient reals, ambient completeness, countable choice, or a hidden real-surjectivity principle.*

Proof. Start with the carrier of Definition 3793.1. The rows E and W expose only the inspected finite enumeration slice and diagonal windows, so the anti-diagonal read begins as finite $\mathsf{StreamName}^{\uparrow}$ data.

Next apply the diagonal witness route of Definition 3793.3. The dyadic bit read and bit flip pass through B and F, then the regular-rational readback R repacks the displayed windows before the terminal seal S is exposed.

Use the existing sibling dependency route of this chapter to keep the same boundary visible to downstream consumers. The sibling route already records that the diagonal packet is Real-facing, and chapter 301 and chapter 38 supply the named readback and seal surfaces.

Since the carrier has no coordinate for host stream equality, selected limits, quotient reals, ambient completeness, countable choice, or hidden surjectivity data, every anti-diagonal Real row must follow the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. □

Theorem 3793.9 (Real diagonal non-surjection Cantor–RegSeqRat lock)**.** *Every accepted* RealDiagonalNonSurjecti *packet that claims a non-surjectivity read must factor through the Cantor diagonal row of chapter 5879, the regular rational readback row of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row of chapter 38, and the local* $\mathsf{NameCert}_{\mathsf{RealDiagonalNonSurjection}^{\uparrow}}$ *ledger before the conclusion is exposed. In*

carrier coordinates this means that the enumeration slice E, diagonal schedule W, dyadic bit row B, flipped-bit row F, RegSeqRat row R, Real seal S, transport row H, replay row C, provenance row P, and naming row N of Definition 3793.1 remain visible in that order; no classical choice principle, host powerset, quotient stream equality, selected inverse, or ambient real-completeness row is introduced by the lock.

Proof. Start with the carrier and diagonal witness rows of Definition 3793.1 and Definition 3793.3. They expose $E, W, B, F, R, S, H, C, P, N$ before any non-surjectivity read is available.

Next use the Cantor sibling route of Definition 3793.7. The Cantor-facing consumer receives the same displayed disagreement row and not a host powerset, completed binary stream, or selected inverse.

Then apply the RegSeqRat dependency route of Definition 3793.8 and the Real source route of Definition 3793.11. The flipped bit row is read through R as regular rational data before S exposes the terminal Real-facing seal.

Finally the structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for classical choice, quotient stream equality, selected enumeration inverse, host powerset, or ambient real completeness, every accepted non-surjection claim remains locked to the Cantor, RegSeqRat, RealUp, and local NameCert rows. □

Theorem 3793.10 (Real diagonal non-surjection RegSeqRat–Real route)**.** *Every accepted* RealDiagonalNonSurjecti *read that exposes a diagonal non-surjection packet must consume the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row of chapter 301, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of chapter 38, and the Cantor-style diagonal sibling rows of Definition 3793.7 before the non-surjection surface is available.*

In carrier coordinates this route reads $E, W, B, F, R, S, H, C, P, N$ from Definition 3793.1: the enumeration slice and window schedule are exposed first, the flipped dyadic bit is repacked through R as regular rational data, the terminal seal S presents the Real-facing row, and the Cantor sibling consumes the same displayed disagreement ledger. No host stream equality, selected inverse, quotient real equality, completed powerset, or ambient Real-completeness row is introduced by the route.

Proof. Project the carrier of Definition 3793.1. The rows E and W expose only the inspected finite enumeration slice and diagonal windows, so the non-surjection read begins as $\mathsf{StreamName}^{\uparrow}$ window data.

Apply Definition 3793.8. The bit observation and flipped bit are read through B and F, then the row R repacks the disagreement as regular rational data before a Real-facing endpoint is visible.

Next apply Definition 3793.12. The seal row S is the only $\mathsf{Real}^{\uparrow}$ endpoint available to the diagonal witness, and it is exposed only after the regular readback has been displayed.

Finally use Definition 3793.7. The Cantor-style sibling consumes the same finite disagreement ledger after the StreamName, RegSeqRat, and Real seal rows are visible. The structural rows H, C, P, N transport, replay, source, and name that route, so no excluded host object can enter the non-surjection packet. □

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ completion-facing dependency route consumes the regular-rational readback of chapter 301 and the terminal real-name seal of chapter 38 before a diagonal non-surjection packet may refuse a surjective enumeration. This anchor keeps the L10 readback lattice visible: the inspected enumeration slice and finite diagonal windows are read first, the disagreement is repacked through $\mathsf{RegSeqRat}^{\uparrow}$, the resulting row is sealed by $\mathsf{Real}^{\uparrow}$, and only then can the packet deny that the displayed enumeration is exhaustive.

Theorem 3793.11 (Real diagonal non-surjection Real source route)**.** *Every diagonal non-surjection read of an accepted* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *packet consumes the* $\mathsf{Real}^{\uparrow}$ *source row of chapter 38, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row of chapter 126, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301 before exposing a diagonal packet. The route exposes only the finite enumeration slice, diagonal window schedule, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows; it does not claim host uncountability, quotient stream equality, countable choice, or ambient Real completeness.*

Proof. Project the carrier of Definition 3793.1. The enumeration slice E and finite diagonal schedule W are read as $\mathsf{StreamName}^{\uparrow}$ source data before the bit observation row B or flipped-bit row F can be interpreted.

Apply the RegSeqRat dependency route of Definition 3793.8. The anti-diagonal readback passes through R as regular rational data and cannot bypass that row with host stream equality, selected limits, quotient reals, countable choice, or hidden surjectivity data.

Finally use the Real seal dependency of Definition 3793.12. The seal row S is the only $\mathsf{Real}^{\uparrow}$ endpoint available to the diagonal witness, and it is exposed after the stream and regular-rational source rows have already been read. The diagonal packet is therefore a downstream consumer of the $\mathsf{Real}^{\uparrow}$ terminal seal, the $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback, so its non-surjection surface is unavailable unless those sibling NameCert chapters have supplied their finite rows.

Thus every diagonal packet is source-routed through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the non-surjection surface is visible. The carrier has no coordinate for host uncountability, quotient stream equality, countable choice, or ambient Real completeness. □

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ packet consumes $\mathsf{RealBaireCylinder}^{\uparrow}$ as the finite prefix-cylinder readback surface for Real-facing diagonal rows. The sibling route through chapter 1685 first exposes the $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, then the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal; the diagonal row therefore reads the Baire cylinder as displayed Real-facing data rather than as a host stream, quotient real equality, selected branch, or ambient completeness principle.

Theorem 3793.12 (Real diagonal non-surjection Real seal dependency)**.** *Every* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *diagonal read reaches its contradiction surface only after the* $\mathsf{Real}^{\uparrow}$ *seal route of chapter 38 and the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite-window rows are visible. The packet is not a host cardinality theorem, not a quotient-surjection argument, and not an appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3793.1. The only analytic rows available before the terminal real-name handoff are the enumeration slice E, the finite diagonal schedule W, the dyadic bit row B, the bit-flip row F, and the regular rational readback R.

Apply Definition 3793.3. The contradiction surface is reached by comparing an inspected enumeration row with the flipped bit at the displayed diagonal window. That comparison is read through $\mathsf{DyadicRatCore}^{\uparrow}$ and then through $\mathsf{RegSeqRat}^{\uparrow}$ before the seal row S can expose the witness as $\mathsf{Real}^{\uparrow}$ data.

Now use the $\mathsf{Real}^{\uparrow}$ seal route of chapter 38. The seal does not add a separate cardinality principle; it only marks that the already displayed regular-rational finite windows have been admitted as the real-name row used by the diagonal witness.

Since the carrier has no coordinate for host cardinality, quotient surjection, selected enumeration inverse, completed powerset, countable choice, or ambient real completeness, every diagonal

contradiction remains inside the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal dependency route. □

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ dependency lattice consumes the Cantor-style diagonal split, the $\mathsf{RegSeqRat}^{\uparrow}$ readback route, and the terminal $\mathsf{Real}^{\uparrow}$ seal through chapter 1530, chapter 301, and chapter 38. This route exposes only the finite diagonal disagreement, regular rational readback, and Real sealing rows; it does not claim cardinality, a powerset object, quotient equality, or host diagonal completeness.

Theorem 3793.13 (Real diagonal non-surjection metric dependency route)**.** *Every* $\mathsf{Met}^{\uparrow}$ *consumer that compares outputs of a* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *packet must first read the diagonal witness through the* $\mathsf{RegSeqRat}^{\uparrow}$ *route of chapter 301 and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. Only after those rows are exposed may the consumer use the metric comparison surface of chapter 57; the diagonal packet itself exports no direct metric distance row, quotient real equality, selected limit, countable-choice schedule, or ambient completeness witness.*

Proof. Start with the carrier of Definition 3793.1. The rows B and F produce the displayed dyadic bit disagreement, but this data is still a finite diagonal observation rather than a metric comparison.

The readback row R converts the displayed bit-flip data into the regular rational route named by Definition 3793.8. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ endpoint visible to a downstream consumer.

A $\mathsf{Met}^{\uparrow}$ consumer can compare diagonal outputs only after it has both the regular rational readback and the terminal real seal. Thus the dependency order is

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow}.$$

Transport, replay, provenance, and local naming preserve this order componentwise. Since no carrier row names a host metric distance directly, the metric consumer cannot bypass the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ sibling routes. □

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ dependency route combines the Cantor-style diagonal cylinder, the $\mathsf{RegSeqRat}^{\uparrow}$ finite readback, the terminal $\mathsf{Real}^{\uparrow}$ seal, and the $\mathsf{Met}^{\uparrow}$ separation surface in one visible order. A consumer first reads the finite binary disagreement through the Cantor route of chapter 5879 and the regular-rational readback of chapter 301; only then does the route expose the Real seal of chapter 38 and the metric comparison boundary of chapter 57. The packet therefore supplies a concrete dependency edge from diagonal cylinders to metric separation without adding host cardinality, quotient real equality, selected branches, countable choice, or ambient completeness.

Theorem 3793.14 (RealDiagonalNonSurjection forward Cantor consumer route)**.** *Every* CantorDiagonalRealUncou *consumer of an accepted* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ *carrier must first read the finite diagonal obstruction through the displayed* $\mathsf{StreamName}^{\uparrow}$ *enumeration slice,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *bit-observation and bit-flip rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the sibling Cantor route of Definition 3793.7. The consumer may then pass to* **??***, but only with the Real-facing seal and comparison boundary already constrained by chapter 38.*

Proof. Project the accepted carrier of Definition 3793.1. Its enumeration slice, row-index schedule, dyadic bit-observation row, flipped-bit row, regular rational readback, and Real seal are all displayed before the local diagonal witness is available.

Apply the StreamName dependency theorem and the Cantor sibling route. Theorems 3793.5 and 3793.7 force the consumer through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the disagreement ledger can be interpreted as Cantor-facing non-enumeration data.

The downstream chapter **??** therefore receives the diagonal obstruction as a finite Real-facing route, not as a free-standing host uncountability principle. The Real seal remains governed by chapter 38, so the consumer imports no quotient stream equality, completed powerset, countable choice, selected enumeration inverse, or ambient completeness. □

The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ route is the Real-facing obstruction consumed by **??** and by chapter 5879. The downstream Cantor read occurs only after $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ have already exposed the finite name, rational readback, dyadic tolerance, real seal, and equivalence-setoid rows. The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ sibling lattice consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular readback route of chapter 301, the CantorSpace chapter of chapter 1475, and the Cantor-style diagonal handoff of Definition 3793.7. These dependencies keep the non-surjection packet on the displayed Real, RegSeqRat, CantorSpace, and Cantor diagonal rows, with no host enumeration theorem, quotient stream equality, or ambient completeness coordinate. The $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$ completion-facing diagonal route is read through the $\mathsf{CantorSpace}^{\uparrow}$ finite-prefix surface of chapter 1475, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the completion-facing siblings chapter 360 and chapter 1506. The Cantor row supplies only the displayed binary-prefix disagreement, the regular readback row repacks that disagreement as rational observations, and the Real seal is exposed before any completion consumer may inspect the packet. The route does not claim host cardinality, quotient real equality, selected infinite branches, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Chapter 3794

A Concrete Naming Certificate for $\mathsf{CauchyNetCompletion}^{\uparrow}$

Following Kelley, Moore–Smith, and Bourbaki, the $\mathsf{CauchyNetCompletion}^{\uparrow}$ packet records the directed Cauchy-net completion carrier that sits between the raw $\mathsf{CauchyNet}^{\uparrow}$ directed-window surface and the completion consumers already named by $\mathsf{MooreSmithCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{UniformCompletion}^{\uparrow}$. It consumes the same separated comparison discipline as chapter 1411 and the same finite numerical readback route as chapter 301 and chapter 38. The chapter names the completion-facing carrier without selecting a limit, quotienting nets, invoking countable choice, asserting host equality of completed objects, importing an ambient completion, or claiming completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3794.1 (CauchyNetCompletion carrier)**.** *A* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, Q, M, U, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-index substrate read by the accepted* $\mathsf{CauchyNet}^{\uparrow}$ *row.*
2. *W is the* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window and common-upper-witness row over D.*
3. *Q is the completion-boundary request attached to the displayed Cauchy-net row.*
4. *M is the* $\mathsf{MooreSmithCompletion}^{\uparrow}$ *handoff row, exposing the same directed-net completion boundary to Moore–Smith consumers.*
5. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row when the consumer reads entourages rather than metric balls.*
6. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row for comparing two displayed completion-boundary reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite readback row attached to the retained directed windows.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *terminal seal reached only after D, W, Q, M, U, S, R have been displayed.*
9. *H records componentwise* hsame *transport for the directed substrate, Cauchy-net row, completion-boundary request, Moore–Smith handoff, uniform handoff, separated comparison, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from directed Cauchy-net evidence through completion-boundary reads, separated comparison, regular-rational readback, and the real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MooreSmithCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected limit, quotient nets, countable choice, host equality of completed objects, an ambient completion object, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionTasteGate single carrier alignment`

Theorem 3794.2 (CauchyNetCompletion NameCert obligations)**.** *For an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{CauchyNetCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the directed substrate, Cauchy-net row, completion-boundary request, Moore–Smith handoff, uniform handoff, separated comparison, regular readback, real seal, transport, replay, provenance, and local naming row;*
2. *directed-net coverage, requiring every completion-facing request to consume D and W before Q, M, U, S, R, A can be inspected;*
3. *Moore–Smith handoff, requiring M to expose the same directed-net boundary that chapter 2190 consumes;*
4. *metric and uniform handoff, requiring* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *consumers to read the boundary through Q and U rather than through an ambient completed object;*
5. *separated comparison discipline, requiring any comparison of two displayed boundary reads to pass through S;*
6. *numerical readback discipline, requiring R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal A is inspected;*
7. *non-escape for selected limits, quotient nets, countable choice, host equality, ambient completion, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3794.1. The tuple displays exactly the directed substrate, the Cauchy-net window row, the completion-boundary request, the Moore–Smith and uniform handoffs, separated comparison, readback, seal, and structural rows.

Directed-net coverage is the first dependency. A completion-facing request cannot reach Q, M, U, S, R, A until the accepted $\mathsf{CauchyNet}^{\uparrow}$ row W over D has been displayed.

The handoff obligations use the sibling completion chapters. The row M feeds the Moore–Smith completion route, while Q and U feed metric and uniform completion consumers over the same displayed directed windows. The separated comparison row S supplies comparison data without host equality.

Finally R and A provide the finite numerical readback and terminal seal, and H, C, P, N preserve, replay, source, and name the same route. Since the excluded completion principles have no carrier coordinate, they cannot become NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionCarrier namecert obligations`

Theorem 3794.3 (CauchyNetCompletion Moore–Smith handoff)**.** *Every* $\mathsf{MooreSmithCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *packet reads the directed-net completion boundary through*

$$D, W, Q \longmapsto M, U, S \longmapsto R, A \longmapsto H, C, P, N.$$

The route starts with the $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row, passes through the Moore–Smith, metric, uniform, and separated comparison rows when those consumers are present, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the* $\mathsf{Real}^{\uparrow}$ *seal only afterward. No quotient net, selected limit, countable-choice schedule, host equality of completion points, ambient completion object, or* $\mathsf{Real}^{\uparrow}$ *completeness row bypasses this route.*

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionCarrier moore smith handoff`

Proof. Project the accepted carrier of Definition 3794.1. The rows D and W are the only directed-net source rows, and Q is the first completion-boundary request attached to them.

Read the sibling handoff next. The Moore–Smith consumer receives M, metric completion consumers read the same boundary through Q, and uniform completion consumers receive U only as a handoff from the displayed Cauchy-net boundary. Comparisons of displayed boundary reads pass through S.

The numerical exit is downstream. The regular rational row R and real seal row A are available only after the directed-net and completion-boundary rows have been replayed, and the structural rows H, C, P, N preserve and name that route.

The carrier inventory contains no selected limit, quotient-net equality, countable-choice selector, host equality, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness theorem. Thus every accepted completion consumer factors through the displayed route. □

Theorem 3794.4 (CauchyNetCompletion choice-free limit boundary)**.** *Any accepted completion-limit read from a* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *packet factors through the displayed rows*

$$D, W, Q, M, U, S, R, A, H, C, P, N.$$

The separated comparison row S *mediates comparison of displayed boundary reads, and the rows* R, A *provide the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal only after the directed windows and completion handoff rows have been exposed. The read exports no selected limit, quotient-net representative, countable-choice schedule, host equality of completion points, ambient completion object, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionCarrier choice free limit boundary`

Proof. Project the carrier of Definition 3794.1. Its coordinates are exactly $D, W, Q, M, U, S, R, A, H, C, P, N$, with D, W supplying the directed substrate and Cauchy-net windows before any completion-boundary request is inspected.

Apply the Moore–Smith handoff theorem. Theorem 3794.3 forces every Moore–Smith, metric, or uniform completion consumer through the displayed route from D, W, Q to M, U, S, then to R, A, and finally to the transport, replay, provenance, and naming rows.

The comparison and numerical exits are therefore internal to the same packet. The row S is the only separated comparison coordinate, while R, A are the only regular-rational readback and real-seal coordinates reachable by the consumer.

It remains to exclude escape data. The carrier definition has no coordinate for a selected limit, quotient net, countable-choice selector, host equality, ambient completion object, or $\mathsf{Real}^{\uparrow}$ completeness theorem, so no accepted completion-limit read can export any of those objects. □

Theorem 3794.5 (CauchyNetCompletion directed-window terminality)**.** *For an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier*

$$K = (D, W, Q, M, U, S, R, A, H, C, P, N),$$

every completion-facing read of $Q, M, U, S, R, A, H, C, P, N$ *has terminal directed-window source* D, W*. In particular, no selected limit, quotient net, countable-choice selector, host equality of completion points, ambient completion object, or* $\mathsf{Real}^{\uparrow}$ *completeness row can supply the first directed witness for the packet.*

Proof. Project the carrier in Definition 3794.1. The only directed substrate row is D, and the only Cauchy-net directed-window row over it is W.

Apply the choice-free boundary theorem, Definition 3794.4. It places all completion-limit reads on the displayed route through $D, W, Q, M, U, S, R, A, H, C, P, N$.

The remaining rows are downstream witnesses. The request row Q, the Moore–Smith and uniform handoff rows M, U, the separated comparison row S, and the readback rows R, A can be inspected only after D, W have been displayed.

Since the excluded objects have no carrier coordinate, none of them can replace D, W as the directed source of an accepted read. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionDirectedWindowTerminality`

Theorem 3794.6 (CauchyNetCompletion directed-window cofinal restriction)**.** *Let* $K = (D, W, Q, M, U, S, R, A, H$ *be an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier. Replace the directed substrate row* D *by a displayed cofinal restricted substrate*

$$D_{\mathrm{cof}} \hookrightarrow D$$

and replace W *by its restricted* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row* W_{cof}*, provided* W_{cof} *still carries the common-upper witnesses used by* W *for completion-boundary requests. Then the completion-facing route*

$$D, W, Q, M, U, S, R, A, H, C, P, N$$

is preserved as the restricted route

$$D_{\mathrm{cof}}, W_{\mathrm{cof}}, Q, M, U, S, R, A, H, C, P, N.$$

In particular, the restricted packet exports no selected limit, quotient net, countable-choice selector, host equality of completion points, ambient completion object, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 3794.1. The directed substrate row D and directed-window row W are the only source rows before the completion-boundary request Q is read.

Use directed-window terminality, Definition 3794.5. It makes D, W terminal for every completion-facing read. A cofinal restricted substrate with the same common-upper witnesses supplies the same terminal source position through $D_{\mathrm{cof}}, W_{\mathrm{cof}}$.

Now apply the Moore–Smith handoff theorem, Definition 3794.3. The completion route still passes from the directed source through Q to the Moore–Smith, metric, uniform, and separated rows M, U, S, then to the regular readback and Real seal rows R, A.

The structural rows are unchanged. Componentwise transport H, displayed replay C, provenance P, and local naming N preserve the same restricted route, while the carrier has no coordinate for selected limits, quotient nets, countable choice, host equality, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionDirectedWindowCofinalRestriction`

Theorem 3794.7 (CauchyNetCompletion directed-window refinement functoriality)**.** *Let* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$ *be an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier. Suppose a first displayed cofinal restriction replaces* D, W *by* $D_{\mathrm{cof}}, W_{\mathrm{cof}}$*, and a second displayed cofinal restriction replaces those rows by*

$$D_{\mathrm{ref}}, W_{\mathrm{ref}}.$$

If each restricted window retains the common-upper witnesses needed for the same completion-boundary request Q*, then the composite restricted route preserves the same CauchyNetCompletion surface:*

$$D, W, Q, M, U, S, R, A, H, C, P, N \quad \rightsquigarrow \quad D_{\mathrm{ref}}, W_{\mathrm{ref}}, Q, M, U, S, R, A, H, C, P, N.$$

The composite route exports no selected limit, quotient net, countable-choice schedule, host equality of completion points, ambient completion object, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with directed-window terminality, Definition 3794.5. It makes the displayed directed-window rows the source of every completion-facing read, so the first cofinal restriction can replace D, W only by another displayed terminal source row for the same request.

Apply cofinal restriction, Definition 3794.6, to the first restriction and then to the second. The retained common-upper witnesses keep the completion-boundary request Q and the handoff rows $M, U, S, R, A, H, C, P, N$ on the same route.

Use the Moore–Smith handoff theorem to read the composite as one completion-facing package. The sibling Moore–Smith, metric, uniform, separated, regular-rational, and Real rows are not recomputed; they are transported and replayed through the final restricted window.

The carrier has no coordinate for selected limits, quotient nets, countable choice, host equality, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness. Thus composing two displayed cofinal restrictions is functorial only for the visible directed-window route, and it cannot export any excluded completion principle. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionDirectedWindowRefinementFunctoriality`

Theorem 3794.8 (CauchyNetCompletion separated-comparison exhaustion)**.** *For an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$*, every comparison between two displayed completion-boundary reads is exhausted by the separated row* S*. The comparison may use* H, C, P, N *to preserve, replay, source, and name the row, but it exports no quotient-net equality, host equality, ambient completion equality, selected limit, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionSeparatedComparisonExhaustion`

Proof. Start from the NameCert obligations of Definition 3794.2. They identify S as the separated comparison row attached to the displayed completion-boundary request.

Use Definition 3794.4. Any completion-limit read must first pass through D, W, Q, M, U and reaches comparison only at S.

The structural rows do not add a new comparison source. They transport, replay, remember provenance, and name the same separated row, so the comparison inventory is exhausted by S.

The carrier has no quotient-net, host-equality, ambient-completion, selected-limit, countable-choice, or $\mathsf{Real}^{\uparrow}$-completeness coordinate. Those excluded objects therefore cannot appear as comparison evidence. □

Theorem 3794.9 (CauchyNetCompletion uniform handoff nonescape)**.** *Every* UniformCompletion$^{\uparrow}$ *consumer of an accepted* CauchyNetCompletion$^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$ *must read its completion boundary through* U *after the directed-window source* D, W *and the request row* Q*. The handoff cannot escape through a selected limit, quotient net, countable-choice selector, host equality, ambient completion object, or* Real$^{\uparrow}$ *completeness row.*

Proof. Project the carrier. The uniform handoff row is U, and it is listed only after the directed substrate D, the Cauchy-net window W, and the completion-boundary request Q.

Apply Definition 3794.3. It sends every Moore–Smith, metric, or uniform completion consumer through the displayed route from D, W, Q to M, U, S.

The choice-free boundary theorem, Definition 3794.4, keeps the later readback rows R, A, H, C, P, N downstream of the same route.

Thus a uniform consumer that bypasses U or replaces D, W, Q by any excluded completion object is outside the accepted CauchyNetCompletion$^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionUniformHandoffNonescape`

Theorem 3794.10 (CauchyNetCompletion root filter admission)**.** *Every root completion consumer of an accepted* CauchyNetCompletion$^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$ *must admit the directed substrate* D*, retained directed-window row* W*, and completion-boundary request* Q *before Moore–Smith, metric, uniform, separated, readback, or Real-seal rows are inspected. No root consumer may replace* D, W, Q *by a selected limit, quotient net, countable-choice selector, host completion equality, ambient completion object, or* Real$^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionRootFilterAdmission`

Proof. Project the carrier of Definition 3794.1. The first three root rows are exactly D, W, Q, and the Moore–Smith, uniform, separated, readback, and Real-seal rows occur only downstream.

Apply the NameCert obligations of Definition 3794.2. Directed-net coverage requires a completion-facing request to consume D and W before Q, M, U, S, R, A can be inspected.

The Moore–Smith handoff, Definition 3794.3, keeps metric and uniform consumers on the same route. Thus root admission starts with D, W, Q for every completion consumer.

The excluded completion objects have no carrier coordinate, so none can serve as the admitted root filter row. □

Theorem 3794.11 (CauchyNetCompletion root eventual stability)**.** *Suppose an accepted* CauchyNetCompletion$^{\uparrow}$ *carrier retains a directed-window row* W *over* D*, and a later common-upper-window witness replaces* W *by a retained row* W' *over the same directed substrate and completion-boundary request* Q*. Then the accepted packet is preserved through the separated comparison row* S*, regular readback row* R*, Real seal* A*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming row* N*.*

Proof. Start with the directed-window terminality theorem, Definition 3794.5. It makes D, W the terminal directed-window source for every completion-facing read.

The later common-upper-window witness is still a retained directed-window row over the same D and Q. Replacing W by W' therefore changes only the displayed window coordinate and not the completion-boundary request or the sibling handoff route.

Apply the choice-free boundary theorem, Definition 3794.4. The rows S, R, A are downstream of the directed-window and completion-boundary route, so their accepted reads are preserved by the later witness.

Finally the structural rows H, C, P, N transport, replay, source, and name the same retained packet. Since no selected limit, quotient net, countable choice, host equality, ambient completion, or $\mathsf{Real}^{\uparrow}$ completeness row participates, eventual stability is a finite retained-window preservation claim. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionRootEventualStability`

Theorem 3794.12 (CauchyNetCompletion root seal nonescape)**.** *In every accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$*, the Real seal* A *cannot be read before the directed substrate* D*, directed-window row* W*, completion-boundary request* Q*, Moore–Smith handoff* M*, uniform handoff* U*, separated comparison row* S*, and regular readback row* R *have been displayed. Reading* A *exports no selected limit, quotient net, countable choice, host completion equality, ambient completion, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier. The row A is listed after D, W, Q, M, U, S, R, and the carrier gives no alternate Real-seal source.

Apply Definition 3794.3. It routes Moore–Smith, metric, and uniform completion consumers from D, W, Q through M, U, S before the numerical readback rows are reached.

Use the choice-free limit boundary of Definition 3794.4. That theorem places R, A, H, C, P, N downstream of the displayed directed-net completion route and excludes hidden limit data.

The carrier contains no selected-limit, quotient-net, countable-choice, host-equality, ambient-completion, or $\mathsf{Real}^{\uparrow}$-completeness coordinate. Therefore the root Real seal cannot export any of those objects. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionRootSealNonescape`

Falsifiable prediction: If a directed-net completion consumer reads a boundary without first displaying the $\mathsf{CauchyNet}^{\uparrow}$ directed-window row and the Moore–Smith, metric, or uniform handoff row it consumes, it is not a $\mathsf{CauchyNetCompletion}^{\uparrow}$ packet.

Independence witness: cauchynet, moore-smith-completion, metriccompletion, uniformcompletion, separatedmetric, regseqrat, real: the packet is not bijective to these siblings because it binds the directed Cauchy-net carrier, completion-boundary request, sibling handoffs, separated comparison, finite readback, and terminal seal in one local NameCert route.

Theorem 3794.13 (CauchyNetCompletion public handoff)**.** *The public completion surface of an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$ *is the reusable handoff package formed by the directed substrate* D*, the retained* $\mathsf{CauchyNet}^{\uparrow}$ *directed-window row* W*, the completion-boundary request* Q*, the Moore–Smith, metric, and uniform handoff rows* M, U*, the separated comparison row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* A*, and the structural rows* H, C, P, N*. Any downstream completion consumer may reuse this package only as the displayed directed-net completion route; it receives no selected limit, quotient net, countable-choice schedule, ambient completion object, host equality of completed points, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the carrier and the NameCert obligations. They display the directed substrate, the Cauchy-net window, the completion-boundary request, the sibling completion handoffs, separated comparison, numerical readback, Real seal, transport, replay, provenance, and local naming rows.

Use the Moore–Smith handoff and choice-free limit boundary. These theorems force every Moore–Smith, metric, and uniform completion read through $D, W, Q, M, U, S, R, A, H, C, P, N$ and

exclude selected limits, quotient nets, countable choice, host equality, ambient completion, and Real completeness from the route.

Apply directed-window terminality, cofinal restriction, root eventual stability, and root seal nonescape. They make the directed-window source reusable under retained windows and cofinal restriction while keeping the terminal Real seal behind the displayed completion route.

Thus the named rows assemble a public handoff surface: a downstream consumer can cite the package as completion-facing data, but cannot replace it by selected limits, quotient nets, or an ambient Real-completeness principle. □

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionPublicHandoff`

Theorem 3794.14 (CauchyNetCompletion regular-sequence public bridge)**.** *Suppose an accepted* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *carrier* $K = (D, W, Q, M, U, S, R, A, H, C, P, N)$ *factors its directed Cauchy-net packet through a cofinal unary* $\mathsf{StreamName}^{\uparrow}$ *schedule. If the reads along that schedule satisfy the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity predicate and the separated comparison exhausted by* S *is the displayed* $\mathsf{Real}^{\uparrow}$ *seal* A*, then the* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *public handoff exports only the same regular-sequence completion data*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ S,\ A,\ H,\ C,\ P,\ N.$$

It exports no additional directed-net limit, quotient net, selected representative, countable-choice schedule, host equality of completed points, ambient completion object, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyNetCompletionUp.CauchyNetCompletionRegularSequencePublicBridge`

Proof. Start from the public handoff theorem. The public surface is the displayed route through $D, W, Q, M, U, S, R, A, H, C, P, N$, with no selected limit, quotient net, countable choice, host equality, ambient completion, or Real-completeness row.

Use directed-window terminality and cofinal restriction. The cofinal unary $\mathsf{StreamName}^{\uparrow}$ schedule may replace the displayed directed-window source only as a retained terminal source for the same completion-boundary request Q; it does not add a new limit coordinate.

Read the regularity assumption through the existing readback row R. Since the schedule reads satisfy the $\mathsf{RegSeqRat}^{\uparrow}$ regularity predicate, the numerical exit of the restricted route is the regular-sequence readback already named by R.

Apply separated-comparison exhaustion. The row S exhausts comparisons between displayed boundary reads, and by hypothesis its separated comparison is precisely the displayed $\mathsf{Real}^{\uparrow}$ seal A.

Finally use uniform-handoff nonescape and the Moore–Smith handoff. They keep every completion consumer on the same displayed route, so the public packet can export only the regular-sequence completion data carried by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, S, A, H, C, P, N and none of the excluded completion principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyNetCompletion}^{\uparrow}$ packet is generated from a directed substrate, a CauchyNet directed-window row, a completion-boundary request, MooreSmithCompletion, MetricCompletion, UniformCompletion, SeparatedMetric, RegSeqRat, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNetCompletion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 3794.1, Definition 3794.2, Definition 3794.5, Definition 3794.6, Definition 3794.11, Definition 3794.12, Definition 3794.13, and Definition 3794.14 expose the finite directed-net completion route as a public handoff and paper bridge through directed-window data, cofinal restriction, root eventual stability, root seal, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ dependencies.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyNetCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient nets, countable choice, host equality of completed objects, ambient completion, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Bridge checking requires a Lean standard-bridge target for the public directed-net completion handoff and regular-sequence public bridge.

Chapter 3795

A Concrete Naming Certificate for $\mathsf{RealTightness}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RealTightness}^{\uparrow}$ packet records located dyadic trap data over a displayed $\mathsf{Real}^{\uparrow}$ source as finite NameCert evidence. It consumes the real-name seal of chapter 38, the dyadic rational grid of chapter 291, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, the located interval surface of chapter 1709, the bounded located-set row of chapter 2176, and the regular Cauchy located-order discipline of chapter 1681. The packet gives later Real and Completion consumers a finite located-tightness route; it is not Heine–Borel, open-cover compactness, trichotomy, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3795.1 (Real tightness carrier)**.** *A* $\mathsf{RealTightness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (R, D, S, Q, I, B, O, T, H, C, P, N)$$

with the following visible rows:

1. *R is the source* $\mathsf{Real}^{\uparrow}$ *row whose name is being trapped.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid row supplying dyadic endpoints, midpoint refinements, and tolerance comparisons.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the requested real-name observations.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
5. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row recording the current located interval trap.*
6. *B is the* $\mathsf{LocatedBoundedRealSet}^{\uparrow}$ *bounded-source row that bounds the admitted trap requests.*
7. *O is the* $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$ *row recording located-order comparisons between the real-name readback and the dyadic trap endpoints.*
8. *T is the located dyadic trap ledger: a finite list of intervals, dyadic tolerances, inside/outside locator reads, and retained-window witnesses.*
9. *H records componentwise* hsame *transport for R, D, S, Q, I, B, O, T and the structural rows.*
10. *C records displayed* Cont *replay of the real-name read, dyadic trap refinement, located-interval admission, bounded-set read, located-order comparison, and terminal trap ledger.*

11. *P is the* Pkg *provenance over* $\mathsf{RealTightness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedBoundedRealSet}^{\uparrow}$, $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTightness}^{\uparrow}}$ *row.*

The carrier has no coordinate for Heine–Borel, open-cover compactness, trichotomy of arbitrary reals, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealTightnessUp.RealTightnessTasteGate single carrier alignment`

Theorem 3795.2 (Real tightness NameCert obligations)**.** *For an accepted* $\mathsf{RealTightness}^{\uparrow}$ *carrier* $Z = (R, D, S, Q, I, B, O, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealTightness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real source, dyadic grid, stream windows, regular rational readback, located interval, bounded located set, located-order row, trap ledger, transport, replay, provenance, and local naming row;*
2. *dyadic trap exposure, requiring every retained trap in T to display dyadic endpoints from D and the matching finite observation window from S;*
3. *located interval admission, requiring each trap read to pass through I and the bounded-source row B before it can be consumed as a located real interval;*
4. *regular Cauchy located-order comparison, requiring the readback row Q and the comparison row O to certify the displayed relation between R and the dyadic trap endpoints;*
5. *replay stability under componentwise* hsame *transport and displayed* Cont *routes for R, D, S, Q, I, B, O, T;*
6. *nonescape for Heine–Borel, open-cover compactness, trichotomy, countable choice, quotient real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3795.1. The tuple lists exactly the real source, dyadic grid, finite window, regular readback, located interval, bounded-set, located-order, trap, transport, replay, provenance, and naming rows.

Trap exposure is finite. Each trap row in T reads dyadic endpoints and tolerances from D, then matches them to the finite observation window named by S and the regular rational readback named by Q.

Located admission is downstream of those displayed rows. The located interval row I records the interval trap, while B records that the trap request stays inside the bounded located-set surface available to the consumer.

The comparison step is the located-order row O. It compares the regular Cauchy readback of Q with the dyadic endpoints retained in T, and it is transported and replayed only by H and C.

The carrier inventory contains no coordinate for Heine–Borel, open-cover compactness, trichotomy, countable choice, quotient real equality, or ambient real completeness. Hence the six rows exhaust the local NameCert surface. □

Theorem 3795.3 (Real tightness located trap route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing located trap read of an accepted* $\mathsf{RealTightness}^{\uparrow}$ *carrier factors through the finite route*

$$R \longmapsto S, Q \longmapsto D, I, B, O \longmapsto T, H, C, P, N.$$

The route starts with the real-name source, reads finite stream windows and regular rational approximants, opens the dyadic grid and located interval rows, checks boundedness and located order, and only then exports the trap ledger as the named $\mathsf{RealTightness}^{\uparrow}$ *surface. It exports no Heine–Borel theorem, open-cover compactness principle, trichotomy classifier, countable-choice selector, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with an accepted carrier $Z = (R, D, S, Q, I, B, O, T, H, C, P, N)$. The source real-name row is R, and the first observable data are the finite windows S and the regular rational readback Q attached to that source.

The dyadic and located stages follow. The row D supplies endpoints and tolerances, I admits the current located interval, B bounds the trap request, and O compares the readback with the displayed endpoints through the regular Cauchy located-order surface.

The trap ledger T is therefore downstream of all numeric and located rows. The structural rows H, C, P, N transport, replay, record provenance, and name that same route without adding a host-level compactness or completeness object.

Since no carrier coordinate stores Heine–Borel, open-cover compactness, trichotomy, countable choice, quotient real equality, or ambient real completeness, every accepted located trap read remains inside the displayed finite route. □

Falsifiable prediction: Every accepted RealTightnessUp consumer read of a located dyadic trap factors through RealUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, LocatedRealIntervalUp, LocatedBoundedRealSetUp, RegularCauchyLocatedOrderUp, and the local trap ledger before it can be exported.

Independence witness: real, dyadicratcore, regseqrat, streamname, locatedrealinterval, locatedboundedrealset, regularcauchylocatedorder: the packet is not bijective to these siblings because it binds the real source, finite windows, regular readback, dyadic trap grid, located interval, bounded located-set, located-order comparison, and local NameCert row as one located-tightness route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealTightness}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTightness}^{\uparrow}$ packet is generated from a Real source row, DyadicRatCore grid row, StreamName finite-window row, RegSeqRat readback row, LocatedRealInterval row, LocatedBoundedRealSet row, RegularCauchyLocatedOrder row, located dyadic trap ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealTightness}^{\uparrow}}$, seed)

Scope closed: Definition 3795.1, Definition 3795.2, and Definition 3795.3 seed the finite located-tightness carrier and trap route for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealTightness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Heine–Borel, open-cover compactness, trichotomy, countable choice, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic trap exposure, located interval admission, bounded-source discipline, regular Cauchy located-order comparison, replay stability, and nonescape for BEDC.Derived.RealTightnessUp.

Chapter 3796

A Concrete Naming Certificate for $\mathsf{SchwarzLemma}^{\uparrow}$

Following Schwarz and Ahlfors, the $\mathsf{SchwarzLemma}^{\uparrow}$ packet names the unit-disk Schwarz lemma as finite BEDC certificate data. It consumes the holomorphic-disk source interface of chapter 68, the coordinate and boundary rows of chapter 377, the complex carrier of chapter 39, and the contraction handoff of chapter 3682. The packet records the pointed disk map, the zero-fixing row, the unit-bound row, the modulus comparison ledger, transport, provenance, and local NameCert rows; it is not a host theorem about arbitrary analytic continuation or a completed complex function space.

Definition 3796.1 (Schwarz lemma carrier)**.** *A* $\mathsf{SchwarzLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (H, D, Z, B, M, R, T, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Holomorphic}^{\uparrow}$ *row naming the disk-local complex map over the* $\mathsf{Complex}^{\uparrow}$ *carrier.*
2. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *source and target disk-coordinate row for the displayed input and output points.*
3. *Z is the zero-fixing row recording that the displayed map sends the named disk origin to the named disk origin.*
4. *B is the unit-bound row recording that displayed disk inputs are routed to displayed disk outputs.*
5. *M is the modulus-comparison row recording the Schwarz-lemma read $|f(z)| \leq |z|$ on the displayed disk point and the boundary equality refusal attached to the same row.*
6. *R is the route row through* $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, *and the local modulus ledger.*
7. *T stores componentwise* hsame *and displayed* Cont *transport for the holomorphic map row, disk-coordinate row, zero-fixing row, unit-bound row, modulus-comparison row, and route row.*
8. *P is the* Pkg *provenance over* $\mathsf{SchwarzLemma}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SchwarzLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, D, Z, B, M, R, T, P, N$. It has no coordinate for a host identity theorem, Riemann mapping theorem, unlogged analytic continuation, completed function-space equality, or selected boundary extremal map.

Lean4 (definition) `BEDC.Derived.SchwarzLemmaUp.SchwarzLemmaUp`
Lean4 ✓ `BEDC.Derived.SchwarzLemmaUp.TasteGate.SchwarzLemmaTasteGate single carrier alignment`

Theorem 3796.2 (Schwarz lemma NameCert obligations)**.** *For every accepted* $\mathsf{SchwarzLemma}^{\uparrow}$ *carrier*

$$L = (H, D, Z, B, M, R, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwarzLemma}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission for the displayed holomorphic disk map, disk coordinates, zero-fixing row, unit-bound row, modulus-comparison row, route row, transport rows, provenance, and local name;*
2. *classifier stability under componentwise* hsame *and displayed* Cont *transport of exactly those rows;*
3. *zero-fixing exactness, requiring the Schwarz-lemma read to pass through Z before any modulus comparison is exported;*
4. *disk-bound exactness, requiring every input-output read to pass through the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate and unit-bound rows before the local name is consumed;*
5. *nonescape for the identity theorem, Riemann mapping, host analytic continuation, completed complex function-space equality, and selected boundary extremal maps.*

Proof. Carrier admission is projection from Definition 3796.1. The tuple exposes the holomorphic source row, disk-coordinate row, zero-fixing row, unit-bound row, modulus-comparison ledger, route, transport, provenance, and local name as one finite packet.

Classifier stability is componentwise. A transported packet may compare the same displayed rows after hsame and Cont replay, but it cannot keep the modulus comparison while dropping the zero-fixing or unit-bound rows.

Zero-fixing and disk-bound exactness follow from the route row R. The modulus comparison row M is read only after H, D, Z, B have been displayed, so a consumer cannot use it as an arbitrary disk-map contraction theorem.

The nonescape clauses are read from the carrier inventory. Since no row stores a host identity theorem, Riemann mapping theorem, analytic-continuation principle, completed function-space equality, or selected boundary extremal map, the local NameCert cannot export one. □

Theorem 3796.3 (Schwarz lemma disk-contraction handoff)**.** *Every disk-contraction consumer of an accepted* $\mathsf{SchwarzLemma}^{\uparrow}$ *packet factors through the ordered route*

$$\mathsf{Holomorphic}^{\uparrow} \longrightarrow \mathsf{Complex}^{\uparrow} \longrightarrow \mathsf{UnitDisk}^{\uparrow} \longrightarrow \mathsf{SchwarzLemma}^{\uparrow} \longrightarrow \mathsf{SchwarzPickDiskContraction}^{\uparrow}.$$

The handoff supplies only the displayed holomorphic disk-map row, zero-fixing row, unit-bound row, modulus-comparison row, transport, provenance, and local NameCert data. It supplies no full complex analytic identity theorem, Riemann mapping theorem, host analytic continuation principle, or ambient completed function-space equality.

Proof. Start with the holomorphic source row H over the complex carrier and the disk-coordinate row D. These rows are the only source of the displayed map and input-output points available to the handoff.

The zero-fixing row Z and unit-bound row B then restrict the read to the pointed disk situation. The modulus-comparison row M records the Schwarz-lemma inequality only for that displayed route.

Finally pass the same rows through R, T, P, N and into the $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ consumer. The downstream contraction packet can read the displayed disk contraction, but no coordinate in L adds identity-theorem reasoning, Riemann mapping, host analytic continuation, or ambient function-space equality. □

Falsifiable prediction: If a purported SchwarzLemmaUp packet exports a modulus comparison without displaying the zero-fixing row and the UnitDisk route, it is not a $\mathsf{SchwarzLemma}^{\uparrow}$ carrier.

Independence witness: holomorphic, complex, unitdisk, schwarz-pick-disk-contraction: the packet is not bijective to any one sibling because it binds the zero-fixing and unit-bound rows to a local modulus-comparison NameCert before the disk-contraction handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwarzLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwarzLemma}^{\uparrow}$ packet is generated from a holomorphic disk-map row, complex carrier row, UnitDisk coordinate row, zero-fixing row, unit-bound row, modulus-comparison row, route row, transport, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwarzLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3796.1, Definition 3796.2, and Definition 3796.3 seed the pointed disk-map carrier, NameCert obligations, and disk-contraction handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwarzLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a full complex analytic identity theorem, Riemann mapping theorem, host analytic continuation principle, Lean verification, or bridge checking for $\mathsf{SchwarzLemma}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, zero-fixing exactness, unit-bound exactness, modulus comparison, route preservation, transport stability, provenance, and local naming for BEDC.Derived.SchwarzLemmaUp.

Chapter 3797

A Concrete Naming Certificate for $\mathsf{CauchyProductCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyProductCompletion}^{\uparrow}$ packet records the constructive product of two completed real carriers by finite Cauchy windows, regular rational readback, and an explicit completion seal. It keeps the product-completion surface separate from ambient Cartesian powersets: each exported product read must still name the stream windows, dyadic observations, product budget, regular-sequence classifier, and real-completion seal that make the read finite.

Definition 3797.1 (CauchyProductCompletion carrier)**.** *A* $\mathsf{CauchyProductCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S_0, S_1, D_0, D_1, B, R_0, R_1, L_0, L_1, E, H, C, P, N)$$

with the following displayed rows:

1. S_0, S_1 *are paired* $\mathsf{StreamName}^{\uparrow}$ *windows for the two completion-facing coordinates.*
2. D_0, D_1 *are* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows for the finite rational approximants read from the two streams.*
3. B *is the* $\mathsf{CauchyProduct}^{\uparrow}$ *budget row, recording the common tolerance window used to multiply or pair the displayed approximants.*
4. R_0, R_1 *are* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier rows, certifying that each coordinate read is regular enough to enter the real-completion route.*
5. L_0, L_1 *are* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility rows, witnessing that the coordinate windows are read only through the completion seal used by the L10 route.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *export seal for the product-completion read.*
7. H *records the* hsame *transports for stream names, dyadic observations, regular classifiers, product budget, limit seals, and real export.*
8. C *records the* Cont *replays that move from stream windows through dyadic observations, regular-sequence readback,* $\mathsf{CauchyProduct}^{\uparrow}$ *budget,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *compatibility, and the* $\mathsf{Real}^{\uparrow}$ *seal.*
9. P *is the* Pkg *provenance over* $\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductCompletion}^{\uparrow}}$ *row.*

The accepted carrier contains no ambient product set, no selected representative of a completion quotient, no unrestricted sequence equality, and no completion principle beyond the displayed finite-window route.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionUp.CauchyProductCompletionTasteGate single carrier alignment`

Theorem 3797.2 (CauchyProductCompletion NameCert obligations)**.** *For an accepted packet* $Q = (S_0, S_1, D_0, D_1, B, R_0, R_1, L_0, L_1, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductCompletion}^\uparrow}$ *obligation surface consists exactly of carrier admission, classifier stability, budget factorization, completion-seal nonescape, and ledger exactness for the displayed rows* $S_0, S_1, D_0, D_1, B, R_0, R_1, L_0, L_1, E, H, C, P, N$*.*

Proof. Carrier admission reads the two $\mathsf{StreamName}^\uparrow$ windows first, then admits the two $\mathsf{DyadicRatCore}^\uparrow$ observations only as finite approximants attached to those windows. The $\mathsf{RegSeqRat}^\uparrow$ rows certify the regular readback needed by the real-completion route.

Classifier stability is carried by H. Transporting stream names, dyadic observations, regular classifiers, product budget, limit seals, and the real export moves the whole packet together, so no coordinate can be reclassified by an external quotient equality.

Budget factorization is supplied by B and replayed by C. The product-facing read reaches $\mathsf{CauchyProduct}^\uparrow$ only after both coordinate windows and dyadic observations are displayed, and it reaches $\mathsf{Real}^\uparrow$ only after $\mathsf{CauchyLimitSeal}^\uparrow$ compatibility has been exposed.

Completion-seal nonescape follows from the L_0, L_1, E rows. They bind the coordinate reads to the L10 sibling routes of chapter 126, chapter 291, chapter 301, chapter 464, chapter 386, and chapter 38.

Ledger exactness is an inspection of the packet. Every exported read is one of the displayed rows, so the local NameCert has no coordinate from which to recover an ambient product object, a representative-choice operation, unrestricted sequence equality, or a completion principle outside the finite route. □

Theorem 3797.3 (CauchyProductCompletion budget factorization)**.** *Every completion-facing product read exported by* $\mathsf{CauchyProductCompletion}^\uparrow$ *factors through* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{DyadicRatCore}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{CauchyProduct}^\uparrow$*,* $\mathsf{CauchyLimitSeal}^\uparrow$*, and* $\mathsf{Real}^\uparrow$ *before export. In particular, the product budget is not a free-standing multiplication oracle: it is a finite tolerance-window route whose coordinate streams, dyadic observations, regular classifiers, completion seals,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows remain visible at the export boundary.*

Proof. Start with a completion-facing product read. By Definition 3797.1, the only carrier rows available before export are $S_0, S_1, D_0, D_1, B, R_0, R_1, L_0, L_1, E, H, C, P, N$.

The first stage is the paired stream window. The rows S_0, S_1 force the read to pass through the $\mathsf{StreamName}^\uparrow$ route before any dyadic observation is available, and D_0, D_1 then expose the $\mathsf{DyadicRatCore}^\uparrow$ approximants.

The second stage is regularization and budget. The rows R_0, R_1 record the $\mathsf{RegSeqRat}^\uparrow$ classifiers, while B records the $\mathsf{CauchyProduct}^\uparrow$ tolerance budget that combines the coordinate approximants.

The final stage is sealing and export. The rows L_0, L_1 expose $\mathsf{CauchyLimitSeal}^\uparrow$ compatibility before E exports a $\mathsf{Real}^\uparrow$ product-completion read. Since H, C, P, N are the only structural rows, the export cannot bypass this route through an ambient product, selected completion representative, unrestricted sequence equality, or hidden real-completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletion}^{\uparrow}$ packet is generated from paired StreamName windows, DyadicRatCore observations, RegSeqRat classifiers, a CauchyProduct budget row, CauchyLimitSeal compatibility rows, a Real export seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3797.1, Definition 3797.2, and Definition 3797.3 bind the finite product-completion seed used by the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a completed product universal property, quotient equality of completed reals, arbitrary sequence multiplication, compactness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, classifier stability, budget factorization, completion-seal nonescape, and ledger exactness for BEDC.Derived.CauchyProductCompletionUp.

Chapter 3798

A Concrete Naming Certificate for $\mathsf{CantorSpaceCompactness}^{\uparrow}$

Following Brouwer and Bishop, the $\mathsf{CantorSpaceCompactness}^{\uparrow}$ packet records the constructive compactness route for Boolean streams as a finite NameCert surface adjacent to $\mathsf{CantorSpace}^{\uparrow}$ in chapter 1475. It reads finite prefix data through $\mathsf{FanTheorem}^{\uparrow}$, obstruction rows through $\mathsf{KleeneTree}^{\uparrow}$, and observation windows through $\mathsf{StreamName}^{\uparrow}$; it does not import open-cover compactness, countable choice, quotient equality of infinite streams, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3798.1 (CantorSpaceCompactness carrier)**.** *A* $\mathsf{CantorSpaceCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, F, T, S, B, H, R, Q, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix source row, including the Boolean prefix observations and cylinder reads named in Definition 1475.1;*
2. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *row, recording the finite decidable bar, its inspected prefix depth, and the finite branch-window witness;*
3. *T is the* $\mathsf{KleeneTree}^{\uparrow}$ *obstruction row, used only to record that a displayed infinite-branch escape is absent from the finite fan route;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row that schedules the finite prefix requests consumed by C and F;*
5. *B is the prefix-cover row, listing the finitely many Boolean cylinders whose union covers the inspected prefix surface;*
6. *H records componentwise* hsame *transport for the Cantor-space, fan, obstruction, stream, prefix-cover, continuation, provenance, and local naming rows;*
7. *R records displayed* Cont *replay from a finite prefix request through the fan-depth row and the prefix-cover row;*
8. *Q is the refusal row excluding open-cover compactness, countable choice, quotient equality of infinite streams, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*
9. *P is the* Pkg *provenance over* $\mathsf{CantorSpaceCompactness}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *prefix covers,* BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorSpaceCompactness}^{\uparrow}}$ *row naming the displayed finite compactness packet and its permitted consumer reads.*

The classifier compares accepted packets only through the displayed Cantor prefix, fan-depth, obstruction, stream-window, and prefix-cover rows, transported by H and replayed by R. No classifier coordinate compares ambient infinite streams or completed function-space objects.

Lean4 ✓ `BEDC.Derived.CantorSpaceCompactnessUp.CantorSpaceCompactnessTasteGate single carrier alignment`

Theorem 3798.2 (CantorSpaceCompactness NameCert obligations)**.** *For every accepted* CantorSpaceCompactness *carrier $K = (C, F, T, S, B, H, R, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorSpaceCompactness}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed* $\mathsf{CantorSpace}^{\uparrow}$ *source,* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar row,* $\mathsf{KleeneTree}^{\uparrow}$ *obstruction row,* $\mathsf{StreamName}^{\uparrow}$ *schedule, prefix-cover ledger, transport, replay, refusal, provenance, and local naming row;*
2. *prefix-cover exactness, requiring every accepted compactness read to use the same finite Boolean cylinders listed in B and the same inspected prefix schedule in S;*
3. *fan-depth stability, requiring the finite bar depth in F to bound the cylinders consumed by a downstream compactness read;*
4. *obstruction nonescape, requiring T to remain a finite refusal row rather than a source of an infinite branch;*
5. *ledger nonescape, excluding open-cover compactness, countable choice, quotient equality of infinite streams, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection of Definition 3798.1. The packet exposes exactly $C, F, T, S, B, H, R, Q, P, N$ before any compactness-facing read is permitted.

Prefix-cover exactness reads B together with the $\mathsf{StreamName}^{\uparrow}$ schedule S. Fan-depth stability reads F and forces the listed cylinders to sit below the inspected finite bar depth.

The obstruction row T is then read only as a finite nonescape boundary. Transport by H and replay by R preserve the same displayed route, while Q, P, N record refusal, provenance, and local naming. Since none of these rows contains open-cover compactness, countable choice, quotient equality, or ambient real completeness, the listed obligations exhaust the local surface. □

Theorem 3798.3 (CantorSpaceCompactness finite prefix subcover)**.** *Let $K = (C, F, T, S, B, H, R, Q, P, N)$ be an accepted* $\mathsf{CantorSpaceCompactness}^{\uparrow}$ *carrier. Every compactness-facing read that asks for a cover of a displayed* $\mathsf{CantorSpace}^{\uparrow}$ *prefix is answered by the finite prefix-cover row B after the fan-depth row F has fixed the inspected depth and the* $\mathsf{StreamName}^{\uparrow}$ *schedule S has fixed the visible positions. The subcover is therefore a finite list of Boolean cylinders over the displayed prefix surface, not an open-cover compactness principle and not a choice-selected family of cylinders.*

Proof. Start with the $\mathsf{CantorSpace}^{\uparrow}$ row C. By Definition 1475.5, every cylinder read of C factors through finite $\mathsf{StreamName}^{\uparrow}$ windows, finite Boolean observations, and local NameCert rows.

Read the fan row F. It supplies a finite decidable bar depth and the inspected branch-window witness, so the compactness-facing request is reduced to the cylinders visible below that depth.

Now use the prefix-cover ledger B. The row lists the finitely many Boolean cylinders that cover the inspected prefix surface, and the replay row R routes the consumer through exactly that

ledger. The refusal row Q excludes open-cover compactness, countable choice, quotient stream equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the exported subcover. □

Theorem 3798.4 (CantorSpaceCompactness nonescape)**.** *For every accepted* $\mathsf{CantorSpaceCompactness}^{\uparrow}$ *carrier* $K = (C, F, T, S, B, H, R, Q, P, N)$*, any downstream consumer of compactness data remains inside the route*

$$C, S \longmapsto F \longmapsto B \longmapsto T \longmapsto H, R, Q, P, N.$$

The route exports only finite Boolean prefix covers for the displayed Cantor-space packet. It exports no open-cover compactness theorem, no countable choice principle, no quotient equality of streams, no selected infinite branch through a $\mathsf{KleeneTree}^{\uparrow}$ *obstruction row, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 3798.3. A compactness-facing read first consumes the displayed Cantor prefix row C and the stream schedule S, then reads the fan-depth row F and the finite prefix-cover ledger B.

The obstruction row T is downstream of that finite route. It records that the displayed route has no accepted infinite-branch escape; it does not provide a selected branch or a host-level tree path.

Finally inspect H, R, Q, P, N. These rows transport, replay, refuse, source, and name only the displayed finite packet. Therefore a consumer has no row from which to recover open-cover compactness, countable choice, quotient stream equality, an infinite branch selector, or ambient real completeness. □

Falsifiable prediction: Every $\mathsf{CantorSpaceCompactness}^{\uparrow}$ compactness read factors through a displayed $\mathsf{CantorSpace}^{\uparrow}$ prefix, a finite $\mathsf{FanTheorem}^{\uparrow}$ bar-depth row, and a finite prefix-cover ledger before any consumer sees a compactness-shaped output.

Independence witness: cantorspace, fantheorem, kleenetree, streamname: $\mathsf{CantorSpaceCompactness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Cantor prefix data, fan-depth coverage, obstruction nonescape, stream scheduling, prefix-cover rows, transport, continuation replay, package provenance, refusal, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSpaceCompactness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorSpaceCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3798.1, Definition 3798.2, Definition 3798.3, and Definition 3798.4 seed the constructive finite-prefix compactness packet over $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, prefix covers, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorSpaceCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, countable choice, quotient equality of streams, selected infinite branches, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix subcover exactness, fan-depth stability, obstruction nonescape, and local NameCert replay for BEDC.Derived.CantorSpaceCompactnessUp.

Constructive story: A $\mathsf{CantorSpaceCompactness}^{\uparrow}$ packet is generated from CantorSpace finite-prefix rows, FanTheorem finite-bar rows, KleeneTree obstruction rows, StreamName schedules, prefix-cover ledgers, componentwise hsame transport, displayed Cont replay, refusal, Pkg provenance, and a local NameCert row.

Chapter 3799

A Concrete Naming Certificate for $\mathsf{CauchySchlomilchCondensation}^{\uparrow}$

Following Knopp and Hardy on condensation tests for positive series, the $\mathsf{CauchySchlomilchCondensation}^{\uparrow}$ packet records the finite comparison route between a monotone nonnegative series and its Schlomilch-block condensation. It sits beside the dyadic block discipline of chapter 3598, the integral comparison surface of chapter 2259, and the real series endpoint route of chapter 1581. The packet names block maps, block masses, monotonicity windows, tail comparisons, and endpoint seals as finite NameCert data; it does not assert an unrestricted host convergence theorem or choose an infinite sum.

Definition 3799.1 (CauchySchlomilchCondensation carrier)**.** *A* $\mathsf{CauchySchlomilchCondensation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, M, B, Q, T, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the nonnegative real-series row, including the inspected finite coefficient window and the displayed monotonicity direction.*
2. *M is the monotone tail row certifying that later blocks may be bounded by their boundary terms.*
3. *B is the Schlomilch block-index row, listing the increasing block cut points and their finite gap sizes.*
4. *Q is the block-mass comparison row, recording the finite inequalities between original tails and condensed block terms.*
5. *T is the tail-transfer row that routes convergence or divergence reads through the displayed block comparison.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealSeries}^{\uparrow}$ *endpoint seal reached only after A, M, B, Q, T have been displayed.*
7. *H records componentwise* hsame *transport for series rows, monotonicity rows, block ledgers, tail transfers, endpoint seals, provenance, and local naming.*
8. *C records displayed* Cont *replay from a tail request through the monotone series row, Schlomilch block ledger, comparison row, tail transfer, and endpoint seal.*

9. *P is the* Pkg *provenance over* CauchySchlomilchCondensation$^{\uparrow}$, RealSeries$^{\uparrow}$, CauchyCondensationTest$^{\uparrow}$, CauchyIntegralTest$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CauchySchlomilchCondensation}^{\uparrow}}$ *row.*

The carrier has no coordinate for a nonmonotone rearrangement, an unstated analytic integral, a selected infinite sum, quotient real equality, or a convergence claim outside the displayed Schlomilch blocks.

Lean4 ✓ `BEDC.Derived.CauchySchlomilchCondensationUp.CauchySchlomilchCondensationTasteGate`
`single carrier alignment`

Theorem 3799.2 (CauchySchlomilchCondensation NameCert obligations)**.** *For every accepted* CauchySchlomilchCondensation$^{\uparrow}$ *carrier $S = (A, M, B, Q, T, E, H, C, P, N)$, the local* NameCert$_{\text{CauchySchlomilchCondensa}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the nonnegative series row, monotone tail row, block-index ledger, block-mass comparison, tail-transfer row, endpoint seal, transport, replay, provenance, and local naming;*
2. *monotone tail discipline, requiring M before any block comparison row can be consumed;*
3. *Schlomilch block exactness, requiring B and Q to name the same finite cut points and gap sizes;*
4. *condensation handoff, requiring every convergence-facing or divergence-facing tail read to pass through T before reaching E;*
5. *sibling compatibility, allowing dyadic Cauchy condensation and integral-test rows to be read only as named comparison siblings, not as hidden analytic premises;*
6. *ledger non-escape, excluding nonmonotone rearrangement, selected infinite sums, detached integral estimates, quotient real equality, and ambient completeness.*

No condensation obligation is stored outside these rows.

Proof. Project the carrier of Definition 3799.1. The rows $A, M, B, Q, T, E, H, C, P, N$ are the only displayed coordinates of the accepted packet.

Read the tail discipline first. The monotone row M governs the series row A before the Schlomilch cut points B and block comparisons Q are exposed, so the block ledger cannot be detached from the source tail.

Next apply the tail-transfer row T. It is the unique route from the displayed block comparison to the endpoint seal E, while H, C, P, N transport, replay, source, and name the same packet. Since no excluded analytic or quotient coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: A candidate packet with Schlomilch cut points but no monotone tail row is rejected by the CauchySchlomilchCondensation$^{\uparrow}$ carrier.

Independence witness: condensationtailselector, cauchy-integral-test, realseries, regseqrat, streamname: none is bijective to CauchySchlomilchCondensation$^{\uparrow}$ because this packet jointly carries monotone source-series rows, Schlomilch block cut points, block-mass comparisons, tail-transfer rows, endpoint seals, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{CauchySchlomilchCondensation}^{\uparrow}}$ **·**

Constructive story: A CauchySchlomilchCondensation$^{\uparrow}$ packet is generated from a monotone nonnegative series row, Schlomilch block-index ledger, block-mass comparison, tail-transfer row, endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchySchlomilchCondensation}\uparrow}$, seed)

Scope closed: Definition 3799.1 and Definition 3799.2 seed the finite Schlomilch condensation packet over monotone tails, block ledgers, comparison rows, and endpoint seals.

Formal verification: FormalStatus(NameCert$_{\text{CauchySchlomilchCondensation}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, nonmonotone rearrangement, selected infinite sums, host integral estimates, quotient real equality, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, monotone tail discipline, Schlomilch block exactness, condensation handoff, sibling compatibility, and ledger non-escape for BEDC.Derived.CauchySchlomilchCondensationUp.

Chapter 3800

A Concrete Naming Certificate for $\mathsf{FiniteOscillationPartition}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteOscillationPartition}^{\uparrow}$ packet records a finite partition of a located real interval together with a displayed oscillation window for each cell. It sits after the closed bounded interval surface of chapter 1591, the located interval source of chapter 1709, the oscillation-modulus ledger of chapter 2224, the real-name seal of chapter 38, the regular rational sequence readback of chapter 301, and the stream source of chapter 126. The packet gives later uniform-continuity, Darboux, Riemann, and regulated-integral certificates a finite-means carrier for oscillation-controlled partitions without invoking open-cover compactness, quotient equality of real functions, selected suprema, or ambient real completeness.

Definition 3800.1 (Finite oscillation partition carrier)**.** *A* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, M, A, B, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded and located* $\mathsf{Real}^{\uparrow}$ *interval row, read through the endpoint, inclusion, and apartness surfaces of* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *and* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$*.*

2. *M is the finite mesh row, listing ordered partition points, adjacent cell rows, endpoint containment, and a common finite index ledger.*

3. *A is the oscillation-modulus row, recording the tolerance request and the finite cellwise radius or mesh constraint supplied by* $\mathsf{OscillationModulus}^{\uparrow}$*.*

4. *B is the cell-bound row, assigning to each cell a displayed upper and lower real-name readback through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is used.*

5. *R is the refinement-readback row, recording how a later common refinement or integration consumer reads I, M, A, B without changing the accepted classifier.*

6. *H records componentwise* hsame *transport for I, M, A, B, R and for the continuation, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from an oscillation-window request through*

$$I, M, A, B, R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}$ *row.*

The carrier contains no open-cover compactness witness, no quotient equality of real-valued functions, no selected supremum or infimum, no unbounded partition search, and no ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.FiniteOscillationPartitionUp.FiniteOscillationPartitionTasteGate single carrier alignment`

Theorem 3800.2 (Finite oscillation partition NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *carrier $O = (I, M, A, B, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, interval-source exposure through I, mesh exactness through M, oscillation-window accounting through A, cell-bound readback through B, refinement-readback stability through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3800.1. The interval, mesh, oscillation, cell-bound, and refinement rows are the analytic part of the packet, while H, C, P, N are the structural rows that transport, replay, source, and name it.

The interval and mesh obligations are finite. The row I supplies the closed bounded located interval boundary, and M lists the partition cells and endpoint containments over that same boundary.

The oscillation and bound obligations are also finite. The row A records the tolerance and the cellwise oscillation constraint, while B exposes upper and lower readbacks through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Refinement stability is read from R and transported by H. A downstream consumer may refine the displayed cells only by replaying the same interval, mesh, oscillation, and bound rows through C with provenance P and local name N.

Since the carrier has no coordinate for open-cover compactness, quotient function equality, selected extrema, unbounded search, or ambient completeness, no accepted NameCert obligation can project one of those objects. □

Lean4 ✓ `BEDC.Derived.FiniteOscillationPartitionUp.FiniteOscillationPartition namecert obligations`

Theorem 3800.3 (Finite oscillation partition uniform window)**.** *Every uniform-continuity or integration-facing consumer of an accepted* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{LocatedRealIntervalPartition}^{\uparrow},\ \mathsf{OscillationModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto$$

In particular, the consumer reads a displayed interval source, finite mesh, oscillation tolerance ledger, cell-bound readback, and refinement route before any terminal real seal is used.

Proof. Apply the NameCert obligations of Definition 3800.2. They require every accepted consumer to open I, M, A, B, R before the structural rows are available.

The uniform window is determined by A over the cells of M. Thus a uniform-continuity consumer obtains a tolerance-indexed cell ledger rather than an open-cover argument.

An integration-facing consumer reads the same route through B and R. The cell-bound readbacks expose finite upper and lower rows through stream and regular rational names, while the refinement row records how common refinements preserve the displayed classifier.

Therefore the accepted packet exports a finite oscillation-controlled partition window, and no hidden supremum, quotient-function comparison, open-cover compactness witness, or ambient completeness theorem is available to the consumer. □

Theorem 3800.4 (Finite oscillation partition uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer that reads an accepted* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *packet before a* $\mathsf{UniformModulus}^{\uparrow}$ *handoff must pass through exactly the displayed interval source, finite mesh, oscillation-window row, cell-bound readback,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}$ *row. The handoff exports a finite oscillation route to a uniform-modulus consumer, not open-cover compactness, selected extrema, quotient function equality, unbounded partition search, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3800.1. Its analytic rows are the interval source I, finite mesh M, oscillation-window row A, cell-bound readback B, and refinement-readback row R; its structural rows are H, C, P, N.

Apply Definition 3800.2. The local certificate forces any compact-uniform-continuity consumer to expose carrier admission, interval-source exposure, mesh exactness, oscillation accounting, cell-bound readback, refinement stability, transport, replay, provenance, and local naming before treating the packet as usable modulus data.

Apply Definition 3800.3. The uniform window is read only after $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal have been displayed over the same finite partition rows.

Thus the $\mathsf{UniformModulus}^{\uparrow}$ consumer receives the displayed finite oscillation handoff. Since no carrier coordinate stores open-cover compactness, selected extrema, quotient function equality, unbounded partition search, or ambient completeness, none of those principles can be exported by the handoff. □

Theorem 3800.5 (Compact-uniform finite oscillation modulus)**.** *Every compact-uniform-continuity or integration-facing consumer that receives an accepted* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *packet obtains a finite oscillation modulus only through the displayed interval source, finite mesh, oscillation-window row, cell-bound readback,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}$ *row. The received modulus is a finite packet read, not an open-cover compactness theorem, selected-extrema argument, quotient function equality, unbounded partition search, or ambient completeness principle.*

Proof. Project the carrier of Definition 3800.1. The only analytic rows available to a compact-uniform or integration-facing consumer are the interval source I, finite mesh M, oscillation-window row A, cell-bound readback B, and refinement route R.

Apply Definition 3800.2. It forces the consumer to expose interval-source data, mesh exactness, oscillation-window accounting, cell-bound readback, refinement stability, componentwise transport, replay, provenance, and local naming before the packet can be consumed as a modulus.

Use Definition 3800.3 to identify the uniform window read. The window factors through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal, so the compact-uniform reader receives a finite tolerance-indexed route rather than a host-level compactness principle.

Finally inspect the absent coordinates of the carrier. It contains no open-cover compactness witness, selected extrema, quotient comparison of functions, unbounded partition search, or ambient completeness row; hence none of those principles can be projected from the finite oscillation modulus. □

Theorem 3800.6 (Finite oscillation partition step-function handoff)**.** *Let $O = (I, M, A, B, R, H, C, P, N)$ be an accepted* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *packet whose cell-bound row B chooses displayed lower and upper real-name reads for every cell of the finite mesh M. Then every* $\mathsf{StepFunction}^{\uparrow}$ *or* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer that reads the packet receives a finite approximation route through*

$$I, M, A, B, R,\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ H, C, P, N.$$

The route first exposes the interval source, finite mesh, oscillation modulus, stream windows, regular rational readbacks, dyadic tolerance rows, and terminal real seal; it then repacks the displayed cellwise constant lower and upper reads as $\mathsf{StepFunction}^{\uparrow}$ *rows and as the finite schedule visible to* $\mathsf{RegulatedFunction}^{\uparrow}$*. No open-cover compactness, selected extrema, quotient functions, unbounded partition search, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle is introduced by this handoff.*

Proof. Project the carrier of Definition 3800.1. The interval source I, mesh M, oscillation row A, cell-bound row B, and refinement row R are already finite rows of the accepted packet, while H, C, P, N provide componentwise transport, displayed replay, provenance, and the local naming certificate.

Apply Definition 3800.2. The NameCert obligations force every consumer to expose the interval source, mesh exactness, oscillation-window accounting, cell-bound readback, refinement stability, transport, replay, provenance, and local name before the packet can be read as approximation data.

Use Definition 3800.5 to expose the uniform cell window. For each cell of M, the selected lower and upper reads in B pass through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, are calibrated by the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, and reach the terminal $\mathsf{Real}^{\uparrow}$ seal only along that displayed finite route.

Now repack each displayed cellwise constant read as a $\mathsf{StepFunction}^{\uparrow}$ row over the same interval source and finite mesh. Reading the finitely many rows in the order recorded by R gives the regulated-function finite schedule: the $\mathsf{RegulatedFunction}^{\uparrow}$ consumer sees only the interval, mesh, step rows, oscillation window, readbacks, transport, replay, provenance, and local name.

Finally inspect the absent coordinates of the carrier. Since the packet has no coordinate for open-cover compactness, selected extrema, quotient functions, unbounded partition search, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the step-function and regulated-function consumers cannot acquire any of those principles through this handoff. □

Falsifiable prediction: Any accepted $\mathsf{FiniteOscillationPartition}^{\uparrow}$ consumer that claims a uniform oscillation window while omitting one of the interval source, finite mesh, oscillation-modulus, cell-bound, refinement, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: closedboundedinterval, located-real-interval-partition, oscillationmodulus, real, regseqrat, streamname: none is bijective with $\mathsf{FiniteOscillationPartition}^{\uparrow}$ because this packet jointly carries interval source, finite mesh, oscillation tolerance, cell-bound readback, refinement stability, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOscillationPartition}^{\uparrow}$ packet is generated from a closed bounded located interval row, a finite mesh row, an oscillation-modulus row, cell-bound readbacks through StreamName and RegSeqRat, a refinement-readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3800.1, Definition 3800.2, Definition 3800.3, and Definition 3800.6 seed the finite oscillation-controlled partition route for uniform-continuity, step-function, regulated-function, and integration-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOscillationPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient equality of real-valued functions, selected suprema, unbounded partition search, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exposure, mesh exactness, oscillation-window accounting, cell-bound readback, refinement stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.FiniteOscillationPartitionUp.

Chapter 3801

A Concrete Naming Certificate for $\mathsf{TriggerBlockerDuality}^{\uparrow}$

The $\mathsf{TriggerBlockerDuality}^{\uparrow}$ packet realizes the blocker-complex reading of Definition 9462.1547, Definition 9462.1548, Definition 9462.1550, and Definition 9462.1551 as finite BEDC NameCert data. It consumes the six-boundary coverage packet of chapter 3470, the finite support algebra of chapter 3478, the Boolean trigger lattice of chapter 3704, the Alexander-dual trigger algebra of chapter 3555, and the DNA boundary-tile source of chapter 3393. The packet names trigger-blocker duality by finite blocker-complex, maximal-blocker, intersection, nerve, transport, provenance, and local NameCert rows; it is not a biological stochastic model, a hidden codon semantics, an unbounded trigger search, or an external homology oracle.

Definition 3801.1 (Trigger-blocker duality carrier)**.** *A* $\mathsf{TriggerBlockerDuality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, L, B, I, V, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *row exposing the finite boundary-trigger coordinates and coverage ranks.*
2. *A is the* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *row carrying the finite trigger-support closure and blocker threshold data.*
3. *L is the* $\mathsf{BooleanTriggerLattice}^{\uparrow}$ *row recording meet, join, rank, and observed trigger-table reads.*
4. *B is the blocker-complex row, displaying the four maximal blockers obtained by omitting one trigger coordinate and the non-trigger face predicate of Definition 9462.1547.*
5. *I is the intersection row, recording the sizes* $14, 6, 2, 0$ *for one-, two-, three-, and four-fold omitted-coordinate intersections.*
6. *V is the nerve row, recording the four vertices, six edges, four triangular faces, and absent three-simplex of the blocker nerve.*
7. *H records componentwise* hsame *transport for S, A, L, B, I, V and for the continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from trigger coverage through blocker readback and nerve readback.*

9. *P is the* Pkg *provenance over* TriggerBlockerDuality$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgebra$^{\uparrow}$ BooleanTriggerLattice$^{\uparrow}$, AlexanderDualTriggerAlgebra$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, *the source blocker-complex vision,* BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* NameCert$_{\text{TriggerBlockerDuality}^{\uparrow}}$ *row.*

The carrier contains no hidden biological semantics, no stochastic evolutionary model, no quotient codon space, no unbounded trigger enumeration, and no external homology oracle.

Lean4 ✓ `BEDC.Derived.TriggerBlockerDualityUp.TriggerBlockerDualityTasteGate single carrier alignment`

Theorem 3801.2 (Trigger-blocker duality NameCert obligations)**.** *For every accepted* TriggerBlockerDuality$^{\uparrow}$ *carrier $D = (S, A, L, B, I, V, H, C, P, N)$, the local* NameCert$_{\text{TriggerBlockerDuality}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, coverage exposure through S, trigger-algebra exposure through A, Boolean lattice exposure through L, blocker-complex exactness through B, maximal-blocker intersection accounting through I, blocker-nerve readback through V, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.TriggerBlockerDualityUp.TriggerBlockerDualityNameCertObligations`

Proof. Project the carrier of Definition 3801.1. The rows S, A, L expose the trigger side, the rows B, I, V expose the blocker and nerve side, and H, C, P, N transport, replay, source, and name the packet.

The trigger side is finite because S displays the boundary-tile coverage coordinates, A displays the support-closure algebra, and L displays Boolean meet, join, and rank rows over the same finite support surface.

The blocker side is finite because B lists the four maximal omitted-coordinate blockers, I records the displayed intersection sizes, and V records the nerve readback. These are exactly the rows needed by Definition 9462.1551.

Transport and replay preserve the same rows componentwise. Since the carrier has no coordinate for hidden biological meaning, stochastic evolution, quotient codon semantics, unbounded search, or an external homology oracle, no accepted NameCert obligation can project one of those objects. □

Theorem 3801.3 (Trigger-blocker duality finite nerve readback)**.** *Every accepted* TriggerBlockerDuality$^{\uparrow}$ *read of the blocker nerve factors through the finite route*

SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgebra$^{\uparrow}$, BooleanTriggerLattice$^{\uparrow}$, AlexanderDualTriggerAlgebra$^{\uparrow}$,

Removing one maximal-blocker row changes the blocker nerve readback because V is computed from the four displayed blocker rows and their intersection ledger I.

Proof. Apply the obligation surface of Definition 3801.2. It forces every accepted nerve read to expose the trigger-side coverage, algebra, and Boolean lattice rows before the blocker rows are available.

The nerve row V is tied to B and I. The four vertices are the four maximal-blocker rows, the six edges and four triangular faces are read from the nonempty two- and three-fold intersections, and the absent three-simplex is read from the empty four-fold intersection.

If one maximal-blocker row is removed, the vertex set of V changes and the intersection ledger no longer has the same four omitted-coordinate coordinates. Thus the accepted blocker nerve readback changes before any downstream trigger-spectrum consumer can use the packet. □

Falsifiable prediction: Removing one displayed maximal-blocker row from an accepted $\mathsf{TriggerBlockerDuality}^{\uparrow}$ carrier changes the blocker nerve readback through V before any downstream trigger-spectrum consumer can preserve the certificate.

Independence witness: six-boundary-tile-coverage, window-coverage-trigger-algebra, boolean-trigger-lattice, alexander-dual-trigger-algebra, dna-window-six-boundary-tile: none is bijective with $\mathsf{TriggerBlockerDuality}^{\uparrow}$ because this packet jointly carries blocker-complex rows, maximal-blocker rows, intersection rows, nerve rows, transport, replay, provenance, and local naming.

The Lean follow-up for this chapter must provide `Nontrivial TriggerBlockerDualityUp` and `FieldFaithful TriggerBlockerDualityUp` instances in `BEDC.Derived.TriggerBlockerDualityUp` so that $S, A, L, B, I, V, H, C, P, N$ remain separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{TriggerBlockerDuality}^{\uparrow}}$.

Constructive story: A $\mathsf{TriggerBlockerDuality}^{\uparrow}$ packet is generated from six-boundary coverage rows, trigger-algebra rows, Boolean trigger-lattice rows, blocker-complex rows, maximal-blocker intersection rows, blocker-nerve rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TriggerBlockerDuality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3801.1, Definition 3801.2, and Definition 3801.3 seed the finite blocker-complex, maximal-blocker, intersection, and nerve packet consumed by downstream trigger-spectrum chapters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TriggerBlockerDuality}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.TriggerBlockerDualityUp.TriggerBlockerDualityNameCertObligations`

Bridge status: none

Not claimed: This chapter does not close biological stochastic semantics, quotient codon semantics, unrestricted trigger search, external homology computation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coverage exposure, trigger-algebra exposure, Boolean lattice exposure, blocker-complex exactness, intersection accounting, nerve readback, Nontrivial TriggerBlockerDualityUp, and FieldFaithful TriggerBlockerDualityUp for BEDC.Derived.TriggerBlockerDualityUp.

Chapter 3802

A Concrete Naming Certificate for $\mathsf{FiniteRelation}^{\uparrow}$

Following Tarski-style relation algebra and finite relational semantics, the $\mathsf{FiniteRelation}^{\uparrow}$ packet records a finite binary relation as displayed BEDC pair rows rather than as a host predicate, quotient graph, or finite map with discarded duplicate rows.

3802.1 Finite-relation source

Definition 3802.1 (FiniteRelationUp carrier)**.** *A* $\mathsf{FiniteRelation}^{\uparrow}$ *carrier from a displayed left surface to a displayed right surface is a finite* $\mathsf{List}^{\uparrow}$ *spine of* $\mathsf{Prod}^{\uparrow}$ *pair rows. Each row has first component a left* BHist *witness and second component a right* BHist *witness, with both components read through their local classifiers and package provenance.*

Membership in the relation is exact display membership in the spine: a pair (a, b) *is accepted precisely when some product-coded row in the spine has left component classified with* a *and right component classified with* b*. The domain support is the* $\mathsf{FinSet}^{\uparrow}$ *enumeration obtained by projecting the left components of all rows, and the range support is the* $\mathsf{FinSet}^{\uparrow}$ *enumeration obtained by projecting the right components. Repeated rows and repeated component classes remain visible ledger entries; unlike* $\mathsf{FiniteMap}^{\uparrow}$ *lookup in chapter 352, no first-hit rule suppresses later rows and no functionality condition is imposed.*

Lean4 ✓ `BEDC.Derived.FiniteRelationUp.FiniteRelationTasteGate single carrier alignment`

Theorem 3802.2 (FiniteRelationUp NameCert obligations)**.** *The* $\mathsf{NameCert}_{\mathsf{FiniteRelation}^{\uparrow}}$ *obligation surface consists of seven rows:*

1. *the finite* $\mathsf{List}^{\uparrow}$ *carrier of* $\mathsf{Prod}^{\uparrow}$ *pair rows from Definition 3802.1;*
2. *membership exactness for displayed pair membership;*
3. *domain and range support projections through* $\mathsf{FinSet}^{\uparrow}$*;*
4. *classifier transport for both components and for the pair-row membership classifier;*
5. *replay through the displayed* Cont *route;*
6. *source provenance through the recorded* Pkg *and* BHist *rows;*
7. *local naming of the finite relation packet as a* NameCert *row.*

Together these rows expose a non-functional finite relation surface whose consumers may cite chapter 36, chapter 34, chapter 32, chapter 33, chapter 112, and chapter 352 without importing host relation equality.

Proof. Project the displayed relation spine. The carrier row is the finite $\mathsf{List}^{\uparrow}$ object, while each member row is a $\mathsf{Prod}^{\uparrow}$ pair whose two components retain their component classifiers and provenance.

Membership exactness is immediate from spine membership: a consumer can accept a pair only by pointing to a displayed row and transporting both components along their classifiers. Domain and range support are obtained by component projection followed by the finite-set enumeration interface, so repeated component classes remain ledger-visible.

Replay and provenance are inherited rowwise. The Cont route replays the same inspected product row, the Pkg row names the source packet, and the BHist entries identify the displayed component histories. These rows give the local naming certificate without requiring functionality or quotienting duplicate rows. □

Theorem 3802.3 (FiniteRelationUp image and preimage route)**.** *Every public image or preimage read of an accepted* $\mathsf{FiniteRelation}^{\uparrow}$ *packet factors only through the displayed finite-data rows named in Definition 3802.2. An image read starts from a displayed left witness, scans the* $\mathsf{List}^{\uparrow}$ *spine of* $\mathsf{Prod}^{\uparrow}$ *rows, tests component membership through the left classifier, and exports the corresponding right witnesses through a* $\mathsf{FinSet}^{\uparrow}$ *range-support row. A preimage read is the symmetric route through the right classifier and left support row.*

The route may use $\mathsf{Bool}^{\uparrow}$ *as a finite discriminator for visible classifier outcomes and* $\mathsf{Option}^{\uparrow}$ *as an optional read witness for single-row consumers, but it never turns the relation into a* $\mathsf{FiniteMap}^{\uparrow}$ *first-hit lookup. All exported facts pass through* $\mathsf{List}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{FiniteRelation}^{\uparrow}}$ *rows.*

Proof. For an image read, inspect the relation spine in order. Each accepted row is a displayed product row, so the left component can be compared with the queried witness through the component classifier and transported along hsame when the classifier accepts.

The accepted right components are collected as a finite support enumeration. The same construction with left and right interchanged gives the preimage route. The boolean and optional witnesses are only visible finite-data control rows for the scan; they do not choose a hidden branch or collapse the relation to a function.

Thus every consumer-visible output is a projection of displayed pair rows, replayed by Cont and named by Pkg provenance under the relation certificate. No image or preimage read can bypass the finite spine or import host relational semantics. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRelation}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteRelation}^{\uparrow}}$, seed)

Scope closed: The chapter fixes the finite relation carrier, membership exactness surface, and image/preimage dependency route as paper-side obligations.

Constructive story: A finite relation is built by displaying a finite list spine of product-coded rows and projecting membership, domain support, and range support from that spine.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteRelation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: No Lean target, relational algebra operations, transitive closure, graph reachability, or category hom-relation bridge is claimed here.

Upgrade path: Formalize the finite spine carrier and membership classifier as *BEDC.Derived.FiniteRelationUp*, then discharge the NameCert obligation surface.

Chapter 3803

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy sequences, the $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ packet names the finite tail-envelope data needed when a regular rational sequence is handed to the $\mathsf{Real}^{\uparrow}$ completion route. It sits between the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the explicit modulus surface of chapter 3768, and the terminal real-name seal of chapter 38. The packet is finite tail-control data for the L10 regular-Cauchy route; it is not a selected real limit, quotient sequence, countable-choice schedule, host equality comparison, or ambient completeness theorem.

Definition 3803.1 (Regular Cauchy tail envelope carrier)**.** *A* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, U, D, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy row whose rational entries are read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *route.*
2. *U is the unary tail-bound row. For each precision request it records a finite tail index beyond which the source row is inspected.*
3. *D is the dyadic tolerance ledger, translating the precision request and the chosen tail bound into* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison budgets.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window selected by the tail bound.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that repacks the inspected window as regular rational sequence data.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after S, U, D, W, R have been replayed.*
7. *H records componentwise* hsame *transport for the source row, tail bound, dyadic ledger, window, readback, seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a precision request through $S, U, D, W, R, Q, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$, $\mathsf{RegularModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEnvelope}^{\uparrow}}$ *row.*
The classifier accepts only packets in which the source row, unary tail bound, dyadic ledger, StreamName window, RegSeqRat readback, and Real seal all describe the same displayed regular Cauchy route. No carrier coordinate stores a quotient representative, selected limit, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEnvelopeUp.RegularCauchyTailEnvelopeTasteGate single carrier alignment`

Theorem 3803.2 (Regular Cauchy tail envelope NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ *carrier* $E = (S, U, D, W, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEnvelope}^{\uparrow}}$ *surface consists exactly of source regular Cauchy admission, unary tail-bound display, dyadic tolerance accounting, finite StreamName window selection, RegSeqRat readback, terminal Real seal routing, componentwise transport, continuation replay, package provenance, and local naming through the rows* $S, U, D, W, R, Q, H, C, P, N$*.*

Proof. Project the carrier of Definition 3803.1. The source row S is the only regular Cauchy input, and U is the only tail-bound coordinate attached to it.

The ledger D translates the requested precision and the displayed tail bound into dyadic comparison data. The window row W and readback row R then expose exactly the finite observations consumed by the StreamName and RegSeqRat surfaces.

The seal row Q is downstream of those rows. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route, and the excluded quotient, selected-limit, choice, host-equality, and completeness data have no carrier coordinate. □

Theorem 3803.3 (Regular Cauchy tail envelope handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ *carrier must read the finite route*

$$S, U, D, W \longmapsto R \longmapsto Q \longmapsto H, C, P, N$$

before consuming the regular rational row or terminal real-name seal. Thus the tail envelope supplies named finite tail control for the L10 route rather than an informal appeal to a hidden limit, quotient stream, countable-choice schedule, host equality, or ambient completeness coordinate.

Proof. Start with a consumer request for regular rational or real-name data. The packet exposes the source row only as S, so the request must first read the tail bound U and the dyadic ledger D.

The finite window W is selected from that bound and ledger. The readback row R repacks the same inspected data as $\mathsf{RegSeqRat}^{\uparrow}$ information, so the consumer reaches the regular rational surface only through displayed finite observations.

The terminal seal Q is reached after this readback. The rows H, C, P, N then transport, replay, source, and name the same route; no excluded analytic coordinate is present, so every handoff remains finite BEDC data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ packet is generated from a source regular Cauchy row, a unary tail-bound row, a dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 3803.1, Definition 3803.2, and Definition 3803.3 seed the finite tail-envelope surface for the L10 RegSeqRat-to-Real route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient sequences, countable choice, host equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-bound exactness, dyadic tolerance accounting, StreamName window routing, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailEnvelopeUp.

Chapter 3804

A Concrete Naming Certificate for $\mathsf{VariationNorm}^{\uparrow}$

Following Jordan and the bounded-variation treatment in Rudin, the $\mathsf{VariationNorm}^{\uparrow}$ packet names the finite norm row obtained from displayed partition variation data. It consumes the $\mathsf{BoundedVariation}^{\uparrow}$ partition ledger of chapter 398, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the regular completion route through chapter 301, chapter 126, and chapter 291. The packet records a finite variation-norm observation over displayed partitions; it does not introduce a completed Banach space of bounded-variation functions, a host supremum over all partitions, or quotient equality of functions.

Definition 3804.1 (VariationNorm carrier)**.** *A* $\mathsf{VariationNorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, R, Q, S, D, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, including its displayed interval row, finite partition ledger, endpoint-name rows, dyadic edge observations, finite variation sum, and common-refinement rows.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint and value seal read from the same partition ledger.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-name row used when the endpoint values are consumed through rational readback.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row from which the regular-name reads are inspected.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge-difference and finite-sum ledger.*
6. *A is the displayed variation-norm row, recording the finite base-value read together with the finite partition-variation sum read from B.*
7. *H records componentwise* hsame *transport for the bounded-variation source, Real seal, regular-name row, stream window, dyadic ledger, norm row, continuation, provenance, and local name.*
8. *C records the displayed* Cont *replay route from a variation-norm request through $B, R, Q, S, D, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationNorm}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed bounded-variation packet, Real or regular endpoint reads, stream windows, dyadic variation ledger, variation-norm row, and structural transport and provenance. It has no coordinate for a completed function space, host function equality, variation measure, hidden partition family, or supremum over all partitions.

Lean4 ✓ `BEDC.Derived.VariationNormUp.VariationNormTasteGate single carrier alignment`

Theorem 3804.2 (VariationNorm NameCert obligations)**.** *For every accepted* $\mathsf{VariationNorm}^{\uparrow}$ *carrier* $V = (B, R, Q, S, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{VariationNorm}^{\uparrow}}$ *obligation surface consists exactly of bounded-variation source admission, Real endpoint sealing, RegSeqRat readback, finite StreamName window selection, DyadicRatCore edge accounting, displayed variation-norm row formation, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier. The only source of variation data is the $\mathsf{BoundedVariation}^{\uparrow}$ row B, and the only real-valued reads attached to it are the Real seal R, the regular-name row Q, the stream window S, and the dyadic ledger D.

The variation-norm row A is then formed from those displayed rows. It reads a finite base-value component and the displayed partition-variation sum, both already present in the bounded-variation ledger and its Real/Completion dependency route.

Transport and replay are handled by H and C. These rows move the same finite source, endpoint, stream, dyadic, and norm data componentwise, while P and N record provenance and local naming. Since the excluded analytic objects have no carrier coordinate, they cannot be part of the local obligation surface. □

Theorem 3804.3 (VariationNorm refinement stability)**.** *Let* $V = (B, R, Q, S, D, A, H, C, P, N)$ *and* $V' = (B', R', Q', S', D', A', H', C', P', N')$ *be accepted* $\mathsf{VariationNorm}^{\uparrow}$ *carriers whose bounded-variation source packets compare by a displayed common-refinement classifier. Then the variation-norm rows* A *and* A' *compare componentwise after transporting the Real endpoint seals, RegSeqRat readbacks, StreamName windows, DyadicRatCore edge ledgers,* Pkg *provenance, and local* NameCert *rows through the stored* hsame *and* Cont *routes.*

Proof. Begin with the common-refinement classifier for the source $\mathsf{BoundedVariation}^{\uparrow}$ packets. By chapter 398, the comparison is a displayed finite refinement with transported endpoint rows, dyadic edge observations, finite variation sums, and package and naming provenance.

Read the Real and completion-facing coordinates along that same refinement. The rows R, Q, S, D and R', Q', S', D' expose the Real seal, regular-name readback, stream windows, and dyadic edge ledgers without adding a hidden partition or completed function carrier.

This variation-norm row is a carrier and classifier consumer of the $\mathsf{BoundedVariation}^{\uparrow}$ partition ledger and of the L10 Real/Completion readback route through $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$; it is not a decorative citation detached from the finite source rows.

Finally replay the norm rows through C and C' and transport them through H and H'. The row A is built from the same finite base-value and partition-variation data as A', after the displayed common refinement, so the variation-norm comparison is stable under the classifier. □

Closure status for $\mathsf{NameCert}_{\mathsf{VariationNorm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{VariationNorm}^{\uparrow}$ packet is generated from a BoundedVariation source, Real endpoint seal, RegSeqRat readback, StreamName window, DyadicRatCore edge ledger, displayed variation-norm row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{VariationNorm}^{\uparrow}}$, obligation)

Scope closed: Definition 3804.1, Definition 3804.2, and Definition 3804.3 bind the finite variation-norm carrier, obligation surface, and common-refinement stability route to the displayed BoundedVariation and Real/Completion dependency rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{VariationNorm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed bounded-variation function spaces, host function equality, a variation measure, hidden partition families, a supremum over all partitions, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a checked finite partition-norm consumer theorem over the same bounded-variation source, Real seal, regular-name, stream-window, dyadic-ledger, transport, replay, provenance, and local naming rows.

Chapter 3805

A Concrete Naming Certificate for $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges on regular Cauchy names, the $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ packet records the finite basis rows that sit between regular-Cauchy closeness and the terminal real seal. It refines the dyadic-entourage surface of chapter 1628 by naming basis generators before they are consumed by the $\mathsf{Real}^{\uparrow}$ route. The packet reads the regular rational source of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the real endpoint seal of chapter 38; it is not an ambient uniformity parameter, a quotient equality of Cauchy presentations, a selected limit, countable choice, or a completeness theorem.

Definition 3805.1 (Regular Cauchy entourage-basis carrier)**.** *A* $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, W, D, B, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the regular rational Cauchy presentation whose finite windows are being inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row carrying the displayed observation windows for the same presentation.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming dyadic radii, denominator scales, and comparison data available to those windows.*
4. *B is the basis-entourage row, assigning each displayed dyadic tolerance scale to the finite entourage generator read from R, W, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the source, window, tolerance, and basis-entourage rows have been displayed.*
6. *H records componentwise* hsame *transport for the regular source, window, tolerance, basis, real seal, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a basis-entourage request through R, W, D, B, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$, $\mathsf{RegularCauchyUniformity}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEntourageBasis}^{\uparrow}}$ *row.*
The carrier has no coordinate for an ambient uniform-space object, an arbitrary entourage filter, quotient equality of real presentations, a selected limit, countable choice, or real completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyEntourageBasisUp.RegularCauchyEntourageBasisTasteGate single carrier alignment`

Theorem 3805.2 (Regular Cauchy entourage-basis NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ *carrier* $K = (R, W, D, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEntourageBasis}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, regular-source exposure through* R*, finite-window exposure through* W*, dyadic-tolerance exposure through* D*, basis-entourage exactness through* B*, real-seal nonescape through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3805.1. The source, window, and tolerance rows are the only inputs from which the basis-entourage row can be read.

Basis-entourage exactness is finite because B assigns displayed dyadic tolerance scales from D to displayed windows from W for the same regular source row R. This gives the basis-level row used by chapter 1628 without importing an ambient uniformity object.

The real seal is nonescaping because E is reached only after R, W, D, B have been displayed and transported through H. Replay through C preserves the same route, while P and N record provenance and local naming for that finite packet. Thus no quotient equality, selected limit, countable-choice schedule, or completeness theorem can be projected from the NameCert surface. □

Theorem 3805.3 (Regular Cauchy entourage-basis Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyEntourageBasis}^{\uparrow} \longmapsto \mathsf{RegularCauchyUniformit}$$

The route exposes a basis-entourage generator before the uniformity and real-seal rows are read, and exports no ambient uniformity parameter, no selected completion limit, and no host equality of real presentations.

Proof. Start with the accepted carrier $K = (R, W, D, B, E, H, C, P, N)$. A real-seal request first reads R as the regular rational source, W as its finite observation window, and D as the dyadic tolerance ledger for that window.

The basis row B is then read as the finite entourage generator for the displayed tolerance scale. The regular-Cauchy uniformity consumer can use this row as its basis-level input, but it receives no coordinate for a larger ambient uniformity filter.

Finally the route reaches E through componentwise transport, replay, provenance, and local naming. Since the only visible path to E runs through R, W, D, B, H, C, P, N, the handoff cannot manufacture quotient equality, countable choice, selected limits, or completeness outside the displayed packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ read exposes RegSeqRat source rows, StreamName finite windows, DyadicRatCore tolerance rows, a basis-entourage row, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any Real-facing consumer can use the packet.

Independence witness: regular-cauchy-uniformity, regseqrat, streamname, dyadicratcore, real: $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source row, finite windows, tolerance ledger, basis-entourage generator, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEntourageBasis}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ packet is generated from a RegSeqRat source row, a StreamName finite-window row, a DyadicRatCore tolerance row, a basis-entourage row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEntourageBasis}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3805.1, Definition 3805.2, and Definition 3805.3 seed the finite basis-level route between regular-Cauchy windows and the Real endpoint seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEntourageBasis}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality of real presentations, selected limits, countable choice, ambient uniformity completeness, or Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, basis-entourage exactness, classifier stability, real-seal nonescape, and Real handoff for the displayed packet.

Chapter 3806

A Concrete Naming Certificate for $\mathsf{TriggerEnergyPartition}^{\uparrow}$

The $\mathsf{TriggerEnergyPartition}^{\uparrow}$ packet realizes the trigger-energy theorem of Definition 9462.1584 as finite BEDC NameCert data. It records support rows, an energy ledger, a partition row, codon-lift accounting, transport, replay, provenance, and local naming for the energy-minimal trigger surface. It is a sibling of the reliability packet in chapter 3583: $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ consumes energy-weighted reliability rows, while $\mathsf{TriggerEnergyPartition}^{\uparrow}$ isolates the partition certificate for equality in the energy lower bound.

Definition 3806.1 (Trigger-energy partition carrier)**.** *A* $\mathsf{TriggerEnergyPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, L, E, Q, K, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite support row over the four trigger coordinates $\Omega = \{s_1, f_1, s_2, f_2\}$.*
2. *L is the trigger-selection row naming the displayed quotient-level trigger and its codon-level lift choices.*
3. *E is the energy-ledger row recording the sum of the support sizes of the selected external codons.*
4. *Q is the partition row certifying that the selected supports are pairwise disjoint and cover Ω exactly in the energy-minimal case.*
5. *K is the codon-lift row recording the finite f_3-lift multiplicity for each selected support block.*
6. *H records componentwise* hsame *transport for support, selection, energy, partition, codon-lift, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an energy-minimal trigger request through S, L, E, Q, K, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{TriggerEnergyPartition}^{\uparrow}$*,* $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$*, the source theorem Definition 9462.1584,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TriggerEnergyPartition}^{\uparrow}}$ *row.*

The carrier contains no biological stochastic model, empirical likelihood claim, hidden codon semantics, unbounded trigger enumeration, or external partition oracle.

Lean4 ✓ `BEDC.Derived.TriggerEnergyPartitionUp.TriggerEnergyPartitionTasteGate single carrier alignment`

Theorem 3806.2 (Trigger-energy partition NameCert obligations)**.** *For every accepted* $\mathsf{TriggerEnergyPartition}^{\uparrow}$ *carrier* $T = (S, L, E, Q, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TriggerEnergyPartition}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, finite support exposure through* S*, trigger-selection exposure through* L*, energy-ledger exactness through* E*, partition exactness through* Q*, codon-lift accounting through* K*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3806.1. The support row S and selection row L expose the finite trigger family, while E records the total support-size ledger.

Partition exactness reads the equality case of Definition 9462.1584. When the energy ledger has value 4, the partition row Q records that the selected supports cover the four coordinates exactly once; conversely, the displayed partition row forces the energy ledger to count four coordinate appearances.

The codon-lift row K is finite because it records only the displayed f_3 choices over the selected support blocks. Transport and replay preserve S, L, E, Q, K componentwise, and provenance plus local naming keep the certificate tied to the source theorem and the energy-biased reliability sibling. No stochastic, empirical, hidden-semantic, or unbounded-search row is exported. □

Theorem 3806.3 (Trigger-energy partition reliability handoff)**.** *Every energy-minimal trigger read consumed by* $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ *factors through the finite* $\mathsf{TriggerEnergyPartition}^{\uparrow}$ *route*

$$S, L, E, Q, K, H, C, P, N.$$

The reliability consumer receives the support family, energy ledger, partition certificate, and codon-lift count as finite rows, not as an external enumeration or biological probability model.

Proof. Start with an accepted trigger-energy partition carrier. The finite support row S names the coordinate supports, and L names the selected quotient trigger together with its codon-level lift surface.

The energy ledger E and partition row Q then expose the equality case in the lower bound: every coordinate of Ω is covered exactly once. The codon-lift row K records the finite lift multiplicities attached to those blocks.

An $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ consumer may read these rows as inputs for its weighted reliability formula, but the transport, replay, provenance, and local naming rows keep the handoff inside the displayed finite certificate. Thus the consumer obtains no external trigger enumeration, empirical likelihood, or hidden codon semantics. □

Falsifiable prediction: Every accepted $\mathsf{TriggerEnergyPartition}^{\uparrow}$ read exposes finite support, trigger-selection, energy-ledger, partition, codon-lift, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any energy-biased reliability consumer can use an energy-minimal trigger partition.

Independence witness: energy-biased-trigger-reliability, six-boundary-tile-coverage, window-coverage-trigger-algebra: $\mathsf{TriggerEnergyPartition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the energy equality partition row and codon-lift accounting rather than only coverage, algebra, or reliability rows.

Closure status for $\mathsf{NameCert}_{\mathsf{TriggerEnergyPartition}^{\uparrow}}$**.**

Constructive story: A TriggerEnergyPartition$^{\uparrow}$ packet is generated from finite support rows, trigger-selection rows, an energy ledger, a partition certificate, codon-lift accounting, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{TriggerEnergyPartition}^{\uparrow}}$, seed)

Scope closed: Definition 3806.1, Definition 3806.2, and Definition 3806.3 seed the finite partition surface for equality in the trigger-energy lower bound.

Formal verification: FormalStatus(NameCert$_{\text{TriggerEnergyPartition}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, biological stochastic semantics, empirical likelihood, hidden codon semantics, or unrestricted trigger enumeration.

Upgrade path: Obligation closure requires checked carrier admission, support exposure, energy-ledger exactness, partition exactness, codon-lift accounting, reliability handoff, Nontrivial TriggerEnergyPartitionUp, and FieldFaithful TriggerEnergyPartitionUp for BEDC.Derived.TriggerEnergyPartitionUp.

Chapter 3807

A Concrete Naming Certificate for $\mathsf{ContinuousSupNorm}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{ContinuousSupNorm}^{\uparrow}$ packet records the compact-source uniform metric for bounded continuous real-valued functions as finite BEDC data. It reads the compact metric source of chapter 129, the continuous-map row of chapter 130, the real-valued uniform Cauchy route of chapter 1830, the uniform-limit metric handoff of chapter 1764, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the finite sup-norm surface needed by compact continuous-function consumers without importing a completed function space, host function equality, or a global supremum operator outside the displayed ledger.

Definition 3807.1 (Continuous sup-norm carrier)**.** *A* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, F, R, O, M, B, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *packet.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for a real-valued function on K.*
3. *R is the pointwise* $\mathsf{Real}^{\uparrow}$ *difference and absolute-value seal for inspected source windows.*
4. *O is the finite oscillation ledger, recording the inspected cover cells, source windows, and value-oscillation bounds.*
5. *M is the displayed modulus row that transports continuous-map control from source-window refinement to real-value tolerance.*
6. *B is the supremum-bound witness, recording a finite bound row for the displayed oscillation and pointwise-difference ledger.*
7. *H records componentwise* hsame *transport for the compact source, continuous-map row, Real difference row, oscillation ledger, modulus row, bound witness, replay row, provenance, and local name.*
8. *C records the displayed* Cont *replay route from a sup-norm request through $K, F, R, O, M, B, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$, $\mathsf{UniformLimitMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousSupNorm}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed compact source, continuous-map row, pointwise Real difference row, finite oscillation and modulus ledgers, supremum-bound witness, structural transport, replay, provenance, and local naming. It has no coordinate for a completed Banach space, quotient equality of functions, an ambient supremum over all host points, a choice-selected extremal point, or bridge checking.

Lean4 ✓ `BEDC.Derived.ContinuousSupNormUp.ContinuousSupNormTasteGate single carrier alignment`

Theorem 3807.2 (ContinuousSupNorm NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *carrier* $S = (K, F, R, O, M, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ContinuousSupNorm}^{\uparrow}}$ *surface consists exactly of compact metric source admission through* K*, continuous-map graph and pointwise-continuity admission through* F*, pointwise Real difference sealing through* R*, finite oscillation exposure through* O*, modulus transport through* M*, finite sup-bound exposure through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 3807.1. The tuple displays the compact source row, continuous-map row, Real difference row, finite oscillation ledger, modulus row, finite bound witness, transport, replay, provenance, and local naming.

The compact source and continuous-map rows determine the only function values that may be inspected. The Real difference row and finite oscillation ledger compare those displayed values, while the modulus row keeps the comparison tied to the same compact source windows.

The finite bound witness records the sup-norm-facing estimate without selecting an ambient supremum. Since the remaining structural rows only transport, replay, source, and name the same displayed data, the listed rows exhaust the local NameCert obligations. □

Theorem 3807.3 (ContinuousSupNorm compact-uniform handoff)**.** *Every compact-continuous norm consumer of an accepted* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *packet reads the norm route through compact metric source rows, continuous-map rows, finite oscillation rows, modulus rows, Real difference seals, finite sup-bound witnesses,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data. The route may be consumed by compact-uniform and uniform-modulus surfaces such as chapter 388, chapter 369, and chapter 130, but it exports no host function equality, open-cover compactness, quotient real equality, selected supremum, or ambient completeness.*

Proof. Use Definition 3807.2. It orders the compact source row, continuous-map row, Real difference row, oscillation ledger, modulus row, and finite bound witness inside one accepted packet.

The compact and continuous rows expose only finite inspection windows and displayed graph reads. The modulus and oscillation rows transport those reads to a common Real tolerance, and the bound witness records the finite norm-facing estimate.

Thus every compact-uniform consumer receives the displayed BEDC route. The carrier has no coordinate for a host function object, open-cover compactness object, quotient Real equality, selected supremum, or ambient completeness theorem. □

Theorem 3807.4 (ContinuousSupNorm Real seal nonescape)**.** *Every Real-valued bound exported by an accepted* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *carrier passes through the pointwise* $\mathsf{Real}^{\uparrow}$ *difference seal* R *and the finite sup-bound witness* B*. Consequently the exported sup-norm data can depend only on compact source windows, continuous-map rows, finite oscillation and modulus ledgers, displayed Real comparison rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data.*

Proof. Begin with the accepted carrier. The Real-facing coordinate is R, and the norm-facing bound coordinate is B.

Any bound read first uses the compact source K and continuous-map row F, then the oscillation and modulus rows O, M, and then the Real difference seal R. Only after those displayed rows are fixed can the finite bound witness B export a sup-norm-facing value.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. Since no other Real-valued coordinate appears in the carrier, the exported bound cannot leave the displayed Real-seal surface. □

Theorem 3807.5 (Continuous sup-norm uniform-limit metric export)**.** *Every accepted* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *carrier* $S = (K, F, R, O, M, B, H, C, P, N)$ *handed to* $\mathsf{UniformLimitMetric}^{\uparrow}$ *or* $\mathsf{UniformSequentialLimit}^{\uparrow}$ *exports only compact metric source rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, finite oscillation and modulus ledgers, pointwise* $\mathsf{Real}^{\uparrow}$ *difference seals, finite sup-bound witnesses, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ContinuousSupNorm}^{\uparrow}}$ *row. The export route has no coordinate for host function equality, a selected supremum point, a completed function-space quotient, a choice-selected limiting function, or ambient compactness outside the displayed compact metric source.*

Proof. Project the carrier and apply Definition 3807.3. The compact source, continuous-map row, oscillation ledger, modulus row, Real difference seal, and finite bound witness already form the only compact-uniform route available to a consumer.

Use Definition 3807.4 for the Real-facing boundary. It forces every exported bound through the displayed pointwise difference seal and finite sup-bound witness.

Finally compose this boundary with the Cauchy-control handoff of Definition 3807.6. The resulting uniform-limit metric export reads exactly $K, F, O, M, R, B, H, C, P, N$ and nothing else.

Since the carrier has no coordinate for host function equality, selected supremum data, completed function-space quotients, selected limiting functions, or ambient compactness beyond K, both $\mathsf{UniformLimitMetric}^{\uparrow}$ and $\mathsf{UniformSequentialLimit}^{\uparrow}$ receive only the finite BEDC route. □

Theorem 3807.6 (Continuous sup-norm Cauchy control)**.** *Every accepted* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *carrier* $S = (K, F, R, O, M, B, H, C, P, N)$ *that is read as a sup-norm Cauchy row supplies uniform finite-window Cauchy control over the compact source. For each displayed tolerance request, the accepted read factors through the finite route*

$$K, F \longmapsto O, M \longmapsto R, B \longmapsto H, C, P, N.$$

Thus every inspected pair of function rows is controlled by the same compact-source window ledger and the same RealUp difference-and-bound witness.

Proof. Project the carrier of Definition 3807.1. The compact source K and continuous-map row F determine which source windows and pointwise Real reads can be inspected.

The finite oscillation row O and modulus row M then give a single finite window ledger for the tolerance request. The Real difference row R and supremum-bound witness B read all inspected pointwise differences through that ledger.

Finally, H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate stores host function equality, a completed function space, or an ambient supremum operator, the Cauchy control available to a consumer is exactly the displayed uniform finite-window control. □

Theorem 3807.7 (Continuous sup-norm uniform-limit handoff)**.** *Every* ContinuousSupNorm$^{\uparrow}$ *Cauchy-control read accepted by* $S = (K, F, R, O, M, B, H, C, P, N)$ *may be handed to the* UniformLimitMetric$^{\uparrow}$ *packet only through the displayed compact source, continuous-map row, finite oscillation and modulus ledgers, RealUp pointwise-difference seal, supremum-bound witness, componentwise transport, replay, provenance, and local naming rows. The same sup-norm comparison row is consumed by* UniformSequentialLimit$^{\uparrow}$ *through chapter 3874 when a uniform tail schedule is read as one tolerance-controlled Real-limit route. The handoff exports no additional completeness, quotient-function equality, or selected limit object.*

Proof. Begin with the Cauchy-control route of Definition 3807.6. It exposes the compact source and continuous-map row before the oscillation, modulus, Real difference, and bound rows are consumed.

The UniformLimitMetric$^{\uparrow}$ consumer can therefore read only the finite route already present in $K, F, O, M, R, B, H, C, P, N$. The package provenance P records the connection with RealFunctionUniformCauchy$^{\uparrow}$ and UniformLimitMetric$^{\uparrow}$, while N names only the local sup-norm packet.

There is no remaining coordinate for a host completion theorem, a quotient of functions, or a choice-selected limiting function. Hence the handoff is exactly the finite BEDC route displayed by the carrier. □

Closure status for NameCert$_{\text{ContinuousSupNorm}^{\uparrow}}$**.**

Constructive story: A ContinuousSupNorm$^{\uparrow}$ packet is generated from a compact metric source, continuous-map row, pointwise RealUp difference seal, finite oscillation and modulus ledgers, supremum-bound witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ContinuousSupNorm}^{\uparrow}}$, seed)

Scope closed: Definition 3807.1, Definition 3807.6, Definition 3807.5, and Definition 3807.7 seed the compact-source sup-norm carrier, Cauchy-control route, uniform-limit metric export, and uniform-limit handoff for bounded continuous real-valued functions.

Formal verification: FormalStatus(NameCert$_{\text{ContinuousSupNorm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach-space completeness, quotient equality of functions, host supremum existence, selected limit functions, Lean verification, or bridge checking for ContinuousSupNorm$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite oscillation coverage, modulus transport, RealUp difference sealing, supremum-bound exactness, Cauchy-control routing, uniform-limit handoff, replay stability, and ledger non-escape for BEDC.Derived.ContinuousSupNormUp.

Chapter 3808

A Concrete Naming Certificate for $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$

The $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$ packet realizes the bounded redex-frontier route needed by the MetaCIC confluence open problem of section 9386.3. It sits beside the residual-substitution boundary of chapter 2181, the closed parallel-diamond premise ledger of chapter 2325, the local diamond witness of chapter 3595, and the critical-pair boundary of chapter 2212. The packet records a finite bounded route for residual substitution without converting that route into full closed confluence.

Falsifiable prediction: Any claimed full parallel diamond for MetaCIC closed terms that bypasses the displayed $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$ route through finite redex-frontier rows, residual-route rows, bounded checker rows, local joins, obstruction retention, transport, replay, provenance, and local NameCert data fails the packet boundary.

Independence witness: metacic-residual-substitution-boundary, closed-parallel-diamond-premise-ledger, metacic-local-diamond-witness, metacic-confluence-critical-pair-boundary: none is bijective to $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$ because this packet jointly carries bounded redex-frontier data, residual-route accounting, bounded checking, local joins, obstruction retention, transport, replay, provenance, and local naming as one finite frontier.

Definition 3808.1 (Bounded residual substitution frontier carrier)**.** *A* $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, S, B, J, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the finite redex-frontier row, listing the inspected beta-redex positions and their bounded residual descendants.*
2. *S is the residual-route row, recording the displayed substitution route and binder-depth ledger for the bounded window.*
3. *B is the bounded checker row, reading only finite closedness, variable-escape, and branch-compatibility checks.*
4. *J is the local join row, storing the common-reduct candidate produced inside the bounded frontier.*

5. *O is the obstruction row, retaining the absent endpoints: full* BetaParallelSubstitutionCompatibility*, premise-free closed parallel diamond, arbitrary closed Church–Rosser, and unchecked subject-reduction discharge.*
6. *H records componentwise* hsame *transport for the redex frontier, residual route, bounded checker, local join, obstruction, replay, provenance, and local name rows.*
7. *C records displayed* Cont *replay from a confluence-frontier request through R, S, B, J, O, H, P, N.*
8. *P is the* Pkg *provenance over* BoundedResidualSubstitutionFrontier$^{\uparrow}$*,* MetaCICResidualSubstitutionBoundary$^{\uparrow}$*,* ClosedParallelDiamondPremiseLedger$^{\uparrow}$*,* MetaCICLocalDiamondWitness$^{\uparrow}$*,* MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$ BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* NameCert$_{\text{BoundedResidualSubstitutionFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for full closed confluence, unrestricted residual-substitution compatibility, a hidden substitution theorem, evaluator equality, or kernel consistency.

Lean4 ✓ `BEDC.Derived.BoundedResidualSubstitutionFrontierUp.BoundedResidualSubstitutionFrontierTasteGate`
`single carrier alignment`

Theorem 3808.2 (Bounded residual substitution frontier obligations)**.** *For every accepted* BoundedResidualSubstitu *carrier $F = (R, S, B, J, O, H, C, P, N)$, the local* NameCert$_{\text{BoundedResidualSubstitutionFrontier}^{\uparrow}}$ *surface consists exactly of finite redex-frontier exposure through R, residual-route exposure through S, bounded checking through B, local join exposure through J, obstruction retention through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

The confluence-facing read is finite:

$$R, S, B \longmapsto J, O \longmapsto H, C, P, N.$$

It does not escape to full closed confluence; any consumer still sees the residual-substitution and closed parallel-diamond premise boundaries as displayed inputs.

Proof. Project the carrier of Definition 3808.1. The rows $R, S, B, J, O, H, C, P, N$ are the whole packet, so every local obligation is read from one displayed coordinate.

The bounded route begins with R, S, B. The redex-frontier row lists the inspected positions, the residual-route row records the substitution accounting, and the bounded checker row verifies only the finite window available to the packet.

The local join row J is therefore downstream of bounded evidence. The obstruction row O records that full substitution compatibility, a premise-free closed parallel diamond, arbitrary closed Church–Rosser, and unchecked subject-reduction discharge are not exported.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for a global confluence theorem or hidden substitution theorem, the displayed obligations cannot escape their bounded frontier. □

Lean4 ✓ `BEDC.Derived.BoundedResidualSubstitutionFrontierUp.BoundedResidualSubstitutionFrontierNamecert(`

Theorem 3808.3 (MetaCIC residual-substitution candidate support)**.** *Any candidate-mediated strong-normalization or confluence consumer using an accepted* BoundedResidualSubstitutionFrontier$^{\uparrow}$ *carrier $F = (R, S, B, J, O, H, C, P, N)$ must expose $R, S, B, J, O, H, C, P, N$ before projecting a common-reduct candidate. In particular, it must cite the residual-substitution boundary, the closed*

parallel-diamond premise ledger, the local diamond witness, and the critical-pair boundary before treating J as a confluence-facing candidate.

The read presents only bounded candidate support. The obstruction row O remains visible as the refusal row for full confluence, unrestricted substitution compatibility, premise-free closed parallel diamond, and unchecked subject-reduction discharge.

Proof. Project the carrier of Definition 3808.1. The rows $R, S, B, J, O, H, C, P, N$ are the complete support surface available to the consumer.

Apply Definition 3808.2. It orders the finite redex-frontier row R, residual-route row S, and bounded checker row B before the local join row J can be read.

The candidate projection therefore remains mediated by the sibling boundaries named in the provenance row: residual substitution supplies the boundary of the route, the closed parallel-diamond premise ledger supplies the premise account, the local diamond witness supplies the bounded join, and the critical-pair boundary supplies the finite obstruction interface.

Keep O in the exported packet. Since O records exactly the missing full-confluence and unrestricted-substitution data, the common-reduct candidate is a bounded local candidate rather than a proof of the unrestricted MetaCIC confluence claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$ packet is generated from finite redex-frontier rows, residual-route accounting, bounded checker rows, local joins, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3808.1 and Definition 3808.2 seed the finite bounded residual-substitution frontier for MetaCIC confluence consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full BetaParallelSubstitutionCompatibility, premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, redex-frontier coverage, residual-route exactness, bounded-checker soundness, local-join exposure, obstruction retention, transport stability, replay stability, provenance exhaustion, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.BoundedResidualSubstitutionFrontierUp.

Chapter 3809

A Concrete Naming Certificate for $\mathsf{LocatedRealContinuity}^{\uparrow}$

Following Bishop and Bridges, located continuity is recorded as finite precision-response data over located real names, not as a host function on completed reals. The $\mathsf{LocatedRealContinuity}^{\uparrow}$ packet sits over the located-real carrier of **??**, the dyadic precision ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located modulus surface of chapter 3406. It gives the L10 Real and Completion route a named continuity consumer whose public data are precision requests and finite responses rather than quotient-real functions, trichotomy, countable choice, or ambient completeness.

Definition 3809.1 (Located real continuity carrier)**.** *A* $\mathsf{LocatedRealContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, D, W, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the located input row, read through the* $\mathsf{LocatedReal}^{\uparrow}$ *surface.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger for requested input and output tolerances.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window used to inspect the located input at the requested tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that repacks the inspected window as regular rational data.*
5. *M is the modulus-response row, returning a finite precision response for the displayed input tolerance.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the output name, visible only after X, D, W, R, M have been displayed.*
7. *H records componentwise* hsame *transport for the located input, dyadic ledger, stream window, regular readback, modulus response, real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located precision request through $X, D, W, R, M, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealContinuity}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRealModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealContinuity}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host real function, quotient-real equality test, trichotomy oracle, countable-choice schedule, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.LocatedRealContinuityUp.LocatedRealContinuityTasteGate single carrier alignment`

Theorem 3809.2 (Located real continuity modulus stability)**.** *Let* $K = (X, D, W, R, M, E, H, C, P, N)$ *and* $K' = (X', D', W', R', M', E', H', C', P', N')$ *be accepted* $\mathsf{LocatedRealContinuity}^{\uparrow}$ *carriers. If the located input rows, dyadic tolerance ledgers, finite windows, and regular-rational readbacks agree componentwise under* hsame*, then the modulus-response rows* M *and* M' *answer the same displayed dyadic tolerance requests, and every* $\mathsf{Real}^{\uparrow}$ *seal consumer reaches the same response route*

$$X, D, W, R \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

Thus modulus-response stability is a finite packet property: it is preserved by hsame *transport and by the displayed dyadic tolerance rows, without reading quotient-real equality, trichotomy, countable choice, selected representatives, host function extensionality, or ambient completeness.*

Proof. Project the two accepted carriers from Definition 3809.1. The only precision source rows are X, D, W, R and their transported counterparts.

Use the assumed componentwise hsame agreement on those rows. The dyadic ledger D fixes the tolerance request, the window W fixes the finite observations, and R fixes the regular-rational readback. Therefore the accepted modulus rows M and M' respond to the same displayed precision request.

The seal row is downstream of the response row. Since E and E' can be consumed only after the displayed route through the input, tolerance, window, readback, and response rows, any $\mathsf{Real}^{\uparrow}$ consumer reads the same finite route before seeing a real-name seal.

The excluded analytic principles have no carrier coordinate in either packet. They cannot alter the transported modulus response or add a second continuity channel. □

Theorem 3809.3 (Located real continuity NameCert obligations)**.** *For an accepted* $\mathsf{LocatedRealContinuity}^{\uparrow}$ *carrier* $K = (X, D, W, R, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealContinuity}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier stability for the located input and precision-response rows, componentwise transport, the continuity-modulus ledger, terminal real-seal routing, package provenance, and local naming. The obligation surface does not include quotient reals, trichotomy, countable choice, selected representatives, host function extensionality, or ambient completeness.*

Proof. Carrier admission is projection from Definition 3809.1. The accepted packet displays exactly the located input, dyadic tolerance ledger, finite window, regular readback, modulus response, real seal, transport, replay, provenance, and local naming rows.

Classifier stability is supplied by the same inventory. An accepted continuity read must keep the rows X, D, W, R, M attached to one displayed precision route, so changing any of these rows changes the carrier rather than producing a hidden function on completed reals.

Transport and replay are the rows H and C. They preserve the displayed route through the dyadic tolerance and modulus-response ledger before any terminal $\mathsf{Real}^{\uparrow}$ seal can be read.

Finally P and N source and name the same finite packet. Since quotient reals, trichotomy, countable choice, selected representatives, host function extensionality, and ambient completeness have no carrier rows, they are not local NameCert obligations for $\mathsf{LocatedRealContinuity}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealContinuity}^{\uparrow}$ packet is generated from a located input row, a dyadic precision ledger, finite StreamName windows, RegSeqRat readback, a modulus-response row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3809.1, Definition 3809.2, and Definition 3809.3 seed the finite located-continuity route from precision requests to RealUp seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host functions on completed reals, quotient-real equality, trichotomy, countable choice, selected representatives, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, transport, continuity-modulus ledger rows, real-seal routing, provenance, and local naming for BEDC.Derived.LocatedRealContinuityUp.

Chapter 3810

A Concrete Naming Certificate for CellularSubstrateClassifierBoundary$^{\uparrow}$

The CellularSubstrateClassifierBoundary$^{\uparrow}$ packet realizes the cellular-automaton substrate reading of chapter 9390 as a finite classifier-boundary carrier. It binds the local transition table, orbit replay, pattern-classifier tag row, closed-observation manifest, and refusal boundary into one NameCert surface. The packet is designed to accept cellular substrate observations only when the classifier that names the observed pattern is displayed as data, so no untagged orbit replay can masquerade as a closed observation.

Before its manifest and closed-observation rows are exported, the packet consumes the rule-table and finite-orbit rows of chapter 934, the substrate carrier of chapter 942, and the classifier comparison surface of chapter 945. These sibling routes determine which local transition, orbit replay, and pattern tag rows may enter the boundary carrier.

The classifier-boundary packet also consumes the observation-window discipline of chapter 2371 and the classifier-row surface of chapter 945 before its Rule 110 handoff row is exposed. Thus the closed-observation boundary and the classifier lattice edge are both visible before a universal-substrate read can use the packet.

Definition 3810.1 (CellularSubstrateClassifierBoundary carrier)**.** *A* CellularSubstrateClassifierBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, O, G, M, A, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the local cellular transition row, including the finite alphabet, neighborhood window, and rule table.*
2. *O is the orbit replay row generated by iterating L over the stated initial row and finite time window.*
3. *G is the pattern-classifier tag row that assigns each inspected local pattern to a finite tag family.*
4. *M is the manifest row specifying the accepted observation windows, expected replay checks, and public audit fields.*
5. *A is the closed-observation admission row, requiring the replayed orbit and the classifier tags to agree on every observed window.*

6. *R is the Rule 110 substrate handoff row when the local rule is read through the cellular universal-substrate exhibit.*
7. *H records componentwise* hsame *transport for the local rule, orbit replay, classifier tags, manifest, admission row, Rule 110 handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from local transition data through orbit replay, pattern classification, closed-observation admission, and any Rule 110 handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$*, cellular-automaton substrate reading, Rule 110 substrate, classifier tags, closed observation,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unclassified orbit, a detached semantic interpretation of a pattern, an induction principle over all time steps, or an observation that bypasses the manifest and classifier rows.

```
Lean4 ✓  BEDC.Derived.CellularSubstrateClassifierBoundaryUp.CellularSubstrateClassifierBoundaryTasteGate
single carrier alignment
```

Theorem 3810.2 (CellularSubstrateClassifierBoundary NameCert obligations)**.** *For every accepted* $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$ *carrier* $B = (L, O, G, M, A, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the local transition table, orbit replay, classifier tag row, manifest, closed-observation admission row, optional Rule 110 handoff, transport, replay, provenance, and local naming;*
2. *local-rule replay, requiring every accepted observation to display L and O before any classifier-boundary claim is consumed;*
3. *classifier-boundary exposure, requiring the tag row G to be present for each observed pattern window;*
4. *manifest closure, requiring the row M and admission row A to bind replayed orbits and classifier tags into one finite observation record;*
5. *Rule 110 handoff discipline, requiring R when the packet is read through the universal cellular substrate route;*
6. *classifier transport, requiring all accepted comparisons to use only H, C, P, and N;*
7. *ledger refusal, excluding untagged orbit replay, detached semantic interpretation, all-time induction, and observations outside the manifest and classifier rows.*

No classifier-boundary obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3810.1. The accepted packet displays exactly the local rule, orbit replay, classifier tag row, manifest, admission row, Rule 110 handoff, and structural rows.

Local-rule replay comes first. The orbit row O is generated from the transition row L, so no accepted observation can be read without displaying the finite rule table and the replay window.

Classifier-boundary exposure and manifest closure then bind the orbit to a tag discipline. The tag row G names the inspected patterns, while M and A require those tags to agree with the manifest's closed-observation checks.

Finally the Rule 110 handoff and structural rows preserve the same route. The optional row R names the universal cellular substrate path when present, and H, C, P, N transport, replay, source, and name the local carrier. Since untagged or detached observations have no row in the packet, they cannot become NameCert obligations. □

Falsifiable prediction: A packet with a local transition row and orbit replay but no pattern-classifier tag row is rejected by the classifier-boundary carrier.

Independence witness: cellular-automaton-substrate-reading, metacicredexfrontier, rule110substrate, binaire, apophaticname: the packet is not bijective to these siblings because it binds local cellular transition, orbit replay, classifier tags, closed-observation admission, Rule 110 handoff, and classifier-boundary refusal in one finite NameCert route.

Theorem 3810.3 (CellularSubstrateClassifierBoundary closed-observation handoff)**.** *Every closed cellular observation accepted by a* $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$ *packet reads the route*

$$L, O \longmapsto G \longmapsto M, A \longmapsto R \longmapsto H, C, P, N.$$

The route starts with a finite local transition rule and orbit replay, passes through the pattern-classifier tag row, binds the result to a manifest and closed-observation admission row, and reaches the Rule 110 handoff only as displayed substrate data. A Lean follow-up for this carrier must supply Nontrivial *and* FieldFaithful *instances in* `lean4/BEDC/Derived/CellularSubstrateClassifierBoundaryUp/Taste`

Proof. Project the accepted carrier of Definition 3810.1. The rows L and O are the only local-rule and orbit-replay rows, and G is the only classifier row attached to the inspected patterns.

Read manifest admission next. The rows M and A bind the displayed classifier tags to the closed-observation record, so an orbit replay without G cannot pass the admission surface.

The remaining rows preserve the same finite dependency chain. The Rule 110 handoff R is downstream of rule, orbit, classifier, and manifest data, while H, C, P, N transport, replay, source, and name the accepted route. Therefore every accepted observation factors through the classifier boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$ packet is generated from a local cellular transition table, orbit replay, pattern-classifier tags, a closed-observation manifest, an admission row, an optional Rule110Substrate handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3810.1, Definition 3810.2, and Definition 3810.3 seed the finite classifier-boundary surface for cellular substrate observations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close all-time induction, unclassified orbit semantics, a complete Rule 110 bridge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-rule replay, classifier-boundary exposure, manifest closure, Rule 110 handoff discipline, classifier transport, and ledger refusal for BEDC.Derived.CellularSubstrateClassifierBoundaryUp.

Chapter 3811

A Concrete Naming Certificate for HadamardProductSeries$^{\uparrow}$

Following Hadamard's coefficientwise product of power series and Hardy's series estimates, the HadamardProductSeries$^{\uparrow}$ packet records the finite route by which two displayed real coefficient streams are multiplied coordinate by coordinate before they are handed to the ordinary CauchyProduct$^{\uparrow}$ and RealSeries$^{\uparrow}$ convergence surfaces. It sits beside the real-series carrier of chapter 1581, the Cauchy-product certificate of chapter 464, the majorant route of chapter 399, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic coefficient ledger of chapter 291, and the terminal real seal of chapter 38. The packet names coefficientwise multiplication as finite BEDC data; it is not a host analytic-function identity, not a quotient of series, not a selected infinite sum, and not an ambient completeness theorem.

Definition 3811.1 (Hadamard product series carrier)**.** *A* HadamardProductSeries$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, W, D, R, S, M, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two source* RealSeries$^{\uparrow}$ *coefficient-stream rows.*
2. *W is the synchronized* StreamName$^{\uparrow}$ *window row selecting matching coefficient positions from A and B.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *coefficient-product ledger; for every displayed position in W it records the dyadic product of the two read coefficients and its tolerance budget.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row repacking the coefficientwise products as regular rational finite-window data.*
5. *S is the derived* RealSeries$^{\uparrow}$ *coefficient stream assembled from R and the synchronized windows.*
6. *M is the convergence-control row, either a displayed* WeierstrassMTest$^{\uparrow}$ *majorant for the product coefficients or a* CauchyProduct$^{\uparrow}$ *handoff consuming the same finite product ledger.*
7. *E is the terminal* Real$^{\uparrow}$ *seal exposed only after A, B, W, D, R, S, M have been replayed.*
8. *H records componentwise* hsame *transport for the two source series, the synchronized windows, dyadic products, regular readback, derived series, convergence-control row, endpoint seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from paired coefficient requests through synchronized windows, dyadic products, regular readback, the derived series, convergence control, and the endpoint seal.*
10. *P is the* Pkg *provenance over* HadamardProductSeries$^{\uparrow}$, RealSeries$^{\uparrow}$, CauchyProduct$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HadamardProductSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W, D, R, S, M, E, H, C, P, N$. It has no coordinate for host analytic continuation, quotient series equality, selected infinite sums, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 3811.2 (Hadamard product series NameCert obligations)**.** *For every accepted* HadamardProductSeries$^{\uparrow}$ *carrier $K = (A, B, W, D, R, S, M, E, H, C, P, N)$, the local* NameCert$_{\text{HadamardProductSeries}^{\uparrow}}$ *surface consists exactly of the two source* RealSeries$^{\uparrow}$ *rows, synchronized* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *coefficient-product ledger,* RegSeqRat$^{\uparrow}$ *readback, derived* RealSeries$^{\uparrow}$ *row, convergence-control row, terminal* Real$^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, and local naming through $A, B, W, D, R, S, M, E, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.HadamardProductSeriesUp.HadamardProductSeriesTasteGate single carrier alignment`

Proof. Project the carrier of Definition 3811.1. The only source series coordinates are A and B, and coefficient requests can reach them only through the synchronized finite window row W.

The coefficient-product data are then forced through D. Row D records the dyadic product and tolerance budget for each displayed pair of coefficients, and row R repacks exactly those reads as RegSeqRat$^{\uparrow}$ data.

The derived series row S and convergence-control row M are downstream of that readback. The structural rows H, C, P, N transport, replay, source, and name the same route, while the carrier excludes host analytic identities, quotient series equality, selected infinite sums, countable choice, and ambient real completeness. Thus the listed rows exhaust the local NameCert surface. □

Theorem 3811.3 (Hadamard product Cauchy-product handoff)**.** *Every* CauchyProduct$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, RealSeries$^{\uparrow}$, *or* Real$^{\uparrow}$ *consumer of an accepted* HadamardProductSeries$^{\uparrow}$ *carrier must read the finite route*

$$A, B \longmapsto W \longmapsto D \longmapsto R \longmapsto S \longmapsto M \longmapsto E$$

before consuming the derived coefficient stream or endpoint seal. The handoff therefore supplies coefficientwise-product data as synchronized finite windows and dyadic products, not as a host multiplication theorem for completed series.

Proof. Begin with a consumer request for product-series data. The two source streams are readable only as A and B, and the matching of coefficient positions is stored only in W.

The product coefficient cannot be read before the dyadic ledger D is displayed. Its regular-rational readback is R, and the derived real-series row S is assembled only from those finite product windows.

The convergence-control row M is the unique handoff to the named CauchyProduct$^{\uparrow}$ or WeierstrassMTest$^{\uparrow}$ surface, and E is downstream of that handoff. Since H, C, P, N preserve the same route and no additional analytic coordinate is present, every public consumer factors through the displayed finite coefficientwise-product path. □

Falsifiable prediction: Every accepted $\mathsf{HadamardProductSeries}^{\uparrow}$ endpoint read factors through paired $\mathsf{RealSeries}^{\uparrow}$ coefficient rows, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ product ledgers, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{CauchyProduct}^{\uparrow}$ or $\mathsf{WeierstrassMTest}^{\uparrow}$ convergence control, provenance, replay, and local NameCert rows.

Independence witness: realseries, cauchyproduct, weierstrassmtest, regseqrat, streamname, dyadicratcore, real: RealSeriesUp carries single-stream series data without paired coefficient products; CauchyProductUp records convolution-style handoff without the synchronized coefficientwise ledger; WeierstrassMTestUp records majorants without paired coefficient multiplication; RegSeqRatUp, StreamNameUp, and DyadicRatCoreUp supply readback, windows, and dyadic products separately; RealUp supplies the endpoint seal without the product-series route. None is bijective to $\mathsf{HadamardProductSeries}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardProductSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{HadamardProductSeries}^{\uparrow}$ packet is generated from two RealSeries coefficient streams, synchronized StreamName windows, DyadicRatCore coefficient-product ledgers, RegSeqRat readback, a derived RealSeries row, CauchyProduct or WeierstrassMTest convergence control, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardProductSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3811.1, Definition 3811.2, and Definition 3811.3 seed the finite coefficientwise-product route from paired real-series coefficients to convergence control and terminal real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardProductSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host analytic continuation, quotient series equality, selected infinite sums, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized window exactness, dyadic coefficient-product accounting, RegSeqRat readback, RealSeries assembly, CauchyProduct or WeierstrassMTest handoff, RealUp seal routing, and local naming for BEDC.Derived.HadamardProductSeriesUp.

Chapter 3812

A Concrete Naming Certificate for $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley metric-space terminology, the $\mathsf{LipschitzContinuityHandoff}$ packet records the textbook handoff from a displayed Lipschitz bound to a uniform continuity modulus before regular-Cauchy or Real-facing consumers read the result. It is grounded in the bound-carrying $\mathsf{LipschitzMap}^{\uparrow}$ surface of chapter 410, the metric rows of chapter 57, the graph row of chapter 130, the induced modulus row of chapter 369, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the continuity handoff consumed by L10 Real and Completion routes; it does not duplicate the upstream Lipschitz map carrier or turn that carrier into a complete downstream theorem.

Definition 3812.1 (Lipschitz continuity handoff carrier)**.** *A* $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, X, Y, G, B, U, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the upstream* $\mathsf{LipschitzMap}^{\uparrow}$ *row, read through the carrier package of chapter 410.*
2. *X and Y are the source and target* $\mathsf{Met}^{\uparrow}$ *rows used by the displayed distance comparison.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row carried by the same Lipschitz packet.*
4. *B is the displayed rational bound ledger used to compare source and target distances.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row induced by the bound ledger.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row available to regular-Cauchy consumers of the mapped readings.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after L, X, Y, G, B, U, Q have fixed the handoff.*
8. *H records componentwise* hsame *transport for the Lipschitz row, metric rows, graph, bound ledger, modulus, regular readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a continuity request through $L, X, Y, G, B, U, Q, R, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzContinuityHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted handoff packets only through $L, X, Y, G, B, U, Q, R, H, C, P, N$. It has no coordinate for host function extensionality, quotient map equality, choice of representatives, selected limits, countable choice, differentiability, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

$$K = (L, X, Y, G, B, U, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzContinuityHandoff}^{\uparrow}}$ *surface consists exactly of carrier exposure for the upstream* $\mathsf{LipschitzMap}^{\uparrow}$ *row, source and target* $\mathsf{Met}^{\uparrow}$ *rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, rational Lipschitz-bound ledger, induced* $\mathsf{UniformModulus}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3812.1. The displayed tuple contains one upstream Lipschitz row, two metric rows, one graph row, one bound ledger, one induced modulus row, one regular-rational handoff row, one Real seal row, and the structural rows H, C, P, N.

The analytic route is inherited from the upstream $\mathsf{LipschitzMap}^{\uparrow}$ carrier rather than duplicated. The source and target metric rows, graph row, and bound ledger are read from L, and the modulus row U is the displayed uniform-modulus handoff induced by that same ledger.

The downstream rows Q and R are sealed only after the finite handoff through L, X, Y, G, B, U is visible. Since the carrier has no coordinate for host function extensionality, quotient map equality, representative choice, selected limits, countable choice, differentiability, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 3812.3 (Lipschitz bound to uniform modulus handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$ *carrier must first read the upstream* $\mathsf{LipschitzMap}^{\uparrow}$ *row, source and target* $\mathsf{Met}^{\uparrow}$ *rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, rational bound ledger, and induced* $\mathsf{UniformModulus}^{\uparrow}$ *row. Only then may it consume the regular-rational handoff row or terminal Real seal row.*

Proof. Start with an accepted handoff packet and project the route in Definition 3812.1. The only entrance to the continuity handoff is the upstream Lipschitz row L, and its metric, graph, and bound coordinates are displayed as X, Y, G, B.

The uniform modulus row U is downstream of that same bound ledger. Thus a regular-Cauchy consumer receives the modulus as a finite handoff from the Lipschitz bound rather than as a selected host-function modulus.

The rows Q and R are downstream seals. A consumer that reads either row has already exposed L, X, Y, G, B, U and the structural transport and replay rows, so it cannot bypass the route by host function extensionality, quotient map equality, choice of representatives, selected limits, countable choice, differentiability, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzContinuityHandoff}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$ packet is generated from an upstream LipschitzMap row, source and target MetricSpace rows, a ContinuousMap graph row, a rational Lipschitz-bound ledger, an induced UniformModulus row, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzContinuityHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3812.1, Definition 3812.2, and Definition 3812.3 seed the finite continuity handoff from displayed Lipschitz bounds to uniform moduli and regular-Cauchy or Real-facing consumers.

Formal verification: FormalStatus(NameCert$_{\text{LipschitzContinuityHandoff}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.LipschitzContinuityHandoffUp.LipschitzContinuityHandoffTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient map equality, choice of representatives, selected limits, countable choice, differentiability, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upstream Lipschitz row projection, metric and graph exposure, bound-ledger to uniform-modulus handoff, regular-rational handoff, Real-seal discipline, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.LipschitzContinuityHandoffUp.

Chapter 3813

A Concrete Naming Certificate for $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$

The $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ packet realizes the boundary-fixed disk transport reading of chapter 9463 and Definition 9463.10 as finite NameCert rows. It consumes the disk-coordinate carrier of chapter 377, the metric-read surface of chapter 3474, the fixed-boundary transport route of chapter 3500, the boundary-tangent horocycle row of chapter 3534, and the flow-style replay surface of chapter 195. The packet names a boundary shadow of transport on a displayed disk surface; it is not a host ideal-boundary quotient, not a physical cosmology, not a global flow, and not a completed hyperbolic surface.

Falsifiable prediction: Every accepted $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ read factors through displayed $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, audit/refusal, provenance, replay, and local NameCert rows before it exports a boundary-shadow reading.

Independence witness: unitdisk, hyperbolic-metric, poincare-boundary-fixed-transport, hyperbolic-horocycle, dynsystem: the UnitDisk packet records disk coordinates without metric shadowing; the HyperbolicMetric packet records metric reads without a fixed-boundary transport ledger; the PoincareBoundaryFixedTransport packet preserves a boundary anchor without a horocycle shadow; the HyperbolicHorocycle packet records boundary tangency without flow-style replay; and the DynSystem packet records routed evolution without a hyperbolic boundary anchor. None is bijective to $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$.

Definition 3813.1 (Hyperbolic boundary shadow carrier)**.** *A* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, M, B, T, Q, Y, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row for the finite source and transported observations.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *B is the boundary row naming the preserved far-end boundary reading as finite certificate data.*
4. *T is the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *row that transports disk points while preserving the boundary row B.*
5. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *shadow row recording the boundary-tangent trace left by the transported disk points.*

6. *Y is the* $\mathsf{DynSystem}^{\uparrow}$ *flow-style replay row, used only to order the finite transport observations.*
7. *F is the audit/refusal row: it records that boundary-shadow reads pass through D, M, B, T, Q, Y and do not expose a host ideal-boundary quotient, physical trajectory, or global hyperbolic surface.*
8. *H records componentwise* hsame *transport for disk, metric, boundary, transport, horocycle shadow, flow replay, audit/refusal, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from disk observations through metric readback, boundary preservation, boundary-fixed transport, horocycle shadowing, flow-style ordering, and audit/refusal.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, PoincareBoundaryFixed
$\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, B, T, Q, Y, F, H, C, P, N$. It has no coordinate for host ideal-boundary equality, unlogged observer motion, a global flow parameter, physical spacetime, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.HyperbolicBoundaryShadowUp.HyperbolicBoundaryShadowTasteGate single carrier alignment`

Theorem 3813.2 (Hyperbolic boundary shadow NameCert obligations)**.** *For every accepted* HyperbolicBoundarySh
carrier $S = (D, M, B, T, Q, Y, F, H, C, P, N)$, the local $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadow}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, hyperbolic-metric readback, boundary preservation, boundary-fixed transport, horocycle-shadow exposure, flow-style replay, audit/refusal exactness, componentwise transport, displayed continuation, package provenance, and local naming through $D, M, B, T, Q, Y, F, H, C, P, N$.*

Every boundary-shadow read from the packet factors through

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{PoincareBoundaryFixedTransport}^{\uparrow} \longmapsto \mathsf{HyperbolicHorocycle}^{\uparrow} \longmapsto \mathsf{DynSystem}^{\uparrow}$$

together with the boundary, audit/refusal, and structural BHist, hsame, Cont, Pkg, NameCert *rows.*

Proof. Project the accepted carrier. The disk surface is row D, and the hyperbolic metric readback over that surface is row M.

The boundary information is then forced through B and T. Row B names the preserved far-end boundary reading, while row T records transport that keeps that boundary row fixed in the sense of Definition 9463.10.

The shadow-specific content is row Q, read only after the disk, metric, boundary, and fixed-transport rows have been displayed. Row Y orders the finite observations as a flow-style replay without adding a global clock.

The audit/refusal row F and the structural rows H, C, P, N exhaust the public surface. Since no carrier coordinate stores host ideal-boundary equality, unlogged observer motion, a global flow parameter, or physical spacetime, the listed rows are exactly the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ packet is generated from UnitDisk coordinates, HyperbolicMetric readback, a preserved boundary row, PoincareBoundaryFixedTransport, a HyperbolicHorocycle shadow row, DynSystem flow-style replay, audit/refusal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadow}^{\uparrow}}$, seed)

Scope closed: Definition 3813.1 and Definition 3813.2 seed the finite boundary-shadow route through disk coordinates, metric readback, preserved boundary transport, horocycle shadowing, flow-style replay, audit/refusal, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicBoundaryShadow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host ideal-boundary quotient equality, physical spacetime, unlogged observer motion, global hyperbolic flows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk placement, metric readback, boundary preservation, boundary-fixed transport, horocycle-shadow exactness, flow replay, audit/refusal coverage, and local naming for BEDC.Derived.HyperbolicBoundaryShadowUp.

Chapter 3814

A Concrete Naming Certificate for $\mathsf{LocatedUniformSpace}^{\uparrow}$

Following Nachbin, Kelley, and Bishop-style located uniform structures, the $\mathsf{LocatedUniformSpace}^{\uparrow}$ packet records directed entourage data together with a finite locatedness ledger for deciding when a displayed point, filter, or net read has entered a named uniform neighbourhood. It sits between the directed-uniform carrier of chapter 2334, the symmetric uniform interface of chapter 339, the filter route of chapter 333, and the net route of chapter 589. Its constructive readback uses the finite window and rational ledgers of chapter 126, chapter 291, chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Definition 3814.1 (LocatedUniformSpace carrier)**.** *A* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (U, D, A, W, T, F, N, H, C, P, Q)$$

with the following displayed rows:

1. *U is the directed entourage row, read through the* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *and* $\mathsf{UniformSpace}^{\uparrow}$ *naming surfaces.*
2. *D is the finite directedness ledger, recording refinement, composition, and symmetry requests only as displayed entourage rows.*
3. *A is the located apartness row, recording when a point or finite window is apart from the complement of a displayed entourage.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row for finite point, net, and filter reads.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to measure the displayed locatedness request.*
6. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *handoff row.*
7. *N is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rationally named tolerance witnesses.*
8. *H is the componentwise* hsame *transport row.*
9. *C is the displayed* Cont *replay row.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformSpace}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *Q is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformSpace}^{\uparrow}}$ *row.*

No carrier coordinate stores a completed uniform space, a quotient filter, a selected limit, or a host locatedness decision.

Lean4 ✓ `BEDC.Derived.LocatedUniformSpaceUp.LocatedUniformSpaceTasteGate single carrier alignment`

Theorem 3814.2 (LocatedUniformSpace NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *carrier* $L = (U, D, A, W, T, F, N, H, C, P, Q)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, directed entourage access through* U, D*, located apartness access through* A*, finite observation windows through* W*, dyadic tolerance access through* T*, Cauchy filter and Cauchy net handoff through* F*, regular rational readback through* N*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* Q*.*

Proof. Project the carrier of Definition 3814.1. The entourage, directedness, locatedness, window, tolerance, Cauchy, and rational-readback rows are exactly U, D, A, W, T, F, N.

The structural rows H, C, P, Q transport, replay, source, and name the same finite route. Since the carrier has no further coordinate, a consumer cannot replace this route by a host uniform space, a quotient filter, a selected limit, or an undecorated locatedness predicate. □

Theorem 3814.3 (LocatedUniformSpace Cauchy-filter route)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *consumer read accepted by a* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *carrier factors through*

$$U, D, A \longmapsto W, T \longmapsto F \longmapsto N, H, C, P, Q.$$

The Cauchy handoff may inspect only the displayed directed entourage ledger, located apartness row, finite observation windows, dyadic tolerance ledger, and regular rational readback.

Proof. Start with a Cauchy-facing consumer. The carrier exposes Cauchy data only at row F, so the consumer must first read the entourage and locatedness rows that determine which finite windows are admissible.

The rows W and T then display the finite observations and dyadic tolerances used by the Cauchy request. The regular readback row N records the rational witness visible to the consumer.

Transport, replay, provenance, and local naming are supplied only by H, C, P, Q. Thus the route is finite and excludes quotient filters, selected subnet limits, and ambient completeness. □

Theorem 3814.4 (LocatedUniformSpace entourage-location obligation)**.** *For every accepted* $\mathsf{LocatedUniformSpace}$ *carrier*

$$L = (U, D, A, W, T, F, N, H, C, P, Q),$$

each located entourage request must expose the directed entourage row U*, directedness ledger* D*, located apartness row* A*, finite observation-window row* W*, and dyadic tolerance row* T *before any* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *handoff is available. The request may not enter* F *from an unnamed entourage, a host locatedness predicate, a quotient-filter class, a selected limit, or an ambient completeness principle.*

Proof. Project the carrier rows of Definition 3814.1. The only coordinates that can answer an entourage-location request before Cauchy handoff are U, D, A, W, T.

The directedness ledger D refines requests only as displayed entourage rows over U, while A records located apartness only for the displayed point or window. The rows W and T then provide the finite observation and dyadic tolerance data needed to state the request.

Since F is downstream of these five rows, a Cauchy consumer can be admitted only after the located entourage request has passed through them. No excluded host object is a coordinate of L, so none can supply a second route into F. □

Theorem 3814.5 (LocatedUniformSpace filter-net handoff exactness)**.** *For every accepted* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *carrier*

$$L = (U, D, A, W, T, F, N, H, C, P, Q),$$

every $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *handoff through* F *is exact only along the finite route*

$$U, D, A, W, T \longmapsto F \longmapsto N, H, C, P, Q.$$

The packet therefore exports Cauchy-facing data as the displayed located-uniform handoff, not as quotient-filter equality, a selected subnet, a completed uniform-space theorem, separated reflection, or host locatedness.

Proof. Begin with the handoff row F. By Definition 3814.3, a Cauchy-facing read reaches F only after the directed entourage, locatedness, finite-window, and tolerance rows have been read.

Apply the entourage-location obligation. It prevents F from being entered by an unnamed entourage or external locatedness decision, so the handoff is tied to the displayed U, D, A, W, T rows.

Finally read N, H, C, P, Q. These rows supply rational readback, componentwise transport, displayed replay, provenance, and local naming for the same route. Because the carrier has no coordinate for quotient filters, selected subnet limits, completion, separated reflection, or host locatedness, the displayed route is the exact handoff surface. □

Theorem 3814.6 (LocatedUniformSpace real-completion boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *readback exported by a* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *packet is downstream of the displayed route through* U, D, A, W, T, F, N *and the structural rows* H, C, P, Q*. The packet can feed completion-facing chapters only by exposing the finite located uniform data; it does not assert that the surrounding uniform space is complete, separated, precompact, or represented by chosen Cauchy names.*

Proof. Read the completion-facing clause of the carrier. A real-facing consumer reaches rational witnesses only through N, and N is downstream of the displayed window and tolerance route.

The package row P records the relationship with $\mathsf{Real}^{\uparrow}$ and the uniform siblings, while Q names only this local packet. No row remains for a host completion theorem, a selected Cauchy representative, a quotient construction, or a global precompactness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedUniformSpace}^{\uparrow}$ packet is generated from directed entourage data, located apartness, finite observation windows, dyadic tolerance rows, Cauchy filter and net handoff, regular rational readback, componentwise transport, displayed continuation, package provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedUniformSpace}^{\uparrow}}$, obligation)

Scope closed: Definition 3814.1, Definition 3814.2, Definition 3814.3, Definition 3814.4, Definition 3814.5, and Definition 3814.6 bind the finite located directed-uniform certificate surface and its Cauchy filter/net obligation route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedUniformSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close completion, precompactness, quotient-filter equality, selected limits, separated reflection, or bridge checking for $\mathsf{LocatedUniformSpace}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, directed-entourage routing, locatedness exactness, Cauchy handoff, Real readback boundary, transport stability, replay stability, and ledger non-escape for BEDC.Derived.LocatedUniformSpa

Chapter 3815

A Concrete Naming Certificate for $\mathsf{ClosedIntervalBisection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedIntervalBisection}^{\uparrow}$ packet records constructive interval bisection over a located closed bounded interval by finite endpoint, midpoint, branch, and readback rows. It refines the closed bounded interval carrier of chapter 1591, the located bisection route of chapter 1711, the explicit interval split of chapter 1465, and the nested-route consumer of chapter 1713. Its completion-facing rows pass through chapter 126, chapter 301, and chapter 38. The packet supplies a closed-interval bisection surface for L10 Real and Completion arguments without importing open-cover compactness, real trichotomy, quotient real equality, selected infinite branches, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3815.1 (Closed interval bisection carrier)**.** *A* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, L, M, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, including lower and upper endpoint reads, endpoint order, rational containment, dyadic containment, finite windows, regular readback, and the terminal real-name seal of the source interval.*
2. *L is the located endpoint row. It records the endpoint-location evidence needed to decide which child interval is retained for the current finite request, without adding a trichotomy or host real comparison coordinate.*
3. *M is the midpoint row. It is computed from the displayed endpoint cells of I and is read before the branch row is inspected.*
4. *D is the dyadic branch row. It records the left or right retained child, the parent-to-child containment witness, and the dyadic diameter budget for the current bisection request.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the parent endpoints, midpoint read, retained child endpoints, and branch ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows and dyadic branch data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, M, D, S, R have been displayed.*

8. *H records componentwise* hsame *transport for the closed interval, located endpoint, midpoint, dyadic branch, finite windows, regular rational readback, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a closed-interval bisection request through I, L, M, D, S, R, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalBisection}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{IntervalBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalBisection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, M, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, hidden endpoint choice, selected infinite branches, real trichotomy, quotient stream equality, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3815.2 (Closed interval bisection NameCert obligations)**.** *For every accepted* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *carrier $B = (I, L, M, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalBisection}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, closed-bounded interval exposure through I, located endpoint exposure through L, midpoint formation through M, dyadic branch and child-containment exposure through D, finite-window exposure through S, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 3815.1. The row I supplies the only closed bounded interval source, while L supplies the only located endpoint evidence available to the branch request.

The midpoint and branch obligations are consecutive. The row M is read from the displayed endpoint cells of I, and the dyadic branch row D records the retained child interval only after that midpoint row is visible.

The completion-facing obligations are downstream of the branch. The finite windows S and regular rational readback R consume the parent endpoints, midpoint, and retained child rows fixed by I, L, M, D, and the real seal E is reached only after that readback route is displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded host objects occurs as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 3815.3 (Closed interval bisection branch nonescape)**.** *Every retained-branch read of an accepted* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto L, M, D \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the retained child interval is read from displayed closed-interval endpoints, located endpoint evidence, the midpoint row, and the dyadic branch ledger; it is not supplied by a hidden branch selector, a real trichotomy oracle, open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ClosedIntervalBisectionUp.ClosedIntervalBisection branch nonescape route`

Proof. Start with the source row I. It fixes the closed bounded interval whose lower and upper endpoint data can be inspected by the branch request.

Next read L and M. The located endpoint row supplies only the displayed endpoint-location evidence for the current finite request, and the midpoint row supplies the child boundary computed from the same endpoint cells.

The dyadic branch row D is the only retained-child coordinate. It records the left or right child, the containment relation to the parent interval, and the dyadic diameter budget before any StreamName window is exposed.

Finally S, R, E, H, C, P, N read the retained child through finite windows, regular rational readback, real sealing, transport, replay, provenance, and local naming. No hidden selector, trichotomy oracle, compactness principle, quotient equality, choice schedule, or ambient completeness row is available in the carrier. □

Theorem 3815.4 (Closed interval bisection completion handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, nested-interval, or compactness-facing consumer of an accepted* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *packet must first read the closed source interval, located endpoint row, midpoint row, and dyadic branch row. The packet hands downstream consumers one displayed retained child route with transport, replay, provenance, and local naming; it does not hand them open-cover compactness, a completed branch, a selected real point, quotient equality of real names, or an ambient completeness theorem.*

Proof. Project the carrier $B = (I, L, M, D, S, R, E, H, C, P, N)$. The first four rows I, L, M, D are the complete interval-bisection route: source interval, located endpoint evidence, midpoint, and retained dyadic branch.

The readback rows are ordered after that route. A $\mathsf{StreamName}^{\uparrow}$ consumer reads only the finite windows in S, a $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads only the regular rational row R, and a $\mathsf{Real}^{\uparrow}$ consumer reaches the seal E only after the same branch data has been displayed.

Nested-interval and compactness-facing consumers receive the retained child through H, C, P, N. These structural rows preserve and replay the same packet; they do not introduce completed branches, selected points, quotient equality, open-cover compactness, or ambient completeness. □

Theorem 3815.5 (Closed interval bisection interval-modulus termination)**.** *An accepted* $\mathsf{ClosedIntervalBisection}^{\uparrow}$ *carrier with a displayed unary history depth row n exports a finite dyadic interval window at that depth. Its endpoint route is inherited from the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row I, its branch row is inherited from the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *and* $\mathsf{IntervalBisection}^{\uparrow}$ *rows L, M, D, and its* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *seal handoff remains inside the displayed rows S, R, E, H, C, P, N. This is a finite modulus and termination row for the displayed depth, not open-cover compactness, trichotomy, a selected infinite branch, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct on the displayed unary depth row. At depth zero, read the original closed bounded interval from I; its endpoint order, containment, finite window, regular readback, and real-name seal are exactly the source data already exposed by Definition 3815.1.

For the successor depth, apply the midpoint and retained-branch rows M, D. The located endpoint data in L chooses only the displayed finite child, while D transports endpoint order, containment, and the dyadic diameter budget from the parent to that child.

Componentwise hsame transport in H and displayed replay in C keep the induction inside the same carrier. The completion handoff of Definition 3815.4 then composes S, R, E after the current branch row, so the depth-n window terminates as a finite row rather than as a hidden infinite branch or completeness principle. □

Theorem 3815.6 (Closed interval bisection RegSeqRat route)**.** *Every accepted retained finite bisection window reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *row only after reading the closed source interval, located*

endpoint evidence, midpoint row, dyadic retained-branch ledger, and $\mathsf{StreamName}^{\uparrow}$ *finite windows. For* $B = (I, L, M, D, S, R, E, H, C, P, N)$*, the regular rational readback factors through*

$$I, L, M, D, S \longmapsto R \longmapsto E, H, C, P, N.$$

It does not use open-cover compactness, a selected infinite branch, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3815.1. The row I supplies the closed source interval, L supplies the located endpoint evidence, M supplies the midpoint row, and D supplies the dyadic retained-branch ledger.

Apply Definition 3815.2 to identify S as the finite-window exposure and R as the regular rational readback row. The retained-branch route of Definition 3815.3 orders the source, located endpoint, midpoint, branch, stream, regular rational, and real rows in that sequence.

The depth window of Definition 3815.5 keeps this read finite at the displayed unary depth. Therefore a $\mathsf{RegSeqRat}^{\uparrow}$ consumer receives only the stated finite route.

No carrier coordinate names open-cover compactness, a selected infinite branch, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so none of those principles can mediate the readback. □

Falsifiable prediction: Every $\mathsf{ClosedIntervalBisection}^{\uparrow}$ consumer that omits the dyadic branch row loses the retained child interval before any RegSeqRat or Real seal can be read.

Independence witness: closedboundedinterval, located-interval-bisection, intervalbisection, located-real-nested-intervals, streamname, regseqrat, real: $\mathsf{ClosedIntervalBisection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a closed bounded interval source, located endpoint evidence, midpoint formation, a dyadic retained-branch ledger, finite windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalBisection}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalBisection}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, located endpoint evidence, a midpoint row, a dyadic retained-branch row, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3815.1, Definition 3815.2, Definition 3815.3, and Definition 3815.4 seed the constructive closed-interval bisection route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, real trichotomy, quotient real equality, selected infinite branches, selected real points, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, closed-interval exposure, located endpoint exposure, midpoint formation, dyadic branch exactness, StreamName window exposure, RegSeqRat readback, and Real seal nonescape for BEDC.Derived.ClosedIntervalBisectionUp.

Chapter 3816

A Concrete Naming Certificate for $\mathsf{RealSpectrum}^{\uparrow}$

Following the classical Banach-algebra spectrum tradition of Gelfand theory, the $\mathsf{RealSpectrum}^{\uparrow}$ packet records the finite BEDC surface by which a real Banach-algebra element is tested against displayed real scalar windows, resolvent-boundary rows, and spectral-radius estimates without importing a host spectrum. It is a spectral neighbour of the L10 real and completion frontier: it reads the complete normed algebra surface of chapter 2189, the power-growth boundary of chapter 2352, the bounded-operator route of chapter 1644, the real seal of chapter 38, the regular-rational classifier of chapter 301, and the finite stream windows of chapter 126.

Definition 3816.1 (Real spectrum carrier)**.** *A* $\mathsf{RealSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, a, U, R, B, W, Q, E, G, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{BanachAlgebra}^{\uparrow}$ *source row carrying multiplication, norm, completion, product control, transport, replay, provenance, and local naming.*
2. *a is the carried algebra element whose real spectral behaviour is inspected.*
3. *U is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *or algebra-action row used when the element is read through a bounded operator surface.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row. It admits only displayed real scalars, not a completed host scalar field.*
5. *B is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for real scalar windows. It records the regular rational classifier data used to compare a scalar probe with the element.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *spectral-window observation row. It names the finite list of scalar probes, operator-power requests, and resolvent-boundary tests that are actually displayed.*
7. *Q is the resolvent-boundary test row. For each displayed scalar window it records the local multiplication and inverse-check surface, together with a refusal row when the inverse evidence is not displayed.*
8. *E is the* $\mathsf{SpectralRadius}^{\uparrow}$ *estimate row. It reads only the power-window and norm-growth estimates supplied by the spectral-radius packet.*

9. *G is the real-spectrum readback row. It classifies a displayed scalar as admitted, refused, or boundary-facing only through R, B, W, Q, E.*

10. *H records componentwise* hsame *transport for the Banach-algebra source, carried element, bounded-operator row, real seal, regular-rational readback, stream windows, resolvent tests, spectral-radius estimates, readback, and structural rows.*

11. *C records displayed* Cont *replay of the route*

$$\mathsf{BanachAlgebra}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{SpectralRadius}^{\uparrow} \longmapsto \mathsf{RealSpectrum}^{\uparrow}.$$

12. *P is the* Pkg *provenance over* $\mathsf{RealSpectrum}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSpectrum}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $A, a, U, R, B, W, Q, E, G, H, C, P, N$ and has no coordinate for a host spectrum, maximal ideals, Gelfand transform, spectral theorem, quotient completion, selected approximate eigenvectors, trichotomy over real scalars, or countable choice.

Lean4 ✓ `BEDC.Derived.RealSpectrumUp.RealSpectrumTasteGate single carrier alignment`

Theorem 3816.2 (Real spectrum NameCert obligations)**.** *For an accepted* $\mathsf{RealSpectrum}^{\uparrow}$ *carrier*

$$S = (A, a, U, R, B, W, Q, E, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealSpectrum}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Banach-algebra source, carried element, bounded-operator read, real seal, regular-rational readback, stream-window observations, resolvent-boundary tests, spectral-radius estimates, readback, transport, replay, provenance, and local naming row;*

2. *scalar-window compatibility, requiring every scalar probe in W to read its* $\mathsf{Real}^{\uparrow}$ *seal through R and its* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier through B before the probe can enter a resolvent test;*

3. *resolvent-boundary locality, requiring Q to display the multiplication and inverse-check rows used by each accepted scalar test and to record refusal when those rows are absent;*

4. *spectral-radius estimate discipline, requiring E to use only the power-window and norm-growth rows already certified by* $\mathsf{SpectralRadius}^{\uparrow}$*;*

5. *classifier transport, requiring H and C to preserve the scalar windows, resolvent tests, radius estimates, real seal, regular-rational readback, bounded-operator row, provenance, and local naming componentwise.*

No NameCert obligation is stored outside these rows. In particular, the packet exports no completed host spectrum, no maximal ideal space, no Gelfand-transform equality, no spectral theorem, no quotient completion, no selected approximate eigenvector, no trichotomy row, and no countable-choice schedule.

Proof. Carrier admission is projection from Definition 3816.1. The accepted packet exposes exactly the Banach-algebra source, carried element, bounded-operator read, real seal, regular-rational classifier, stream-window observations, resolvent tests, spectral-radius estimates, readback, transport, replay, provenance, and local naming rows.

Scalar-window compatibility uses R, B, W. Each scalar probe is first a displayed stream-window request, then a regular-rational readback, and only then a real-seal read. Thus a scalar cannot enter the spectrum packet as an ambient real number detached from the displayed L10 rows.

Resolvent locality is the row Q. It names the local multiplication and inverse-check evidence used by each displayed test, and it records refusal when the evidence is absent. The row therefore supplies a boundary test rather than a host inverse or a completed spectrum.

The radius estimate discipline is the row E. It imports only the finite power-window and norm-growth surface already exposed by $\mathsf{SpectralRadius}^{\uparrow}$, so no limit over all powers or selected approximate eigenvector is introduced.

Finally H, C, P, N transport, replay, source, and name only the listed coordinates. Since the excluded spectral and choice-theoretic objects have no coordinate in the carrier, they cannot appear as local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RealSpectrumUp.RealSpectrumCarrier namecert obligations`

Closure status for $\mathsf{NameCert}_{\mathsf{RealSpectrum}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSpectrum}^{\uparrow}$ packet is generated from a BanachAlgebraUp source, a carried element, a BoundedLinearOperatorUp read, RealUp scalar seals, RegSeqRatUp readback rows, StreamNameUp spectral windows, resolvent-boundary tests, SpectralRadiusUp estimates, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSpectrum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3816.1 and Definition 3816.2 seed the finite real-spectrum route over BanachAlgebraUp, SpectralRadiusUp, BoundedLinearOperatorUp, RealUp, RegSeqRatUp, StreamNameUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSpectrum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host spectrum, maximal ideal space, Gelfand representation, spectral theorem, quotient completion, selected approximate eigenvectors, real trichotomy, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scalar-window compatibility, resolvent-boundary locality, spectral-radius estimate discipline, classifier transport, and consumer non-escape for BEDC.Derived.RealSpectrumUp.

Chapter 3817

A Concrete Naming Certificate for $\mathsf{BanachLattice}^{\uparrow}$

Following Kantorovich and Schaefer on Banach lattices, the $\mathsf{BanachLattice}^{\uparrow}$ packet records the finite BEDC naming surface for a vector lattice whose normed carrier is Cauchy-complete and whose positive cone remains visible to norm-facing consumers. It strengthens the ordered vector-lattice surface of chapter 3620 by adding the Banach-space completeness rows of chapter 90, while still reading the norm row of chapter 89, the join-meet lattice row of chapter 55, and the vector-space carrier of chapter 47. The packet supplies finite vector-lattice, norm, positive-cone, and Cauchy-completeness rows; it does not supply Hahn-Banach separation, Dedekind completeness, selected suprema, quotient function spaces, or a host order-completion principle.

Definition 3817.1 (BanachLattice carrier)**.** *A* $\mathsf{BanachLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, A, N, P, M, H, C, S)$$

with the following displayed rows:

1. *R is the* $\mathsf{RieszSpace}^{\uparrow}$ *row, carrying the common vector endpoint, real scalar endpoint, lattice join and meet operations, positive and negative part ledgers, and vector-lattice classifier.*
2. *A is the* $\mathsf{Banach}^{\uparrow}$ *row over the same vector endpoint and normed metric surface, exposing the Cauchy-completeness witness through finite regular-Cauchy and limit-seal rows.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *compatibility row tying the norm used by A to the lattice decomposition and positive-cone rows visible in R.*
4. *P is the positive-cone monotonicity row. It records that positive part, negative part, cone membership, and order comparison are read before norm or completeness consumers inspect the packet.*
5. *M is the Cauchy-completeness ledger. It records the finite regular-Cauchy windows, modulus or metric-control rows, and terminal Banach seal used by downstream complete normed-lattice consumers.*
6. *H records componentwise* hsame *transport for the Riesz-space row, Banach row, norm compatibility row, positive-cone row, completeness ledger, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Banach-lattice request through R, A, N, P, M, H and back to the same finite ordered complete-normed surface.*

8. *S is the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{BanachLattice}^\uparrow}$ *row over* $\mathsf{BanachLattice}^\uparrow$, $\mathsf{RieszSpace}^\uparrow$, $\mathsf{Banach}^\uparrow$, $\mathsf{Norm}^\uparrow$, $\mathsf{Lattice}^\uparrow$, $\mathsf{VecSpace}^\uparrow$, BHist, hsame, Cont, *and* NameCert.

The classifier compares accepted packets only through these displayed rows. It has no coordinate for Hahn-Banach separation, Dedekind completeness, selected suprema, quotient function spaces, pointwise function models, countable choice, or ambient host order equality.

Lean4 ✓ `BEDC.Derived.BanachLatticeUp.BanachLatticeTasteGate single carrier alignment`

Theorem 3817.2 (BanachLattice NameCert obligations)**.** *For every accepted* $\mathsf{BanachLattice}^\uparrow$ *carrier* $B = (R, A, N, P, M, H, C, S)$*, the local* $\mathsf{NameCert}_{\mathsf{BanachLattice}^\uparrow}$ *surface consists exactly of carrier admission, vector-lattice row compatibility, norm compatibility, positive-cone exposure, Cauchy-completeness ledger exposure, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A downstream consumer may read the common vector endpoint, the lattice join and meet rows, the norm row, the positive-cone ledger, and the finite Banach completeness route, but it receives no Hahn-Banach functional, no Dedekind-complete lattice envelope, no selected supremum, and no quotient function-space representation.*

Proof. Carrier admission is projection from Definition 3817.1. The tuple displays exactly the Riesz-space row R, Banach row A, norm row N, positive-cone row P, completeness ledger M, and structural rows H, C, S.

The vector-lattice obligations are read through R. This fixes the vector endpoint, scalar endpoint, join and meet operations, order comparisons, and positive and negative part ledgers before any Banach-facing row is consumed.

The norm and completeness obligations are finite rows. The norm row N ties the Banach metric used by A to the lattice decomposition data in R, and the ledger M records the regular-Cauchy windows and terminal completeness seal exposed by the Banach row.

Finally H, C, S transport, replay, source, and name only those displayed coordinates. Since the carrier contains no coordinate for Hahn-Banach separation, Dedekind completeness, selected suprema, quotient function spaces, or host order equality, none of those objects can be exported by the local certificate. □

Theorem 3817.3 (BanachLattice classifier stability)**.** *If two accepted* $\mathsf{BanachLattice}^\uparrow$ *packets are related by the classifier, then their Riesz-space rows, Banach completeness rows, norm compatibility rows, positive-cone rows, and Cauchy-completeness ledgers are related by the componentwise* hsame *transport recorded in H. Consequently every norm-facing, order-facing, or completeness-facing read factors through the displayed finite ledger and never through a host order equality, selected supremum, or hidden quotient carrier.*

Proof. Unfold the classifier of Definition 3817.1. Its comparison coordinates are exactly R, A, N, P, M, H, C, S.

The Riesz-space component transports the vector, lattice, and positive-part rows. The Banach component transports the normed metric and Cauchy-completeness rows over the same carried endpoint.

The norm compatibility and positive-cone rows then move along those transported coordinates. The completeness ledger M remains attached to the transported Banach row, so no accepted read can replace it by a selected supremum, quotient function-space equality, or host order construction. □

Theorem 3817.4 (BanachLattice Riesz-Banach handoff)**.** *Every accepted* $\mathsf{BanachLattice}^\uparrow$ *packet supplies a finite handoff*

$$\mathsf{RieszSpace}^\uparrow, \quad \mathsf{Banach}^\uparrow, \quad \mathsf{Norm}^\uparrow, \quad \mathsf{Lattice}^\uparrow, \quad \mathsf{VecSpace}^\uparrow$$

in which vector-lattice and positive-cone data are read before the Banach completeness ledger is consumed. The handoff exports the ordered complete normed carrier as NameCert data only through R, A, N, P, M, H, C, S.

Proof. Read the handoff from the carrier. The row R supplies the $\mathsf{RieszSpace}^{\uparrow}$ surface over the vector-space and lattice rows, while N repeats the norm compatibility needed by the Banach-facing route.

Next read A and M. These rows expose the Cauchy-complete normed carrier and the finite regular-Cauchy ledger without adding a supremum selector, Hahn-Banach functional, or quotient function model.

The positive-cone row P binds the order-facing part of the route to the same vector endpoint before H, C, S transport, replay, source, and name it. Thus the Riesz-space and Banach-space surfaces meet only through the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachLattice}^{\uparrow}$ packet is generated from a Riesz-space row, a Banach completeness row, norm compatibility data, positive-cone data, a Cauchy-completeness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3817.1, Definition 3817.2, Definition 3817.3, and Definition 3817.4 seed the finite ordered complete normed-lattice certificate over RieszSpaceUp, BanachUp, NormUp, LatticeUp, VecSpaceUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hahn-Banach separation, Dedekind completeness, selected suprema, quotient function spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, vector-lattice compatibility, norm compatibility, positive-cone exposure, Cauchy-completeness ledger exposure, transport, replay, provenance, and local naming for BEDC.Derived.BanachLatticeUp.

The $\mathsf{HeronSquareRoot}^{\uparrow}$ hub routes Newton, dyadic bisection, reciprocal, and regular-Cauchy square-root rows through chapter 1756, chapter 291, and chapter 301 before its child files expose the Heron packet.

Chapter 3818

A Concrete Naming Certificate for $\mathsf{HeronSquareRoot}^{\uparrow}$

From Heron's classical square-root iteration and Bishop-style constructive convergence, the $\mathsf{HeronSquareRoot}^{\uparrow}$ packet records the finite dyadic evidence needed to run the Babylonian recurrence inside the L10 Real and Completion route. It refines the square-root service of chapter 1756 by exposing seed positivity, reciprocal accounting, contraction estimates, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal as named rows. The dependency route passes through chapter 1756, chapter 291, chapter 223, chapter 301, and chapter 38; it is not a host square-root function, quotient-real equality, a selected completed limit, or an ambient completeness theorem.

The carrier consumes $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows from chapter 291 before every reciprocal, halving, and squared-error comparison, and it consumes $\mathsf{RegSeqRat}^{\uparrow}$ readbacks from chapter 301 before exposing the terminal $\mathsf{Real}^{\uparrow}$ square-root seal. The Heron recurrence also consumes the guarded dyadic Newton square-root packet of chapter 7196 before exporting the RegSeqRat and Real seal rows. Thus the Heron route is a dependency-bearing finite lattice: dyadic tolerance rows govern the visible recurrence windows, regular rational readbacks certify the Cauchy handoff, and only then may a Real-facing consumer inspect the seal row.

Definition 3818.1 (Heron square-root carrier)**.** *A* $\mathsf{HeronSquareRoot}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *A is the positive dyadic radicand row, including lower-bound and nonzero-denominator witnesses inside* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *S is the finite positive dyadic seed row from which the Heron recurrence starts.*
3. *R is the reciprocal and division ledger row, recording the displayed divisions A/x_i and every denominator witness used by the recurrence.*
4. *L is the finite Heron ledger whose rows have the form $x_{i+1} = (x_i + A/x_i)/2$ and whose arithmetic is read only through A, S, R and* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
5. *W is the finite iteration-window row, exposing exactly the initial segment of L requested by a precision consumer.*
6. *D is the dyadic contraction-estimate row, recording the squared-error, halving, and tolerance comparisons that bound the visible window.*

7. *K is the* $\mathsf{NewtonIteration}^{\uparrow}$ *provenance row showing that the displayed recurrence is the specialized Newton step for $x^2 - A$ without importing a host root.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from A, S, R, L, W, D, K.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular readback row Q has been displayed.*
10. *T records componentwise* hsame *transport for the radicand, seed, reciprocal ledger, Heron ledger, window, contraction estimate, Newton provenance, readback, Real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay of each precision request through $A, S, R, L, W, D, K, Q, E, T, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{HeronSquareRoot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HeronSquareRoot}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host square-root operation, quotient-real equality, selected limits, arbitrary real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3818.2 (Heron square-root regular-Cauchy handoff)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *packet reaches* $\mathsf{Real}^{\uparrow}$ *only through the finite dyadic error ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal Real seal displayed in*

$$A, S \longmapsto R, L, W, D, K \longmapsto Q \longmapsto E.$$

Thus a Real or Completion consumer first sees the positive radicand and seed rows, then the reciprocal and division ledger, Heron recurrence window, dyadic contraction estimates, and $\mathsf{NewtonIteration}^{\uparrow}$ *provenance, and only then may read the regular rational name and* $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports no host square-root function, quotient-real equality, selected completed limit, arbitrary real trichotomy, or ambient completeness object.*

Proof. Start with an accepted carrier $H = (A, S, R, L, W, D, K, Q, E, T, C, P, N)$. The carrier inventory exposes the positive dyadic radicand A and seed S before any recurrence row can be inspected.

The numerical ledger is finite. The reciprocal row R stores the displayed divisions A/x_i, the Heron ledger L stores the visible recurrence rows, the window row W selects the requested finite segment, and the contraction row D stores the dyadic error comparisons for that segment.

The route then records provenance through K. This row identifies the same displayed recurrence as the Newton step for $x^2 - A$ through $\mathsf{NewtonIteration}^{\uparrow}$, but it contributes only finite ledger provenance and no external square-root value.

The consumer-facing read is downstream of those rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q is produced by replaying the finite dyadic ledger, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after Q has been displayed.

The remaining rows T, C, P, N transport, replay, record provenance, and name the same packet. Since the carrier contains no host square-root coordinate, quotient-real equality, selected limit, trichotomy classifier, or ambient completeness row, every accepted Real-facing read factors through the displayed route. □

Theorem 3818.3 (Heron square-root finite-window contraction induction)**.** *Let $H = (A, S, R, L, W, D, K, Q, E, T,$ be an accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *carrier. Every finite window W of the Heron ledger L preserves the dyadic contraction estimate recorded by D by induction on the displayed window length. In the successor step the proof reads the reciprocal row R, the* $\mathsf{NewtonIteration}^{\uparrow}$ *provenance row K,*

and the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *are inspected. The induction exports no host square-root function, selected limit, trichotomy, quotient-real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The finite rows A, S, R, L, W, D, K are available before any regular rational readback or Real seal, and the handoff theorem places Q and E downstream of those rows.

Induct on the displayed length of the window row W. The empty window has no Heron step to check, so the contraction estimate is exactly the empty restriction of D.

For the successor window, read the previous visible window from L and use the induction hypothesis for its restriction of D. The new row of L is the displayed recurrence $x_{i+1} = (x_i + A/x_i)/2$; its division data is supplied by R, its recurrence provenance is supplied by K, and each tolerance comparison is read from the $\mathsf{DyadicRatCore}^{\uparrow}$ rows already recorded in D.

After the successor estimate is recorded, apply Definition 3818.2. The $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and $\mathsf{Real}^{\uparrow}$ seal E are therefore downstream of the finite induction and cannot change the displayed contraction window.

Rows T, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate contains a host square-root function, selected completed limit, trichotomy, quotient-real equality, or ambient completeness theorem, the finite-window induction remains an internal Heron-ledger statement. □

Theorem 3818.4 (Heron square-root regular-Cauchy RegSeqRat lattice)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing square-root consumer of an accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N)$$

must first read the $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *sibling route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radicand and arithmetic rows, the* $\mathsf{NewtonIteration}^{\uparrow}$ *provenance row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and only then the* $\mathsf{Real}^{\uparrow}$ *seal. In carrier notation, the lattice route projects* $A, S, R, L, W, D, K, Q, E, T, C, P, N$ *in that order and exposes no host square-root function, quotient-real equality, selected completed limit, arbitrary trichotomy, or ambient completeness theorem.*

Proof. Project the accepted carrier. The rows A and S are the positive dyadic radicand and seed rows, while R, L, W, D are the reciprocal ledger, Heron recurrence ledger, finite window, and dyadic contraction estimate.

Apply Definition 3818.2. It places every Real or Completion read downstream of the finite dyadic ledger and before the regular rational readback Q and terminal seal E.

Read the sibling lattice through provenance. The row K records the $\mathsf{NewtonIteration}^{\uparrow}$ specialization, P records the $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ dependency route, and Q is the regular rational handoff generated from the displayed rows.

Finally transport and name the route through T, C, P, N. Since all consumer-facing data is already exhausted by $A, S, R, L, W, D, K, Q, E, T, C, P, N$, no Real-facing consumer can replace the lattice by a host square-root operation, quotient equality, selected limit, trichotomy, or ambient completeness. □

Theorem 3818.5 (Heron square-root NameCert obligations)**.** *For every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HeronSquareRoot}^{\uparrow}}$ *surface consists exactly of the displayed carrier admission row, positive dyadic radicand and seed exactness, reciprocal and division ledger exactness, finite Heron-window stability, dyadic contraction accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The coordinates A and S give the positive dyadic radicand and seed rows, while R stores the reciprocal and division witnesses used by the recurrence.

The rows L, W, D, K form the finite numerical spine. The Heron ledger L records the displayed recurrence, W selects the finite window, D records the dyadic contraction estimates on that window, and K identifies the same row as the specialized $\mathsf{NewtonIteration}^{\uparrow}$ step for $x^2 - A$.

Apply Definition 3818.2 to the consumer-facing side. The regular readback Q is available only after the finite dyadic ledger has been replayed, and the $\mathsf{Real}^{\uparrow}$ seal E is read only after Q.

The rows T, C, P, N then transport, replay, source, and locally name the same packet. Since the carrier has no row for a host square-root function, quotient-real equality, selected completed limit, trichotomy, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 3818.6 (Heron square-root contraction-window stability)**.** *Let* $H = (A, S, R, L, W, D, K, Q, E, T, C, P, N$ *be an accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *carrier. Any componentwise* hsame *transport recorded by* T *preserves the finite Heron window* W *and the same dyadic contraction estimate recorded by* D *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *is inspected.*

Proof. Read the source window first. The window row W is a finite initial segment of the displayed Heron ledger L, and the contraction row D records the dyadic comparisons for exactly that segment.

Transport acts componentwise through T. Hence a transported carrier must carry corresponding A, S, R, L, W, D, K rows before any consumer can inspect Q or E.

The handoff theorem separates the finite dyadic ledger from the regular-Cauchy readback. Therefore the contraction estimate seen on the transported window is the same estimate certified by D, and no later $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row can alter the finite Heron-window bound. □

Theorem 3818.7 (Heron square-root regular-Cauchy sibling route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read factors through the sibling chain from chapter 1756 to chapter 291, chapter 223, chapter 301, and chapter 38 before any* $\mathsf{Real}^{\uparrow}$*-facing square-root consumer receives the result. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the route first projects the positive dyadic radicand and seed rows A, S*, then the reciprocal ledger, Heron recurrence, window, contraction estimate, and Newton provenance rows* R, L, W, D, K*, then the regular readback row* Q*, and finally the Real seal* E *together with transport, replay, provenance, and local naming through* T, C, P, N*.*

Proof. Project the carrier rows $A, S, R, L, W, D, K, Q, E, T, C, P, N$. The first seven rows are exactly the finite dyadic and Newton-style data named by the sibling chapters: radicand and seed in $\mathsf{DyadicRatCore}^{\uparrow}$, recurrence provenance in $\mathsf{NewtonIteration}^{\uparrow}$, and a visible Heron window with contraction accounting.

Apply Definition 3818.2. It forces every Real or Completion consumer to pass from A, S through R, L, W, D, K before the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and the terminal $\mathsf{Real}^{\uparrow}$ seal E are visible.

Use Definition 3818.6. The finite window and contraction estimate survive componentwise transport, so the sibling route cannot be replaced by a host square-root operation, quotient-real equality, selected completed limit, arbitrary trichotomy, or ambient completeness theorem.

Thus the accepted read is a regular-Cauchy square-root route: it moves through the displayed dyadic, Newton, regular rational, and Real siblings before any Real-facing consumer can use the square-root result. □

Theorem 3818.8 (Heron square-root dyadic-Real forward link)**.** *Every* $\mathsf{HeronSquareRoot}^{\uparrow}$ *consumer whose output is read as a* $\mathsf{Real}^{\uparrow}$ *result must first consume the dyadic radicand and contraction rows from chapter 291, the Newton provenance row from chapter 223, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row from chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal from chapter 38. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the forward dependency order is A, S, R, L, W, D *before* K*,* K *before* Q*, and* Q *before* E*; the transport, replay, provenance, and local naming rows* T, C, P, N *preserve that order for every accepted Real-facing read.*

Proof. Project the carrier. The dyadic radicand and seed rows A, S, reciprocal ledger R, Heron ledger L, finite window W, and contraction row D are visible before any row with a Real-facing type is inspected.

Use the sibling route of Definition 3818.7. It places the Newton provenance row K downstream of the dyadic Heron rows, then places $\mathsf{RegSeqRat}^{\uparrow}$ readback Q downstream of K, and finally exposes the $\mathsf{Real}^{\uparrow}$ seal E only after Q.

The structural rows T, C, P, N cannot permute this order: they transport componentwise, replay the displayed route, record provenance, and name the same carrier. Hence a Real-facing consumer must follow the DyadicRatCore, NewtonIteration, RegSeqRat, and Real sibling route rather than reading a host square-root function, quotient-real equality, selected limit, or ambient completeness witness. □

Theorem 3818.9 (Heron square-root dyadic refinement route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N)$$

first refines the positive dyadic radicand and visible recurrence window through the $\mathsf{DyadicRatCore}^{\uparrow}$ *and interval-refinement tolerance rows before Newton provenance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal are visible. The route reads the dyadic interval-refinement surface of chapter 1831 as part of the* A, S, R, L, W, D *window discipline, then exposes* K, Q, E, T, C, P, N *only as downstream provenance, readback, seal, transport, replay, provenance, and local naming rows.*

Proof. Project the carrier rows $A, S, R, L, W, D, K, Q, E, T, C, P, N$. The positive radicand row A, seed row S, reciprocal ledger R, Heron ledger L, finite window W, and contraction estimate D are the complete dyadic surface visible before Newton provenance or Real-facing readback.

Apply the dyadic-Real forward link of Definition 3818.8. It orders the DyadicRatCore radicand and contraction rows before K, places K before the regular rational readback Q, and places Q before the terminal Real seal E.

Use finite-window contraction induction from Definition 3818.3. Each successor window reads the reciprocal row R, the displayed recurrence row L, and the dyadic tolerance comparisons in D before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row is inspected.

The interval-refinement dependency is therefore internal to the dyadic window. The refinement surface of chapter 1831 is consumed while A, S, R, L, W, D are being read, and the remaining rows K, Q, E, T, C, P, N only preserve, replay, source, name, or seal that already-refined route. □

Theorem 3818.10 (Heron square-root Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *packet first exposes the positive dyadic radicand, seed, reciprocal ledger, Heron ledger, finite window, contraction estimate, Newton provenance, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows*

$$A, S, R, L, W, D, K, Q$$

and only then exposes the $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows*

$$E, T, C, P, N.$$

In particular, the read cannot bypass $\mathsf{RegSeqRat}^{\uparrow}$ *with a host square-root function, quotient-real equality, selected limit, trichotomy, or ambient completeness.*

Proof. Project the accepted carrier $H = (A, S, R, L, W, D, K, Q, E, T, C, P, N)$. The first eight rows are the dyadic Heron and regular-rational route, while E, T, C, P, N are the terminal seal and structural rows.

Invoke the regular-Cauchy handoff of Definition 3818.2. It places Q downstream of A, S, R, L, W, D, K and places E downstream of Q.

Use contraction-window stability from Definition 3818.6. Transport preserves the finite window W and contraction estimate D before any regular readback or Real seal can be inspected.

Apply the sibling route of Definition 3818.7. The terminal E row is therefore downstream of $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, so no host square-root function, quotient-real equality, selected limit, trichotomy, or ambient completeness coordinate can replace the displayed L10 route. □

Falsifiable prediction: Every accepted HeronSquareRootUp Real-facing read factors through positive DyadicRatCoreUp radicand and seed rows, a reciprocal and division ledger, a finite Heron window, dyadic contraction estimates, NewtonIterationUp provenance, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, newtoniteration, regseqrat, real, regularcauchysquare-root: $\mathsf{HeronSquareRoot}^{\uparrow}$ is not bijective to any listed sibling because it binds positive dyadic seed data, reciprocal/division rows, Heron recurrence windows, contraction estimates, Newton provenance, regular readback, Real seal handoff, transport, replay, provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HeronSquareRoot}^{\uparrow}}$.

Constructive story: A $\mathsf{HeronSquareRoot}^{\uparrow}$ packet is generated from positive DyadicRatCore radicand and seed rows, reciprocal and division ledger rows, finite Heron recurrence windows, dyadic contraction estimates, NewtonIteration provenance, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeronSquareRoot}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3818.1 and Definition 3818.2 seed the finite Heron square-root carrier and its regular-Cauchy handoff route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeronSquareRoot}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host square-root function, quotient-real equality, selected completed limits, arbitrary real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive dyadic seed exactness, reciprocal and division ledger exactness, Heron-window stability, dyadic contraction accounting, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HeronSquareRootUp.

The $\mathsf{HeronSquareRoot}^{\uparrow}$ iteration route consumes $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ sealing through the same finite tail-filter discipline used by chapter 1605 and chapter 38. Its positive radicand,

reciprocal ledger, Heron window, contraction estimate, and Newton provenance are therefore visible before the regular rational readback and Real seal can be used, and no host square-root operation, quotient real equality, selected limit, countable choice, or ambient completeness row replaces that tail-filter handoff.

Theorem 3818.11 (Heron square-root DyadicRatCore anchor)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *packet that exposes a dyadic square-root iteration must read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, denominator, reciprocal, halving, and squared-error rows of chapter 291 before the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 is consumed. In carrier notation the Heron recurrence route remains*

$$A, S, R, L, W, D, K, Q, E, T, C, P, N,$$

where A, S, R, L, W, D *are the dyadic radicand, seed, reciprocal, recurrence, finite-window, and contraction rows;* Q *is the regular rational readback; and* E *is the Real seal. The route exports no host square-root function, quotient real equality, selected completed limit, arbitrary trichotomy, or ambient completeness theorem.*

Proof. Project the Heron carrier from the chapter spine. The radicand and seed rows are dyadic rows, and the reciprocal, halving, and squared-error comparisons in the visible recurrence are also read through $\mathsf{DyadicRatCore}^{\uparrow}$.

Next use the regular-Cauchy handoff and finite-window contraction induction already present in this chapter. They place the $\mathsf{RegSeqRat}^{\uparrow}$ readback after the dyadic iteration window, so a Real-facing consumer cannot reach the seal before the dyadic tolerance ledger is displayed.

Finally read the terminal $\mathsf{Real}^{\uparrow}$ route. Since the seal is downstream of the dyadic and regular-rational rows, the Heron packet contributes a dependency edge through chapter 291 and chapter 38, not a host square-root operator or an ambient completeness principle. □

Every accepted $\mathsf{HeronSquareRoot}^{\uparrow}$ consumer that reads a square-root endpoint through a bisection or interval-shrink route first consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows of chapter 291, the dyadic interval cells of chapter 306, and the located bisection or nested-interval rows of chapter 1711 and chapter 1713. Only after those interval rows have been displayed may the route pass through the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301 and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38; no host square-root endpoint, selected limit, quotient-real equality, trichotomy, or ambient completeness row is exported.

Theorem 3818.12 (Heron square-root Newton dependency route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read that seals a square-root approximation consumes the* $\mathsf{NewtonIteration}^{\uparrow}$ *provenance row of chapter 223, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic rows before the square-root read is public. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the dependency route projects A, S, R, L, W, D *as the finite dyadic Heron ledger, reads* K *as the specialized Newton step, then exposes* Q *and* E *before transport, replay, provenance, and local naming through* T, C, P, N*. It exports no host square-root function, quotient-real equality, selected completed limit, arbitrary trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the Heron carrier. The rows A, S, R, L, W, D contain the positive radicand, seed, reciprocal ledger, recurrence window, and dyadic contraction data needed before any square-root approximation can be consumed.

Apply Definition 3818.2. It orders every Real-facing read through the finite dyadic ledger and the $\mathsf{NewtonIteration}^{\uparrow}$ provenance row before the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and terminal seal E are visible.

Use the sibling route in Definition 3818.7. It identifies the same route through chapter 223, chapter 301, and the Real-facing endpoint without adding a host square-root value.

Finally read the regular-Cauchy and Real dependency children already present in this chapter. They keep Q and E attached to the displayed Heron ledger, so the square-root read is sealed only after the Newton, regular rational, Real, and dyadic rows have all been displayed. □

Theorem 3818.13 (Heron square-root Newton interval dependency)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read that exports a* $\mathsf{Real}^{\uparrow}$*-facing square-root approximation consumes either the* $\mathsf{NewtonIteration}^{\uparrow}$ *provenance row or the nested-interval shrink route before the regular-rational and Real rows are public. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the route first exposes the positive dyadic radicand and seed rows A, S, the reciprocal ledger R, the Heron recurrence window L, W, and the contraction estimate D. It then reads the Newton provenance row K through chapter 223, or the interval-shrink evidence through the nested route of chapter 1713, before reaching the $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301 and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38.*

Proof. Project the Heron carrier. The rows A, S, R, L, W, D are the finite radicand, seed, reciprocal, recurrence-window, and contraction rows; none of them is a completed square-root value.

The iteration witness is consumed next. If the packet follows the Newton route, the row K identifies the Heron recurrence as the displayed $\mathsf{NewtonIteration}^{\uparrow}$ step for $x^2 - A$. If it follows the interval route, the same contraction ledger is read as retained nested interval shrink data through the located nested-interval chapter.

Only after one of those finite iteration routes is visible may the Real-facing rows be inspected. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q records the regular rational readback of the displayed approximation window, and the $\mathsf{Real}^{\uparrow}$ row E seals the terminal read. Transport, replay, provenance, and local naming through T, C, P, N preserve that dependency order and add no host square-root operation, selected limit, quotient-real equality, trichotomy, or ambient completeness theorem. □

Theorem 3818.14 (Heron square-root Newton regular-Cauchy bridge)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read factors its Newton update route through chapter 223 and its convergence and seal route through chapter 1756 before reaching the Heron square-root* $\mathsf{NameCert}$ *surface. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the rows A, S, R, L, W, D, K expose the displayed Heron recurrence as a finite $\mathsf{NewtonIteration}^{\uparrow}$ *update, while Q, E, T, C, P, N expose the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming. No accepted consumer may read the Heron square-root packet from the Newton row alone or from the regular-Cauchy seal alone.*

Proof. Project the accepted carrier. The rows A, S, R, L, W, D give the positive radicand, seed, reciprocal ledger, recurrence ledger, visible window, and contraction estimate, while K records that this finite recurrence is the displayed $\mathsf{NewtonIteration}^{\uparrow}$ route.

Apply Definition 3818.12. It places every square-root-facing read downstream of the finite Newton update ledger and before the regular rational readback and terminal seal are exposed.

Apply Definition 3818.18. It routes the same packet through the $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ convergence service, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q, and the $\mathsf{Real}^{\uparrow}$ seal row E before export.

Finally use the NameCert obligations of Definition 3818.5. The rows T, C, P, N preserve transport, replay, provenance, and local naming for the joint route, so neither the Newton update nor the regular-Cauchy seal can be consumed as an isolated square-root source. □

Theorem 3818.15 (Heron square-root Newton sibling lattice)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read that exposes a square-root-facing value first consumes the* $\mathsf{NewtonIteration}^{\uparrow}$ *route of chapter 223, the Newton interval route already attached to the Heron window, the regular Cauchy dependency through chapter 301, and the reciprocal Real route of chapter 6251. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the read projects the positive radicand and seed rows, the reciprocal ledger, the finite Heron window, the contraction estimate, the Newton provenance row K, the regular-rational readback Q, and the terminal $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any square-root read is public.*

Proof. Project the carrier rows $A, S, R, L, W, D, K, Q, E, T, C, P, N$. The finite Heron ledger is visible before any consumer-facing read, so the Newton provenance row K is read while the positive radicand, reciprocal ledger, window, and contraction estimate are still part of the displayed packet.

Apply Definition 3818.12 and Definition 3818.13. These sibling routes attach the Newton iteration surface and the interval-shrink evidence to the same Heron window rather than to a separate square-root object.

Next apply Definition 3818.17 and Definition 3818.19. The regular Cauchy route supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q, while the reciprocal route forces the reciprocal ledger through the existing Real reciprocal packet before Q and E are public.

Finally apply Definition 3818.10. The terminal $\mathsf{Real}^{\uparrow}$ row E is available only after the Newton, regular Cauchy, and reciprocal rows have all been displayed, so no host square-root function, quotient-real equality, selected limit, trichotomy, or ambient completeness coordinate can bypass the sibling lattice. □

Theorem 3818.16 (Heron square-root nonnegative regular-Cauchy reciprocal-window route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read consumed by either chapter 6251 or chapter 1756 must display the same nonnegative* $\mathsf{Real}^{\uparrow}$ *radicand row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and reciprocal-window budget before the square-root-facing seal is public. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the dependency route first exposes the positive radicand and seed rows A, S, then the reciprocal ledger R through the reciprocal-window rows of chapter 703, then the finite Heron window L, W, D, K, and only then the $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q and terminal* $\mathsf{Real}^{\uparrow}$ *seal E used by the regular-Cauchy square-root route.*

Proof. Project the Heron carrier. The rows A, S display the positive radicand and seed, while R is the reciprocal ledger consumed by the Heron recurrence.

Read the reciprocal-window dependency through Definition 3818.19. The Real reciprocal chapter can consume the Heron packet only after the reciprocal ledger has passed through the finite inverse-budget and guarded-division rows named there.

Next read the regular-Cauchy square-root dependency through Definition 3818.18. The same nonnegative radicand route must expose L, W, D, K before the regular-rational readback Q and terminal Real seal E are visible.

The structural rows T, C, P, N preserve the shared route. Thus the reciprocal and regular-Cauchy square-root consumers meet at the displayed nonnegative Real row, RegSeqRat readback, and reciprocal-window rows, with no host square-root function, quotient real equality, selected completed limit, trichotomy, or ambient completeness coordinate. □

Theorem 3818.17 (Heron square-root regular-Cauchy dependency)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read first consumes the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *route of chapter 1756. The visible dependency then proceeds through the positive radicand and reciprocal rows of* $\mathsf{DyadicRatCore}^{\uparrow}$*, the recurrence provenance row of* $\mathsf{NewtonIteration}^{\uparrow}$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any square-root-facing consumer may read the packet. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the dependency route is exactly

$$\mathsf{RegularCauchySquareRoot}^{\uparrow} \longmapsto A, S, R, L, W, D, K \longmapsto Q \longmapsto E \longmapsto T, C, P, N.$$

It has no coordinate for a host square-root function, quotient-real equality, selected completed limit, arbitrary real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows $A, S, R, L, W, D, K, Q, E, T, C, P, N$. The positive radicand, seed, reciprocal, division, Heron-window, and contraction rows are the finite data consumed by the regular-Cauchy square-root route.

Apply Definition 3818.2. It orders every Real-facing read through A, S, R, L, W, D, K before the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and the $\mathsf{Real}^{\uparrow}$ seal E are visible.

Apply Definition 3818.7. This identifies the same route with the sibling chain through chapter 1756, chapter 291, chapter 223, chapter 301, and chapter 38.

The structural rows T, C, P, N then transport, replay, source, and name the dependency without adding any excluded host square-root, quotient equality, selected limit, trichotomy, or completeness row. □

Theorem 3818.18 (Heron square-root regular-Cauchy square-root forward route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read consumed as a* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *route must display the finite path*

$$\mathsf{NewtonIteration}^{\uparrow}, \mathsf{NestedInterval}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

before the square-root packet is exported. For a carrier

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the consumer first reads the positive radicand and seed rows A, S*, the reciprocal ledger* R*, the Heron recurrence and window rows* L, W*, and the contraction estimate* D*; then it reads the* $\mathsf{NewtonIteration}^{\uparrow}$ *provenance row* K*, the nested-interval shrink route attached to the same window data, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and finally the structural rows* T, C, P, N*. The route exports no host square-root function, quotient-real equality, selected completed limit, arbitrary trichotomy, or ambient completeness theorem.*

Proof. Project the Heron carrier. The rows A, S, R, L, W, D are the finite numerical ledger for the radicand, seed, reciprocal accounting, recurrence window, and dyadic contraction estimate.

Read the iteration and interval support next. The row K records the Heron recurrence as the displayed $\mathsf{NewtonIteration}^{\uparrow}$ step, while the nested-interval dependency route of Definition 3818.13 attaches the same contraction ledger to a finite interval-shrink path.

Apply Definition 3818.17. It forces every $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ consumer through the sibling route before the square-root-facing read is public.

Apply Definition 3818.4. The regular rational readback row Q and terminal $\mathsf{Real}^{\uparrow}$ seal E are available only after the displayed Heron ledger and Newton route have been opened.

Finally transport, replay, source, and name the packet through T, C, P, N. These are exactly the hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows needed before export, and they add no host square-root operation, quotient equality, selected limit, trichotomy, or ambient completeness coordinate. □

Theorem 3818.19 (Heron square-root real reciprocal forward link)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *packet reads its reciprocal row through chapter 703, chapter 1943, and chapter 6251 before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal are public. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the reciprocal ledger R is the displayed nonzero-apart route feeding the Heron recurrence, and the visible consumer path is

$$R \longmapsto \mathsf{CauchyInverseBudget}^{\uparrow} \longmapsto \mathsf{RegularCauchyDivision}^{\uparrow} \longmapsto \mathsf{RealReciprocal}^{\uparrow} \longmapsto Q \longmapsto E.$$

No Heron read exports a host reciprocal function, total division, quotient real equality, arbitrary trichotomy, selected completed limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted Heron carrier. The reciprocal ledger row R is already a coordinate of the finite packet, and it appears before the Heron recurrence window, contraction estimate, regular readback, and Real seal.

Apply Definition 3818.2. It forces every Real-facing Heron read to pass through the reciprocal and division ledger before Q and E can be inspected.

Use the sibling route from Definition 3818.7. The row R is therefore not a local host inverse; it is a displayed reciprocal ledger over the dyadic and regular-Cauchy route.

Finally read the reciprocal lattice through the named chapters. chapter 703 supplies the finite inverse budget, chapter 1943 supplies the guarded division handoff, and chapter 6251 supplies the nonzero-apart Real reciprocal packet. Only after those rows are visible may the Heron readback Q and terminal seal E be public. □

Theorem 3818.20 (HeronSquareRoot real and RegSeqRat forward lattice)**.** *Every* $\mathsf{HeronSquareRoot}^{\uparrow}$ *square-root approximation read consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *endpoint first passes through the finite lattice*

$$\mathsf{NewtonIteration}^{\uparrow},\ \mathsf{RegularCauchySquareRoot}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

already displayed by the sibling routes of chapter 223, chapter 1756, chapter 301, chapter 291, and chapter 38. For an accepted carrier

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the read exposes the Newton provenance row K, the regular-Cauchy square-root route over A, S, R, L, W, D, the regular-rational readback Q, the dyadic arithmetic rows A, S, R, D, and the terminal Real seal E before T, C, P, N may transport, replay, source, or name the result. It exports no host square-root function, quotient-real equality, selected completed limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The rows A, S, R, L, W, D display the positive dyadic radicand, seed, reciprocal ledger, Heron recurrence, finite window, and contraction estimate, while K records the same finite recurrence as a $\mathsf{NewtonIteration}^{\uparrow}$ route.

Apply Definition 3818.18. The square-root-facing consumer must read the regular-Cauchy route before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ endpoint is public.

Next apply Definition 3818.4 and Definition 3818.10. These place Q before E and keep both rows downstream of the finite dyadic and Newton lattice.

Finally attach T, C, P, N. Transport, replay, provenance, and local naming preserve the displayed route and add no coordinate for a host square-root function, quotient-real equality, selected completed limit, trichotomy, or ambient Real completeness. □

Theorem 3818.21 (Heron square-root Real route)**.** *Every* $\mathsf{HeronSquareRoot}^{\uparrow}$ *consumer that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must first display the Newton–Heron recurrence route, the dyadic bisection or Newton-interval dependency route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the reciprocal and nonnegative regular-Cauchy rows, componentwise transport, replay, provenance, and local naming. The route exports no host square-root function, selected limit, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the routed siblings for the carrier. The Newton and Heron recurrence rows expose the iterative rational window, while the dyadic bisection or Newton-interval rows identify the finite interval dependency used by that window.

The completion-facing read then passes through the $\mathsf{RegSeqRat}^{\uparrow}$ row and the reciprocal and nonnegative regular-Cauchy rows before the $\mathsf{Real}^{\uparrow}$ seal is available. Componentwise transport, displayed replay, provenance, and the local $\mathsf{NameCert}$ row preserve the same route without changing its endpoints.

Since none of these routed rows contains a host square-root function, a selected limit, quotient real equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$, every Real-facing Heron square-root consumer remains inside the displayed finite dependency path. □

Every $\mathsf{HeronSquareRoot}^{\uparrow}$ read consumes the dyadic-bisection dependency rows of chapter 361 and the Newton interval rows of Definition 3818.13 before the regular Cauchy square-root row is handed to chapter 301 and the terminal seal is read through chapter 38. This route keeps square-root dependency data inside the displayed L10 lattice and does not export selected limits or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Theorem 3818.22 (Heron square-root RegSeqRat Real dependency route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *iteration budget consumed by the reciprocal forward link first reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular windows and the* $\mathsf{Real}^{\uparrow}$ *seal rows already displayed by the Heron carrier. For*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the reciprocal route of Definition 3818.19 exposes the square-root approximation only after the regular readback Q and terminal seal E are attached to the same positive radicand, seed, reciprocal ledger, Heron recurrence window, dyadic contraction estimate, and Newton provenance rows. Thus the visible dependency passes through chapter 6251, chapter 301, and chapter 38 without adding a host square-root function, quotient real equality, selected completed limit, arbitrary trichotomy, or ambient completeness coordinate.

Proof. Project the Heron carrier. The rows A, S, R, L, W, D, K are the finite radicand, seed, reciprocal, recurrence, window, contraction, and Newton-provenance rows consumed before any square-root-facing read is public.

Apply Definition 3818.19. Its reciprocal forward path reads the existing reciprocal chapter through the same row R and then returns to the Heron readback boundary rather than fabricating a separate inverse or square-root object.

Now read the regular-rational and real rows. The row Q is the $\mathsf{RegSeqRat}^{\uparrow}$ regular-window readback produced from the displayed Heron iteration budget, and E is the terminal $\mathsf{Real}^{\uparrow}$ seal visible only after that readback.

Finally transport and replay through T, C, P, N. These rows keep the reciprocal, RegSeqRat, and Real dependencies on the same finite Heron route, so the square-root approximation is exposed as a displayed NameCert dependency rather than a host operation, quotient equality, selected limit, trichotomy, or completeness principle. □

Theorem 3818.23 (Heron square-root RegSeqRat forward dependency)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *endpoint must first pass through chapter 1756. For*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the square-root-facing dependency displays the regular-Cauchy source route before exposing the Heron rows $A, S, R, L, W, D, K, Q, E, T, C, P, N$*. Thus the RegSeqRat or Real consumer reads the positive radicand, seed, reciprocal ledger, recurrence window, contraction estimate, Newton provenance, regular readback, Real seal, transport, replay, provenance, and local naming only after the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *handoff is visible.*

Proof. Project the Heron carrier. The rows A, S, R, L, W, D, K display the radicand, seed, reciprocal ledger, recurrence window, contraction estimate, and Newton provenance before the regular readback row Q or terminal Real seal row E can be consumed.

Invoke the regular-Cauchy handoff through Definition 3818.18 and Definition 3818.17. These routes force the square-root-facing read through chapter 1756 before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ endpoint receives the Heron packet.

Now use the RegSeqRat Real dependency route of Definition 3818.22. It keeps Q and E downstream of the same A, S, R, L, W, D, K rows and therefore prevents a detached square-root approximation from entering the regular-rational or Real boundary.

Finally close through T, C, P, N. Transport, replay, provenance, and local naming preserve the same dependency order, so the read exports a finite Heron route rather than a host square-root function, quotient Real equality, selected completed limit, arbitrary trichotomy, or ambient completeness coordinate. □

Theorem 3818.24 (Heron square-root sibling consumer lattice)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *consumer route used by chapter 6251, chapter 6793, and chapter 7196 first reads the Heron square-root packet's dyadic approximation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{HeronSquareRoot}^{\uparrow}}$ *rows.*

Proof. Project the accepted Heron carrier from the chapter spine. The rows A, S, R, L, W, D expose the dyadic radicand, seed, reciprocal ledger, Heron recurrence window, and contraction estimate before any downstream consumer can inspect the regular-rational readback Q or terminal $\mathsf{Real}^{\uparrow}$ seal E.

Apply the Heron reciprocal, continuity, and Newton sibling routes already recorded in this chapter. The real reciprocal forward link routes the reciprocal row through chapter 6251; the nonnegative regular-Cauchy reciprocal-window route keeps the same Heron window visible for square-root continuity consumers; and the Newton sibling lattice keeps the dyadic Newton route attached to the displayed approximation rows.

Now read the downstream chapters. chapter 6251, chapter 6793, and chapter 7196 therefore receive the Heron packet only after Q, E, T, C, P, N have preserved readback, Real sealing, transport, replay, provenance, and local naming. No consumer route obtains a host square-root value, a hidden reciprocal, quotient-real equality, selected completion, or ambient completeness row. □

Theorem 3818.25 (Heron square-root sibling dependency lattice)**.** *Every* $\mathsf{HeronSquareRoot}^{\uparrow}$ *read that is exposed to a Real or Completion consumer must pass through the displayed Newton, regular-Cauchy, RegSeqRat, and Real siblings before the terminal square-root value is public. For a carrier*

$$H = (A, S, R, L, W, D, K, Q, E, T, C, P, N),$$

the lattice order first reads the positive radicand and seed rows, then the Heron recurrence and Newton provenance rows of chapter 223, then the regular-Cauchy square-root route of chapter 1756, then the $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, and finally the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. The route exports no host square-root operation, quotient Real equality, selected completed limit, arbitrary trichotomy, countable choice, or ambient completeness theorem.*

Proof. Project the accepted Heron carrier. The rows A, S, R, L, W, D, K expose the positive source data, reciprocal ledger, visible Heron window, dyadic contraction estimate, and Newton provenance before any Real-facing row is available.

Apply the existing Heron handoff and sibling-route theorems. They place the $\mathsf{NewtonIteration}^{\uparrow}$ row on the same finite recurrence window, route the convergence read through $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, and force the $\mathsf{RegSeqRat}^{\uparrow}$ row Q to be inspected before the terminal $\mathsf{Real}^{\uparrow}$ seal E.

The square-root boundary is therefore a consumer of the same displayed seal, not an independent oracle. Transport, replay, provenance, and local naming through T, C, P, N preserve the order of the sibling rows, so the public Heron read remains inside the horizontal dependency lattice and cannot export any excluded host or quotient object. □

Theorem 3818.26 (Heron square-root sibling dependency route)**.** *Every* $\mathsf{HeronSquareRoot}^{\uparrow}$ *consumer that exports a square-root approximation must first read the initial positive* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$ *rows, the* $\mathsf{NewtonIteration}^{\uparrow}$ *update route, the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *convergence readback, and the* $\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}$ *interval discipline. These sibling rows are a dependency route for the Heron packet, not a new square-root existence theorem, not a host square-root function, and not a selected completed limit.*

Proof. Project the Heron carrier through the already displayed radicand, seed, reciprocal ledger, recurrence window, dyadic contraction, readback, terminal seal, transport, replay, provenance, and local naming rows.

Read the initial numerical rows first. The positive $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ data supply the radicand and rational seed interface before any iterative square-root approximation can be consumed.

Next follow the sibling routes. The $\mathsf{NewtonIteration}^{\uparrow}$ row records the Heron update, $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ records the constructive convergence readback, and $\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}$ records the interval discipline that keeps the approximation inside finite dyadic windows.

The recurrence also reads the reciprocal-accounting route before the regular readback and Real seal become public. Its reciprocal ledger passes through chapter 703, chapter 1943, and chapter 6251, matching the forward link of Definition 3818.19.

Thus the public Heron read is a horizontal dependency route through the existing Newton, regular-Cauchy, Real, rational, and interval siblings. It exports only the displayed dependency order and adds no square-root theorem, selected limit, quotient-real equality, trichotomy, or ambient completeness coordinate. □

Theorem 3818.27 (Heron square-root sibling route)**.** *Every accepted* $\mathsf{HeronSquareRoot}^{\uparrow}$ *packet must read* $\mathsf{DyadicRatCore}^{\uparrow}$ *radicand and tolerance data from chapter 291,* $\mathsf{NewtonIteration}^{\uparrow}$ *recurrence rows from chapter 223, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301 together with the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows used by chapter 1756 before it exports the square-root route. The Heron carrier therefore sits on the displayed sibling lattice rather than on a host square-root function, selected completed limit, quotient-real equality, trichotomy row, or ambient completeness coordinate.*

Chapter 3819

A Concrete Naming Certificate for $\mathsf{ContractiveMap}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{ContractiveMap}^{\uparrow}$ packet records a displayed contraction between metric carriers as finite NameCert data. It sits over the source and target metric rows of chapter 57, the complete-metric consumer boundary of chapter 128, the tolerance export surface of chapter 369, the endpoint discipline of chapter 396, and the finite orbit route of chapter 2359. The packet names the map-level shrink surface that Banach and Picard consumers can inspect before any fixed point, completed limit, quotient equality, or host function extensionality is available.

Definition 3819.1 (Contractive map carrier)**.** *A* $\mathsf{ContractiveMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, f, k, D, G, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row and Y is the target* $\mathsf{Met}^{\uparrow}$ *row.*
2. *f is the finite map-code row from carried source histories to carried target histories.*
3. *k is the contraction-constant row, with displayed nonnegativity and strict unit-bound evidence.*
4. *D is the metric-distance witness row recording source-distance and target-distance requests for the accepted map reads.*
5. *G is the graph row witnessing that every accepted application of f is a finite BEDC graph read.*
6. *S is the shrink ledger recording each displayed comparison*

   $$d_Y(f(x), f(y)) \leq k\, d_X(x, y)$$

   for source histories carried by X and graph reads carried by G.
7. *H records componentwise* hsame *transport for the source and target metric rows, map-code row, contraction constant, distance witnesses, graph row, shrink ledger, continuation rows, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from source metric requests through f, k, D, G, S to target metric responses, uniform-modulus handoff, Picard iteration reads, and fixed-point consumers.*

9. *P is the* Pkg *provenance over* ContractiveMap$^\uparrow$, Met$^\uparrow$, CompleteMetric$^\uparrow$, UniformModulus$^\uparrow$, BanachFixedPoint$^\uparrow$, PicardIteration$^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{ContractiveMap}^\uparrow}$ *row.*

The carrier has no coordinate for a selected fixed point, a completed Picard limit, quotient equality of maps, host function extensionality, ambient completeness, or bridge checking.

Lean4 ✓ `BEDC.Derived.ContractiveMapUp.ContractiveMapTasteGate single carrier alignment`

Theorem 3819.2 (Contractive map NameCert obligations)**.** *For every accepted* ContractiveMap$^\uparrow$ *carrier $K = (X, Y, f, k, D, G, S, H, C, P, N)$, the local* NameCert$_{\text{ContractiveMap}^\uparrow}$ *surface consists exactly of source and target metric exposure, map-code admission, contraction-constant exactness, distance-witness exposure, graph replay, shrink-ledger replay, componentwise transport, displayed continuation, package provenance, and local naming through the rows $X, Y, f, k, D, G, S, H, C, P, N$.*

Proof. Project the carrier. The analytic rows are precisely the source metric X, target metric Y, map code f, contraction constant k, distance witnesses D, graph row G, and shrink ledger S.

The contraction obligation is replayed from the same rows. A target-distance read must pass through G, use the distance witnesses in D, and cite the comparison stored in S against the same constant row k.

The structural rows preserve that packet and add no analytic coordinate. Transport through H, replay through C, provenance through P, and local naming through N keep the displayed route intact, so the listed rows exhaust the NameCert surface. □

Theorem 3819.3 (Contractive map Picard consumer handoff)**.** *Every* PicardIteration$^\uparrow$ *or* BanachFixedPoint$^\uparrow$ *consumer of an accepted* ContractiveMap$^\uparrow$ *carrier receives contraction evidence only through*

$$X, Y, f, k, D, G, S, H, C, P, N.$$

The handoff exports metric-distance shrink replay and the strict unit-bound row for k; it does not export fixed-point existence, complete-metric convergence, quotient equality of maps, a selected endpoint, or host function extensionality.

Proof. Start with the NameCert obligations of Definition 3819.2. They make the shrink ledger S the only row that can justify a Picard or Banach contraction read.

A Picard consumer therefore reads the graph row G, the distance witnesses D, and the contraction constant k before it can replay a one-step or finite-orbit shrink comparison. The continuation row C transports this order to uniform-modulus, iteration, and fixed-point consumers without adding a limit point.

Completeness and endpoint selection remain outside the packet. A Banach consumer must attach its own complete-metric and endpoint rows, while the ContractiveMap$^\uparrow$ handoff supplies only the finite map-level shrink data. □

Theorem 3819.4 (Contractive map constant-row exactness)**.** *For every accepted* ContractiveMap$^\uparrow$ *carrier $K = (X, Y, f, k, D, G, S, H, C, P, N)$, every contraction read exposed by* NameCert$_{\text{ContractiveMap}^\uparrow}$ *uses the displayed constant row k together with its nonnegativity and strict unit-bound evidence. No Picard, Banach, or uniform-modulus consumer may replace k by an unstored scalar or by a scalar recovered from ambient host data.*

Proof. Project the carrier and apply the NameCert obligations of Definition 3819.2. The obligation list has a single contraction-constant coordinate, namely the row k, and it records the strict unit-bound evidence as part of that row.

The Picard handoff of Definition 3819.3 exports the same row to downstream consumers. Since the handoff excludes host function extensionality, quotient equality of maps, completed limits, and selected endpoints, there is no second route from which a different contraction scalar can be read. □

Theorem 3819.5 (Contractive map distance-witness stability)**.** *For every accepted* $\mathsf{ContractiveMap}^{\uparrow}$ *carrier* $K = (X, Y, f, k, D, G, S, H, C, P, N)$*, each source-distance or target-distance request used in a contraction comparison factors through the distance-witness row* D*. If the request involves a displayed application of* f*, the same read is tied to the graph row* G *before it can be used by the shrink ledger* S*.*

Proof. Project the carrier. The obligations in Definition 3819.2 list distance-witness exposure and graph replay as separate rows, and the proof of that theorem identifies D as the row carrying source-distance and target-distance requests.

A contraction comparison in S is therefore not a free metric assertion. It first reads the relevant source and target distance witnesses through D, and when the comparison evaluates f it reads the corresponding finite graph entry through G. The continuation row C can replay this order, but it cannot bypass either displayed row. □

Theorem 3819.6 (Contractive map shrink-ledger replay)**.** *For every accepted* $\mathsf{ContractiveMap}^{\uparrow}$ *carrier* $K = (X, Y, f, k, D, G, S, H, C, P, N)$*, every shrink comparison available to* $\mathsf{PicardIteration}^{\uparrow}$*,* $\mathsf{BanachFixedPoint}^{\uparrow}$*, or* $\mathsf{UniformModulus}^{\uparrow}$ *consumers is one of the comparisons stored in* S *and transported, replayed, provenanced, and locally named through* H, C, P, N*. The carrier exposes no additional contraction inequality outside those rows.*

Proof. Project the carrier and read the shrink-ledger clause of Definition 3819.2. That clause makes S the row recording the displayed comparisons

$$d_Y(f(x), f(y)) \leq k\, d_X(x, y)$$

for carried source histories and graph reads.

The consumer handoff in Definition 3819.3 sends the same finite shrink data to Picard and Banach consumers, and the carrier definition routes uniform-modulus handoff through the same continuation surface. Componentwise transport through H, displayed replay through C, provenance through P, and local naming through N preserve the stored ledger entries rather than generating fresh analytic inequalities. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContractiveMap}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractiveMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3819.1, Definition 3819.2, Definition 3819.3, Definition 3819.4, Definition 3819.5, and Definition 3819.6 seed the finite contraction-map surface for metric, graph, constant, shrink-ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractiveMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not assert fixed-point existence, complete-metric convergence, quotient equality of maps, selected endpoints, Lean verification, axiom-clean audit, or bridge checking for $\mathsf{ContractiveMap}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, contraction-constant exactness, graph replay, distance-witness exposure, shrink-ledger replay, Picard handoff, and field faithfulness for $X, Y, f, k, D, G, S, H, C, P, N$.

Constructive story: A ContractiveMap$^{\uparrow}$ packet is generated from source and target metric rows, a finite map-code row, a contraction constant below one, metric-distance witnesses, a graph row, a shrink ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3820

A Concrete Naming Certificate for $\mathsf{ClosedBoundedSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedBoundedSequence}^{\uparrow}$ packet records a bounded real sequence as finite BEDC source rows rather than as a completed sequence space or a compactness theorem. It is the bounded-sequence neighbour of the closed interval carrier in chapter 1591 and the Bolzano–Weierstrass route of chapter 1254. The carrier exposes only the finite bound interval row, the sequence windows read through chapter 126, the regular rational readbacks of chapter 301, the dyadic bound ledger of chapter 291, the terminal real seal of chapter 38, transport, replay, provenance, and local naming.

Definition 3820.1 (Closed bounded sequence carrier)**.** *A* $\mathsf{ClosedBoundedSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the bound interval row, read through the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *certificate of chapter 1591;*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows inspecting the requested sequence coordinates;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same coordinate windows;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording dyadic lower and upper bound comparisons against the interval row I;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for each inspected coordinate, reached only after I, W, R, D have been displayed;*
6. *H records componentwise* hsame *transport of the interval, window, readback, dyadic, and seal rows;*
7. *C records displayed* Cont *replay from interval bounds through finite sequence windows and coordinate seals;*
8. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedSequence}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedSequence}^{\uparrow}}$ *row.*

The carrier exports no general sequential compactness principle, no countable choice selector, no selected convergent subsequence, and no ambient space of all bounded sequences. Its public object is the finite bounded-coordinate packet B.

Lean4 ✓ `BEDC.Derived.ClosedBoundedSequenceUp.TasteGate.ClosedBoundedSequenceTasteGate single carrier alignment`

Theorem 3820.2 (Closed bounded sequence NameCert obligations)**.** *For the carrier of Definition 3820.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for* $B = (I, W, R, D, E, H, C, P, N)$*; bound-interval admission through* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*; coordinate-window admission through* $\mathsf{StreamName}^{\uparrow}$*; regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$*; dyadic containment of every inspected coordinate through* $\mathsf{DyadicRatCore}^{\uparrow}$*; terminal coordinate sealing through* $\mathsf{Real}^{\uparrow}$*; classifier preservation under* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier. Its interval row, coordinate-window rows, readback rows, dyadic bound ledger, Real seals, transport, replay, provenance, and local name are visible coordinates of one finite packet.

Read the bound before the coordinate seals. The $\mathsf{ClosedBoundedInterval}^{\uparrow}$ row supplies the lower endpoint, upper endpoint, endpoint order, and containment ledgers, while W, R, D inspect only finitely many sequence coordinates against that same interval.

The structural rows close the naming surface. Componentwise hsame transport and displayed Cont replay preserve exactly the listed rows, and the provenance and local naming rows source that finite route without adding sequential compactness, a choice-selected subsequence, or an ambient sequence-space object. □

Theorem 3820.3 (Closed bounded sequence Cauchy-subsequence window)**.** *Every* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or Cauchy-subsequence consumer of an accepted* $\mathsf{ClosedBoundedSequence}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the displayed rows $I, W, R, D, E, H, C, P, N$*. The route supplies bounded coordinate windows and dyadic containment readbacks, but it does not supply general sequential compactness, countable choice, a selected convergent subsequence, or an ambient completeness theorem.*

Proof. Start from the carrier inventory. The only sequence-facing rows are the finite windows W, regular rational readbacks R, dyadic bound ledger D, and coordinate seals E, all attached to the bound interval row I.

Next route the downstream consumer through the same rows. A $\mathsf{BolzanoWeierstrass}^{\uparrow}$ or Cauchy-subsequence consumer can request a bounded-coordinate window, but the request is replayed by C only after I, W, R, D, E have been transported by H and sourced by P, N.

The excluded principles are not carrier coordinates. Since the packet contains no selector for an infinite subsequence, no global compactness row, no countable choice row, and no ambient complete sequence space, the consumer receives only the displayed finite bounded-window route. □

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrass}^{\uparrow}$ or Cauchy-subsequence read of a $\mathsf{ClosedBoundedSequence}^{\uparrow}$ packet factors through a bound interval row, finite StreamName coordinate windows, RegSeqRat readbacks, a DyadicRatCore bound ledger, RealUp coordinate seals, transport, replay, provenance, and local naming.

Independence witness: closedboundedinterval, bolzanoweierstrass, streamname, regseqrat, dyadicratcore, real: $\mathsf{ClosedBoundedSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly

carries a bounded sequence source, finite coordinate windows, dyadic bound readbacks, coordinate seals, and a consumer-facing bounded-window route.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBoundedSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedBoundedSequence}^{\uparrow}$ packet is generated from a closed bounded interval row, finite sequence windows, regular rational readbacks, dyadic bound comparisons, RealUp coordinate seals, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBoundedSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3820.1, Definition 3820.2, and Definition 3820.3 bind the finite bounded-coordinate carrier before Bolzano–Weierstrass and Cauchy-subsequence consumers add their own extraction rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBoundedSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, general sequential compactness, countable choice, selected convergent subsequences, or ambient sequence-space completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier preservation, bound-readback, and Cauchy-subsequence handoff for BEDC.Derived.ClosedBoundedSequenceUp.

Chapter 3821

A Concrete Naming Certificate for $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$ packet records the finite radius-choice ledger used in the Heine–Cantor route. It reads compact finite-net data from chapter 129, pointwise continuity rows from chapter 130, finite lower-bound folds from chapter 619, dyadic tolerance bookkeeping from chapter 291, and the uniform-modulus consumer surface of chapter 369. The chapter is a finite NameCert carrier for the radius handoff; it is not an open-cover compactness proof, a semantic continuity theorem, or a choice function over all points.

Definition 3821.1 (Compact continuity radius-choice carrier)**.** *A* $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, M, Q, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric finite-net row, read through* $\mathsf{CompactMetric}^{\uparrow}$*;*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row at the displayed finite centers;*
3. *M is the finite center-to-radius matching ledger;*
4. *Q is the positive rational radius ledger attached to the selected center rows;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger;*
6. *L is the* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *lower-bound fold over the displayed radius rows;*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff row reached from the finite lower-bound ledger;*
8. *H records componentwise* hsame *transport for compact-net, continuous-map, radius, dyadic, fold, and handoff rows;*
9. *C records displayed* Cont *replay from finite-net centers and pointwise radii to the uniform-modulus handoff;*
10. *P is the* Pkg *provenance over* $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{HeineCantor}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactContinuityRadiusChoice}^{\uparrow}}$ *row.*

The carrier exposes the finite radius ledger and its consumer handoff. It has no coordinate for an external radius-selection function, open-cover compactness, semantic function equality, or a point chosen outside the finite compact-net bundle.

Lean4 (definition) `BEDC.Derived.CompactContinuityRadiusChoiceUp.CompactContinuityRadiusChoiceUp`

Theorem 3821.2 (Compact continuity radius-choice NameCert obligations)**.** *For the carrier of Definition 3821.1, the local* $\mathsf{NameCert}_{\mathsf{CompactContinuityRadiusChoice}^{\uparrow}}$ *surface consists exactly of carrier admission for* $R = (K, F, M, Q, D, L, U, H, C, P, N)$*; compact finite-net admission through* $\mathsf{CompactMetric}^{\uparrow}$*; pointwise-radius admission through* $\mathsf{ContinuousMap}^{\uparrow}$*; radius matching through* M, Q, D*; finite lower-bound folding through* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$*; the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through* U*; classifier preservation under* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier. The compact finite-net row, continuous-map pointwise rows, radius ledgers, dyadic comparisons, lower-bound fold, uniform-modulus handoff, transport, replay, provenance, and local name are all visible coordinates.

The radius choice is finite. Each radius row is attached to a displayed compact-net center and a displayed pointwise-modulus row; the lower-bound fold consumes only those finitely many positive rational and dyadic comparisons.

The consumer handoff is therefore confined to the displayed route. Componentwise transport and replay preserve the same rows, while provenance and local naming record the route without adding a global selector, open-cover compactness object, semantic continuity theorem, or point outside the finite bundle. □

Theorem 3821.3 (Compact continuity radius-choice uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{FiniteNetMinimumFold}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

Equivalently, the handoff receives the compact finite-net centers, pointwise radius rows, dyadic tolerance comparisons, the finite lower-bound ledger, and the displayed transport, replay, provenance, and local naming rows. It receives no open-cover compactness object, no external radius-selection function, no semantic continuity theorem, and no point selected outside the finite net.

Proof. Start with the compact-net and pointwise-modulus rows. The carrier exposes K and F before any radius row can be folded, so every radius is tied to a displayed finite center and a displayed continuous-map modulus row.

Next read the finite lower-bound ledger. The rows M, Q, D, L package the radius matching, positive rational radius data, dyadic comparisons, and finite minimum fold. This is the only source of a tolerance-only handoff to $\mathsf{UniformModulus}^{\uparrow}$.

Finally apply the structural rows. The route H, C, P, N transports, replays, sources, and names exactly the finite radius-choice ledger, so a uniform-modulus consumer cannot add open-cover compactness, a global radius-selection function, semantic continuity, or an off-net selected point. □

Falsifiable prediction: Every $\mathsf{UniformModulus}^{\uparrow}$ read of a $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$ packet factors through CompactMetric finite-net centers, ContinuousMap pointwise radii, DyadicRatCore tolerance comparisons, a FiniteNetMinimumFold lower-bound ledger, transport, replay, provenance, and local naming.

Independence witness: compactmetric, continuousmap, uniformmodulus, finitenetminimumfold, dyadicratcore, heinecantor: $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite compact-net radius ledger and the UniformModulus-facing lower-bound handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactContinuityRadiusChoice}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactContinuityRadiusChoice}^{\uparrow}$ packet is generated from compact finite-net centers, ContinuousMap pointwise radius rows, radius matching ledgers, dyadic tolerance comparisons, a finite lower-bound fold, a UniformModulus handoff row, hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactContinuityRadiusChoice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3821.1, Definition 3821.2, and Definition 3821.3 bind the finite radius-choice carrier feeding the Heine–Cantor uniform-modulus route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactContinuityRadiusChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, semantic continuity, global radius selection, or off-net point choice.

Upgrade path: Obligation closure requires checked carrier admission, classifier preservation, finite radius fold, and UniformModulus handoff for BEDC.Derived.CompactContinuityRadiusChoiceUp.

Chapter 3822

A Concrete Naming Certificate for $\mathsf{DuhamelPrinciple}^{\uparrow}$

Following Pazy's semigroup treatment of evolution equations and Evans' variation-of-constants discussion for forced linear problems, the $\mathsf{DuhamelPrinciple}^{\uparrow}$ packet records the finite BEDC route by which a homogeneous evolution row, a forcing row, and an integral convolution row are read as one solution handoff. It sits after the real-time surface of chapter 38, the integration interface of chapter 123, the ODE local-flow source of chapter 193, the dynamical-system flow packet of chapter 195, and the semigroup associativity surface of chapter 79. The carrier names the forcing route; it does not assert a host solution operator, classical existence theorem, quotient trajectory equality, or choice-selected mild solution.

Definition 3822.1 (DuhamelPrinciple carrier)**.** *A* $\mathsf{DuhamelPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, E, F, G, I, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Real}^{\uparrow}$ *time-window row, including the initial time, endpoint time, and inspected finite subintervals.*
2. *E is the homogeneous evolution row, read as an* $\mathsf{Ode}^{\uparrow}$ *local-flow or* $\mathsf{DynSystem}^{\uparrow}$ *flow packet and constrained by the* $\mathsf{Semigroup}^{\uparrow}$ *composition ledger.*
3. *F is the forcing-data row, recording the displayed inhomogeneous source samples and their* $\mathsf{Real}^{\uparrow}$ *readbacks.*
4. *G is the propagator action row, pairing each displayed forcing sample with the elapsed-time evolution row that carries it toward the endpoint.*
5. *I is the* $\mathsf{Integral}^{\uparrow}$ *convolution row over the finite time window, with its partition, approximation, and endpoint ledgers visible as integral data.*
6. *S is the solution readback row, exposing the homogeneous contribution and the integral forcing contribution as the endpoint history inspected by downstream consumers.*
7. *H records componentwise* hsame *transport for time windows, evolution rows, forcing rows, propagator rows, integral rows, solution readbacks, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a Duhamel request through $T, E, F, G, I, S, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{DuhamelPrinciple}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Semigroup}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DuhamelPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, E, F, G, I, S, H, C, P, N$. It has no coordinate for a host semigroup on a completed function space, an unobserved Bochner integral, a selected solution operator, classical choice, quotient trajectory equality, or global well-posedness.

Lean4 ✓ `BEDC.Derived.DuhamelPrincipleUp.DuhamelPrincipleTasteGate single carrier alignment`

Theorem 3822.2 (DuhamelPrinciple NameCert obligations)**.** *For every accepted* $\mathsf{DuhamelPrinciple}^{\uparrow}$ *carrier $D = (T, E, F, G, I, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DuhamelPrinciple}^{\uparrow}}$ *obligation surface consists exactly of real-time window admission, homogeneous evolution readback, forcing-data admission, propagator action exposure,* $\mathsf{Integral}^{\uparrow}$ *convolution readback, endpoint solution readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier. The time row T fixes the inspected interval before the evolution, forcing, or convolution rows are read. The homogeneous row E is already a named ODE or dynamical-system flow route, and its semigroup composition behavior is visible only through the displayed $\mathsf{Semigroup}^{\uparrow}$ ledger.

Read the forcing and propagator rows next. The row F supplies the inhomogeneous samples and real readbacks, while G records how the displayed evolution row carries each sample toward the endpoint. No host trajectory space is introduced at this stage.

The integral row I is then the only source of convolution data. Its partition, approximation, and endpoint ledgers are inherited from $\mathsf{Integral}^{\uparrow}$, and the solution row S may inspect only the homogeneous contribution together with that displayed convolution endpoint.

Finally use H and C to transport and replay the same finite rows, and use P and N for provenance and local naming. Since all excluded analytic objects lack carrier coordinates, they cannot enter the local NameCert obligation surface. □

Theorem 3822.3 (DuhamelPrinciple forcing route)**.** *Every downstream* $\mathsf{Ode}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, *stability, or PDE consumer of an accepted* $\mathsf{DuhamelPrinciple}^{\uparrow}$ *packet reads the inhomogeneous contribution through the finite route*

$$T, E, F, G \longmapsto I \longmapsto S \longmapsto H, C, P, N.$$

Thus the forced endpoint is available only as homogeneous evolution plus the displayed $\mathsf{Integral}^{\uparrow}$ *convolution of forcing data against the propagator row. The route exports no host solution operator, unbounded semigroup theorem, chosen mild solution, quotient trajectory equality, or ambient completeness principle.*

Proof. Begin with a forcing-facing consumer. The real-time row T and the homogeneous evolution row E determine the displayed elapsed-time cells and the semigroup-style composition ledger available to the packet.

Read F and G after that boundary is fixed. The forcing samples are paired with visible propagator action rows, so the consumer sees only finitely displayed source observations and their transported endpoint contributions.

The convolution is then read from I. This invokes the $\mathsf{Integral}^{\uparrow}$ carrier and ledger discipline over the same time window, so partitions and approximations remain integral rows rather than hidden choices.

The endpoint row S repacks the homogeneous part and the forcing convolution as the public readback. Transport, replay, provenance, and naming are supplied by H, C, P, N, which preserve the same route and leave every absent analytic object outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{DuhamelPrinciple}\uparrow}$.

Constructive story: A $\mathsf{DuhamelPrinciple}^{\uparrow}$ packet is generated from a RealUp time window, homogeneous ODE or DynSystem evolution row, Semigroup composition ledger, forcing-data row, propagator action row, IntegralUp convolution row, solution readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DuhamelPrinciple}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3822.1, Definition 3822.2, and Definition 3822.3 seed the finite variation-of-constants carrier, obligation surface, and forcing route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DuhamelPrinciple}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host solution operators, unbounded semigroup theorems, chosen mild solutions, quotient trajectory equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, forcing-route exactness, IntegralUp convolution readback, evolution transport stability, solution nonescape, and TasteGate field faithfulness for BEDC.Derived.DuhamelPrincipleUp.

Chapter 3823

A Concrete Naming Certificate for $\mathsf{LocatedSequenceLimit}^{\uparrow}$

Following Bishop and Bridges on located real limits of Cauchy sequences, the $\mathsf{LocatedSequenceLimit}^{\uparrow}$ packet records the finite evidence that a displayed stream name, regular rational sequence, and real-name seal describe the same located limit route. It sits between the stream observation surface of chapter 126, the regular rational sequence surface of chapter 301, the terminal real-name seal of chapter 38, the Cauchy criterion route of chapter 1509, and the located Cauchy surface of chapter 1595. The packet is finite L10 NameCert data for a located sequence limit; it is not a selected quotient representative, an ambient completeness theorem, a trichotomy decision, or a countable-choice schedule.

Definition 3823.1 (Located sequence limit carrier)**.** *A* $\mathsf{LocatedSequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row, exposing only finite windows of the displayed sequence name.*
2. *W is the located-window ledger. For each displayed precision request it records the finite inspected window, the located side of the comparison, and the tolerance budget used by the read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the inspected windows as regular rational sequence data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the stream window and regular rational readback agree on the same located limit route.*
5. *H records componentwise* hsame *transport for the stream source, located window, regular readback, real seal, replay, provenance, and local name.*
6. *C records displayed* Cont *replay from a precision request through*

$$S, W \longmapsto R \longmapsto E.$$

7. *P is the* Pkg *provenance over* $\mathsf{LocatedSequenceLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvergenceCrite}$ $\mathsf{LocatedCauchySequence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceLimit}^{\uparrow}}$ *row.*

The classifier accepts only packets in which the finite stream windows, located comparison ledger, regular rational readback, and real-name seal describe one displayed limit route. No carrier coordinate stores a quotient sequence, selected representative of the limit, host equality on reals, trichotomy oracle, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LocatedSequenceLimitUp.TasteGate.LocatedSequenceLimitTasteGate single carrier alignment`

Theorem 3823.2 (Located sequence limit NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSequenceLimit}^{\uparrow}$ *carrier* $L = (S, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceLimit}^{\uparrow}}$ *surface consists exactly of stream-window admission, located-window tolerance accounting, regular rational readback, real-name seal routing, componentwise transport, continuation replay, package provenance, and local naming through the rows* S, W, R, E, H, C, P, N*. The* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *and* $\mathsf{LocatedCauchySequence}^{\uparrow}$ *siblings may consume the packet only through those displayed rows.*

Proof. Project the carrier of Definition 3823.1. The sequence is visible only through the finite stream row S, and the located comparison evidence is visible only through the window ledger W.

The readback row R repacks the same finite observations as $\mathsf{RegSeqRat}^{\uparrow}$ data. The real-name row E is downstream of S, W, R, so a real-facing consumer reaches the limit seal only after replaying the displayed located route.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Since the carrier has no coordinate for quotient sequences, selected representatives, host equality, trichotomy, or ambient completeness, the listed NameCert rows are exhaustive. □

Theorem 3823.3 (Located sequence limit Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, *or* $\mathsf{LocatedCauchySequence}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedSequenceLimit}^{\uparrow}$ *carrier must read*

$$S, W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the terminal real-name seal cannot be replaced by host real equality, a quotient completion object, a selected subsequence, trichotomy on signs, or an ambient completeness proof.

Proof. Begin with a consumer request for real-limit or Cauchy-facing data. The packet exposes sequence observations only through S, and every located precision request is accounted for by W.

The regular rational readback row R is the only bridge from the inspected windows to a rational sequence surface. Thus the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ seal E only after the finite route has been replayed.

The rows H, C, P, N transport, replay, source, and name the same route. No excluded analytic object is present in the tuple, so no downstream consumer can extract one from the packet. □

Theorem 3823.4 (Located sequence limit window uniqueness)**.** *Let*

$$L = (S, W, R, E, H, C, P, N) \quad \textit{and} \quad L' = (S', W', R', E', H', C', P', N')$$

be accepted $\mathsf{LocatedSequenceLimit}^{\uparrow}$ *packets. If they expose the same source* $\mathsf{StreamName}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, located-window ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, then they determine the same finite located-limit route. In particular, there are not two different accepted finite L10 windows for the same located request.*

Proof. Project both packets through the carrier definition Definition 3823.1. The hypotheses identify the only visible source row S, the only located-window ledger W, and the only regular readback row R available to either packet.

Apply the NameCert obligation theorem Definition 3823.2. It states that all accepted located-limit data are exhausted by the displayed rows S, W, R, E, H, C, P, N, so the two packets have no additional coordinate on which their finite routes could diverge.

Finally use the Real seal nonescape theorem Definition 3823.3. The terminal seal is reached only through the same stream, located-window, and readback route, and the carrier contains no selected quotient representative, ambient completeness proof, trichotomy oracle, or countable-choice schedule. Thus the accepted packets determine one finite located-limit route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequenceLimit}\uparrow}$.

Constructive story: A $\mathsf{LocatedSequenceLimit}^{\uparrow}$ packet is generated from StreamName observations, located finite-window tolerance data, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSequenceLimit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3823.1, Definition 3823.2, Definition 3823.3, and Definition 3823.4 seed the finite located sequence-limit surface for the L10 StreamName-to-RegSeqRat-to-Real route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSequenceLimit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window accounting, RegSeqRat readback, Real seal routing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.LocatedSequenceLimitUp.

Chapter 3824

A Concrete Naming Certificate for $\mathsf{DedekindGapLocatedCut}^{\uparrow}$

Following Bishop and Bridges constructive located cuts, the $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ packet records the finite lower-upper separation data that a completion or real-comparison consumer may inspect before any construction of $\mathsf{Real}^{\uparrow}$ is claimed. It is a located-cut boundary over the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational sequence route of chapter 301, the terminal real-name seal of chapter 38, and the located-supremum consumer surface of chapter 1427. The packet supplies a gap-located comparison boundary consumed by $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readers; it is not a Dedekind construction of $\mathsf{Real}^{\uparrow}$, not quotient equality of cuts, and not an ambient completeness principle.

Definition 3824.1 (Dedekind gap located cut carrier)**.** *A* $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, U, D, W, R, S, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-cut ledger: finite rational cells certified to lie below the boundary.*
2. *U is the upper-cut ledger: finite rational cells certified to lie above the boundary.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap row. For every displayed tolerance request it names a dyadic bracket or a separating dyadic cell between the currently exposed lower and upper ledgers.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for the finite lower, upper, and gap requests actually read by a consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the windowed lower-upper data as regular rational observations.*
6. *S is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *boundary handoff row available to consumers that need an upper-bound or lower-approximation surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is exposed only after L, U, D, W, R, S have been displayed.*
8. *H records componentwise* hsame *transport for lower cells, upper cells, dyadic gaps, stream windows, regular readback, located-supremum handoff, real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay through the ordered route $L, U, D, W, R, S, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{DedekindGapLocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindGapLocatedCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, D, W, R, S, E, H, C, P, N$. It has no coordinate for quotient equality of cuts, a selected real representative, countable choice, trichotomy, a host order-completeness theorem, or a Dedekind construction of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DedekindGapLocatedCutUp.DedekindGapLocatedCutTasteGate single carrier alignment`

Theorem 3824.2 (Dedekind gap located cut carrier boundary)**.** *Every accepted* $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ *carrier is read through the displayed route*

$$L, U, D, W, R, S, E, H, C, P, N.$$

Thus a consumer receives lower-cut cells, upper-cut cells, dyadic gap witnesses, finite stream windows, regular rational readback, a located-supremum boundary handoff, a terminal Real seal, transport, replay, provenance, and local naming. No accepted read exposes quotient equality of lower-upper cuts, a selected real representative, trichotomy, countable choice, ambient completeness, or a construction of $\mathsf{Real}^{\uparrow}$ *from Dedekind cuts.*

Proof. Project the carrier of Definition 3824.1. The rows L and U are the only lower and upper cut data, while D supplies the finite dyadic gap evidence inspected by the request.

The rows W and R place those gap observations inside a finite observation schedule and regular rational readback. The located-supremum row S is downstream of the same windowed data, and the real seal E is reached only after that route is displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not fields of the carrier, no consumer can recover them from an accepted $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ read. □

Theorem 3824.3 (Dedekind gap located cut obligations)**.** *For an accepted* $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ *carrier $G = (L, U, D, W, R, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DedekindGapLocatedCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower and upper ledgers, dyadic gap exposure, StreamName window exposure, RegSeqRat readback, LocatedSupremum boundary handoff, Real seal exposure, componentwise transport, displayed replay, provenance, and local naming. The obligations do not include a quotient of cuts, a host real equality test, selected supremum data outside S, or any completeness assertion for* $\mathsf{Real}^{\uparrow}$.

Proof. Carrier admission lists the rows $L, U, D, W, R, S, E, H, C, P, N$, so the local NameCert surface begins with a finite inventory rather than an external real construction.

The computational obligations are read in order. Dyadic gap exposure comes from D, window discipline from W, regular rational readback from R, and the upper-bound or lower-approximation consumer handoff from S before the terminal seal E can be consumed.

Transport and replay do not enlarge the inventory. The rows H and C preserve the same displayed data, while P and N record provenance and local naming, so the listed obligations exhaust the accepted packet. □

Theorem 3824.4 (Dedekind gap RegSeqRat boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ *packet factors through the finite route*

$$L, U \longmapsto D \longmapsto W \longmapsto R \longmapsto S \longmapsto E.$$

The route exposes a located lower-upper gap boundary that $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers may use for comparison work. It does not identify cuts by quotient equality, select a representing real, assert a Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, or import ambient order completeness.*

Proof. Start with the lower and upper ledgers L, U. A consumer sees only the displayed finite cells, so the request is a boundary read rather than an equality of cuts.

The dyadic row D supplies the gap witness requested at the displayed precision, and W records the finite observation window in which that witness is inspected. The readback row R then repacks the same window as regular rational sequence data.

The located-supremum handoff S and terminal seal E remain downstream of those rows. Consequently every RegSeqRat or Real-facing read is a routed boundary read, with no coordinate for the excluded quotient, selection, construction, or completeness claims. □

Falsifiable prediction: An accepted $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ read is refuted if a RegSeqRat or Real-facing consumer can remove the lower ledger, upper ledger, dyadic gap row, StreamName window, RegSeqRat readback, LocatedSupremum handoff, Real seal, transport, replay, provenance, or local naming while preserving the same packet claim.

Independence witness: dyadicratcore, streamname, regseqrat, real, locatedsupremum: $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lower and upper cut ledgers, dyadic gap witnesses, finite observation windows, regular rational readback, located-supremum handoff, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindGapLocatedCut}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindGapLocatedCut}^{\uparrow}$ packet is generated from lower-cut ledgers, upper-cut ledgers, dyadic gap witnesses, StreamName windows, RegSeqRat readback, a LocatedSupremum boundary handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindGapLocatedCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3824.1, Definition 3824.2, Definition 3824.3, and Definition 3824.4 seed the L10 located-cut boundary consumed by RegSeqRat and Real-facing comparison packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindGapLocatedCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Dedekind construction of RealUp, quotient equality of cuts, selected real representatives, trichotomy, countable choice, ambient order completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-upper gap exposure, dyadic tolerance transport, StreamName window discipline, RegSeqRat readback, LocatedSupremum handoff, and Real seal nonescape for BEDC.Derived.DedekindGapLocatedCutUp.

Chapter 3825

A Concrete Naming Certificate for $\mathsf{FastCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FastCauchyCriterion}^{\uparrow}$ packet records the finite criterion data by which displayed fast Cauchy windows, monotone fast-modulus control, regular rational readback, and the terminal real-name seal may be inspected together before a Real or Completion consumer reads the result. It sits between the fast sequence surface of chapter 2185, the fast modulus discipline of chapter 1781, the regular rational readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is criterion data for a displayed regular-Cauchy route; it is not quotient real equality, a selected representative, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3825.1 (FastCauchyCriterion carrier)**.** *A* $\mathsf{FastCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row recording the inspected sequence values used by the criterion.*
2. *D is the dyadic tolerance scale row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, against which the fast-window comparisons are measured.*
3. *M is the monotone* $\mathsf{FastCauchyModulus}^{\uparrow}$ *row, displaying the threshold discipline that sends a requested tolerance to a later inspected window and preserves monotonicity of the request ledger.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *compatibility row, recording that the displayed windows and dyadic bounds form the regular rational readback consumed by Real and Completion routes.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row, available only after S, D, M, R have been displayed.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerance scale, monotone modulus, regular rational readback, and Real seal handoff.*
7. *C records displayed* Cont *replay for window inspection, tolerance comparison, monotone threshold use, RegSeqRat compatibility, and Real seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{FastCauchyCriterion}^{\uparrow}$*,* $\mathsf{FastCauchySequence}^{\uparrow}$*,* $\mathsf{FastCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FastCauchyCriterion}^{\uparrow}}$ *row.*

The carrier exports no quotient equality of real names, no selected representative of a Cauchy class, no countable-choice schedule, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.FastCauchyCriterionUp.FastCauchyCriterionTasteGate single carrier alignment`

Theorem 3825.2 (FastCauchyCriterion NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchyCriterion}^{\uparrow}$ *carrier* $K = (S, D, M, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FastCauchyCriterion}^{\uparrow}}$ *surface consists exactly of finite StreamName window admission, dyadic tolerance-scale admission, monotone fast-modulus threshold exposure, RegSeqRat compatibility, RealUp seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The rows S, D, M, R, E are the only analytic rows available to a criterion consumer, and they appear in the order needed by the fast Cauchy route: finite windows first, dyadic tolerances next, the monotone threshold ledger next, regular rational readback next, and the Real seal last.

Read the sibling routes through provenance. The row M is the visible threshold discipline of chapter 1781, while S, D, R are the finite window, dyadic tolerance, and regular rational surfaces already used by chapter 2185.

The structural rows do not add analytic content. The transport row H moves only the displayed coordinates componentwise, the replay row C repeats the same threshold and comparison route, and P, N source and name that finite surface. Thus no NameCert obligation remains outside $S, D, M, R, E, H, C, P, N$. □

Theorem 3825.3 (FastCauchyCriterion modulus readback)**.** *Let* $K = (S, D, M, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FastCauchyCriterion}^{\uparrow}$ *carrier. Every requested precision read obtains its fast threshold from* M*, opens only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows recorded in* S*, checks the dyadic bound through* D*, and hands the resulting regular schedule to* R *before any* $\mathsf{Real}^{\uparrow}$ *seal in* E *is consumed. The readback is therefore a finite criterion route over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not a selected representative or an ambient completeness argument.*

Proof. Start with the monotone modulus row. The request is sent to the displayed threshold in M, and monotonicity keeps later precision requests inside the same finite threshold ledger rather than invoking a choice sequence.

Open the finite windows through S and compare them through D. These rows provide exactly the inspected values and dyadic tolerance account needed for a fast Cauchy criterion, so the route remains inside the displayed BHist packet.

Finally read R and then E. The $\mathsf{RegSeqRat}^{\uparrow}$ compatibility row consumes the same windows and tolerances, and the $\mathsf{Real}^{\uparrow}$ handoff is downstream of that compatibility row. Componentwise transport, replay, provenance, and local naming preserve the same route and add no quotient equality, selected representative, countable choice, or ambient completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{FastCauchyCriterion}^{\uparrow}$ precision read exposes one finite StreamName window row, one dyadic tolerance-scale row, one monotone FastCauchyModulus row, one RegSeqRat compatibility row, one RealUp seal handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer may read the criterion.

Independence witness: fastcauchysequence, fastcauchymodulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{FastCauchyCriterion}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries windows, tolerance scale, monotone threshold discipline, regular readback, Real seal handoff, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{FastCauchyCriterion}^{\uparrow}$ packet is generated from finite StreamName windows, a dyadic tolerance scale, a monotone FastCauchyModulus row, RegSeqRat compatibility, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3825.1, Definition 3825.2, and Definition 3825.3 seed the finite criterion surface connecting fast Cauchy sequence windows, fast modulus thresholds, RegSeqRat readback, and Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{FastCauchyCriterion}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, monotone modulus exposure, dyadic tolerance readback, RegSeqRat compatibility, Real seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.FastCauchyCriterionUp

Chapter 3826

A Concrete Naming Certificate for CauchyCompletionKleisliCategory$^{\uparrow}$

Following Mac Lane's Kleisli-category formulation, the CauchyCompletionKleisliCategory$^{\uparrow}$ packet records the finite category-level surface of the L10 completion monad. It sits after the completion monad of chapter 378, the Kleisli-arrow packet of chapter 1845, the universal-property surface of chapter 397, and the finite real-name route through chapter 126, chapter 301, chapter 291, and chapter 38. The chapter names a category of completion consumers through displayed finite rows; it is not a quotient completion, not a selected limit, not host equality of completed objects, and not ambient Real$^{\uparrow}$ completeness.

Definition 3826.1 (CauchyCompletionKleisliCategory carrier)**.** *A* CauchyCompletionKleisliCategory$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, U, A, B, E, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the object row, reading each completion-facing object through* CauchyCompletionMonad$^{\uparrow}$ *and the regular rational name surface.*
2. *U is the unit-arrow row, recording the monad unit route from displayed source rows into the completion packet.*
3. *A is the Kleisli-arrow row, whose arrows are completion-valued maps exposed by* CauchyCompletionKleisli$^{\uparrow}$*.*
4. *B is the bind-composition row, recording composition only through the monad bind schedule and the displayed Kleisli route.*
5. *E is the identity and associativity ledger, comparing unit and bind composites as finite BEDC routes rather than as host function equalities.*
6. *R is the real-completion handoff row, routing completion consumers through* CompletionUniversalProperty$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*, and* Real$^{\uparrow}$ *seals.*
7. *H records componentwise* hsame *transport for object, unit, arrow, bind, ledger, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for unit-arrow reads, bind composition, completion consumers, and terminal* Real$^{\uparrow}$ *seal requests.*

9. *P is the* Pkg *provenance over* CauchyCompletionKleisliCategory$^{\uparrow}$, CauchyCompletionMonad$^{\uparrow}$, CauchyCompletionKl CompletionUniversalProperty$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* NameCert$_{\text{CauchyCompletionKleisliCategory}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completions, selected representatives, selected limits, host equality of arrows, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyCompletionKleisliCategoryUp.CauchyCompletionKleisliCategoryUp`

Theorem 3826.2 (CauchyCompletionKleisliCategory NameCert obligations)**.** *For every accepted* CauchyCompletionKleisliCategory$^{\uparrow}$ *carrier $K = (O, U, A, B, E, R, H, C, P, N)$, the local* NameCert$_{\text{CauchyCompletionKleisli}}$ *surface consists exactly of object exposure, unit-arrow exposure, Kleisli-arrow exposure, bind-composition exposure, identity and associativity ledger exposure, real-completion handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 3826.1. The object, unit, arrow, bind, ledger, and real-completion handoff rows are precisely O, U, A, B, E, R.

The unit-arrow row is read through CauchyCompletionMonad$^{\uparrow}$, while the arrow and bind rows are read through CauchyCompletionKleisli$^{\uparrow}$. The ledger E compares the category identities and associative composites only after those rows have been displayed.

The real-facing handoff R routes every completion consumer through CompletionUniversalProperty$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ seals. Thus a consumer cannot read a terminal real-completion claim before the finite Cauchy-name and dyadic rows are visible.

Finally H, C, P, N preserve, replay, source, and name the same finite packet. Since no quotient completion, selected representative, selected limit, host equality, or ambient completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 3826.3 (CauchyCompletionKleisliCategory real-completion handoff)**.** *Every* Real$^{\uparrow}$ *or completion-facing consumer of an accepted* CauchyCompletionKleisliCategory$^{\uparrow}$ *packet factors through the ordered route*

CauchyCompletionMonad$^{\uparrow}$, CauchyCompletionKleisli$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, D

The route may use unit arrows and bind composition inside the Kleisli category, but it exports no quotient completion, selected limit, host equality of arrows, selected representative, or ambient Real$^{\uparrow}$ *completeness principle.*

Proof. First read the monad and Kleisli rows. The unit arrows come from U, and the composition row B uses the bind schedule attached to the displayed Kleisli-arrow row A.

Next read the category ledger. The row E records the identity and associativity comparisons as finite route comparisons over O, U, A, B, so the categorical equations are consumed as BEDC ledger data rather than as host equality of functions.

Finally pass to real-completion consumers through R. The handoff row requires the universal-property surface and the finite name route through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ before any terminal seal is available.

The structural rows H, C, P, N keep this route inside the displayed packet. There is no carrier coordinate that could supply a quotient completion, selected limit, host arrow equality, selected representative, or ambient completeness theorem. □

Falsifiable prediction: A $\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}$ completion consumer that reads a $\mathsf{Real}^{\uparrow}$ seal without first exposing the monad, Kleisli-arrow, universal-property, stream-window, regular-rational, dyadic-tolerance, transport, replay, provenance, and local NameCert rows refutes the packet.

Independence witness: cauchycompletionmonad, cauchycompletionkleisli, completionuniversal-property, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}$ because the category packet jointly carries objects, unit arrows, Kleisli arrows, bind composition, categorical ledgers, completion handoff, transport, replay, provenance, and local naming in one finite carrier.

Lean follow-up requires a finite carrier namespace at `BEDC.Derived.CauchyCompletionKleisliCategoryUp` with the displayed object, unit, Kleisli-arrow, bind-composition, ledger, handoff, transport, replay, provenance, and naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}$ packet is generated from completion-object rows, unit-arrow rows, Kleisli-arrow rows, bind-composition rows, identity and associativity ledgers, real-completion handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3826.1, Definition 3826.2, and Definition 3826.3 seed the finite Kleisli-category completion packet for L10 consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality of arrows, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-arrow exposure, Kleisli-arrow exposure, bind-composition exposure, categorical ledger exactness, real-completion handoff, transport stability, replay stability, provenance exhaustion, and non-escape for BEDC.Derived.CauchyCompletionKleisliCategoryUp.

Chapter 3827

A Concrete Naming Certificate for MetaCICConfluenceResidualChecker$^{\uparrow}$

The MetaCICConfluenceResidualChecker$^{\uparrow}$ packet realizes the substitution-sensitive confluence frontier of chapter 9378 as finite checker data. It sits beside the substitution-boundary packet of chapter 3791, the bounded residual frontier of chapter 3808, the critical-pair boundary of chapter 2212, and the local diamond witness of chapter 3595. The packet records which typed windows, redex frontiers, local joins, obstruction rows, and replay routes have actually been checked before a confluence consumer may cite the conditional handoff.

Falsifiable prediction: A MetaCIC confluence read that treats a residual-substitution peak as checked while omitting the finite typed-window, redex-frontier, bounded-checker, local-join, obstruction, transport, replay, provenance, and local NameCert rows refutes MetaCICConfluenceResidualChecker$^{\uparrow}$.

Independence witness: metacic-confluence-substitution-boundary, bounded-residual-substitution-frontier, metacic-confluence-critical-pair-boundary, metacic-local-diamond-witness: none is bijective to MetaCICConfluenceResidualChecker$^{\uparrow}$ because the checker packet jointly carries typed windows, redex frontiers, bounded checker outcomes, local joins, obstruction retention, transport, replay, provenance, and local naming as one finite confluence frontier.

Definition 3827.1 (MetaCIC confluence residual-checker carrier)**.** *A* MetaCICConfluenceResidualChecker$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, R, B, J, O, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row containing the source term, the two parallel reducts, the residual substitution window, and the candidate common reduct.*
2. *R is the redex-frontier row, listing the inspected beta positions, binder depths, residual descendants, and free-variable exposure checks.*
3. *B is the bounded-checker row, recording the finite closedness, substitution-support, variable-escape, and branch-compatibility checks.*
4. *J is the local-join row, storing the finite replay path to the candidate common reduct when the checker accepts.*

5. *O is the obstruction row, naming the still-visible endpoints: unrestricted substitution compatibility, premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, evaluator equality, and kernel consistency.*
6. *S is the checker-status row, recording whether the inspected residual window is accepted, rejected, or left at the named obstruction boundary.*
7. *H records componentwise* hsame *transport for typed windows, redex frontiers, bounded checks, local joins, obstruction rows, checker status, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a confluence-frontier query through $T, R, B, J, O, S, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$, $\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}$, $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$, $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It contains no coordinate for full confluence, unrestricted residual-substitution compatibility, hidden conversion, evaluator equality, subject reduction, or kernel consistency.

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceResidualCheckerUp.MetaCICConfluenceResidualCheckerTasteGate`
`single carrier alignment`

Theorem 3827.2 (MetaCIC confluence residual-checker obligations)**.** *For every accepted* MetaCICConfluenceResidu *carrier $Q = (T, R, B, J, O, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}}$ *surface consists exactly of typed-window exposure through T, redex-frontier exposure through R, bounded checking through B, local-join exposure through J, obstruction retention through O, checker-status exposure through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3827.1. The rows T, R, B, J, O, S are the checker-facing data, and the rows H, C, P, N are the structural certificate data.

The checker begins at T and R. These rows display the finite typed peak, the residual substitution window, the inspected redex positions, binder-depth ledger, and free-variable exposure checks.

The row B records the bounded decision surface, while J records only the local candidate join made available by that bounded surface. The checker-status row S separates accepted windows, rejected windows, and windows that remain at the named substitution obstruction.

The obstruction row O prevents the bounded read from being cited as global confluence. Transport, replay, provenance, and local naming preserve the same finite packet, and no hidden conversion, evaluator equality, subject reduction, or kernel-consistency coordinate is present. □

Theorem 3827.3 (MetaCIC confluence residual-checker handoff)**.** *Every confluence-audit consumer of an accepted* $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$ *carrier factors through the finite route*

$$T, R, B \longmapsto J, S, O \longmapsto H, C, P, N.$$

The route may hand off a checked residual window to the substitution-boundary, bounded-frontier, critical-pair, and local-diamond packets named above, but it does not supply unrestricted substitution compatibility, a premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, evaluator equality, or kernel consistency.

Proof. First read the finite window. The rows T and R expose the typed peak, residual substitution window, redex frontier, binder-depth ledger, and free-variable checks.

Next apply the bounded checker row B. If the finite checks accept, the local join row J and checker-status row S expose the handoff; if they reject or stop at the boundary, S and O keep the obstruction visible.

Finally route the handoff through H, C, P, N. These rows transport, replay, source, and name the same finite packet, and the provenance row points only to the substitution-boundary, bounded-frontier, critical-pair, and local-diamond packets.

The carrier therefore has no path to a global confluence theorem or hidden substitution theorem. Lean follow-up requires Nontrivial and FieldFaithful instances for `BEDC.Derived.MetaCICConfluenceResidualChec` at exactly this displayed carrier surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$ packet is generated from typed-window rows, redex-frontier rows, bounded-checker rows, local joins, checker-status rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3827.1, Definition 3827.2, and Definition 3827.3 seed the finite residual-substitution checker packet for MetaCIC confluence consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution compatibility, premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, redex-frontier coverage, bounded-checker exactness, local-join exposure, checker-status determinacy, obstruction retention, transport stability, replay stability, provenance exhaustion, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.MetaCICConfluenceResidualChec

Chapter 3828

A Concrete Naming Certificate for $\mathsf{DarbouxContinuity}^{\uparrow}$

Darboux/Bishop–Bridges constructive analysis treats interval continuity as a finite route from a closed bounded source interval, through an explicitly continuous graph, into bracketed intermediate-value data before any completed real image is read. The $\mathsf{DarbouxContinuity}^{\uparrow}$ packet records that route over chapter 1591, chapter 130, chapter 1402, chapter 291, chapter 301, and chapter 38. It is a local continuity certificate for L10 interval-image consumers, not an open-cover compactness principle, not quotient real equality, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3828.1 (DarbouxContinuity carrier)**.** *A* $\mathsf{DarbouxContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, G, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded interval source row, carrying endpoint order, containment, finite-net source, and source-obligation data from* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*.*
2. *G is the continuous-map graph row over the interval source, recording the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus, graph, and classifier-compatible point route.*
3. *V is the intermediate-value crossing row, recording the admitted sign or order crossing data read through* $\mathsf{IntermediateValue}^{\uparrow}$*.*
4. *D is the dyadic bracket ledger from* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording finite rational brackets for endpoints, graph samples, crossing windows, and tolerance budgets.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the bracketed endpoint, sample, and crossing observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after I, G, V, D, R have been displayed.*
7. *H is the componentwise* hsame *row for the interval, graph, crossing, bracket, readback, seal, replay, provenance, and local naming data.*
8. *C records displayed* Cont *replay from any interval-continuity consumer through I, G, V, D, R, E and then through the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{DarbouxContinuity}^{\uparrow}$*,* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{IntermediateValue}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxContinuity}^{\uparrow}}$ *row.*

The carrier has no coordinate for host open covers, selected subcovers, quotient real equality, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.DarbouxContinuityUp.DarbouxContinuityTasteGate single carrier alignment`

Theorem 3828.2 (DarbouxContinuity NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxContinuity}^{\uparrow}$ *carrier* $T = (I, G, V, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DarbouxContinuity}^{\uparrow}}$ *surface consists exactly of closed-interval source admission, continuous-map graph exposure, intermediate-value crossing exposure, dyadic bracket accounting, RegSeqRat readback, Real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier rows. The interval source I, graph row G, crossing row V, dyadic ledger D, readback row R, and seal row E are the only analytic rows available to a consumer.

Read the structural rows separately. The transport row H preserves those analytic rows componentwise, while C replays the same displayed route for interval-continuity consumers.

The provenance and naming rows P, N attach the packet to the cited closed-interval, continuous-map, intermediate-value, dyadic, regular-readback, and Real certificates. No excluded cover, quotient, trichotomy, choice, or completeness coordinate is present. □

Theorem 3828.3 (DarbouxContinuity source route)**.** *Every* $\mathsf{DarbouxContinuity}^{\uparrow}$ *consumer that reads an interval-image or crossing value must first enter through the closed bounded interval source of chapter 1591, then through the continuous graph of chapter 130, then through the crossing row of chapter 1402, and only then through the dyadic, RegSeqRat, and Real rows of chapter 291, chapter 301, and chapter 38.*

Proof. Start with the source interval row I. Its endpoint, containment, finite-net, and readback obligations supply the finite interval boundary before any graph or image row is available.

Next read the graph and crossing rows. The continuous-map row G supplies the displayed modulus and graph route, and V supplies the intermediate-value crossing data relative to that graph.

Finally expose D, R, E through the same route. The dyadic bracket ledger, regular readback, and Real seal are downstream of I, G, V, so a consumer cannot start from an ambient interval image or a completed real-value selection. □

Theorem 3828.4 (DarbouxContinuity graph exposure)**.** *For every accepted* $\mathsf{DarbouxContinuity}^{\uparrow}$ *carrier* $T = (I, G, V, D, R, E, H, C, P, N)$*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row* G *is exposed only after the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row* I *has been displayed. Any crossing read through* V *depends on that graph exposure and therefore cannot be read as an interval-image fact detached from the source interval and continuous-map graph.*

Proof. Project the carrier of Definition 3828.1. The row I is the source interval coordinate, and G is explicitly described as the continuous-map graph row over that source.

Now inspect the crossing row. The row V records intermediate-value crossing data read through the graph row G, so a consumer of V must have already displayed both the source interval row and the continuous graph row.

The structural rows H, C, P, N only transport, replay, source, and name this route. They add no detached image coordinate, so every accepted crossing read remains dependent on the I then G exposure order. □

Theorem 3828.5 (DarbouxContinuity Real-seal handoff)**.** *For every accepted* $\mathsf{DarbouxContinuity}^{\uparrow}$ *carrier* $T = (I, G, V, D, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *row* E *is terminal. It may be read only after the dyadic bracket ledger* D *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *expose the bracketed endpoint, sample, and crossing observations used by the intermediate-value route.*

Proof. Project the analytic rows. The dyadic ledger D stores the finite rational brackets, and the row R is the regular rational readback for those bracketed observations.

The seal row is downstream. In Definition 3828.1, E is exposed only after I, G, V, D, R have been displayed, so the completed real-name read cannot precede the bracket ledger or its regular readback.

Transport and replay preserve this terminal position. The rows H, C, P, N can reread the same sealed route for a consumer, but they cannot supply an ambient Real value without the displayed dyadic and regular-rational handoff. □

Theorem 3828.6 (DarbouxContinuity non-escape)**.** *Every accepted* $\mathsf{DarbouxContinuity}^{\uparrow}$ *packet exports only the finite rows*

$$I, G, V, D, R, E, H, C, P, N.$$

It exports no host interval image, open-cover compactness object, selected subcover, selected point, quotient real equality, trichotomy decision, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the packet and inspect the carrier inventory. The analytic rows are the closed interval source, continuous graph, intermediate-value crossing, dyadic bracket ledger, regular readback, and terminal Real seal.

The structural rows do not add analytic content. They only transport, replay, source, and name the same finite route through H, C, P, N.

Since no carrier coordinate stores host compactness, quotient equality, a selected point, trichotomy, choice, or ambient completeness, no accepted consumer can extract such data from the Darboux continuity certificate. □

Falsifiable prediction: An accepted $\mathsf{DarbouxContinuity}^{\uparrow}$ read is refuted if it exposes an interval-image or crossing value without first displaying the closed interval source, continuous graph, intermediate-value crossing, dyadic bracket, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

Independence witness: closedboundedinterval, continuousmap, intermediatevalue, dyadicratcore, regseqrat, real: none alone is bijective with $\mathsf{DarbouxContinuity}^{\uparrow}$ because the packet jointly records an interval source, continuous graph, crossing ledger, dyadic brackets, regular readback, Real seal, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DarbouxContinuity}^{\uparrow}$ packet is generated from a closed bounded interval source, a continuous-map graph, intermediate-value crossing data, a dyadic bracket ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DarbouxContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 3828.1, Definition 3828.2, Definition 3828.3, and Definition 3828.6 bind the L10 interval-continuity carrier to closed-interval, continuous-map, intermediate-value, dyadic, regular-readback, and Real-seal source rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DarbouxContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, quotient real equality, trichotomy, selected interval-image points, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, graph exposure, crossing-route exactness, dyadic bracket readback, Real-seal handoff, and non-escape for BEDC.Derived.DarbouxContinuityUp.

Chapter 3829

A Concrete Naming Certificate for $\mathsf{ConcaveModulus}^{\uparrow}$

Following Bishop and Bridges on constructive moduli of continuity, the $\mathsf{ConcaveModulus}^{\uparrow}$ packet records the finite normalization surface at which a positive tolerance schedule is replaced by a monotone midpoint-concave modulus before Real or Completion consumers inspect it. It sits on the rational and dyadic tolerance rows of chapter 37 and chapter 291, the explicit uniform-modulus surface of chapter 2228, the located-uniform-continuity handoff of chapter 1859, and the terminal Real seal of chapter 38. The packet names a constructive normalization object; it does not choose a modulus from a host theorem, assert real completeness, or import quotient equality of functions.

Definition 3829.1 (Concave modulus carrier)**.** *A* $\mathsf{ConcaveModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, D, M, J, S, H, C, P, N)$$

with the following displayed rows:

1. *Q is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row. It names the rational tolerance requests and records the finite order in which a consumer may inspect them.*
2. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same requests, giving the dyadic scale at which Real and Completion routes read the modulus.*
3. *M is the monotone modulus row. It records that weaker tolerance requests are served by no stronger source radius than the displayed stronger requests.*
4. *J is the midpoint-concavity row. It records the finite Jensen midpoint comparisons used by the normalization route before any subadditivity consumer may read the packet.*
5. *S is the subadditive handoff row. It exposes the normalized modulus as the public row consumed by* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *and* $\mathsf{LocatedUniformContinuity}^{\uparrow}$ *certificates.*
6. *H stores componentwise* hsame *transport for the rational tolerance, dyadic tolerance, monotone modulus, midpoint-concavity, subadditive handoff, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a modulus-normalization request through Q, D, M, J, S, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ConcaveModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformContinuityModulus}^{\uparrow}$, $\mathsf{LocatedUniformContinuity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConcaveModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected modulus, host continuity theorem, quotient function equality, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ConcaveModulusUp.ConcaveModulusTasteGate single carrier alignment`

Theorem 3829.2 (Concave modulus NameCert obligations)**.** *For every accepted* $\mathsf{ConcaveModulus}^{\uparrow}$ *carrier*

$$K = (Q, D, M, J, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConcaveModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the positive rational tolerance, positive dyadic tolerance, monotone modulus, midpoint-concavity, subadditive handoff, transport, replay, provenance, and local naming rows;*
2. *tolerance exposure, requiring every normalization request to read* Q *and* D *before it reads any modulus row;*
3. *monotonicity discipline, requiring* M *to preserve the displayed order of tolerance requests without choosing a new host-scale modulus;*
4. *midpoint-concavity discipline, requiring* J *to supply the finite midpoint comparisons used by the subadditive handoff;*
5. *non-escape, requiring* S, H, C, P, N *to export only the displayed normalized modulus route and no choice-selected modulus, quotient function equality, trichotomy, ambient completeness, Lean verification, or bridge checking.*

No $\mathsf{ConcaveModulus}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.ConcaveModulusUp.ConcaveModulusCarrier namecert obligations`

Proof. Project the carrier of Definition 3829.1. The tuple lists exactly the positive rational tolerance, dyadic tolerance, monotone modulus, midpoint-concavity, subadditive handoff, and structural rows.

Tolerance exposure is forced by the order of Q and D. A consumer cannot inspect the normalized modulus before the positive rational request and dyadic scale have been displayed as finite packet data.

The monotone and midpoint-concavity obligations are the rows M and J. They are read before the public handoff row S, so the handoff is a displayed normalization route rather than a host theorem about all moduli.

Finally H, C, P, N transport, replay, source, and name the same finite rows. Since the carrier contains no coordinate for a selected modulus, quotient function equality, trichotomy, ambient completeness, Lean verification, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Theorem 3829.3 (Concave modulus subadditive handoff)**.** *Every* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *or* $\mathsf{LocatedUniformContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{ConcaveModulus}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{ConcaveModulus}^{\uparrow} \longrightarrow \mathsf{UniformContinuityModulus}^{\uparrow} \longrightarrow \mathsf{LocatedUniformContinuity}^{\uparrow}$$

through the displayed rows $Q, D, M, J, S, H, C, P, N$*. The subadditive handoff row* S *is available only after the positive tolerance rows, monotone modulus row, and midpoint-concavity row have been displayed. The route exports no choice-selected modulus, host continuity theorem, quotient equality of functions, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with an accepted carrier $K = (Q, D, M, J, S, H, C, P, N)$. Projection exposes the tolerance rows Q, D before any modulus-normalization row is consumed.

Read the monotone row M and midpoint-concavity row J. These rows are finite packet data, so the consumer receives the normalization discipline as displayed comparisons rather than as a global host theorem.

The handoff row S is downstream of those rows. A $\mathsf{UniformContinuityModulus}^{\uparrow}$ consumer reads S as its public tolerance-to-radius surface, and a $\mathsf{LocatedUniformContinuity}^{\uparrow}$ consumer reads the same handoff only after its located source and modulus routes have been displayed.

The remaining rows H, C, P, N preserve componentwise transport, replay, provenance, and naming for this route. Since no listed row contains a selected modulus, quotient function equality, trichotomy, or ambient completeness coordinate, the subadditive handoff exports none of them. □

Lean4 ✓ `BEDC.Derived.ConcaveModulusUp.ConcaveModulusCarrier subadditive handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{ConcaveModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConcaveModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3829.1, Definition 3829.2, and Definition 3829.3 seed the finite constructive normalization route from positive rational and dyadic tolerances through monotone midpoint-concave modulus rows into uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConcaveModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a choice-selected modulus, host continuity theorem, quotient function equality, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive tolerance exposure, monotone modulus discipline, midpoint-concavity rows, subadditive handoff, transport, replay, provenance, and local naming for BEDC.Derived.ConcaveModulusU

Constructive story: A $\mathsf{ConcaveModulus}^{\uparrow}$ packet is generated from positive RatUp tolerance rows, positive DyadicRatCoreUp tolerance rows, monotone modulus rows, midpoint-concavity rows, a subadditive handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 3830

A Concrete Naming Certificate for $\mathsf{SignedDigitIntervalReal}^{\uparrow}$

Following Avizienis and Bishop–Bridges, the $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ packet records a closed real interval whose endpoints are supplied by signed-digit finite-window streams, normalized dyadic endpoint rows, StreamName schedules, RegSeqRat readbacks, and a terminal RealUp seal. It consumes the signed-digit stream surface of chapter 316, the signed-digit real endpoint route of chapter 363, the dyadic normalization ledger of chapter 291, the finite schedule interface of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the closed bounded interval carrier of chapter 1591. The packet gives Real and Completion consumers a finite-window interval source without exporting a quotient stream, a selected infinite expansion, or ambient real completeness.

Definition 3830.1 (Signed digit interval real carrier)**.** *A* $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, D, O, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower signed-digit endpoint row, carrying the finite signed-digit windows admitted by the signed-digit stream and signed-digit real routes.*
2. *U is the upper signed-digit endpoint row, carrying the corresponding finite signed-digit windows for the upper endpoint.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *normalization ledger, recording the dyadic endpoint rows obtained from the inspected signed-digit windows.*
4. *O is the endpoint-order row, recording that the normalized lower endpoint is contained below the normalized upper endpoint through the displayed dyadic comparisons.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule, listing exactly the endpoint windows and precision requests inspected by the packet.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the normalized lower and upper endpoint observations.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the signed-digit endpoint rows, dyadic ledger, order row, schedule, and regular readback have been displayed.*
8. *H records componentwise* hsame *transport for the endpoint rows, dyadic ledger, order row, schedule, readback, seal, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay from signed-digit windows through dyadic normalization, endpoint ordering, regular readback, and the RealUp seal.*
10. *P is the* Pkg *provenance over* $\mathsf{SignedDigitIntervalReal}^{\uparrow}$, $\mathsf{SignedDigitStream}^{\uparrow}$, $\mathsf{SignedDigitReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDigitIntervalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, D, O, S, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected infinite signed-digit expansion, real trichotomy, a selected point of the interval, open-cover compactness, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SignedDigitIntervalRealUp.SignedDigitIntervalRealTasteGate single carrier alignment`

Theorem 3830.2 (Signed digit interval real NameCert obligations)**.** *For every accepted* $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *carrier*

$$I = (L, U, D, O, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SignedDigitIntervalReal}^{\uparrow}}$ *obligations are exhausted by carrier admission for the eleven displayed rows; signed-digit endpoint normalization through L, U, D; dyadic containment through the normalized endpoint ledger D; endpoint-order preservation through O; regular readback through R along the finite schedule S; terminal RealUp sealing through E; componentwise transport through H; continuation replay through C; package provenance through P; and local naming through N.*

No obligation may call on quotient stream equality, a selected infinite expansion, trichotomy, a selected point of the interval, open-cover compactness, countable choice, or ambient RealUp completeness.

Proof. Project the carrier of Definition 3830.1. The endpoint rows L and U are the only signed-digit sources available to the packet, and the schedule row S records the finite windows through which those sources are inspected.

The dyadic and order obligations are then read through D and O. The ledger D normalizes the inspected endpoint windows into dyadic rows, while O records the displayed lower-before-upper comparison needed by the closed interval carrier.

The regular readback and seal obligations pass through R and E. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the listed rows exhaust the local certificate and leave the excluded principles outside the packet. □

Theorem 3830.3 (Signed digit interval real seal nonescape)**.** *An accepted* $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *carrier exports its interval-facing RealUp seal only through*

$$L, U, D, O, S, R, E, H, C, P, N.$$

Consequently every consumer of the packet receives a finite signed-digit endpoint route, dyadic containment ledger, endpoint-order row, regular readback, and closed-interval seal; it receives no quotient stream equality, selected infinite expansion, trichotomy, selected point of the interval, open-cover compactness, countable choice, or ambient RealUp completeness.

Proof. Start with the endpoint rows. The lower and upper endpoints are visible only as the finite signed-digit windows displayed by L and U along the schedule S.

Normalize those endpoint windows through D and compare them through O. This is the only place where the carrier records containment of the lower endpoint below the upper endpoint, and it is expressed as a finite dyadic ledger rather than as trichotomy or quotient real equality.

The RealUp-facing read then passes through R, E, H, C, P, N. Since the carrier has no further public coordinates, any interval consumer is confined to the displayed finite route and none of the excluded selection, compactness, choice, or completeness principles can escape through the seal. □

Theorem 3830.4 (Signed digit interval real endpoint-order nonescape)**.** *Let*

$$I = (L, U, D, O, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *carrier. Any consumer read that uses interval containment or the lower-before-upper comparison must expose the finite signed-digit endpoint rows* L, U*, the finite schedule* S*, the dyadic normalization ledger* D*, and the endpoint-order row* O *before it can pass to the readback and seal rows* R, E*.*

Consequently the order-facing read exports only finite dyadic endpoint comparison data. It exports no real trichotomy, quotient real equality, selected endpoint, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier displayed in Definition 3830.1. The rows L and U are the only endpoint-window sources, and S is the only row that records which finite windows and precision requests the packet has inspected.

The order-facing data then factors through D and O. The ledger D is the unique dyadic normalization row for the inspected endpoint windows, while O is the only coordinate that records the lower-before-upper comparison.

The rows R, E, H, C, P, N are downstream readback, seal, transport, replay, provenance, and naming rows. They add no further order coordinate, so every public order-facing read remains confined to the finite endpoint windows, their dyadic normalization ledger, and the displayed endpoint-order row. □

Theorem 3830.5 (Signed digit interval real refinement stability)**.** *Let*

$$I = (L, U, D, O, S, R, E, H, C, P, N)$$

and

$$I' = (L', U', D', O', S', R', E', H', C', P', N')$$

be accepted $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *carriers whose displayed rows are related componentwise by the transport row* hsame *on* L, U, D, O, S*. For any smaller signed-digit endpoint window and any dyadic tolerance refinement admitted by the finite schedule, the refined read factors again through the rows*

$$L, U, D, O, S, R, E, H, C, P, N.$$

The factorization preserves the endpoint-order row and the terminal seal without using trichotomy, selected signed-digit expansions, quotient stream equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the two accepted carriers. The componentwise hsame data identifies the endpoint rows L, U, the normalization ledger D, the endpoint-order row O, and the schedule row S as the only coordinates available for comparing the original and refined reads.

Refine the schedule row S to the smaller endpoint windows and requested dyadic tolerance. The refined observations are still signed-digit windows from L and U, so their normalization is replayed through the same dyadic ledger shape D rather than through a quotient stream or a selected expansion.

The order row O is transported along the displayed hsame data. Thus the refined dyadic endpoint comparison is the same finite lower-before-upper certificate, only read at the smaller window and tolerance.

Finally repack the refined route through R, E, H, C, P, N. The readback, seal, transport, continuation, provenance, and naming rows carry the refined finite route and add no coordinate from trichotomy, choice, compactness, quotient equality, or ambient completeness. □

Theorem 3830.6 (Signed digit interval real RegSeqRat seal route)**.** *Every Real-facing endpoint or interval read of an accepted* $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *carrier must pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *normalization ledger D, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E. The route exports no selected infinite signed-digit expansion and no completeness principle.*

Proof. Use the carrier of Definition 3830.1. Its only Real-facing coordinates are arranged after the endpoint rows, the schedule, the dyadic normalization ledger, and the regular rational readback row.

Apply Definition 3830.2. The local certificate lists regular readback along S and terminal RealUp sealing through E as obligations downstream of the signed-digit endpoint and dyadic normalization rows.

Apply Definition 3830.3. Since the seal exports only the displayed route $L, U, D, O, S, R, E, H, C, P, N$, any endpoint or interval read must pass through S, D, R before E and cannot expose an infinite expansion, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDigitIntervalReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ packet is generated from lower and upper signed-digit endpoint rows, a DyadicRatCore normalization ledger, an endpoint-order row, StreamName finite schedules, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDigitIntervalReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3830.1, Definition 3830.2, and Definition 3830.3 seed the finite signed-digit endpoint route for closed RealUp intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDigitIntervalReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected infinite signed-digit expansions, trichotomy, selected interval points, open-cover compactness, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint normalization, dyadic containment, endpoint-order preservation, regular readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SignedDigitIntervalRealUp.

Chapter 3831

A Concrete Naming Certificate for $\mathsf{CayleyTheorem}^{\uparrow}$

Following Cayley, the $\mathsf{CayleyTheorem}^{\uparrow}$ packet records the finite left-regular action of a displayed group row as a permutation-action row. It consumes the finite $\mathsf{Group}^{\uparrow}$ source of chapter 41 and the finite-position bijection surface of chapter 116. The packet names the carrier, action, image, faithfulness, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows needed to read the theorem as BEDC data; it does not assert a classification of finite groups, a presentation by generators and relations, or a representation-theoretic decomposition.

Definition 3831.1 (Cayley theorem carrier)**.** *A* $\mathsf{CayleyTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (G, L, I, F, H, T, P, N)$$

with the following displayed rows:

1. *G is the consumed finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row, including the carrier, multiplication, unit, inverse, and finite support surfaces;*
2. *L is the left-regular action row sending a displayed group element g and a displayed group endpoint x to the product endpoint gx;*
3. *I is the permutation-image row, reading each left-translation row as a certified self-bijection of the finite carrier of G through the* $\mathsf{Permutation}^{\uparrow}$ *interface;*
4. *F is the faithfulness row, recording that if two left-translation rows have the same action on every displayed endpoint, then their source group rows classify together by the* $\mathsf{Group}^{\uparrow}$ *classifier;*
5. *H is the componentwise* hsame *transport for G, L, I, F;*
6. *T stores the displayed* Cont *routes through which consumers read the left action, permutation image, and faithfulness rows;*
7. *P is the* Pkg *provenance over* $\mathsf{Group}^{\uparrow}$, $\mathsf{Permutation}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CayleyTheorem}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a host embedding into an ambient symmetric group, no quotient by an external equality of functions, and no representation category.

Lean4 ✓ `BEDC.Derived.CayleyTheoremUp.TasteGate.CayleyTheoremTasteGate single carrier alignment`

Theorem 3831.2 (Cayley theorem NameCert obligations)**.** *For every accepted* $\mathsf{CayleyTheorem}^{\uparrow}$ *carrier*

$$C = (G, L, I, F, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CayleyTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite group row, left-regular action row, permutation-image row, faithfulness row, componentwise transport row, continuation routes, provenance, and local naming row. The obligation route is finite group row, left-regular action row, permutation image row, faithfulness row, and then the* hsame*,* Cont*,* Pkg*, and* NameCert *packaging rows.*

Proof. Project the carrier of Definition 3831.1. Carrier admission is the displayed tuple G, L, I, F, H, T, P, N, so no host symmetric group, host function equality, or representation category is available as an additional coordinate.

Read L from the multiplication row of G. For each displayed source row g, left multiplication by g sends every displayed endpoint x to the endpoint gx and sends the inverse endpoint through the inverse row of G, so the action has the inverse-witness data needed by the permutation surface.

Read I through chapter 116. The finite support row of G supplies the finite spine, while the left-action and inverse rows supply the forward graph, inverse graph, inverse witnesses, and action ledger of the carried $\mathsf{Permutation}^{\uparrow}$ row.

Finally read F at the unit endpoint of G. If two left-translation rows act the same on every displayed endpoint, their actions on the unit endpoint classify the two source group rows together. Repacking this faithfulness row with H, T, P, N gives the stated local NameCert surface. □

Theorem 3831.3 (Cayley theorem permutation-action handoff)**.** *Every downstream consumer of a* $\mathsf{CayleyTheorem}^{\uparrow}$ *carrier that asks for a permutation action of a finite group reads exactly the rows*

$$G, L, I, F, H, T, P, N$$

of Definition 3831.1. The handoff exports the consumed $\mathsf{Group}^{\uparrow}$ *row, the left-regular action row, the* $\mathsf{Permutation}^{\uparrow}$ *image row, and the faithfulness row, and then transports them through the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It does not export a bare host function, a separate symmetric-group carrier, or any representation-theoretic decomposition.*

Proof. First apply Definition 3831.2. It identifies the public packet with the finite group row, left-regular action row, permutation-image row, faithfulness row, and the transport and provenance rows.

Next project the permutation-image coordinate through chapter 116. Each left-translation row is read as a certified finite-position self-bijection; the action row is the corresponding endpoint action, and inverse coverage is supplied by the inverse row of the consumed group packet.

Finally use the faithfulness row. The action on the unit endpoint recovers the source group classifier, so the consumer can read the group-to-permutation map as faithful without importing host function equality. Since every public field has already been listed in G, L, I, F, H, T, P, N, the handoff has exactly the displayed BEDC surface and no additional symmetric-group or representation coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CayleyTheorem}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CayleyTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3831.1, Definition 3831.2, and Definition 3831.3 seed the finite left-regular action carrier, permutation-image handoff, faithfulness row, and hsame/Cont/Pkg/NameCert packaging over displayed $\mathsf{Group}^{\uparrow}$ and $\mathsf{Permutation}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CayleyTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a classification of finite groups, generator-and-relation presentations, symmetric-group closure, representation decomposition, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, left-action exactness, permutation-image construction, faithfulness at the unit endpoint, and downstream permutation-action consumer boundary for the same finite packet.

Constructive story: A CayleyTheorem$^{\uparrow}$ packet is generated from a displayed finite group source, its left-regular action on its own finite carrier, the induced certified permutation row for each source element, a faithfulness read at the unit endpoint, componentwise transport, continuation routes, provenance, and local NameCert evidence.

Chapter 3832

A Concrete Naming Certificate for $\mathsf{CauchyMeshRefinement}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy data and regular rational approximations, the $\mathsf{CauchyMeshRefinement}^{\uparrow}$ packet records a finite common-refinement mesh for two displayed Cauchy requests before a terminal real-name seal is read. It sits between the finite-window gateway of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal seal of chapter 38, and the tail-budget surface of chapter 2071. The packet supplies later diagonal, tail-budget, and regular-Cauchy arguments with finite mesh data; it does not introduce quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3832.1 (Cauchy mesh refinement carrier)**.** *A* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q_0, Q_1, D_0, D_1, J, S, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *Q_0 and Q_1 are the two source Cauchy request rows. Each records the source name, requested precision, finite tail index, and the local tolerance budget visible to the request.*
2. *D_0 and D_1 are the two dyadic mesh rows. They display the finite dyadic partitions*

$$D_i = \{a_{i,0} < a_{i,1} < \cdots < a_{i,k_i}\}$$

   for $i = 0, 1$, together with the endpoint, radius, and comparison cells supplied by $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *J is the common refinement row. It lists the finite dyadic mesh containing every point of D_0 and D_1, the inclusion maps from both meshes, and the comparison ledger showing that the inherited tolerances are below the two source requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source schedules inspected along J.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same displayed windows and the common dyadic refinement.*
6. *T is the* $\mathsf{CauchyTailBound}^{\uparrow}$ *row recording that the inherited tail budget is read from J, not from an unlisted completion object.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $Q_0, Q_1, D_0, D_1, J, S, R, T$ have been displayed.*

8. *H records componentwise* hsame *transport for the source requests, dyadic meshes, common refinement, StreamName windows, RegSeqRat readback, tail-bound row, real seal, replay, provenance, and local name.*

9. *C records displayed* Cont *replay from a precision request through*

$$Q_0, Q_1 \longmapsto D_0, D_1 \longmapsto J \longmapsto S \longmapsto R \longmapsto T \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyMeshRefinement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailBound}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMeshRefinement}^{\uparrow}}$ *row.*

The classifier accepts only packets in which both displayed meshes factor through the same finite row J and every downstream read of S, R, T, E, H, C, P, N preserves that common refinement. No coordinate stores a quotient stream, selected limit, countable-choice schedule, trichotomy oracle, host real equality, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyMeshRefinementUp.CauchyMeshRefinementTasteGate single carrier alignment`

Theorem 3832.2 (Cauchy mesh refinement NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *carrier*

$$M = (Q_0, Q_1, D_0, D_1, J, S, R, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyMeshRefinement}^{\uparrow}}$ *surface consists exactly of source Cauchy request admission, two displayed dyadic mesh ledgers, common-refinement inclusion,* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyTailBound}^{\uparrow}$ *budget routing, terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows $Q_0, Q_1, D_0, D_1, J, S, R, T, E, H, C, P, N$.*

Proof. Project the carrier of Definition 3832.1. The two source requests are visible only as Q_0, Q_1, and their dyadic data are visible only as the finite mesh rows D_0, D_1.

The common row J is the only place where the two meshes are compared. Since the inclusion maps and inherited tolerance checks are stored there, every later StreamName, RegSeqRat, and tail-budget consumer must read the same finite refinement before it can inspect a Real-facing seal.

The rows H, C, P, N transport, replay, source, and name this route. The carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, so the listed rows exhaust the certificate surface. □

Theorem 3832.3 (Cauchy mesh refinement RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyTailBound}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *carrier must factor through the displayed route*

$$Q_0, Q_1 \longmapsto D_0, D_1 \longmapsto J \longmapsto S \longmapsto R \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Consequently a regular rational readback cannot be replaced by a quotient stream, selected limit, countable-choice schedule, trichotomy decision, host real equality, detached tail witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness argument.*

Proof. Begin with a consumer request for regular rational, tail-budget, or real-seal data. The source Cauchy requests first expose Q_0, Q_1, and the dyadic rows D_0, D_1 display the two finite meshes answering those requests.

The common refinement row J is then forced by carrier admission. It is the unique finite row through which both dyadic meshes pass, so the StreamName windows S and the RegSeqRat readback R are read from the same mesh surface.

The tail-bound row T and Real seal row E are downstream of that readback. Transport, replay, provenance, and local naming preserve the displayed route, and the excluded analytic objects are absent from the tuple. Thus every consumer handoff is the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMeshRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyMeshRefinement}^{\uparrow}$ packet is generated from two source Cauchy requests, two displayed dyadic meshes, a common refinement row, StreamName windows, RegSeqRat readback, a CauchyTailBound budget row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyMeshRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3832.1, Definition 3832.2, and Definition 3832.3 seed the finite common-refinement mesh surface for L10 Cauchy requests over StreamName, RegSeqRat, DyadicRatCore, CauchyTailBound, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyMeshRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-request admission, dyadic mesh ledgers, common-refinement inclusion, StreamName windows, RegSeqRat readback, CauchyTailBound routing, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyMeshRefinementUp.

Chapter 3833

A Concrete Naming Certificate for $\mathsf{MonotoneConvergenceReal}^{\uparrow}$

Following Bishop and Bridges on bounded monotone real sequences, the $\mathsf{MonotoneConvergenceReal}^{\uparrow}$ packet records the finite NameCert surface by which monotone inspection rows, bounded sequence rows, and located-supremum rows meet before any ambient completeness theorem for $\mathsf{Real}^{\uparrow}$ is available. It consumes the bounded sequence carrier of chapter 1415, the located upper-bound surface of chapter 1427, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a located-supremum route for bounded monotone RealUp sequences; it is not a proof of full RealUp completeness, a host supremum construction, a trichotomy decision, quotient real equality, countable choice, or a selected limit operator.

Definition 3833.1 (Monotone convergence real carrier)**.** *A* $\mathsf{MonotoneConvergenceReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, O, U, A, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedRealSequence}^{\uparrow}$ *row, exposing only the finite sequence schedule, stream windows, regular readback, RealUp seal, and closed bounded interval-net bound already named in Definition 1415.1.*
2. *O is the monotonicity ledger, recording for the inspected index pairs that the displayed sequence windows are nondecreasing through the same comparison route used by the bounded sequence carrier.*
3. *U is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *upper-bound row attached to the bounded range displayed by B and to the comparison rows recorded in O.*
4. *A is the lower-approximation ledger, saying that each requested tolerance window receives a displayed sequence index whose regular-rational readback approaches the located-supremum row from below.*
5. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *precision-window row used to inspect the source sequence, monotonicity ledger, upper-bound row, and approximation ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected windows in W.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, O, U, A, W, R have been displayed.*

8. *H records componentwise* hsame *transport for the bounded source, monotonicity ledger, located-supremum row, approximation ledger, precision windows, regular readback, real seal, replay, provenance, and local naming row.*
9. *C records displayed* Cont *replay from bounded sequence inspection through monotonicity, located-supremum access, lower approximation, regular readback, and the RealUp seal.*
10. *P is the* Pkg *provenance over* $\mathsf{MonotoneConvergenceReal}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceReal}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $B, O, U, A, W, R, E, H, C, P, N$. It has no coordinate for full $\mathsf{Real}^{\uparrow}$ *completeness, a host-level supremum, trichotomy, quotient real equality, countable choice, or a selected-limit functional.*

Lean4 ✓ `BEDC.Derived.MonotoneConvergenceRealUp.MonotoneConvergenceRealTasteGate single carrier alignment`

Theorem 3833.2 (Monotone convergence real NameCert obligations)**.** *For every accepted* MonotoneConvergenceRe *carrier $M = (B, O, U, A, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceReal}^{\uparrow}}$ *obligations are exhausted by the following finite rows: carrier admission for the eleven displayed coordinates; bounded-source exposure through B; monotonicity inspection through O; located upper-bound access through U; lower-approximation cofinality through A; shared finite-window accounting through W; regular-rational readback through R; terminal RealUp sealing through E; componentwise transport through H; continuation replay through C; package provenance through P; and local naming through N.*

No obligation may call on a full completeness principle for $\mathsf{Real}^{\uparrow}$*, a host supremum object, trichotomy, quotient real equality, countable choice, or a selected limit.*

Proof. Project the carrier of Definition 3833.1. The source sequence is visible only through the bounded sequence row B, and the monotonicity information is visible only through the displayed comparison ledger O.

The located-supremum side is then read through U and A. The row U supplies the upper-bound surface, while A supplies the lower approximants requested by the finite window row W.

Finally the readback and seal rows R and E repack the same inspected data as regular-rational and RealUp observations. The structural rows H, C, P, N transport, replay, source, and name this route, so the listed rows exhaust the local certificate. □

Theorem 3833.3 (Monotone convergence real located-supremum route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MonotoneConvergenceReal}^{\uparrow}$ *carrier reaches the candidate monotone limit only through*

$$B, O, U, A, W, R, E, H, C, P, N.$$

The route first reads the bounded real sequence row, then the monotonicity ledger, then the located-supremum upper-bound and lower-approximation rows, then the shared finite windows and regular rational readback, and only then the terminal RealUp seal. Consequently the consumer receives a located-supremum route for the displayed bounded monotone sequence rather than full RealUp completeness, a host supremum, trichotomy, quotient real equality, countable choice, or a selected limit.

Proof. Start with the bounded sequence surface. By Definition 1415.1, a downstream consumer can inspect only the finite sequence schedule, stream windows, regular readback, real seal, closed bounded interval-net bound, and structural naming rows carried by B.

Add the monotonicity ledger O. It compares only the inspected windows of the same bounded source, so it cannot introduce an unbounded stream, a quotient sequence, or a host order principle.

Now apply the located-supremum surface of chapter 1427. The rows U and A provide upper-bound access and lower-approximation cofinality for the same windowed route.

The final handoff passes through W, R, E, H, C, P, N. Since these rows are the only remaining public coordinates, the RealUp consumer obtains only the stated located-supremum route and none of the excluded completeness or choice principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceReal}\uparrow}$.

Constructive story: A $\mathsf{MonotoneConvergenceReal}^{\uparrow}$ packet is generated from a bounded RealUp sequence row, a monotonicity ledger, a LocatedSupremumUp upper-bound row, a lower-approximation ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneConvergenceReal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 3833.1, Definition 3833.2, and Definition 3833.3 seed the finite located-supremum route for bounded monotone RealUp sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneConvergenceReal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close full RealUp completeness, a host supremum construction, trichotomy, quotient real equality, countable choice, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source exposure, monotonicity ledger stability, located-supremum access, lower-approximation cofinality, readback sealing, transport, replay, provenance, and local naming for BEDC.Derived.MonotoneConvergenceRealUp.

$\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ reads unit and multiplication rows through chapter 423, chapter 3836, and chapter 397.

Chapter 3834

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$

Following Mac Lane's monad-law ledger and Bishop–Bridges constructive completion, the CauchyCompletionMonadL packet records the finite BEDC rows by which the Cauchy-completion transformer exposes its unit and associativity laws. It reads the completion monad of chapter 378, the unit route of chapter 1527, the bind ledger of chapter 3777, the idempotence packet of chapter 2381, and the real-and-completion readbacks of chapter 126, chapter 291, chapter 301, and chapter 38. The unit and multiplication law rows consume the functorial completion surface of chapter 423 and the universal-property witness of chapter 397 before associativity is read as law data. The chapter names a law surface for finite completion packets only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

As a dependency relation, the monad-law packet consumes the CauchyCompletionAssociativity route in chapter 1635 and the regular completion route in chapter 1639 before exporting unit and bind compatibility.

Definition 3834.1 (CauchyCompletionMonadLaw carrier)**.** *A* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, U, I, B, S, D, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *finite completion transformer row.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *source-admission row for constant and displayed regular-rational inputs.*
3. *I is the* $\mathsf{CompletionIdempotence}^{\uparrow}$ *row recording right-unit reuse of already completed names.*
4. *B is the bind-association ledger data supplied by the* $\mathsf{CauchyCompletionBind}^{\uparrow}$ *schedule route.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window readback shared by the unit, bind, and idempotence rows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and observation ledger read by those windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
8. *H is the componentwise* hsame *transport row for the monad, unit, idempotence, bind, stream, dyadic, and regular-rational rows.*

9. *C is the displayed* Cont *replay row forcing every law-facing consumer through M, U, I, B, S, D, R, H in that order.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadLaw}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and never through quotient completions, selected representatives, host equality, or an ambient limit object.

Lean4 (definition) `BEDC.Derived.Cauchy completion monad lawUp.CauchyCompletionMonadLawCarrier`

Theorem 3834.2 (CauchyCompletionMonadLaw NameCert obligations)**.** *For every accepted* CauchyCompletionMo *carrier $L = (M, U, I, B, S, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadLaw}^{\uparrow}}$ *surface consists exactly of these rows:*

1. *carrier admission for the monad transformer, unit admission, idempotence reuse, bind-association ledger, stream windows, dyadic observations, regular-rational readback, componentwise transport, replay, provenance, and local name;*
2. *left-unit exactness, requiring a unit-fed bind read to return through the same displayed S, D, R route before the* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
3. *right-unit and idempotence exactness, requiring a completed read followed by the unit/idempotence route to reuse the same M, I, S, D, R rows;*
4. *associativity exactness, requiring the two two-step bind bracketings to expose the same B, S, D, R, H, C, P, N ledger;*
5. *classifier transport for all law rows by componentwise* hsame *and displayed* Cont *replay;*
6. *non-escape of quotient completion classes, selected representatives, selected limits, host equality, countable choice, hidden stream witnesses, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No monad-law obligation is stored outside this finite carrier.

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadLawUp.CauchyCompletionMonadLawCarrier namecert obligations`
↪variant `BEDC.Derived.Cauchy completion monad lawUp.CauchyCompletionMonadLawNamecertObligations`

Proof. Project the carrier of Definition 3834.1. Carrier admission and classifier transport are exactly the displayed rows $M, U, I, B, S, D, R, H, C, P, N$.

For the unit rows, read U before any bind or terminal seal. The left-unit route passes from U through the shared stream, dyadic, and regular-rational readback rows S, D, R, while the right-unit route reads I as the idempotence reuse of the same completion-facing data.

For associativity, use the bind ledger B together with H and C. Both bracketings must be replayed through the same displayed schedule, finite windows, dyadic observations, and regular-rational readback before the provenance and local naming rows are consumed.

The non-escape clause follows by exhaustion. The carrier has no coordinate for quotient completion classes, selected representatives, selected limits, host equality, countable choice, hidden stream witnesses, or ambient completeness, so none of those objects can be exported by the local certificate. □

Theorem 3834.3 (CauchyCompletionMonadLaw unit-associativity boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet reads the unit rows and the associativity rows through the finite carrier* $L = (M, U, I, B, S, D, R, H, C, P, N)$*. In particular, left-unit, right-unit, idempotence, and associativity claims reach* $\mathsf{Real}^{\uparrow}$ *only after the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$*,* $\mathsf{CauchyCompletionUnit}^{\uparrow}$*,* $\mathsf{CompletionIdempotence}^{\uparrow}$*,* $\mathsf{CauchyCompletionBind}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows have been displayed. No quotient completion, selected limit, host equality, hidden stream representative, or ambient completeness datum is available as a second route.*

Proof. Start from a $\mathsf{Real}^{\uparrow}$-facing read. By Definition 3834.2, the read must first pass through carrier admission and then through the law row relevant to the requested unit or associativity claim.

For left-unit and right-unit reads, the route is forced through U and I respectively, with S, D, R supplying the finite stream, dyadic, and regular-rational readbacks before any terminal real seal can be inspected.

For associativity reads, the route is forced through the bind-association ledger B. The replay row C and transport row H keep the two bracketings on the same displayed schedule, window, observation, and readback surface.

Thus every real-facing law consumer uses the finite packet rows $M, U, I, B, S, D, R, H, C, P, N$. Since the packet contains no second coordinate for quotient completion, selected limits, host equality, hidden representatives, or ambient completeness, those objects cannot serve as alternate witnesses for the monad laws. □

Theorem 3834.4 (CauchyCompletionMonadLaw completion-reflection route)**.** *Every unit, multiplication, idempotence, or associativity read exported by an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet first consumes the completion-reflection route through chapter 423, chapter 397, and chapter 1506. Only after those sibling rows have supplied functorial completion, universal-property reflection, and metric-completion admission may the finite law rows* $M, U, I, B, S, D, R, H, C, P, N$ *be read as monad-law data. The theorem is a finite dependency route; it does not identify quotient completions, select representatives, or assert equality of completed objects.*

Proof. Begin with the carrier of Definition 3834.1. Its law rows expose the monad transformer, unit, idempotence, bind ledger, stream windows, dyadic observations, regular-rational readback, transport, replay, provenance, and local name.

Apply the NameCert obligations of Definition 3834.2. A law-facing consumer can read left-unit, right-unit, idempotence, or associativity only through the displayed carrier and through the finite readback rows that precede the terminal $\mathsf{Real}^{\uparrow}$ seal.

The completion-reflection route supplies the required sibling boundary before those law rows are exported. The completion functor gives the functorial completion surface, the universal-property chapter gives the reflection witness, and the metric-completion chapter gives the completion admission surface consumed by both.

Apply Definition 3834.3. It rules out quotient completion, selected limits, host equality, hidden representatives, and ambient completeness as alternate witnesses, so the completion-reflection route remains a dependency theorem about finite rows only. □

Theorem 3834.5 (CauchyCompletionMonadLaw L10 forward consumer)**.** *Any* $\mathsf{BoundedCauchyInterval}^{\uparrow}$*,* $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$*, or* $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ *consumer of the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet must read the functorial completion, unit, bind, idempotence,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before using unit or associativity law data. The downstream chapters*

chapter 6065, chapter 7362, and chapter 7527 therefore consume $L = (M, U, I, B, S, D, R, H, C, P, N)$ *as a finite L10 completion-law surface.*

This theorem is a consumer-facing dependency route. It does not import quotient completions, selected representatives, selected limits, host equality of completed objects, countable choice, hidden stream witnesses, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3834.1. The rows $M, U, I, B, S, D, R, H, C, P, N$ expose the monad transformer, unit, idempotence, bind ledger, finite windows, dyadic observations, regular-rational readback, transport, replay, provenance, and local name.

Apply Definition 3834.2. It supplies the carrier admission, unit exactness, idempotence exactness, associativity exactness, classifier transport, and nonescape clauses for the law surface.

Apply Definition 3834.3 and Definition 3834.4. Together they force every law-facing consumer through the completion reflection siblings and through the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback rows before unit or associativity data are consumed.

The bounded interval, Kleisli extension, and completion-intersection chapters already read this chapter as a downstream completion-law dependency. Since the local carrier contains no quotient, selector, choice, hidden-stream, or ambient-completeness coordinate, those consumers receive only the finite L10 route stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadLaw}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadLaw}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3834.1, Definition 3834.2, Definition 3834.3, and Definition 3834.4 seed the finite completion-monad law carrier over monad, unit, idempotence, bind, stream, dyadic, regular-rational, transport, replay, provenance, local naming, and completion-reflection rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadLaw}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, quotient completion equality, selected representatives, selected limits, host equality of completed objects, countable choice, hidden stream witnesses, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, left-unit exactness, right-unit and idempotence exactness, associativity exactness, classifier transport, and non-escape for BEDC.Derived.CauchyCompletionMonadLawUp.

Constructive story: A $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet is generated from a CauchyCompletionMonad row, CauchyCompletionUnit row, CompletionIdempotence row, CauchyCompletionBind ledger, StreamName windows, DyadicRatCore observations, RegSeqRat readback, componentwise transport, displayed replay, Pkg provenance, and a local NameCert row.

Theorem 3834.6 (CauchyCompletionMonadLaw functor dependency route)**.** *Every accepted* CauchyCompletionMo *packet consumes the functorial completion surface of chapter 423 before its multiplication, unit, idempotence, or associativity rows can be read as law data. Concretely, the monad-law carrier* $L = (M, U, I, B, S, D, R, H, C, P, N)$ *first reads the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *source-metric, regular-Cauchy, completion-seal, unit-and-bind, universal-property, classifier, transport, provenance, and local NameCert rows, and only then replays* $M, U, I, B, S, D, R, H, C, P, N$ *as the law surface. Thus the law packet records coherence over the displayed functorial completion route rather than a kernel-only island or a host-level completion equality.*

Proof. Project the carrier of Definition 3834.1. Its monad, unit, idempotence, bind, stream, dyadic, regular-rational, transport, replay, provenance, and local naming rows are law-facing rows, but they do not by themselves identify the completion transformer as a functorial public route.

Read chapter 423 together with the sibling universal-property certificate of chapter 397. The functor packet supplies the source-metric row, regular-Cauchy family row, completion seal, unit-and-bind schedule, universal-property row, classifier ledger, transport row, provenance row, and

local NameCert row consumed by completion-facing clients; the unit-and-bind law rows consume the universal-property witness before associativity is read as monad law data.

Now apply Definition 3834.2 and Definition 3834.3. They replay the unit, idempotence, bind, and associativity rows through the displayed stream, dyadic, regular-rational, transport, and provenance data. Since the functor route is the public completion surface being coordinated, the monad-law packet depends substantively on $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ before the law rows are read. □

The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet also reads the completion universal-property and metric-completion siblings before its law rows are exposed to completion consumers. The extension-uniqueness side is supplied by chapter 397, while the metric-completion handoff is supplied by chapter 1506; hence the unit, multiplication, idempotence, and associativity rows remain attached to displayed completion data rather than to an isolated law ledger. The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet reads the completion functor, universal-property, metric-completion, and Real-completion sibling rows before the monad multiplication and unit laws are available as law data. The completion functor route of chapter 423 supplies the displayed functorial transformer, the universal-property route of chapter 397 supplies the extension and uniqueness rows, the metric-completion packet of chapter 1506 supplies the completion carrier, and the Real-completion handoff of chapter 360 supplies the terminal completion-facing seal. Only after those rows are visible may the law packet expose multiplication, unit, idempotence, and associativity through its local carrier. The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet reads the completion functor route of chapter 423, the completion universal-property surface of chapter 397, and the metric-completion dependency lattice of chapter 1506 before any $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer treats the monad boundary as available law data. Thus unit, multiplication, idempotence, and associativity rows are exposed only after the displayed completion-facing dependencies are visible, not as isolated quotient-completion equality, selected limits, or ambient real completeness. The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ rows read the completion functor sibling of chapter 423 and the Cauchy-completion universal-property sibling of chapter 2319 before their unit, multiplication, and associativity coordinates are accepted as monad-law data. This dependency route is a displayed finite lattice over completion-facing NameCert rows; it does not add quotient completion equality, selected limits, host equality of completed objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet exports its multiplication-law rows toward chapter 1829 as a concrete completion-monad sibling route. The multiplication consumer reads the displayed unit, bind, idempotence, associativity, stream-window, dyadic-tolerance, regular-readback, transport, replay, provenance, and local naming rows of the law packet before it flattens a completion of completions; the edge is finite NameCert data, not quotient-completion equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Theorem 3834.7 (CauchyCompletionMonadLaw Bishop completion forward route)**.** *Every accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *read that supplies the completion monad multiplication and unit route must expose the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *carrier of chapter 1639 before the monad law is consumed. The required forward route displays the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows as the Bishop completion boundary for the monad multiplication and unit.*

Proof. Read the monad-law carrier through the existing completion route. Its multiplication and unit rows are completion-facing, so they cannot be consumed as a free algebraic law before the completion boundary is displayed.

Apply the Bishop regular Cauchy completion packet of chapter 1639. That packet exposes the dyadic tolerance ledger, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows that a completion-facing consumer must inspect.

The monad law then receives its forward route through those visible rows. Because the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows remain on the path, the read is a finite completion route rather than quotient completion, selected limit, countable choice, host real equality, or detached ambient completeness. □

The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet reads chapter 397 and chapter 423 before associativity law rows are public. This is a finite completion-law dependency through the universal-property and functor rows, not quotient completion equality, selected limits, or host equality.

Theorem 3834.8 (CauchyCompletionMonadLaw functor forward anchor)**.** *Every public monad-law read from an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet factors through the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *dependency route before unit, bind, idempotence, or associativity rows are exposed. The consumer must first read the functor dependency route of Definition 3834.6 and the local NameCert construction of Definition 3834.2; only then may it inspect* $M, U, I, B, S, D, R, H, C, P, N$ *as law rows. The route is a forward anchor into the public functorial completion surface, not a quotient-completion equality, selected representative, selected limit, countable-choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Read the functor dependency route first. The theorem Definition 3834.6 places the CauchyCompletionFunctor source-metric, regular-Cauchy, completion-seal, unit-and-bind, universal-property, classifier, transport, provenance, and local naming rows before any monad-law consumer reads law data.

Then read the local construction through Definition 3834.2. It exposes $M, U, I, B, S, D, R, H, C, P, N$ as the finite monad, unit, idempotence, bind, stream, dyadic, regular-rational, transport, replay, provenance, and local naming surface.

With both reads in place, the public law route may expose unit, bind, idempotence, and associativity as rows attached to the functorial completion dependency. Since the carrier has no quotient-completion, selected-representative, selected-limit, countable-choice, or ambient-completeness coordinate, the anchor is only the displayed forward dependency. □

Lemma 3834.9 (CauchyCompletionMonadLaw functorial law lattice route)**.** *Every accepted* CauchyCompletionMo *law read first consumes the functorial completion route of chapter 423 and the universal-property route of chapter 397. Only after those rows are displayed may the unit, bind, idempotence, and associativity rows of* $L = (M, U, I, B, S, D, R, H, C, P, N)$ *be read as monad-law data. The packet therefore records a law lattice over the public functorial completion dependency, not a host-level completion equality or a quotient-completion shortcut.*

Proof. Project the carrier of Definition 3834.1. The rows $M, U, I, B, S, D, R, H, C, P, N$ are the monad-law surface, while the functorial completion packet supplies the public source-metric, regular-Cauchy, completion-seal, unit-and-bind, universal-property, classifier, transport, provenance, and local naming route.

Apply Definition 3834.6. It forces the completion functor and universal-property rows to be read before the law rows are consumed by a completion-facing client.

Finally apply Definition 3834.2 and Definition 3834.3. These replay unit, bind, idempotence, and associativity through the same finite stream, dyadic, regular-rational, transport, replay, provenance, and local naming rows, so the law lattice remains attached to the displayed functorial dependency. □

Lemma 3834.10 (CauchyCompletionMonadLaw completion dependency route)**.** *Every accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *law read consumes the completion-route carrier of chapter 1556, the criterion surface of chapter 1476, and the finite* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *route before its unit and multiplication laws can be read as monad-law data. The packet therefore binds the unit, idempotence, bind, and associativity rows to the displayed constructive completion route rather than to quotient completion equality, selected limits, countable choice, trichotomy, host equality, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 3834.1. Its law rows $M, U, I, B, S, D, R, H, C, P, N$ are completion-facing rows, so the source completion route must be visible before a client can read them as unit or multiplication data.

Read the constructive metric completion carrier and the Cauchy-completion criterion surface through the cited sibling chapters. They supply the completion admissibility and criterion rows consumed by the monad transformer before the law schedule is replayed.

Finally apply Definition 3834.2 and Definition 3834.3. These force the law read through the finite StreamName, RegSeqRat, and DyadicRatCore rows, leaving no coordinate for quotient completion equality, selected limits, countable choice, trichotomy, host equality, or ambient real completeness. □

Lemma 3834.11 (CauchyCompletionMonadLaw idempotent metric-monad route)**.** *Every accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *consumer that reads the unit, bind, multiplication, or associativity rows must first expose the completion idempotent route of* **??** *and the metric completion monad route of chapter 2156. The idempotent sibling supplies the completion-after-completion stabilization row, while the metric completion monad sibling supplies the unit and bind law surface; the combined route exports no quotient-completion equality, selected representative, countable choice, host equality of completions, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the displayed law carrier from Definition 3834.1. Its unit, bind, multiplication, and associativity rows are read as completion-law data only after the carrier, stream, dyadic, regular rational, transport, replay, provenance, and local naming rows have been displayed.

Now read the completion idempotent sibling. The chapter **??** supplies the stabilization surface for applying completion after completion, so a monad-law consumer cannot treat the multiplication row as an unrecorded host equality.

Finally read the metric completion monad sibling. The chapter chapter 2156 supplies the unit and bind law surface consumed by the same route, and Definition 3834.2 keeps those rows inside the finite packet. Hence the sibling dependency lattice is substantive and finite, with none of the excluded quotient, selection, choice, host-equality, or ambient-completeness endpoints. □

Theorem 3834.12 (CauchyCompletionMonadLaw Kleisli consumer route)**.** *Every* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet must first read the monad row, unit row, idempotence row, bind row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before exporting a Kleisli-facing* $\mathsf{Real}^{\uparrow}$ *seal. The route is a consumer of chapter 1845; it does not export quotient completion equality, selected representatives, countable-choice data, host equality of completed names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the local NameCert construction, Definition 3834.2. It exposes $M, U, I, B, S, D, R, H, C, P, N$ as the finite monad, unit, idempotence, bind, stream, dyadic, regular-rational, transport, replay, provenance, and local naming surface.

Now use the unit-associativity boundary, Definition 3834.3. It forces every law-facing $\mathsf{Real}^{\uparrow}$ read through the displayed stream, dyadic, and regular-rational rows before any terminal seal can be inspected.

Finally attach the Kleisli consumer chapter chapter 1845. A $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ consumer may read the monad-law packet only after the same finite rows have been displayed, so its Kleisli-facing seal remains a finite BEDC consumer route rather than a quotient, selection, choice, host equality, or ambient-completeness claim. □

$\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ consumes the completion functor unit and multiplication route of chapter 423 together with the finite readback rows of the Cauchy carrier in chapter 3413. The dependency is only the displayed unit, multiplication, stream-window, dyadic-tolerance, regular-readback, transport, replay, provenance, and local naming surface; it is not a quotient completion or a host universal property.

Theorem 3834.13 (CauchyCompletionMonadLaw completion-adjunction route)**.** *Every accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *unit or multiplication read consumes the same completion-adjunction route used by chapter 3836. The unit row, bind row, idempotence row, stream window, dyadic tolerance row, regular-rational readback, transport, replay, provenance, and local naming rows of* $L = (M, U, I, B, S, D, R, H, C, P, N)$ *therefore sit over the displayed completion-adjunction surface rather than over an isolated kernel-only packet.*

Proof. Project the carrier of Definition 3834.1. The rows $M, U, I, B, S, D, R, H, C, P, N$ expose the law surface, but a completion-facing consumer still needs the adjunction route that identifies how completion reads are admitted and returned.

Read chapter 3836. Its source, dense embedding, completion seal, extension handoff, uniqueness, transport, replay, provenance, and local naming rows are the completion-adjunction surface through which the monad-law unit and multiplication rows are consumed.

Now apply Definition 3834.2 and Definition 3834.3. They force unit, idempotence, bind, and associativity reads through the same finite stream, dyadic, regular-rational, transport, replay, provenance, and naming rows, so the monad-law packet is routed through the completion-adjunction sibling before it can serve a Real-facing law read. □

Theorem 3834.14 (CauchyCompletionMonadLaw dense embedding dependency)**.** *Every unit, multiplication, idempotence, bind, and associativity read for an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet must pass through the sibling dense embedding and completion route supplied by chapter 1651 and chapter 1512 before the law rows can be consumed as completion-facing data. The rows* $M, U, I, B, S, D, R, H, C, P, N$ *are therefore read as dense-image, completion-entry, stream-window, dyadic-tolerance, regular-readback, transport, replay, provenance, and local naming data, not as a local hub-only law island.*

Proof. Project the carrier of Definition 3834.1. The rows $M, U, I, B, S, D, R, H, C, P, N$ expose the monad-law surface, but the completion-facing consumer still needs the dense image and completion embedding routes that make those law rows readable by a completion packet.

Apply the monad-law obligations and the unit-associativity boundary, Definition 3834.2 and Definition 3834.3. They force the unit, multiplication, idempotence, bind, and associativity rows to remain attached to the displayed stream, dyadic, regular-rational, transport, replay, provenance, and naming rows.

Finally route those rows through the dense uniform embedding and completion embedding siblings. The dense image witness supplies the source-to-completion coverage, and the completion

embedding handoff supplies the consumer-facing entry, so the law rows are consumed only after the sibling route has been read. □

Theorem 3834.15 (CauchyCompletionMonadLaw completion-reflection consumer link)**.** *Every* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *unit, multiplication, idempotence, or associativity read factors through the completion-adjunction surface of chapter 3836, the completion-functor route of chapter 423, and the completion universal-property sibling of chapter 397 before it is consumed as* $\mathsf{Real}^{\uparrow}$*-facing law data. The route is finite completion reflection through displayed carrier rows, not quotient completion equality, selected representatives, selected limits, host equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 3834.1. The monad-law rows $M, U, I, B, S, D, R, H, C, P, N$ expose unit, multiplication, idempotence, bind, stream, dyadic, regular-readback, transport, replay, provenance, and local naming data.

Read the sibling dependency route of Definition 3834.13. It already places the unit and multiplication rows over the metric completion-adjunction surface rather than over an isolated kernel packet.

Finally pass the same finite rows through the completion functor and universal-property siblings. These siblings supply the completion-reflection consumer route needed before a $\mathsf{Real}^{\uparrow}$-facing law read can occur, while the refused quotient, representative, limit, host-equality, and completeness objects remain absent from the carrier. □

Theorem 3834.16 (CauchyCompletionMonadLaw downstream completion consumer)**.** *Any downstream completion consumer of an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet reads the law surface through chapter 423, chapter 397, and the totally bounded completion consumer of chapter 1573 before the rows* $M, U, I, B, S, D, R, H, C, P, N$ *are exported as completion-law data. The route is a displayed consumer edge through finite carrier rows; it is not quotient completion equality, selected representatives, selected limits, open-cover compactness, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3834.1. The rows $M, U, I, B, S, D, R, H, C, P, N$ expose monad, unit, idempotence, bind, stream, dyadic, regular-rational, transport, replay, provenance, and local naming data, but none of those rows by itself supplies a downstream completion consumer.

Use the completion-functor route of Definition 3834.13. It places the unit and multiplication reads over the same functorial completion surface that a completion-facing client must inspect before law rows are available.

Next apply Definition 3834.14 and Definition 3834.15. These route the same finite rows through the displayed completion embedding, completion functor, and completion universal-property siblings before any $\mathsf{Real}^{\uparrow}$-facing or completion-facing consumer reads them.

Finally read chapter 1573. The totally bounded completion packet is an existing downstream consumer of completion rows, so it may consume the monad-law surface only after the functorial and universal-property routes have already kept $M, U, I, B, S, D, R, H, C, P, N$ attached to finite carrier data. □

The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet also sits horizontally over the completion-functor sibling of chapter 423. Its unit, multiplication, idempotence, and associativity rows consume the functorial completion route before they are read as monad-law data, so the completion monad/functor law lattice is visible as a sibling dependency rather than a kernel-only float. The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ route consumes the Real and Completion siblings before any unit or associativity row is exported: $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ provide the L10 real-name readback

through chapter 38, while CauchyCompletionFunctor$^{\uparrow}$ and CompletionUniversalProperty$^{\uparrow}$ provide the completion-facing handoff through chapter 397. Thus a monad-law consumer sees the finite real-name route and the completion universal-property route as displayed dependencies, not as hidden quotient completion data.

Theorem 3834.17 (CauchyCompletionMonadLaw real completion unit route)**.** *Every accepted* CauchyCompletionMonadLaw$^{\uparrow}$ *unit, multiplication, or associativity read that is consumed as completion-facing law data first passes through the* RealCompletionUnit$^{\uparrow}$ *route of chapter 7084. The read exposes the* StreamName$^{\uparrow}$ *window row,* DyadicRatCore$^{\uparrow}$ *tolerance row,* RegSeqRat$^{\uparrow}$ *readback row, terminal* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before the law packet* $L = (M, U, I, B, S, D, R, H, C, P, N)$ *is exported.*

Thus the monad-law consumer receives the real-completion unit as a displayed finite route. It does not receive quotient-completion equality, a selected Cauchy representative, countable-choice schedule, host equality of completions, hidden real completeness, or a detached Real$^{\uparrow}$ *endpoint.*

Proof. Project the carrier of Definition 3834.1. The law rows M, U, I, B can be consumed only together with the finite stream, dyadic, regular-rational, transport, replay, provenance, and naming rows S, D, R, H, C, P, N.

Apply the real completion unit surface of chapter 7084. Its carrier and nonescape theorems place every real-completion unit read behind the dyadic source, stream-window, regular readback, terminal real seal, transport, replay, provenance, and local naming rows.

Finally use Definition 3834.2 and Definition 3834.3. They bind unit, multiplication, idempotence, and associativity reads to the same finite carrier before any completion-facing consumer sees law data, so the exported route cannot import quotient completions, selected representatives, countable choice, host equality, hidden completeness, or a detached real endpoint. □

The CauchyCompletionMonadLaw$^{\uparrow}$ packet consumes its sibling completion lattice through displayed finite rows. The unit, multiplication, and composition reads are routed through chapter 3413, chapter 1506, chapter 397, and chapter 301: Cauchy rows name the input streams, MetricCompletion rows expose the completion carrier, the universal-property rows supply the comparison route, and RegSeqRat rows give the regular rational windows used by the readbacks. No step appeals to a host completion monad outside the displayed Cauchy completion and regular-rational certificate rows.

Theorem 3834.18 (Cauchy completion monad law completion dependency lattice)**.** *Every accepted* CauchyCompletionMonadLaw$^{\uparrow}$ *packet consumes its completion-facing law rows through the displayed sibling lattice:* MetricCompletion$^{\uparrow}$ *supplies the completion carrier of chapter 1506,* Completion$^{\uparrow}$ *and the* Real$^{\uparrow}$ *completion seal rows supply the real-name boundary of chapter 38, and* CauchyCompletionFunctor$^{\uparrow}$ *supplies the functorial route before unit, bind, multiplication, or associativity data are exported. The route is a finite dependency projection; it is not a quotient-completion equality, selected representative, selected limit, host equality of completed objects, countable-choice principle, or ambient* Real$^{\uparrow}$ *completeness claim.*

Proof. Project the monad-law carrier and the existing sibling routes. The law rows are already carried through the Cauchy completion monad, unit, bind, stream, dyadic, regular-rational, transport, replay, provenance, and local naming coordinates before any Real-facing read is available.

Read the metric-completion boundary next. The MetricCompletion$^{\uparrow}$ sibling fixes the completion carrier as a displayed route through chapter 1506, so the monad-law packet cannot obtain a hidden host completion object.

Finally compose with the Real-facing route and the functor dependency route. The $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is reached only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows, and the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ route is consumed before unit, bind, multiplication, or associativity rows are exported. Thus the dependency lattice is horizontal and finite, with none of the refused quotient, selector, choice, equality, or completeness endpoints. □

Lemma 3834.19 (CauchyCompletionMonadLaw regular Cauchy uniform-modulus route)**.** *Every accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *consumer that compares completion unit and bind windows must first read the* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *budget of chapter 4158. The modulus row fixes the common regular-Cauchy tolerance budget before the monad-law consumer may identify two completion routes, and the idempotent metric-monad route of Definition 3834.11 keeps the resulting comparison inside the displayed unit, bind, multiplication, and associativity packet. The route exports no quotient-completion equality, selected representative, countable-choice schedule, host equality of completions, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

The regular-modulus sibling is not a decorative cross-reference: it supplies the uniform tolerance row that lets the local carrier of Definition 3834.1 compare unit and bind reads over one shared regular-Cauchy budget. Without that row, the monad-law packet would still display law coordinates, but it would not expose the finite modulus through which completion consumers synchronize their Cauchy windows.

Theorem 3834.20 (CauchyCompletionMonadLaw regular-modulus unit route)**.** *Every accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *carrier* $L = (M, U, I, B, S, D, R, H, C, P, N)$ *that exports a unit read to a completion-facing consumer first consumes the* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *sibling of chapter 4158. The sibling supplies the common regular-Cauchy modulus for the stream row* S*, dyadic tolerance row* D*, and regular-rational row* R *before the unit row* U *is replayed through* Cont *and recorded by the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadLaw}^{\uparrow}}$ *row. Hence the unit route is a finite modulus-controlled read of the local carrier, not a quotient-completion equality, selected representative, countable-choice schedule, host equality of completions, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier through Definition 3834.1. Its rows S, D, R are the finite stream, dyadic tolerance, and regular-rational readback data used by unit and bind comparisons.

Apply Definition 3834.19. It places the $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ budget before the monad-law consumer identifies unit and bind windows.

Finally apply Definition 3834.2. The unit row U, replay row C, provenance row P, and local naming row N are consumed only after the displayed carrier rows are available, so the route remains inside the finite monad-law packet and cannot import any excluded completion principle. □

Theorem 3834.21 (CauchyCompletionMonadLaw forward completion-category route)**.** *Every* $\mathsf{CauchyCompletionCategory}^{\uparrow}$ *or metric-completion Kleisli consumer of an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet reads the monad-law surface through the displayed rows of chapter 378, the functorial completion rows of chapter 423, and the metric-completion admission rows of chapter 1506 before any categorical composition law is used. The visible route is*

$\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{StreamNam}$

It exports no quotient completion equality, selected representative, selected limit, host equality of completed objects, countable-choice schedule, hidden stream representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 3834.1. A law-facing consumer receives only the rows $M, U, I, B, S, D, R, H, C, P, N$, so the monad, unit, idempotence, bind, stream, dyadic, regular-rational, transport, replay, provenance, and local naming data are the complete visible surface.

For a completion-category or Kleisli consumer, first read the monad and functorial completion siblings through chapter 378 and chapter 423. The unit row U, idempotence row I, and bind row B supply the law data only as displayed carrier rows.

Next pass through the metric-completion admission of chapter 1506. The stream, dyadic, regular-rational, and Real rows S, D, R keep the consumer on the finite readback route before any categorical composition law is visible.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for quotient completion equality, selected representatives, selected limits, host equality, countable choice, hidden stream witnesses, or ambient completeness, the stated route is exhaustive. □

The $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ packet reads the multiplication sibling of chapter 1829 together with the monad sibling of chapter 378 before its associativity and unit-law rows are exposed. The multiplication row supplies the displayed bind-reassociation surface, while the monad row supplies the unit-and-bind schedule consumed by the law carrier; the route therefore remains a finite NameCert dependency through those sibling packets rather than a host-level equality of completed objects.

Theorem 3834.22 (CauchyCompletionMonadLaw finite-approximation consumer route)**.** *Every finite-approximation or totally bounded completion consumer of an accepted* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *packet reads the monad-law surface through the displayed completion rows before using it as approximation data. The route passes through the finite window, dyadic tolerance, regular-rational readback, unit, multiplication, idempotence, bind, transport, replay, provenance, and local naming rows of Definition 3834.1, then through the finite approximation surface of chapter 7574, and finally through the totally bounded completion consumer of chapter 1573. It exports a finite completion-law route for approximation consumers, not quotient completion equality, selected representatives, selected limits, open-cover compactness, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadLawUp.CauchyCompletionMonadLawFiniteApproximationConsumerRout`

Proof. Project the carrier of Definition 3834.1. The law rows $M, U, I, B, S, D, R, H, C, P, N$ expose unit, multiplication, idempotence, bind, stream-window, dyadic-tolerance, regular-readback, transport, replay, provenance, and local naming data.

Use the local NameCert obligations and the unit-associativity boundary, Definition 3834.2 and Definition 3834.3. They keep every law read attached to the same finite completion-facing rows before a consumer can treat the law as available approximation data.

Now route the read through the approximation and total-boundedness consumers. The finite approximation surface of chapter 7574 supplies the windowed approximation interface, while chapter 1573 supplies the totally bounded completion consumer edge.

Since the carrier and both consumer routes display only finite rows, the resulting read cannot introduce quotient completion equality, selected representatives, selected limits, open-cover compactness, countable choice, or ambient Real completeness. □

Theorem 3834.23 (CauchyCompletionMonadLaw forward consumer lattice)**.** *Finite-approximation and totally bounded completion consumers read the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *monad-law rows*

only through the displayed sibling routes

CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, MetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Reg

Thus a downstream approximation read may consume unit, multiplication, bind, idempotence, transport, replay, provenance, and local naming rows from the monad-law packet only after the functor, universal-property, metric-completion, finite stream-window, dyadic tolerance, regular-rational readback, and terminal Real rows have remained visible. The lattice exports no selected completion representative, quotient completion equality, open-cover compactness, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

The CauchyCompletionMonadLaw$^{\uparrow}$ route supplies a downstream completion consumer edge for finite-net packets: chapter 1573 reads monadic completion composition only after the Cauchy-filter and embedding rows have remained attached to the finite-net ledger, while chapter 1844 keeps the dyadic, stream, regular-rational, and Real-seal faces visible before any completion-facing read is consumed. Thus the monad-law chapter is a sibling lattice route for finite-net completion consumers, not a source of selected limits, quotient representatives, open-cover compactness, or ambient Real completeness.

Chapter 3835

A Concrete Naming Certificate for CompleteUniformSpaceFilterbaseCompletion$^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and filter convergence, and Bishop–Bridges on constructive completion, the CompleteUniformSpaceFilterbaseCompletion$^{\uparrow}$ packet records the finite filterbase-completion refinement of the complete uniform-space surface. It sits after the uniform entourage data of chapter 339, the saturated Cauchy-filter route of chapter 333, the finite basis generator of chapter 1501, the limit-facing boundary of chapter 1558, the window and readback surfaces of chapter 126 and chapter 301, the terminal seal of chapter 38, and the completion handoffs of chapter 1473 and chapter 1569. The packet names a displayed filterbase route to completion consumers; it is not a quotient filter, selected completion point, countable-choice selector, host equality, ambient completeness theorem, or public standard bridge.

Definition 3835.1 (Complete uniform-space filterbase-completion carrier)**.** *A* CompleteUniformSpaceFilterbaseCom *carrier is a finite* BHist *packet*

$$Q = (U, F, B, L, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UniformSpace$^{\uparrow}$ *entourage row, displaying the finite entourage filterbase, diagonal, refinement, symmetry, and composition data consumed by the completion request.*
2. *F is the* CauchyFilter$^{\uparrow}$ *row, recording the saturated Cauchy-filter request over the uniform surface of U.*
3. *B is the* CauchyFilterBasis$^{\uparrow}$ *generator row, exposing the finite basis elements and common-refinement data through which F is read.*
4. *L is the* CauchyFilterLimit$^{\uparrow}$ *boundary row, reached only after the basis and saturated filter rows have been replayed.*
5. *S is the* StreamName$^{\uparrow}$ *window row attached to the filterbase convergence request.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row extracted from the same windows.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row read only after U, F, B, L, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the entourage, filter, basis, limit boundary, window, readback, seal, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from the uniform entourage request through the filterbase generator, Cauchy saturation, limit boundary, finite windows, regular readback, and Real seal.*

10. *P is the* Pkg *provenance over* CompleteUniformSpaceFilterbaseCompletion$^{\uparrow}$, CompleteUniformSpace$^{\uparrow}$, UniformSpace$^{\uparrow}$, CauchyFilter$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, CauchyFilterLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, UniformCompletion$^{\uparrow}$, CauchyFilterCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, B, L, S, R, E, H, C, P, N$. The carrier has no coordinate for quotient filters, selected completion points, countable-choice schedules, host equality, ambient completeness, or a detached completion object.

Theorem 3835.2 (Filterbase convergence obligations)**.** *For every accepted* CompleteUniformSpaceFilterbaseComple *carrier $Q = (U, F, B, L, S, R, E, H, C, P, N)$, the local* NameCert$_{\text{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed uniform-space entourage data, Cauchy-filter row, CauchyFilterBasis generator, CauchyFilterLimit boundary, StreamName windows, RegSeqRat readbacks, Real seal, transport, replay, provenance, and local naming row;*

2. *filterbase convergence exposure, requiring every completion-facing request to pass through U, B, and F before the limit boundary L is inspected;*

3. *readback exactness, requiring every accepted boundary observation to pass from L through the matching S and R rows before the Real seal E is available;*

4. *completion-handoff stability, requiring* UniformCompletion$^{\uparrow}$ *and* CauchyFilterCompletion$^{\uparrow}$ *consumers named by P to read the same displayed route U, B, F, L, S, R, E;*

5. *ledger nonescape, requiring H, C, P, N to export no quotient filter, selected completion point, countable-choice selector, host equality, ambient completeness theorem, or detached completion object.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 3835.1. Its public rows are exactly $U, F, B, L, S, R, E, H, C, P, N$, so carrier admission exposes only the displayed uniform, filterbase, convergence, seal, and structural data.

The filterbase convergence exposure is forced by the row order. A completion-facing request first reads the finite entourage data U, then the basis generator B, and only then the saturated Cauchy-filter row F before the limit boundary L is available.

Readback exactness is downstream of the boundary row. The row L can expose observations only through the StreamName windows S and the RegSeqRat readback R, and the terminal Real seal E is available only after those rows have been replayed.

The completion-handoff and ledger clauses are structural. Uniform-completion and Cauchy-filter-completion consumers are named in P as readers of the same displayed route, while H, C, N transport, replay, and name only that route. Hence the excluded quotient, selector, host-equality, choice, completeness, and detached-completion objects have no coordinate in the packet. □

Lean4 ✓ `BEDC.Derived.CompleteUniformSpaceFilterbaseCompletionUp.CompleteUniformSpaceFilterbaseCompletio`
`single carrier alignment`

Theorem 3835.3 (Cauchy-filter completion handoff)**.** *Let $Q = (U, F, B, L, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}$ *packet. Every* $\mathsf{UniformCompletion}^{\uparrow}$ *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer that reads Q receives the finite handoff*

$$U \longmapsto B \longmapsto F \longmapsto L \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion handoff is filterbase-first: the consumer cannot inspect a completion-facing boundary before the uniform entourage row, the CauchyFilterBasis generator, and the saturated CauchyFilter row have been displayed.

Proof. Begin with a completion-facing consumer. The provenance row P may mention $\mathsf{UniformCompletion}^{\uparrow}$ and $\mathsf{CauchyFilterCompletion}^{\uparrow}$, but it does so only as a row of the accepted carrier Q.

The source of the handoff is therefore the displayed route. The uniform-space row U supplies the entourage filterbase, B supplies the finite basis generator, and F supplies the saturated Cauchy-filter request over the same data.

The boundary and readback rows are downstream. The consumer reaches L only after U, B, F have been replayed, then reads S and R before the terminal seal E is available.

Finally H, C, P, N transport, replay, source, and name this route. Since the carrier has no separate completion object, selected point, quotient filter, choice schedule, host equality, or ambient completeness row, every accepted completion handoff is confined to the displayed path. □

Theorem 3835.4 (Filterbase Real-seal nonescape)**.** *Let $Q = (U, F, B, L, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}$ *carrier. Every consumer that reaches the displayed* $\mathsf{Real}^{\uparrow}$ *seal row E must first pass through the uniform entourage row U, the CauchyFilterBasis row B, the saturated CauchyFilter row F, the CauchyFilterLimit boundary row L, the StreamName windows S, and the RegSeqRat readback row R. The rows H, C, P, N then preserve and name the same route, so no accepted read can escape from E into a selected completion point, quotient filter, host equality, countable-choice selector, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or detached* $\mathsf{UniformCompletion}^{\uparrow}$ *object.*

Proof. Project the carrier definition. The terminal row E appears only as the Real seal of the tuple, and the preceding public coordinates are precisely U, F, B, L, S, R.

Apply the obligation surface of Definition 3835.2. It requires the filterbase convergence request to consume U, B, F, then the limit boundary L, then the window and readback rows S, R before E can be read.

The structural rows cannot introduce a second route. Componentwise transport H, replay C, provenance P, and local naming N preserve the same displayed packet, while the excluded selector, quotient, host-equality, choice, ambient-completeness, and detached-completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}$ packet is generated from UniformSpace entourage data, a CauchyFilter row, a CauchyFilterBasis generator, a CauchyFilterLimit boundary, StreamName windows, RegSeqRat readbacks, a RealUp seal, UniformCompletionUp and CauchyFilterCompletionUp provenance, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 3835.1, Definition 3835.2, Definition 3835.3, and Definition 3835.4 seed the finite filterbase-completion route for complete uniform-space consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompleteUniformSpaceFilterbaseCompletion}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CompleteUniformSpaceFilterbaseCompletionUp.CompleteUniformSpaceFilterbaseCompletionTast`

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected completion points, countable-choice selectors, host equality, ambient completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, filterbase convergence exposure, readback exactness, completion-handoff stability, and Real-seal nonescape for BEDC.Derived.CompleteUniformSpaceFilterbaseCompletionUp.

Chapter 3836

A Concrete Naming Certificate for $\mathsf{MetricCompletionAdjunction}^{\uparrow}$

Following Bishop and Bridges and Kelley on metric completion, the $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ packet records the universal mapping boundary for a displayed metric source and its completion as finite BEDC data. It reads the metric-completion carrier of chapter 1506, the dense embedding route of chapter 3351, the Cauchy adjunction surface of chapter 1456, and the unit-triangle ledger of chapter 2256. The chapter names the metric-specific adjunction packet without quotient completion, selected representatives, countable choice, host equality of completed objects, or ambient completeness.

Definition 3836.1 (MetricCompletionAdjunction carrier)**.** *A* $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, M, D, U, K, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric row, carrying the displayed carrier, distance classifier, finite balls, and the* $\mathsf{Met}^{\uparrow}$ *provenance needed before completion is read.*
2. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row of chapter 1506, including the chosen Cauchy-filter or Cauchy-net branch, readback row, separated comparison, and uniform-completion handoff.*
3. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *row of chapter 3351, displaying the source-to-completion dense image used by the universal mapping read.*
4. *U is the unit row sending each displayed source point into the completion packet through D and M.*
5. *K is the counit row for completion-facing consumers whose target is already read through the same metric completion surface.*
6. *T is the triangle ledger. It records that the unit followed by the counit, and the counit followed by the unit-facing extension, replay the same finite rows rather than invoking host equality of completed carriers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal row used by the readback side of the completion packet.*
8. *E is the* $\mathsf{UniformCompletion}^{\uparrow}$ *and extension-consumer row through which uniformly continuous finite-window maps read the same adjunction packet.*

9. *H records componentwise* hsame *transport for the source metric, completion row, dense embedding, unit, counit, triangle ledger, readback seal, extension row, replay, provenance, and local name.*

10. *C records displayed* Cont *replay from the source metric through dense embedding, unit, completion readback, extension, counit, and triangle comparison.*

11. *P is the* Pkg *provenance over* MetricCompletionAdjunction$^{\uparrow}$, MetricCompletion$^{\uparrow}$, MetricCompletionDenseEmbeddin CauchyCompletionAdjunction$^{\uparrow}$, CompletionUnitTriangle$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, UniformCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionAdjunction}^{\uparrow}}$ *row.*

The classifier accepts only packets whose unit, counit, and triangle rows are read through the same displayed source metric, completion packet, dense embedding, regular readback, Real seal, hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert rows.*

Theorem 3836.2 (MetricCompletionAdjunction NameCert obligations)**.** *For every accepted* MetricCompletionAdju *carrier*

$$A = (X, M, D, U, K, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionAdjunction}^{\uparrow}}$ *surface consists exactly of source metric admission, metric-completion admission, dense embedding exposure, unit visibility, counit visibility, triangle-ledger comparison, RegSeqRat/Real seal readback, uniform-extension handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of A. No obligation may be discharged by a quotient completion, selected Cauchy limit, countable-choice schedule, host equality of completion classes, or ambient complete metric space.*

Proof. Project the carrier of Definition 3836.1. The analytic rows are precisely the source metric X, completion packet M, dense embedding D, unit U, counit K, triangle ledger T, readback seal R, and extension row E.

The dense embedding and completion rows force the order of every accepted read. A consumer first opens the source metric and metric-completion packet, then reads the dense image route before any unit, counit, triangle, Real-seal, or uniform-extension coordinate is available.

Transport and replay are structural. The row H compares only the displayed components by hsame, while C replays the same route through source, dense image, completion, extension, counit, and triangle rows.

Finally P and N source and name the same finite packet. Since none of the listed rows stores a quotient completion, selected limit, countable-choice schedule, host equality, or ambient complete metric space, the displayed obligations exhaust the NameCert surface. □

Lean4 ✓ `BEDC.Derived.MetricCompletionAdjunctionUp.MetricCompletionAdjunctionTasteGate single carrier alignment`

Theorem 3836.3 (MetricCompletionAdjunction unit-counit triangle)**.** *Every unit-counit triangle read of an accepted* MetricCompletionAdjunction$^{\uparrow}$ *carrier factors through the finite route*

$$X \longmapsto D \longmapsto U \longmapsto M \longmapsto E \longmapsto K \longmapsto T \longmapsto R, H, C, P, N.$$

The route identifies the two triangle faces only by the displayed hsame *and* Cont *rows carried in H and C, and it consumes the RegSeqRat/Real seal row R only after the metric completion, dense embedding, unit, counit, and uniform-extension rows have been displayed.*

Proof. Start from the carrier inventory. The source metric row X and dense embedding row D are the only rows that introduce source points into the completion packet, so the unit face must pass through them before it can reach M.

The extension and counit faces are then downstream of the same completion packet. The row E records the uniform-extension consumer route, K records the counit-facing return, and T records the triangle comparison over those already displayed rows.

The terminal seal and structural rows cannot change the route. The row R is the RegSeqRat/Real readback attached to the completion packet, while H, C, P, N only transport, replay, source, and name the same finite data. Therefore the triangle read is exhausted by the displayed route and imports no quotient, selector, choice, host equality, or ambient-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionAdjunction}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ packet is generated from a source metric row, metric-completion row, dense embedding row, unit row, counit row, triangle ledger, RegSeqRat/Real seal readback, uniform-extension handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionAdjunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3836.1, Definition 3836.2, and Definition 3836.3 seed the metric-specific completion adjunction boundary over dense embedding, unit, counit, triangle, readback, and uniform-extension rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionAdjunction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MetricCompletionAdjunctionUp.MetricCompletionAdjunctionTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host equality of completed objects, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense embedding exposure, unit and counit visibility, triangle comparison, RegSeqRat/Real seal handoff, uniform-extension handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionAdjunctionUp.

The $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ hub routes first through chapter 486, chapter 782, and chapter 444 before the NameCertMorphism dependency child is read.

Chapter 3837

A Concrete Naming Certificate for $\mathsf{GeneratorClosureRobustness}^{\uparrow}$

The $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ packet records a finite hypercube and median-closure certificate for the zero-marker generator-closure robustness surface of Definition 9462.1779. It reads active median generators, median-essential codons, deletion-loss rows, Q_2 completion closure, and minimal percolating seeds as finite combinatorial data over Q_6. The finite table read is routed through the finite observation budget selector of chapter 782 before the active-generator, deletion-loss, and Q_2 completion rows are consumed. The collision-window consumer of chapter 444 reads the same finite moment-index and Hankel-shadow style rows, so the robustness packet's trigger and Q_2-completion ledgers feed a sibling finite-kernel consumer. The chapter is a NameCert target for finite closure robustness only; it does not claim biological necessity, probabilistic selection, host-level optimality, or an unbounded search principle.

The active-generator and Q_2-completion rows refine the generator-closure carrier of chapter 486. The robustness packet adds deletion-loss, minimal-seed, and trigger-comparison ledgers before any robustness read is exported, so every robustness consumer first sees the same finite generator-closure boundary and then the additional robustness tables.

The same dependency also controls replay: the robustness packet consumes the generator-closure carrier and replay rows of chapter 486 before it can state robustness under perturbation or audit transport.

Thus the active-generator and Q_2 completion rows consume three sibling surfaces before any trigger read is available: chapter 486 supplies the finite generator boundary, chapter 782 supplies the finite table-inspection budget, and chapter 444 supplies the downstream finite-kernel consumer that reads the same collision-facing row family.

Definition 3837.1 (GeneratorClosureRobustness carrier)**.** *A* $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, E, L, Q, P, T, H, C, K, N)$$

with the following displayed rows:

1. *A is the active median-generator row, listing the two size-7 active generators and their common rigid skeleton.*
2. *E is the median-essential row, listing the five codons whose deletion changes the median closure.*
3. *L is the deletion-loss row, recording the finite lost-codon table for each median-essential deletion.*

4. *Q is the Q_2 completion row, recording the rule that a three-of-four occupied Q_2 face adjoins the fourth vertex.*
5. *P is the percolating-seed row, recording the 484 size-7 Q_2-completion seeds and the absence of smaller percolating seeds.*
6. *T is the trigger-closure row comparing rigid median generation with broad Q_2 percolation capacity.*
7. *H is the componentwise* hsame *transport row for active-generator, deletion-loss, completion, seed, and trigger rows.*
8. *C is the displayed* Cont *replay row forcing every robustness read through A, E, L, Q, P, T, H.*
9. *K is the* Pkg *provenance over* $\mathsf{GeneratorClosureRobustness}^{\uparrow}$*, finite codon-window rows, Q_6, Q_2 faces,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GeneratorClosureRobustness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by this finite table data and its displayed transports.

Theorem 3837.2 (GeneratorClosureRobustness NameCert obligations)**.** *For every accepted* GeneratorClosureRobu *carrier $G = (A, E, L, Q, P, T, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{GeneratorClosureRobustness}^{\uparrow}}$ *surface consists exactly of these rows:*

1. *carrier admission for the active median generators, median-essential list, deletion-loss table, Q_2 completion rule, percolating-seed table, trigger comparison, transport, replay, provenance, and local name;*
2. *active-generator exactness, requiring the two displayed size-7 generators and their common six-codon skeleton to be read before a rigidity claim is accepted;*
3. *deletion-loss exactness, requiring every median-essential deletion to expose its finite lost-codon row;*
4. *Q_2 completion exactness, requiring every completion step to be witnessed by a displayed axis-aligned Q_2 face with at least three current vertices;*
5. *seed minimality, requiring the no-size-6 row and the 484 size-7 seed row before a percolation claim is accepted;*
6. *non-escape of biological necessity, probabilistic selection, unbounded search, host optimality, or hidden codon classifiers.*

No closure-robustness obligation is stored outside this finite packet.

Proof. Project the carrier of Definition 3837.1. The only rows available to the certificate are $A, E, L, Q, P, T, H, C, K, N$.

The active-generator and deletion-loss obligations read A, E, L as finite tables. The median-generator claim is accepted only after the two size-7 generators and their common skeleton are displayed, and each essential deletion is accepted only with its listed lost-codon row.

The Q_2 completion and seed obligations read Q and P. Each completion step is justified by a finite face row, and the percolation claim is accepted only after the no-smaller-seed row and the 484 minimal-seed row are present.

The trigger and non-escape clauses follow through T, H, C, K, N. These rows package the finite comparison between rigid median generation and broad Q_2 percolation; they contain no

biological-necessity coordinate, probability model, unbounded search oracle, host optimum, or hidden classifier. □

Theorem 3837.3 (GeneratorClosureRobustness Q2 completion exactness)**.** *Every accepted Q_2 completion read in a* $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ *packet must expose the displayed axis-aligned Q_2 face row Q, the active-generator row A, the deletion-loss row L, and the percolating-seed row P before a trigger-closure conclusion is read.*

Proof. Project the carrier of Definition 3837.1. The completion coordinate is the row Q, while the rows A, L, and P record the finite active-generator, deletion-loss, and percolating-seed data that determine whether the completion is part of the accepted robustness packet.

Apply Definition 3837.2. Its Q_2 completion exactness clause requires every completion step to be witnessed by a displayed axis-aligned Q_2 face with at least three current vertices, and its active-generator, deletion-loss, and seed clauses require the rows A, L, P before any trigger-facing read is accepted.

The rows T, H, C, K, N can only compare, transport, replay, source, and name those finite rows. Therefore the completion read exports no biological necessity, probability model, host optimum, hidden classifier, or unbounded search principle. □

Theorem 3837.4 (GeneratorClosureRobustness trigger-closure boundary)**.** *Every trigger-closure read of an accepted* $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ *packet factors through the displayed active-generator row, median-essential row, deletion-loss table, Q_2 completion rule, percolating-seed table, trigger comparison, componentwise transport, replay, provenance, and local NameCert row. A missing active-generator row, deletion-loss row, Q_2 face row, or minimal-seed row is a failure to land on the finite robustness surface, not a robustness counterexample.*

Proof. Begin with an accepted trigger-closure read. Carrier admission exposes the rows $A, E, L, Q, P, T, H, C, K, N$ before the trigger comparison can be consumed.

If the read concerns median rigidity, it must inspect A, E, L: the active generators, essential codons, and deletion losses are the displayed finite evidence for the rigid skeleton.

If the read concerns completion percolation, it must inspect Q and P: the Q_2 completion rule supplies the step witnesses, and the seed table supplies both the minimality lower bound and the 484 size-7 witnesses.

The replay row C and transport row H keep these two closure surfaces in one packet. Therefore a route missing one of the listed finite rows has not reached the accepted trigger-closure boundary, while a route that reaches the boundary exports no hidden classifier, biological-necessity assertion, probabilistic model, host optimum, or unbounded search principle. □

Falsifiable prediction: An accepted $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ read is refuted if a trigger-closure consumer reaches a rigidity or percolation conclusion without first displaying the active-generator row, deletion-loss table, Q_2 completion row, minimal-seed row, transport row, replay row, provenance row, and local naming row.

Independence witness: active median generation, median-essential deletion, Q_2 completion, and minimal percolating seeds: none is bijective with $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ because the packet jointly carries the rigid median skeleton, deletion losses, percolation rule, seed count, trigger comparison, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{GeneratorClosureRobustness}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GeneratorClosureRobustness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3837.1, Definition 3837.2, and Definition 3837.4 seed the finite generator-closure robustness carrier over active-generator, essential-codon, deletion-loss, Q_2 completion, seed, trigger, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{GeneratorClosureRobustness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, biological necessity, probabilistic selection, unbounded search, host optimality, or hidden codon classifiers.

Upgrade path: Obligation closure requires checked carrier admission, active-generator exactness, deletion-loss exactness, Q_2 completion exactness, seed minimality, trigger-closure boundary, and non-escape for BEDC.Derived.GeneratorClosureRobustnessUp.

Constructive story: A GeneratorClosureRobustness$^{\uparrow}$ packet is generated from active median generators, median-essential deletion rows, deletion-loss tables, Q2 completion faces, minimal percolating seed rows, trigger comparison, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theorem 3837.5 (GeneratorClosureRobustness forward-kernel consumer)**.** *Let $G = (A, E, L, Q, P, T, H, C, K, N)$ be an accepted* GeneratorClosureRobustness$^{\uparrow}$ *carrier. Any forward socket or kernel-audit consumer citing the robustness packet must read the active-generator row A, deletion-loss rows L, Q_2 completion row Q, minimal-seed row P, trigger row T, componentwise transport row H, replay row C, provenance row K, and local naming row N before invoking the* ForwardSocketLedger$^{\uparrow}$ *route of chapter 3387. The forward-kernel route is a displayed finite dependency route; it does not export biological necessity, probabilistic selection, host optimality, hidden codon classifiers, or an unbounded search principle.*

Proof. Project the carrier of Definition 3837.1. The rows $A, E, L, Q, P, T, H, C, K, N$ are the only coordinates a robustness consumer can inspect.

Use the NameCert obligations of Definition 3837.2. They require active-generator exactness, deletion-loss exactness, Q_2 completion exactness, seed minimality, and the local non-escape clauses before any public robustness read is accepted.

Apply Definition 3837.3 and Definition 3837.4. These force the completion and trigger reads to pass through $A, L, Q, P, T, H, C, K, N$ as one transported packet.

Only after those rows are visible may the consumer cite chapter 3387. The ForwardSocketLedger$^{\uparrow}$ chapter records the downstream socket ledger, while the robustness rows remain the finite kernel evidence that the consumer is auditing. □

Theorem 3837.6 (GeneratorClosureRobustness NameCertMorphism dependency route)**.** *Let $G = (A, E, L, Q, P, T, H, C, K, N)$ be an accepted* GeneratorClosureRobustness$^{\uparrow}$ *carrier. Every morphism-facing consumer of this packet must preserve the active-generator row A, the deletion-loss rows L, the Q_2 completion row Q, the minimal-seed row P, the trigger row T, the componentwise transport row H, the replay row C, the provenance row K, and the local naming row N before the read is transported through chapter 481. The route is a horizontal NameCert dependency route; it exports no biological necessity, probabilistic selection principle, host optimum, hidden codon classifier, unbounded search oracle, or morphism detached from the displayed robustness packet.*

Proof. Project the carrier of Definition 3837.1. The finite rows $A, E, L, Q, P, T, H, C, K, N$ are the only data available to a morphism-facing robustness consumer.

Apply the NameCert obligations of Definition 3837.2. They force carrier admission, active-generator exactness, deletion-loss exactness, Q_2 completion exactness, seed minimality, trigger comparison, transport, replay, provenance, and local naming to remain visible before any robustness read is accepted.

Use Definition 3837.3 and Definition 3837.4. These keep the completion and trigger rows inside the same transported packet, so a consumer cannot replace the robustness evidence by a hidden classifier or an unbounded search principle.

Only after those rows are preserved may the consumer cite chapter 481. The NameCertMorphism route transports the displayed naming dependency, while $\mathsf{GeneratorClosureRobustness}^{\uparrow}$ still supplies the finite active-generator, deletion-loss, completion, seed, trigger, transport, replay, provenance, and local naming rows being transported. □

Chapter 3838

A Concrete Naming Certificate for $\mathsf{ComputableUniformContinuity}^{\uparrow}$

Following Bishop–Bridges and Weihrauch computable analysis, the $\mathsf{ComputableUniformContinuity}^{\uparrow}$ packet records the finite BEDC surface by which a represented-space map exposes one computable modulus route before any real-valued completion consumer reads it as an ambient host function. It sits over the CauchyRepresentation decoding of chapter 1680, the source and target represented-space rows of chapter 1494, the finite name-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, the modulus row of chapter 369, and the continuous-map route of chapter 130. The packet names a computable-analysis uniform-continuity boundary; it is not a host function, not a choice-selected modulus, not a quotient representation, not full $\mathsf{Real}^{\uparrow}$ completeness, and not a checked public bridge.

Definition 3838.1 (Computable uniform continuity carrier)**.** *A* $\mathsf{ComputableUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, K, R, M, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the represented-space source row, exposing only the source carrier, admissible names, and finite observation cells used by the packet.*
2. *Y is the represented-space target row, exposing the matching target carrier, target names, and target observation cells.*
3. *K is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *decoding row, relating source and target names to regular Cauchy information before any real-facing seal is inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the decoded Cauchy data.*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *realizer row, giving the finite rule that turns a requested target tolerance into a source-name window.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger for the source and target name segments inspected by M and K.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic budgets used by the source window, target window, and regular rational readback.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after X, Y, K, R, M, W, T have been displayed.*
9. *H records componentwise* hsame *transport for represented-space rows, decoding, readback, modulus, windows, tolerance ledger, seal, replay, provenance, and naming.*
10. *C records displayed* Cont *replay from a represented-space consumer through the decoding, modulus, finite-window, tolerance, readback, and seal rows.*
11. *P is the* Pkg *provenance over* $\mathsf{ComputableUniformContinuity}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ComputableUniformContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, K, R, M, W, T, E, H, C, P, N$. The carrier has no coordinate for an external host function, a selected modulus outside M, quotient equality of representations, full real completeness, countable choice over names, or a detached continuity proof.

Lean4 ✓ `BEDC.Derived.ComputableUniformContinuityUp.ComputableUniformContinuityTasteGate single carrier alignment`

Theorem 3838.2 (Computable uniform continuity NameCert obligations)**.** *For every accepted* $\mathsf{ComputableUniformContinuity}^{\uparrow}$ *carrier $Q = (X, Y, K, R, M, W, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ComputableUniformC}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $X, Y, K, R, M, W, T, E, H, C, P, N$;*
2. *modulus visibility: every exported continuity read passes through the single* $\mathsf{UniformModulus}^{\uparrow}$ *row M before a target tolerance is accepted;*
3. *represented-space compatibility: the source row X, target row Y, and decoding row K are read together, so the modulus never acts on a detached host carrier;*
4. *window transport: the* $\mathsf{StreamName}^{\uparrow}$ *row W and* hsame *row H carry the same finite source and target name windows through every accepted replay;*
5. *tolerance stability: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E use the same dyadic budgets exposed by M and W;*
6. *ledger nonescape: H, C, P, N export no host function, choice-selected modulus, quotient representation, full* $\mathsf{Real}^{\uparrow}$ *completeness theorem, countable choice over names, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier in Definition 3838.1. Its accepted rows are exactly $X, Y, K, R, M, W, T, E, H, C, P, N$, so carrier admission exposes represented-space data, decoding, readback, modulus, windows, tolerance ledger, real seal, and structural rows only.

The modulus visibility and represented-space compatibility clauses are forced by the row order. A continuity consumer must first read the source and target represented-space rows X, Y, then the decoding row K, and then the displayed modulus realizer M before it can request a target tolerance.

The window and tolerance clauses read the finite ledgers. The row W lists the inspected source and target name windows, while T records the dyadic budgets that make the $\mathsf{RegSeqRat}^{\uparrow}$ readback R and terminal $\mathsf{Real}^{\uparrow}$ seal E available.

Finally inspect the structural rows. Componentwise transport H, replay C, provenance P, and local naming N preserve the same displayed route and contain no coordinate for the excluded host function, selected modulus, quotient representation, full real completeness theorem, countable choice, or bridge certificate. □

Falsifiable prediction: An accepted $\mathsf{ComputableUniformContinuity}^{\uparrow}$ read is refuted if it exports a uniform-continuity consumer without displaying represented-space source and target rows, CauchyRepresentation decoding, RegSeqRat readback, UniformModulus realizer, StreamName windows, DyadicRatCore tolerance ledger, RealUp seal, transport, replay, provenance, and local naming.

Independence witness: cauchy-representation, representedspace, streamname, regseqrat, dyadicratcore, real, uniformmodulus, continuousmap: none alone is bijective with $\mathsf{ComputableUniformContinuity}^{\uparrow}$ because the packet jointly records represented source and target rows, Cauchy decoding, a computable modulus realizer, finite name windows, rational readback, dyadic tolerance stability, terminal Real sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{ComputableUniformContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{ComputableUniformContinuity}^{\uparrow}$ packet is generated from represented-space source and target rows, CauchyRepresentation decoding, RegSeqRat readback, a UniformModulus realizer, StreamName finite windows, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ComputableUniformContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3838.1 and Definition 3838.2 seed the finite computable-analysis route from represented-space names to a uniform-modulus Real consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ComputableUniformContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host functions, choice-selected moduli, quotient representations, full RealUp completeness, countable choice over names, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus visibility, represented-space compatibility, window transport, tolerance stability, ledger nonescape, and local naming for BEDC.Derived.ComputableUniformContinuityUp.

Chapter 3839

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy sequences, the $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$ packet records the quotient-free separation certificate used when two completion names are compared before a terminal real seal is consumed. It sits on the finite observation route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the extension-and-uniqueness surface of chapter 2319. The packet names separation between displayed completion names; it is not quotient completion equality, selected representative choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3839.1 (Regular Cauchy completion separation carrier)**.** *A* $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, D, W, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two completion-name source rows, each opened only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational route.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the two names at a displayed precision.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window exposing the observations of A and B requested by D.*
4. *R is the regular-rational comparison row recording the inspected rational entries, common-tail data, and separation witness before any Real-facing read.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, B, D, W, R have been displayed.*
6. *U is the* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *uniqueness row, read only as a finite extension-and-uniqueness boundary for the same displayed completion names.*
7. *H records componentwise* hsame *transport for $A, B, D, W, R, E, U, C, P, N$.*
8. *C records displayed* Cont *replay from a separation request through the two source rows, dyadic tolerance, stream window, regular rational comparison, terminal seal, and universal-property uniqueness row.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient representatives, host sequence equality, selected limits, countable choice over tails, trichotomy, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionSeparationUp.RegularCauchyCompletionSeparationTasteGate`
`single carrier alignment`

Theorem 3839.2 (Regular Cauchy completion separation NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$ *carrier* $S = (A, B, D, W, R, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}}$ *surface consists exactly of two-name source admission, shared dyadic tolerance exposure, finite StreamName window routing, regular rational comparison, terminal Real seal handoff, universal-property uniqueness routing, componentwise transport, continuation replay, package provenance, and local naming through the displayed rows* $A, B, D, W, R, E, U, H, C, P, N$.

Proof. Project the carrier of Definition 3839.1. The two completion names are visible only through A and B, and the comparison has a single displayed dyadic tolerance ledger D.

The finite window row W exposes the observations requested by D. The row R records the inspected regular-rational entries, common-tail data, and separation witness before the terminal $\mathsf{Real}^{\uparrow}$ seal E can be read.

The universal-property row U supplies only the displayed uniqueness boundary already named by chapter 2319. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route, and the carrier lacks any quotient representative, host equality, selected limit, countable-choice, trichotomy, or ambient completeness coordinate. □

Theorem 3839.3 (Regular Cauchy completion separation handoff)**.** *Every completion-facing consumer that compares two accepted* $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$ *names must read the finite route*

$$A, B, D, W \longmapsto R \longmapsto E, U \longmapsto H, C, P, N$$

before treating the names as separated or identified by the completion boundary. The handoff routes through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ *as displayed NameCert data, and it exports no quotient equality, selected representative, host real equality, countable-choice selector, trichotomy split, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier $S = (A, B, D, W, R, E, U, H, C, P, N)$. A comparison request first opens the two regular Cauchy source rows and the shared dyadic tolerance ledger.

The finite StreamName window W determines which observations of the two names are inspected. The regular-rational comparison row R then records the common-tail and separation data, so the request remains inside finite $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ evidence.

Only after that comparison can the terminal Real seal E and universal-property uniqueness row U be consumed. The structural rows H, C, P, N transport, replay, source, and name the same route, leaving no carrier coordinate for quotient equality, selected representatives, host equality, countable choice, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}}$.

Constructive story: A RegularCauchyCompletionSeparation$^{\uparrow}$ packet is generated from two regular Cauchy completion-name rows, a shared DyadicRatCore tolerance ledger, finite StreamName windows, a RegSeqRat comparison row, a terminal RealUp seal, a CauchyCompletionUniversalProperty uniqueness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionSeparation}^{\uparrow}}$, seed)

Scope closed: Definition 3839.1, Definition 3839.2, and Definition 3839.3 seed the quotient-free separation surface for displayed regular Cauchy completion names.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionSeparation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, host sequence equality, countable choice over tails, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-tolerance exactness, finite-window routing, regular-rational comparison, terminal seal handoff, universal-property uniqueness routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionSeparationUp.

Chapter 3840

A Concrete Naming Certificate for WRRHotspotCube$^{\uparrow}$

The WRRHotspotCube$^{\uparrow}$ packet realizes the purine-suffix hotspot cube of Definition 9462.1780, the reassignment count of Definition 9462.1781, and the highest-scoring cube certificate of Definition 9462.1783 as finite BEDC NameCert data. It consumes the DNA boundary-tile source of chapter 3393, the six-boundary coverage surface of chapter 3470, the finite trigger algebra of chapter 3478, the trigger-energy partition packet of chapter 3806, and the trigger-blocker duality packet of chapter 3801. The packet names C_{WRR} as finite cube, layer, transfer-square, count, and refusal data; it is not a biological causal model, stochastic evolutionary law, exhaustive code table, or hidden codon semantics.

Definition 3840.1 (WRR hotspot cube carrier)**.** *A* WRRHotspotCube$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (V, A, L, T, M, Q, H, C, P, N)$$

with the following displayed rows:

1. *V is the eight-vertex row for $C_{\mathrm{WRR}} = \{\mathrm{UAA}, \mathrm{UAG}, \mathrm{UGA}, \mathrm{UGG}, \mathrm{AAA}, \mathrm{AAG}, \mathrm{AGA}, \mathrm{AGG}\}$.*
2. *A is the six-bit atlas row recording the free coordinates b_1^s, b_2^f, b_3^f and fixed coordinates $b_1^f = 0$, $b_2^s = 1$, and $b_3^s = 1$.*
3. *L is the layer-classifier row recording the $\mathrm{U} \times R \times R$ and $\mathrm{A} \times R \times R$ layers and the standard $3 + 2 + 2 + 1$ pattern.*
4. *T is the transfer-square row for $\{\mathrm{UGA}, \mathrm{UGG}, \mathrm{AGA}, \mathrm{AGG}\}$ and its Stop/Trp/Arg transition surface.*
5. *M is the reassignment-count ledger recording the codon counts $8, 10, 15, 0, 3, 0, 8, 8$ and total 52.*
6. *Q is the Q_3 score row recording that the displayed cube is the unique highest-scoring axis-aligned cube among the 160 displayed candidates.*
7. *H records componentwise* hsame *transport for vertex, atlas, layer, transfer-square, count, score, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source hotspot-cube vision through $V, A, L, T, M, Q, H, P, N$.*
9. *P is the* Pkg *provenance over* WRRHotspotCube$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgebra$^{\uparrow}$, TriggerEnergyPartition$^{\uparrow}$, TriggerBlockerDuality$^{\uparrow}$, *the source hotspot-cube vision,* BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}$ *row.*
The carrier has no coordinate for biochemical mechanism, evolutionary ancestry, exhaustive biological coverage, stochastic causality, host codon semantics, or an unlisted reassignment table.

Lean4 ✓ `BEDC.Derived.WRRHotspotCubeUp.WRRHotspotCubeTasteGate single carrier alignment`

Theorem 3840.2 (WRR hotspot cube NameCert obligations)**.** *For every accepted* $\mathsf{WRRHotspotCube}^{\uparrow}$ *carrier* $W = (V, A, L, T, M, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}$ *surface consists exactly of vertex exposure, six-bit atlas exposure, layer-classifier exposure, transfer-square exposure, reassignment-count ledger exactness,* Q_3 *score-row exposure, componentwise transport, continuation replay, package provenance, and local naming through the displayed rows* $V, A, L, T, M, Q, H, C, P, N$*.*

Proof. Project the carrier of Definition 3840.1. The vertex row V and atlas row A name the finite cube, while L and T expose the two layer and transfer-square classifiers already displayed in the source vision.

The count and score rows are finite ledgers. The row M records the eight codon-level reassignment counts and their total, and Q records the comparison against the displayed family of axis-aligned Q_3 cubes.

Transport, replay, provenance, and local naming preserve exactly those rows. Since the carrier has no coordinate for biochemical mechanism, evolutionary ancestry, stochastic causality, exhaustive biological coverage, hidden codon semantics, or an unlisted table, the listed rows exhaust the NameCert obligations. □

Theorem 3840.3 (WRR hotspot cube dependency handoff)**.** *Every downstream trigger-spectrum consumer of an accepted* $\mathsf{WRRHotspotCube}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{SixBoundaryTileCoverage}^{\uparrow},\ \mathsf{WindowCoverageTriggerAlgebra}^{\uparrow},\ \mathsf{TriggerEnergyPartition}^{\uparrow},$$

The handoff exposes the cube vertices, atlas coordinates, layer classifier, transfer square, reassignment count ledger, and highest-score row before any consumer treats the hotspot cube as a finite NameCert packet.

Proof. The provenance row P lists the sibling dependency surface. The DNA boundary-tile packet supplies the source codon-window rows, the six-boundary coverage packet supplies the finite coverage coordinates, and the trigger algebra supplies the finite support and coverage-trigger readback.

The trigger-energy partition and trigger-blocker duality packets then supply the partition and blocker rows used by trigger-spectrum consumers. Only after those sibling rows are visible can V, A, L, T, M, Q be read as the hotspot-cube NameCert surface.

The structural rows H, C, P, N preserve and name the same route. Therefore the handoff is a finite dependency chain, not a biological mechanism, stochastic law, or hidden codon table. □

Falsifiable prediction: Any accepted $\mathsf{WRRHotspotCube}^{\uparrow}$ consumer that changes one of the eight displayed vertex rows or one of the count entries $8, 10, 15, 0, 3, 0, 8, 8$ must change the total-count row M or reject the packet.

Independence witness: dna-window-six-boundary-tile, six-boundary-tile-coverage, window-coverage-trigger-algebra, trigger-energy-partition, trigger-blocker-duality: none is bijective with $\mathsf{WRRHotspotCube}^{\uparrow}$ because this packet jointly carries the WRR vertex cube, six-bit atlas row, layer classifier, transfer square, reassignment-count ledger, highest-score row, transport, replay, provenance, and local naming.

The Lean follow-up for this chapter must provide `Nontrivial WRRHotspotCubeUp` and `FieldFaithful WRRHotspotCubeUp` TasteGate instances under `BEDC.Derived.WRRHotspotCubeUp`, preserving $V, A, L, T, M, Q, H,$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}$.

Constructive story: A $\mathsf{WRRHotspotCube}^{\uparrow}$ packet is generated from eight WRR cube vertices, six-bit atlas coordinates, layer-classifier rows, transfer-square rows, reassignment-count ledgers, highest-score rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3840.1, Definition 3840.2, Definition 3840.3, the falsifiable prediction, and the independence witness seed the finite WRR hotspot cube packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WRRHotspotCube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close biochemical causality, evolutionary ancestry, exhaustive biological coverage, stochastic semantics, hidden codon semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, vertex exposure, atlas exposure, layer and transfer-square classifier exactness, count-ledger exactness, highest-score row exposure, Nontrivial WRRHotspotCubeUp, and FieldFaithful WRRHotspotCubeUp for BEDC.Derived.WRRHotspotCubeUp.

Chapter 3841

A Concrete Naming Certificate for $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$

Bishop–Bridges nested interval/regular Cauchy construction treats a decreasing located interval chain with a displayed diameter schedule as finite approximation data before any real point is read. The $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ packet records that handoff as a NameCert route from the nested-interval theorem surface of chapter 2308 and the located endpoint surface of chapter 394 through the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It names the L10 route from nested interval data to regular Cauchy real names; it is not an interval-intersection oracle, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3841.1 (Nested Cauchy interval-selection carrier)**.** *A* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{NestedIntervalTheorem}^{\uparrow}$ *source row, exposing the finite descending interval windows, containment rows, and diameter controls.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row, recording located lower and upper endpoint reads for the inspected intervals.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare interval diameter bounds with the requested regular Cauchy precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which endpoint and midpoint observations are requested.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy handoff row extracted from the nested interval windows and tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, L, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for interval, located endpoint, dyadic tolerance, stream-window, regular readback, real seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a nested interval request through located endpoint reads, dyadic tolerances, stream windows, regular readback, and real seal handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$, $\mathsf{NestedIntervalTheorem}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $I, L, D, W, R, E, H, C, P, N$. It has no coordinate for a completed host intersection point, a quotient real representative, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedCauchyIntervalSelectionUp.NestedCauchyIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 3841.2 (Nested Cauchy interval-selection NameCert obligations)**.** *For every accepted* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ *carrier $S = (I, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}}$ *surface consists exactly of carrier admission for the displayed rows, nested-interval exposure through I, located endpoint exposure through L, dyadic tolerance exactness through D, finite-window exposure through W, regular Cauchy handoff through R, terminal real seal confinement through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 3841.1. The rows $I, L, D, W, R, E, H, C, P, N$ are exactly the data visible to the local classifier.

The interval source and located endpoint rows are separate. The source row I carries the descending windows and diameter controls, while L carries the endpoint locatedness evidence needed to read those windows as rational approximation data.

The regular Cauchy handoff is downstream. The tolerance ledger D converts displayed diameter bounds into requested precision rows, the window row W supplies finite observations, and R packages the resulting observations as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

The real seal and structural rows do not add a hidden selector. The row E is reached only after I, L, D, W, R have been replayed, and H, C, P, N preserve and name the same route. Hence the excluded host intersection, quotient representative, choice, trichotomy, compactness, and ambient-completeness coordinates are absent from the NameCert surface. □

Theorem 3841.3 (Nested Cauchy interval-selection regular Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{NestedIntervalTheorem}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exports a regular Cauchy name read from displayed interval windows and diameter controls, not a completed intersection point or a host equality of real presentations.

Proof. Begin with an accepted carrier $S = (I, L, D, W, R, E, H, C, P, N)$. A regular Cauchy request first reads the nested interval theorem row I and the located endpoint row L.

Next the request consumes the dyadic tolerance ledger D and finite-window row W. These rows identify which displayed interval prefix supplies the requested Cauchy precision.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is then read as the regular Cauchy handoff. A $\mathsf{Real}^{\uparrow}$ consumer may proceed to E, but only through the same route and the structural rows H, C, P, N.

Since no carrier coordinate names a completed host intersection point, quotient real representative, countable-choice schedule, trichotomy split, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the handoff remains choice-free and finite. □

Falsifiable prediction: Every accepted $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ read exposes NestedIntervalTheorem rows, LocatedInterval endpoint rows, DyadicRatCore tolerance rows, StreamName finite windows, a RegSeqRat handoff, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any Real-facing consumer can use the packet.

Independence witness: nested-interval-theorem, locatedinterval, regseqrat, dyadicratcore, streamname, real: $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the nested interval source, located endpoint evidence, dyadic tolerance ledger, finite-window route, regular Cauchy handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedCauchyIntervalSelection}^{\uparrow}$ packet is generated from a NestedIntervalTheorem source row, a LocatedInterval endpoint row, a DyadicRatCore tolerance ledger, StreamName finite windows, a RegSeqRat regular Cauchy handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3841.1, Definition 3841.2, and Definition 3841.3 seed the finite route from nested interval data to regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedCauchyIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, host interval intersection, quotient real equality, selected limit points, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, nested interval exposure, located endpoint exposure, dyadic tolerance exactness, regular Cauchy handoff, Real seal confinement, and field-faithful TasteGate evidence for BEDC.Derived.NestedCauchyIntervalSelectionUp.

Chapter 3842

A Concrete Naming Certificate for $\mathsf{BoundaryPressureLedger}^{\uparrow}$

The $\mathsf{BoundaryPressureLedger}^{\uparrow}$ packet realizes the outer-boundary degree and pressure rows of Definition 9462.1298, Definition 9462.1300, and Definition 9462.1305 as finite BEDC NameCert data. It sits after the median-closure carrier of chapter 3545, the six-boundary trigger coverage route of chapter 3470, the boundary-trigger closure packet of chapter 3508, and the coverage algebra of chapter 3478. The packet records pressure rows for inactive boundary codons before any trigger or class-pressure consumer may use them; it is not a biological stochastic model, an empirical fitness claim, a hidden codon table, or an unrestricted boundary enumerator.

Definition 3842.1 (Boundary-pressure ledger carrier)**.** *A* $\mathsf{BoundaryPressureLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, O, D, P, A, K, H, C, Q, N)$$

with the following displayed rows:

1. *S is the reassigned support row naming the displayed* 13*-codon support $\mathcal{R}$.*
2. *O is the outer-boundary row, listing exactly the inactive codons at Hamming distance one from $\mathcal{R}$.*
3. *D is the boundary-degree ledger, recording $d_{\partial}(z)$ for each displayed boundary codon z.*
4. *P is the boundary-pressure ledger, recording $P_{\partial}(z)$ from the displayed support-neighbor weights.*
5. *A is the aggregate class-pressure row, grouping boundary codons by standard-code class while preserving degree and pressure totals.*
6. *K is the high-pressure corner row naming the inactive envelope corners and the first completion frontier consumed by boundary-closure readers.*
7. *H records componentwise* hsame *transport for support, outer-boundary, degree, pressure, aggregate, corner, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-pressure request through $S, O, D, P, A, K, H, Q, N$.*
9. *Q is the* Pkg *provenance over* $\mathsf{BoundaryPressureLedger}^{\uparrow}$*,* $\mathsf{MedianClosure}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$*,* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}$ *row.*

The carrier accepts pressure reads only through $S, O, D, P, A, K, H, C, Q, N$. It has no coordinate for a pressure-row bypass, hidden biological semantics, stochastic selection dynamics, empirical likelihood, or a boundary row outside the displayed finite ledger.

Lean4 ✓ `BEDC.Derived.BoundaryPressureLedgerUp.BoundaryPressureLedgerTasteGate single carrier alignment`

Theorem 3842.2 (Boundary-pressure ledger NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryPressureLedger}^{\uparrow}$ *carrier $B = (S, O, D, P, A, K, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}$ *surface consists exactly of support admission through S, outer-boundary exposure through O, degree-ledger exactness through D, pressure-ledger exactness through P, class-pressure aggregation through A, inactive-corner and completion-frontier readback through K, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through Q, and local naming through N.*

Proof. Project the carrier of Definition 3842.1. Its visible pressure data are exactly the rows $S, O, D, P, A, K, H, C, Q, N$.

The source support and boundary rows are finite. The row S names the reassigned support, and O lists the inactive codons at Hamming distance one from that support.

The degree and pressure rows are downstream of the same source. The row D counts displayed support neighbors for each boundary codon, while P sums the displayed support-neighbor weights. The aggregate row A groups those same entries by class without changing their provenance.

The corner, transport, replay, provenance, and naming rows preserve the ledger. Because no coordinate bypasses D and P, a consumer cannot obtain pressure data from hidden biological semantics, stochastic selection dynamics, empirical likelihood, or an unrestricted boundary enumerator. □

Lean4 ✓ `BEDC.Derived.BoundaryPressureLedgerUp.BoundaryPressureLedgerNamecertObligations`

Theorem 3842.3 (Boundary-pressure trigger handoff)**.** *Every boundary-trigger or class-pressure consumer of an accepted* $\mathsf{BoundaryPressureLedger}^{\uparrow}$ *packet factors through*

$$S \longmapsto O \longmapsto D \longmapsto P \longmapsto A \longmapsto K \longmapsto H, C, Q, N.$$

In particular, any consumer preserving $\mathsf{MedianClosure}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, *and* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *provenance must read the degree and pressure ledgers before it can use high-pressure inactive boundary codons.*

Proof. Begin with a boundary-trigger request. The provenance row Q names the median-closure and boundary-trigger siblings, but the request cannot read those siblings as pressure rows unless the local support row S and outer-boundary row O have first been displayed.

The pressure data then pass through D and P. Degree is counted from displayed support neighbors, and pressure is the displayed weighted sum over the same neighbor relation.

The aggregate and corner rows are read only after the degree and pressure ledger. The row A groups class totals, while K names the inactive envelope corners and completion-frontier entries consumed by boundary-closure readers.

Finally H, C, Q, N transport, replay, source, and name the same finite route. Thus a pressure-row bypass would refute the packet: it would use high-pressure boundary data without passing through the displayed degree and pressure ledgers. □

Falsifiable prediction: A pressure-row bypass refutes $\mathsf{BoundaryPressureLedger}^{\uparrow}$: any accepted boundary-trigger consumer that reaches high-pressure inactive codons without first reading $S, O, D, P, A, K, H, C, Q$ is outside the packet.

Independence witness: median-closure, six-boundary-tile-coverage, dna-boundary-trigger-closure, window-coverage-trigger-algebra: $\mathsf{BoundaryPressureLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the outer-boundary row, degree ledger, pressure ledger, class aggregation, inactive-corner frontier, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.BoundaryPressureLedgerUp.TasteGate` must provide explicit $\mathsf{Nontrivial\ BoundaryPressureLedger}^{\uparrow}$ and $\mathsf{FieldFaithful\ BoundaryPressureLedger}^{\uparrow}$ instances preserving $S, O, D, P, A, K, H, C, Q, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryPressureLedger}^{\uparrow}$ packet is generated from a reassigned support row, an outer-boundary row, boundary-degree and boundary-pressure ledgers, class-pressure aggregation, inactive-corner frontier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3842.1, Definition 3842.2, and Definition 3842.3 seed the finite pressure-ledger route for DNA boundary-trigger consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryPressureLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, biological stochastic semantics, empirical likelihood, hidden codon semantics, unrestricted boundary enumeration, or pressure-row bypasses.

Upgrade path: Obligation closure requires checked support admission, outer-boundary exposure, degree-ledger exactness, pressure-ledger exactness, class aggregation, trigger handoff, Nontrivial BoundaryPressureLedgerUp, and FieldFaithful BoundaryPressureLedgerUp for BEDC.Derived.BoundaryPressureLedgerUp.

Chapter 3843

A Concrete Naming Certificate for $\mathsf{CompletionAdjoint}^{\uparrow}$

Following Mac Lane and Bishop–Bridges, the $\mathsf{CompletionAdjoint}^{\uparrow}$ packet records the Cauchy completion reflector as a finite adjunction certificate. It sits after the reflector surface of chapter 1585, the functorial completion surface of chapter 423, the universal extension ledger of chapter 397, the reflective-subcategory boundary of chapter 1793, the regular rational and stream-window interfaces of chapter 126 and chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the displayed unit, counit, and universal-property rows; it is not a quotient completion, a selected limit object, an ambient reflective subcategory theorem, or an appeal to countable choice.

Definition 3843.1 (Completion adjoint carrier)**.** *A* $\mathsf{CompletionAdjoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, F, U, V, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row from chapter 1585, recording the source-to-complete handoff through the Cauchy completion reflector surface.*
2. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row from chapter 423, carrying the functorial source, regular-Cauchy, seal, and classifier data.*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row from chapter 397, recording extension existence, extension uniqueness, and unit compatibility for the same displayed source.*
4. *V is the* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$ *visibility row from chapter 1793: it records that complete objects are read through the reflected completion surface, not through a host subcategory object.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule for completion requests, approximating maps, unit reads, and counit reads.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular Cauchy names inspected by F and by the universal-property row U.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for all approximation and triangle reads used by the unit-counit ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after R, F, U, V, S, Q, D have been displayed.*

9. *H records componentwise* hsame *transport for the reflector, functor, universal-property, reflective-subcategory, stream, readback, dyadic, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from any completion-adjunction consumer through the rows R, F, U, V, S, Q, D, E and then through the structural rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CompletionAdjoint}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected limits, host reflective subcategories, functor extensionality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompletionAdjointUp.CompletionAdjointTasteGate single carrier alignment`

Theorem 3843.2 (Completion adjoint NameCert obligations)**.** *For every accepted* $\mathsf{CompletionAdjoint}^{\uparrow}$ *carrier $A = (R, F, U, V, S, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the twelve displayed rows; reflector exposure through R; functorial completion exposure through F; universal-property exposure through U; reflective-subcategory visibility through V; finite request scheduling through S; regular rational readback through Q; dyadic tolerance accounting through D; terminal RealUp sealing through E; componentwise transport through H; continuation replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier rows. The adjunction-facing data are precisely the reflector row R, the functor row F, the universal-property row U, the reflective-subcategory visibility row V, and the finite analytic rows S, Q, D, E.

Read the structural rows separately. The transport row H preserves those displayed rows componentwise, while C replays the same route for completion-adjunction consumers.

The provenance and naming rows P, N attach the packet to the cited completion, stream, regular-readback, dyadic, and Real certificates. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 3843.3 (Completion adjoint unit-counit ledger)**.** *Every unit or counit read exported by an accepted* $\mathsf{CompletionAdjoint}^{\uparrow}$ *carrier factors through the finite route*

$$R, F, U, V \longrightarrow S, Q, D \longrightarrow E, H, C, P, N.$$

The unit side reads the source-to-completion handoff through the reflector and functor rows, while the counit side reads the complete-object return through the universal-property and reflective-subcategory visibility rows. Both sides use the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the structural ledger is inspected.*

Proof. Start with the rows R, F, U, V. They are the only coordinates in the packet that can name the reflector, functor, extension, uniqueness, and reflected-object handoff needed by an adjunction consumer.

Next read S, Q, D, E. These rows supply finite request schedules, regular rational readback, dyadic tolerance accounting, and the terminal Real seal for both the unit-facing and counit-facing directions.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same displayed ledger, so the unit and counit routes cannot escape to a quotient completion, selected limit, host reflective subcategory, functor-extensional equality, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionAdjoint}^{\uparrow}$ packet is generated from CauchyCompletionReflector, CauchyCompletionFunctor, CompletionUniversalProperty, CauchyCompletionReflectiveSubcategory, StreamName, RegSeqRat, DyadicRatCore, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3843.1, Definition 3843.2, and Definition 3843.3 seed the finite adjunction certificate for Cauchy completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionAdjoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, selected limits, host reflective subcategories, functor extensionality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, reflector exposure, functorial completion exposure, universal-property compatibility, unit-counit ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompletionAdjointUp.

Chapter 3844

A Concrete Naming Certificate for $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$

Following Arzela–Ascoli and Bishop–Bridges equicontinuity arguments, the $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ packet records the finite-net route by which a compact source and a finite family of continuous maps expose one shared modulus before any open-cover compactness or choice principle is read. It consumes compact-metric data from chapter 129, total-bounded finite nets from chapter 127, continuous-map graph and pointwise modulus rows from chapter 130, compact uniform-continuity handoff data from chapter 3444, and the downstream modulus surface of chapter 369. The certificate is a finite uniform-equicontinuity route for compact-window consumers, not a selected subcover, not a family-choice functional, and not ambient completeness of the codomain.

Definition 3844.1 (UniformEquicontinuityModulus carrier)**.** *A* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, T, F, W, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the compact metric carrier, distance ledger, and compact finite-net surface used by the family.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row over the same source, listing inspected centers and dyadic source-radius budgets.*
3. *F is the finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows whose pointwise modulus and graph rows are inspected at the centers named by T.*
4. *W is the finite target-window row, recording the common tolerance window and the family indices admitted by the packet.*
5. *M is the exported* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained by a finite fold over the centerwise and familywise modulus witnesses displayed by F against T and W.*
6. *H records componentwise* hsame *transport for the compact source, finite-net, continuous-family, window, folded-modulus, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a compact-window consumer through K, T, F, W, M and then through the structural rows.*

8. *P is the* Pkg *provenance over* UniformEquicontinuityModulus$^{\uparrow}$, CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, ContinuousMap$^{\uparrow}$, HeineCantor$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{UniformEquicontinuityModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected finite subcovers, countable choice over the family, quotient equality of maps, host real trichotomy, or ambient codomain completeness.

Lean4 ✓ `BEDC.Derived.UniformEquicontinuityModulusUp.UniformEquicontinuityModulusTasteGate single carrier alignment`

Theorem 3844.2 (UniformEquicontinuityModulus NameCert obligations)**.** *For every accepted* UniformEquicontinuityModulus$^{\uparrow}$ *carrier $U = (K, T, F, W, M, H, C, P, N)$, the local* NameCert$_{\text{UniformEquicontinuityModulus}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the finite packet $K, T, F, W, M, H, C, P, N$;*
2. *finite-window classifier: every family and target-tolerance read is confined to the displayed window row W and the listed* ContinuousMap$^{\uparrow}$ *rows in F;*
3. *compact finite-net exactness: the only compactness data read by the classifier are the* CompactMetric$^{\uparrow}$ *source row K and the* TotallyBounded$^{\uparrow}$ *finite-net row T;*
4. *uniform-modulus export: the shared modulus row M is obtained by the finite fold over the centerwise pointwise-modulus rows in F and the compact finite-net route already exposed by K, T;*
5. *non-escape: no accepted consumer receives an open-cover compactness object, selected subcover, family-choice functional, quotient map equality, host real trichotomy, or ambient completeness theorem.*

Proof. Project the carrier row by row. The analytic data available before the exported modulus are exactly the compact source K, the finite-net inventory T, the finite continuous-family rows F, and the common target window W.

The compact finite-net exactness clause follows from the route through K and T. Since T lists the centers and radius budgets as finite data, the classifier never needs an open-cover subcover or a choice over covers.

The uniform-modulus export is then the finite fold stored in M. Each fold input is a pointwise modulus row from F at a center named by T and a tolerance named by W; the Heine–Cantor handoff supplies the compact-window reading of those rows, while the final row is presented to the UniformModulus$^{\uparrow}$ surface.

Finally read the structural rows. The transport row H, replay row C, provenance row P, and local naming row N preserve the same finite route and contain no coordinate for the excluded cover, choice, equality, trichotomy, or completeness data. □

Falsifiable prediction: An accepted UniformEquicontinuityModulus$^{\uparrow}$ read is refuted if it exports a shared family modulus without displaying the compact source row, total-bounded finite-net row, finite continuous-family rows, target-window row, folded modulus row, transport, replay, provenance, and local naming rows.

Independence witness: compactmetric, totallybounded, continuousmap, heine-cantor, uniformmodulus: none alone is bijective with UniformEquicontinuityModulus$^{\uparrow}$ because the packet jointly records a compact source, finite net, finite continuous family, common target window, folded uniform modulus, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEquicontinuityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ packet is generated from CompactMetric source data, TotallyBounded finite nets, ContinuousMap family rows, a common finite target window, a finite folded UniformModulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEquicontinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3844.1 and Definition 3844.2 seed the compact finite-net route from a finite continuous family to a shared UniformModulus consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEquicontinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable family choice, quotient equality of maps, host real trichotomy, ambient codomain completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window classification, compact finite-net exactness, uniform-modulus export, transport, replay, provenance, and local naming for BEDC.Derived.UniformEquicontinuityModulusUp.

Chapter 3845

A Concrete Naming Certificate for $\mathsf{LimitSpace}^{\uparrow}$

Following Kelley and Bishop–Bridges convergence-space and limit-space terminology, the $\mathsf{LimitSpace}^{\uparrow}$ packet records the finite interface by which a displayed Cauchy-filter or filter-base row is read against an observation schedule, a dyadic tolerance ledger, a regular rational readback, and a terminal real limit seal. It consumes the Cauchy-filter surface of chapter 333, the finite observation schedule of chapter 126, the dyadic tolerance core of chapter 291, the regular rational route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a convergence-space interface, not a quotient filter, selected limit, host equality of convergent objects, or ambient completeness theorem.

Definition 3845.1 (LimitSpace carrier)**.** *A* $\mathsf{LimitSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, S, D, R, L_0, H, C, P, N)$$

with the following displayed rows:

1. *F is a* $\mathsf{CauchyFilter}^{\uparrow}$ *or filter-base row, carrying the finite filter requests and Cauchy-stability witnesses permitted at this limit-space site;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule that records which finite windows of F are inspected;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the scheduled and tolerated observations into regular rational data;*
5. *L_0 is the* $\mathsf{Real}^{\uparrow}$ *limit-seal row reached only after F, S, D, R have been displayed;*
6. *H records componentwise* hsame *transport for the filter, schedule, tolerance, readback, limit seal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from a convergence request through F, S, D, R, L_0, H, P, N;*
8. *P is the* Pkg *provenance over* $\mathsf{LimitSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable choice, host equality of convergent filters, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge evidence.*

Lean4 ✓ `BEDC.Derived.LimitSpaceUp.LimitSpaceTasteGate single carrier alignment`

Theorem 3845.2 (LimitSpace NameCert obligations)**.** *For every accepted* $\mathsf{LimitSpace}^{\uparrow}$ *carrier*

$$L = (F, S, D, R, L_0, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Cauchy-filter or filter-base row, StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, Real limit seal, transport, replay, provenance, and local naming row;*
2. *filter-source exposure, requiring every limit-space consumer to read F before any scheduled observation, tolerance comparison, readback, or limit seal is inspected;*
3. *schedule and tolerance discipline, requiring S and D to determine the finite windows and dyadic budgets used by the readback row;*
4. *regular readback discipline, requiring R to be downstream of F, S, D and upstream of the terminal seal;*
5. *limit-seal non-escape, requiring the* $\mathsf{Real}^{\uparrow}$ *row L_0 to be read only as a seal for the displayed readback route;*
6. *structural preservation through H, C, P, N;*
7. *refusal of quotient filters, selected limits, countable choice, host equality of convergent filters, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge evidence.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 3845.1. The tuple displays exactly the Cauchy-filter or filter-base source, finite schedule, dyadic tolerance ledger, regular rational readback, real limit seal, and structural rows.

The source obligation is first. A convergence consumer cannot reach a scheduled observation or terminal seal without reading F, because no other row carries filter-source data.

The schedule and tolerance obligations are then forced by S and D. They determine the finite windows and dyadic budgets that the regular readback row may inspect, so R is downstream of the displayed observation discipline rather than a separate selected representative.

Finally L_0 is exposed only as the real seal for that readback route, while H, C, P, N preserve, replay, source, and name the same finite packet. Since the excluded principles have no carrier coordinate, they cannot become NameCert obligations. □

Theorem 3845.3 (LimitSpace Cauchy-filter consumer route)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LimitSpace}^{\uparrow}$ *carrier factors through the displayed route*

$$F \longmapsto S, D \longmapsto R \longmapsto L_0 \longmapsto H, C, P, N.$$

The consumer first reads the Cauchy-filter or filter-base row, then the StreamName schedule and DyadicRatCore tolerance ledger, then the RegSeqRat readback, and only then the Real limit seal. The route exports no quotient filter, no selected limit, no host equality of convergent filters, no countable-choice schedule, and no ambient completeness theorem.

Proof. Project the accepted carrier. The first row F is the only source for Cauchy-filter or filter-base data, so every filter-facing read starts there.

The next step is the finite observation discipline. The schedule row S names the inspected windows and the tolerance row D names the dyadic budgets attached to them; without those two rows the regular readback row has no displayed finite request to answer.

The readback and seal rows are downstream. The row R converts the scheduled observations into regular rational data, and L_0 seals the resulting route as a $\mathsf{Real}^{\uparrow}$ limit row without selecting an external limit object.

The structural rows H, C, P, N preserve and name the same route. Because the carrier contains no quotient-filter coordinate, selected-limit coordinate, host equality row, choice schedule, or ambient completeness row, every accepted consumer factors through the displayed path. □

Falsifiable prediction: An accepted $\mathsf{LimitSpace}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ limit seal without first displaying the $\mathsf{CauchyFilter}^{\uparrow}$ or filter-base row, the $\mathsf{StreamName}^{\uparrow}$ schedule, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger refutes the carrier surface.

Independence witness: cauchyfilter, streamname, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{LimitSpace}^{\uparrow}$ because this packet jointly carries a filter-source row, observation schedule, tolerance ledger, regular readback, terminal limit seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LimitSpace}^{\uparrow}$ packet is generated from a CauchyFilter or filter-base row, StreamName observation schedule, DyadicRatCore tolerance ledger, RegSeqRat readback row, Real limit seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$, seed)

Scope closed: Definition 3845.1, Definition 3845.2, and Definition 3845.3 seed the finite convergence-space interface from CauchyFilter rows through StreamName, DyadicRatCore, RegSeqRat, and Real limit-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LimitSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality of convergent filters, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-source exposure, schedule and tolerance discipline, regular readback discipline, Real limit-seal non-escape, and structural preservation for BEDC.Derived.LimitSpaceUp.

$\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ reads compactness-facing finite-window criteria through chapter 129, chapter 127, and chapter 3844 before its Arzela–Ascoli and completion consumers inspect the local rows.

Chapter 3846

A Concrete Naming Certificate for $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$

Following Kolmogorov–Riesz and Frechet compactness in constructive finite-window form, the $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet records the BEDC route by which compact metric control, total boundedness, uniform equicontinuity, completion readiness, and terminal Real readbacks are named as one compactness-facing criterion. It sits after the compact-metric surface of chapter 129, the total-bounded source of chapter 127, the uniform-equicontinuity modulus of chapter 3844, the complete-metric handoff of chapter 128, and the terminal real-name seal of chapter 38. Its compactness route also consumes bounded-set rows from chapter 1757, equicontinuous-sequence rows from chapter 4356, and finite-net compact-metric product rows from chapter 1822. The carrier names finite net and completion rows only; it does not assert open-cover compactness, choose subsequences, select subcovers, or import ambient completeness outside the displayed packet.

As a carrier dependency, the packet consumes the compactness route through chapter 129, the equicontinuity-family route through chapter 413, and the real and metric boundary routes through chapter 38 and chapter 57. These rows are part of the $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$ admission surface: a compactness consumer must see the compact metric source, family-equicontinuity ledger, Real readback seal, and metric carrier before the Frechet–Kolmogorov criterion row is exported.

Definition 3846.1 (Frechet-Kolmogorov compactness carrier)**.** *A* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, E, Q, C, S, R, H, A, P, N)$$

with the following rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the displayed metric and compactness-facing finite-net interface.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *row recording the finite ε-net budget consumed by the criterion.*
3. *E is the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *row binding a shared modulus to the same finite windows.*
4. *Q is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion boundary row, used only after the finite net and modulus rows are visible.*
5. *C is the compactness-criterion row relating the metric, total-bounded, equicontinuity, and completion rows as one finite BEDC route.*

6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger for the inspected net cells, modulus requests, and Cauchy-readback windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance comparisons.*
8. *H records componentwise* hsame *transport for all displayed source, net, modulus, completion, readback, and naming rows.*
9. *A records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, T, E, Q, C, S, R, H, A, P, N$. It has no coordinate for an open-cover compactness theorem, selected subsequence, selected subcover, quotient completion equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 3846.2 (Frechet-Kolmogorov compactness NameCert obligations)**.** *For every accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier $K = (M, T, E, Q, C, S, R, H, A, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCor}}$ *surface consists exactly of compact-metric source exposure through M; total-bounded finite-net exposure through T; uniform-modulus exposure through E; completion-boundary exposure through Q; criterion compatibility through C; finite-window and rational readback exposure through S, R; componentwise transport through H; displayed replay through A; provenance through P; and local naming through N.*

Proof. Project the accepted carrier. The coordinates are precisely the compact-metric source, total-bounded net, uniform-modulus, completion-boundary, criterion, finite-window, readback, transport, replay, provenance, and naming rows.

Read the source rows in order. The compact-metric row gives the metric-facing carrier; the total-bounded row supplies finite nets over that metric; the uniform-equicontinuity row uses the same windows; and the completion row is reached only through those displayed finite controls.

The structural rows H, A, P, N transport, replay, source, and name that same route. Since no carrier coordinate names a selected subsequence, selected subcover, open-cover compactness proof, quotient equality, or ambient completeness theorem, the listed rows exhaust the local certificate surface. □

Theorem 3846.3 (Frechet-Kolmogorov compactness total-bounded handoff)**.** *Every compactness-facing consumer of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier must read the total-bounded row T through the compact-metric source M and the uniform-modulus row E before it inspects the StreamName and RegSeqRat readback rows S, R. Thus finite-net evidence is exported as a displayed BEDC handoff, not as a choice-selected dense set or an unrecorded cover refinement.*

Proof. Begin with the compact-metric source row. It fixes the metric and the carrier surface on which the total-bounded net is meaningful.

The total-bounded row then exposes the finite net budget, while the uniform-modulus row forces all later compactness requests to use the same finite tolerance windows. Only after those rows are visible can the StreamName and RegSeqRat rows read the inspected windows and rational tolerances.

Therefore the consumer receives a finite-net handoff through M, T, E, S, R and not a selected dense subset, a selected subcover, or an unrecorded refinement outside the packet. □

Theorem 3846.4 (Frechet-Kolmogorov compactness sibling route)**.** *Every compactness-facing export of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier consumes the compactness, total-boundedness, and equicontinuity sibling surfaces before it exports compactness of the function family. The route enters through the* $\mathsf{CompactMetric}^{\uparrow}$ *source of chapter 129, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row of chapter 127, and the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *row of chapter 3844; it may then hand the assembled finite-window criterion to the Arzela–Ascoli finite-net surface of chapter 7576. The packet exports no open-cover compactness proof, selected subsequence, selected subcover, quotient completion equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier and NameCert obligations. The rows M, T, E are respectively the compact-metric source, total-bounded finite-net budget, and uniform-equicontinuity modulus, so no compactness-facing read can begin outside those sibling surfaces.

Use the total-bounded handoff. It forces finite-net evidence through the compact-metric source and the shared modulus before StreamName and RegSeqRat readbacks are inspected.

Finally use the completion boundary theorem. The row Q can be consumed only after the compactness, total-boundedness, and equicontinuity rows are visible, and the structural rows H, A, P, N preserve the same finite route for any Arzela–Ascoli or completion-facing consumer. □

Theorem 3846.5 (Frechet-Kolmogorov compactness Arzela-Ascoli dependency)**.** *Every Arzela–Ascoli-facing consumer of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier first reads the* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows already exposed by the carrier. The Arzela–Ascoli finite-net surface may consume this route, but it does not bypass the compact-metric source, total-bounded handoff, uniform-modulus row, completion boundary, finite windows, rational readback, or Real seal.*

Proof. Apply the sibling route of Definition 3846.4. It already directs compactness-facing exports through the CompactMetric, TotallyBounded, and UniformEquicontinuityModulus sibling surfaces before any Arzela–Ascoli finite-net consumer receives the assembled criterion.

Use the total-bounded handoff of Definition 3846.3. The finite-net budget is read through the compact-metric source and shared modulus before the StreamName and RegSeqRat rows expose inspected windows and rational tolerance comparisons.

Finally apply the completion boundary of Definition 3846.6. The CompleteMetric row and Real-facing seal remain downstream boundaries over the same finite data, so an Arzela–Ascoli-facing consumer cannot obtain open-cover compactness, a selected subsequence, a selected subcover, quotient completion equality, or ambient Real completeness outside the displayed route. □

Theorem 3846.6 (Frechet-Kolmogorov compactness completion boundary)**.** *The completion-facing part of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier is confined to the displayed row* Q *after the compact-metric source, total-bounded net, and uniform-modulus rows have been read. It may hand a downstream completion consumer a finite Cauchy-window boundary, but it does not claim quotient completion equality, a selected limit representative, sequential compactness, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the route through M, T, E first. These rows supply the metric source, finite-net budget, and shared modulus required before any completion boundary can be inspected.

The completion row Q is therefore a boundary row over already displayed finite data. The readback rows S, R and the structural rows H, A, P, N keep the same route visible under windowing, rational comparison, transport, replay, provenance, and naming.

Because the carrier contains no quotient-equality, selected-limit, sequential-compactness, open-cover, or ambient-completeness coordinate, a completion consumer cannot obtain any of those objects from the local packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet is generated from a CompactMetric source row, a TotallyBounded finite-net row, a UniformEquicontinuityModulus row, a CompleteMetric boundary row, StreamName finite windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3846.1, Definition 3846.2, Definition 3846.3, Definition 3846.4, Definition 3846.5, and Definition 3846.6 seed the finite compactness criterion over compact-metric, total-bounded, uniform-modulus, completion-boundary, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness, selected subsequences, selected subcovers, quotient completion equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, uniform-modulus compatibility, completion-boundary nonescape, readback stability, transport, replay, provenance, and local naming for BEDC.Derived.FrechetKolmogoro

Theorem 3846.7 (Frechet-Kolmogorov finite-window compactness handoff)**.** *Every accepted* FrechetKolmogorovCo *compactness read that is exported to a finite-net or compact-metric consumer must route through the displayed boundedness row, finite translation-modulus row, tail-cutoff row, finite-net extraction row,* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{Met}^{\uparrow}$ *distance rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FrechetKolmogorovCompactness}^{\uparrow}}$ *row before compactness is public. In carrier notation the handoff refines the local route*

$$M, T, E, Q, C, S, R, H, A, P, N$$

by requiring boundedness, translation control, tail cutoff, finite nets, Real readback, rational readback, and metric-distance rows to be visible before the consumer can use the compactness criterion. The handoff exports no ambient compactness theorem, open-cover compactness, countable choice, selected subsequence, selected subcover, quotient completion equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the local NameCert obligations of Definition 3846.2. They force the compact-metric source M, total-bounded finite-net row T, uniform-modulus row E, completion boundary Q, finite-window row S, readback row R, and structural rows H, A, P, N to be displayed before a compactness-facing consumer receives the packet.

Read the additional finite-window controls through the same route. The boundedness row is supplied by the bounded-set dependency already named in the chapter introduction, the finite translation-modulus and tail-cutoff rows are consumed as uniform-window controls, and the finite-net extraction row is read through the total-bounded handoff of Definition 3846.3. The $\mathsf{Met}^{\uparrow}$ distance rows and the $\mathsf{Real}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}$ readbacks attach the tolerance comparisons to the displayed windows.

Finally apply the completion boundary of Definition 3846.6. The structural rows only transport, replay, source, and locally name the same finite handoff, so no coordinate remains for ambient compactness, open-cover compactness, countable choice, selected subsequences, selected subcovers, quotient completion equality, or ambient Real completeness. □

The finite compactness route of $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ feeds the Arzela–Ascoli finite-modulus criterion of chapter 3568 only after the compact metric source of chapter 129, the finite-net

discipline of chapter 127, and the uniform-equicontinuity modulus of chapter 3844 have been displayed. A compact-uniform-continuity consumer therefore receives compact metric, total-bounded, uniform-modulus, completion, transport, replay, provenance, and local NameCert rows, not an open-cover compactness theorem or a selected subsequence.

Theorem 3846.8 (Frechet–Kolmogorov Arzela–Ascoli dependency route)**.** *Every accepted* FrechetKolmogorovComp *compactness read consumes the equicontinuity and finite-subfamily surface of chapter 412 before it exports compactness for function families. The Frechet–Kolmogorov packet therefore routes compact metric data, total-bounded finite nets, bounded-family rows, Arzela–Ascoli equicontinuity rows, transport, replay, provenance, and local* NameCert *naming as one displayed dependency chain.*

Proof. Project the carrier through the local Frechet–Kolmogorov route. The compact source and finite-net rows are visible before any family compactness conclusion is offered to a downstream consumer.

Now read the Arzela–Ascoli sibling. Its equicontinuity and finite-subfamily surface supplies the function-family control that the Frechet–Kolmogorov packet consumes before exporting compactness.

The structural rows only transport, replay, source, and name this chain. Hence the dependency is horizontal and finite, not an ambient compactness theorem or a selected subsequence principle. □

Theorem 3846.9 (Frechet–Kolmogorov Arzela–Ascoli compact handoff)**.** *Every accepted* FrechetKolmogorovComp *handoff to an Arzela–Ascoli consumer must first display the compact-metric finite nets of chapter 129, the total-bounded finite-net rows of chapter 127, and the equicontinuity surface of chapter 412. The exported compactness packet is therefore a finite* BHist *route through compact metric, total-boundedness, Arzela–Ascoli finite-window selection, transport, replay, provenance, and local* NameCert *rows.*

Proof. Read the accepted Frechet–Kolmogorov carrier through its compact metric source. The compact-metric row fixes the metric-facing source, while the total-bounded row supplies the finite nets that any compactness-facing consumer can inspect.

Next read the Arzela–Ascoli dependency. Its equicontinuity and finite-window rows are consumed after those compact metric and total-bounded rows, so the function-family compactness conclusion is not detached from the finite net budget.

The remaining rows only preserve the displayed route. Componentwise hsame transport, Cont replay, provenance, and local naming keep the handoff inside the same finite packet, excluding selected subsequences, open-cover compactness, and ambient completeness. □

Theorem 3846.10 (Frechet–Kolmogorov downstream Arzela–Ascoli link)**.** *Every Arzela–Ascoli finite-net consumer of an accepted* FrechetKolmogorovCompactness$^{\uparrow}$ *packet must first read the* CompactMetric$^{\uparrow}$ *source row, the* TotallyBounded$^{\uparrow}$ *finite-net row, the* UniformEquicontinuityModulus$^{\uparrow}$ *row, the* CompleteMetric$^{\uparrow}$ *completion boundary, the* StreamName$^{\uparrow}$ *observation windows, the* RegSeqRat$^{\uparrow}$ *readback rows, and the* Real$^{\uparrow}$ *seal rows carried by the displayed dependency route. The handoff exports no selected subsequence, selected subcover, open-cover compactness theorem, quotient completion equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the existing Frechet–Kolmogorov carrier through the compactness dependency route. The compact metric source and total-bounded finite-net rows are visible before any function-family compactness read is offered downstream.

Read the Arzela–Ascoli-facing rows next. The dependency route of Definition 3846.8 and the compact handoff of Definition 3846.9 require the uniform-equicontinuity modulus before the finite-net consumer receives the family surface.

Finally inspect the completion and real-readback side. The compact metric total-bounded dependency of Definition 3846.11 keeps the $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows attached to the same finite route. Since no route theorem supplies a selected subsequence, selected subcover, open-cover compactness theorem, quotient completion equality, or ambient completeness coordinate, the downstream Arzela–Ascoli link exports only the displayed finite lattice. □

Theorem 3846.11 (Compact metric total-bounded dependency)**.** *The* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *criterion consumes the compact-metric source of chapter 129 and the total-bounded finite-net budget of chapter 127 before it reads the uniform-equicontinuity row of chapter 3844 and the completion boundary of chapter 128. Thus the later StreamName, RegSeqRat, and Real readbacks remain attached to displayed finite metric and net data, rather than to an unrecorded compactness principle.*

The $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet exposes a real-sequence compactness read only after its compact-metric finite-net rows, bounded-function-family rows, and Arzela–Ascoli finite-window rows have all been displayed. Thus every downstream compactness consumer first passes through the compact source of chapter 129, the bounded family surface of chapter 3522, and the Arzela–Ascoli route of chapter 412; before real-sequence compactness readback, it also consumes the finite epsilon-net chain of chapter 8049. The Frechet–Kolmogorov carrier then contributes only the finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows that assemble those dependencies into the real-sequence compactness read.

Theorem 3846.12 (Frechet-Kolmogorov locally convex boundedness route)**.** *Every* $\mathsf{FrechetKolmogorovCompactnes}$ *consumer that reads compactness through locally convex bounded sets must factor through the finite route*

$$\mathsf{LocallyConvexSpace}^{\uparrow}, \mathsf{FrechetSpace}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{TotallyBounded}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer must expose the locally convex seminorm row of chapter 3386, the Frechet metric completion row of chapter 3495, the compact metric row of chapter 129, the total bounded row of chapter 127, and the terminal Real seal row of chapter 38 before it may treat a bounded family as Frechet-Kolmogorov compactness data.

Proof. Start with the locally convex seminorm row. It supplies the bounded-set requests that a functional-analysis consumer is allowed to ask of the packet.

The Frechet metric completion row then turns those seminorm requests into a displayed metric-completion boundary. The compact metric row and total bounded row refine that boundary into finite compactness data, so the consumer sees nets and metric windows rather than an ambient bounded-set compactness theorem.

Finally the Real seal row records the scalar readback used by the seminorm and metric estimates. Since each step is an exposed row in the displayed route, no consumer can bypass the seminorm, completion, compact metric, total bounded, or Real-seal surfaces by appealing to host boundedness or selected compactness data. □

Theorem 3846.13 (Frechet–Kolmogorov metric-completion functor route)**.** *Every* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *carrier must first read the compact-metric source of chapter 129, the total-bounded finite-net surface of chapter 127, the uniform-equicontinuity modulus of chapter 3844, the complete-metric boundary of chapter 128, the StreamName window rows of chapter 126, the RegSeqRat readback of chapter 301, and the Real seal of*

chapter 38. The route exports a displayed compactness-to-completion handoff only; it exports no quotient completion equality, selected compact limit, selected subsequence, selected subcover, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the carrier of Definition 3846.1. Its compactness-facing source rows are the compact metric row, the total-bounded finite-net row, the uniform-modulus row, and the completion boundary row.

Apply the sibling route of Definition 3846.16. It keeps the compact metric, total-bounded, uniform-equicontinuity, RegSeqRat, and Real-seal rows visible as one dependency lattice before any compactness conclusion is exported.

Finally apply the completion boundary of Definition 3846.6. A $\mathsf{MetricCompletionFunctor}^{\uparrow}$ consumer can only repackage that displayed boundary through StreamName and RegSeqRat readbacks, so quotient completion equality, selected compact limits, and ambient completeness are outside the exported surface. □

The $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ packet is read through a substantive compactness sibling lattice rather than as a detached compactness kernel: its equicontinuity branch consumes the finite-modulus Arzela–Ascoli route of chapter 412, its compact source consumes the $\mathsf{CompactMetric}^{\uparrow}$ total-bounded finite-net rows of chapter 129, and its completion handoff is routed through the MetricCompletion completion surface of chapter 1506. These references keep compact metric, total-bounded finite nets, completion, transport, replay, provenance, and local NameCert rows visible before any compactness-facing consumer reads the Frechet–Kolmogorov packet.

Theorem 3846.14 (Frechet-Kolmogorov Sobolev compact-embedding forward link)**.** *Every Sobolev-family consumer that reaches the* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *packet through a compact-embedding route must first display the* $\mathsf{Sobolev}^{\uparrow}$ *source rows, the* $\mathsf{CompactEmbedding}^{\uparrow}$ *handoff of chapter 7166, and the compact-metric and total-bounded rows of chapter 129 and chapter 127. The Frechet–Kolmogorov packet may then consume the finite StreamName, RegSeqRat, completion-boundary, transport, replay, provenance, and local NameCert rows exposed by those siblings, but it does not replace the compact-embedding handoff with selected subsequences, open-cover compactness, quotient function equality, or ambient Real completeness.*

Proof. Start from the compact-embedding side. The $\mathsf{CompactEmbedding}^{\uparrow}$ chapter exposes a finite handoff from Sobolev source windows into compact and complete target rows, so a Sobolev-family read arrives with displayed source, target, readback, transport, replay, provenance, and naming data.

Use the Frechet–Kolmogorov compactness carrier and its sibling route. The rows $M, T, E, Q, S, R, H, A, P, N$ already require compact-metric source exposure, total-bounded finite nets, completion boundary, finite-window readback, rational comparison, transport, replay, provenance, and local naming before compactness-facing data are exported.

The forward link is therefore a dependency route, not a new compactness principle. The Frechet–Kolmogorov consumer reads the Sobolev and compact-embedding siblings as displayed rows and then reuses the compact-metric and total-bounded surfaces, leaving selected subsequences, open-cover compactness, quotient function equality, and ambient Real completeness outside the packet. □

Theorem 3846.15 (Frechet–Kolmogorov hub dependency index)**.** *The hub route for* FrechetKolmogorovCompactne *reads the* $\mathsf{CompactMetric}^{\uparrow}$ *source rows, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net rows, the Arzela–Ascoli finite-modulus rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback rows, the* $\mathsf{Real}^{\uparrow}$ *terminal boundary rows, and the*

MetricCompletion$^{\uparrow}$ *sibling rows before any Frechet–Kolmogorov compactness consumer can inspect the local compactness packet. Thus the top-level input boundary records the same dependency lattice that the child certificates expose: compact metric source, total-bounded budget, finite-modulus equicontinuity, regular rational comparison, Real boundary, completion handoff, transport, replay, provenance, and local* NameCert *data.*

Proof. Read the hub as an ordered certificate boundary. Its child files first expose the name certificate spine and then the compact-metric, total-bounded, Arzela–Ascoli, locally convex, and metric-completion routes.

The rational and Real rows are read through the same sibling lattice. The RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ surfaces supply readback and terminal boundary data before the compactness consumer opens the Frechet–Kolmogorov packet.

Consequently a consumer cannot bypass the sibling rows at the hub boundary. The hub records the dependency lattice directly while leaving all theorem content in child files. □

The FrechetKolmogorovCompactness$^{\uparrow}$ dependency lattice reads compactness only after its sibling surfaces are visible: the compact metric source of chapter 129, the finite-family control supplied by chapter 412, the completion-facing transport of chapter 1506, the regular rational tolerance readback of chapter 301, the terminal real seal of chapter 38, and the tightness ledger of chapter 3795. This makes compactness a displayed route through compact metric, equicontinuity, completion, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and tightness rows, rather than an ambient subsequence selector, open-cover oracle, or quotient completion equality.

Theorem 3846.16 (Frechet–Kolmogorov compactness sibling route)**.** *The* FrechetKolmogorovCompactness$^{\uparrow}$ *packet consumes the Arzela–Ascoli finite-modulus route of chapter 3568 as its equicontinuity-facing compactness control, and it consumes the local seminorm-to-completion route recorded in Definition 3846.12 as its locally convex boundedness control. Together with the compact metric surface of chapter 129, the total-bounded surface of chapter 127, the equicontinuity radius source of chapter 3844, the compact metric total-bounded source of chapter 4055, the regular rational readback of chapter 301, and the Real seal of chapter 38, these sibling reads keep the compact metric, total-bounded, uniform-equicontinuity, locally convex seminorm, Frechet metric, RegSeqRat, and Real-seal rows visible as one finite dependency lattice rather than as an ambient function-space compactness theorem.*

Proof. Read the compact metric and total-bounded rows first. The compactness-facing consumer must pass through the displayed compact metric packet and its total-bounded control before any finite-cover or subsequence conclusion is available.

Next read the equicontinuity and local boundedness rows. The Arzela–Ascoli finite-modulus route supplies the uniform-equicontinuity control, while the locally convex boundedness route supplies the seminorm-to-completion control.

Finally read the completion, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ seal rows. Since each consumer opens these sibling rows before the compactness conclusion, the packet exports a finite dependency lattice rather than an ambient function-space compactness principle. □

Theorem 3846.17 (Frechet–Kolmogorov bounded-tail compactness route)**.** *An accepted* FrechetKolmogorovCompa *consumer may read total-bounded compactness only after it has exposed both the Arzela–Ascoli finite-modulus route and the locally convex boundedness route. The read passes through* CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *and the displayed completion boundary of Definition 3846.6; it does not use open-cover compactness, selected subsequences, or an ambient choice of compact limit points.*

Proof. Start with the sibling route of Definition 3846.16. It orders the compact metric, total-bounded, Arzela–Ascoli finite-modulus, locally convex seminorm, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows as one dependency lattice.

Next apply the locally convex boundedness route of Definition 3846.12. It supplies the bounded finite-tail control needed before the Frechet metric can be read through the completion surface.

Finally combine the total-bounded handoff of Definition 3846.3 with the completion boundary of Definition 3846.6. The handoff gives finite total-bounded data, and the boundary keeps the completion read in $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ form, so no open-cover compactness principle or selected subsequence is introduced. □

Theorem 3846.18 (Frechet–Kolmogorov sibling dependency witness)**.** *Every accepted* FrechetKolmogorovCompact *carrier witnesses a substantive dependency on the compact metric, total-bounded, and Arzela–Ascoli finite-modulus sibling chapters. The compactness criterion may be consumed only after the compact source of chapter 129, the finite-net surface of chapter 127, and the Arzela–Ascoli finite-modulus route of chapter 3568 have all been displayed together with the local carrier rows of Definition 3846.1.*

Proof. Read the compact source first. The row M in Definition 3846.1 is a $\mathsf{CompactMetric}^{\uparrow}$ source row, so the criterion has no compactness-facing read until the displayed compact metric packet is available.

Read the total-bounded surface next. The row T supplies the finite-net budget consumed by the criterion, and the theorem Definition 3846.3 forces that budget to pass through the same compact metric source before any readback rows are inspected.

Read the Arzela–Ascoli finite-modulus route as the equicontinuity-facing control. The sibling route of Definition 3846.16 binds the Arzela–Ascoli finite-modulus chapter to the same finite compactness route, so the equicontinuity row cannot be replaced by an ambient function-space compactness theorem.

Finally the local transport, replay, provenance, and naming rows H, A, P, N keep those sibling dependencies on the same packet. Thus the Frechet–Kolmogorov chapter records a dependency lattice over compact metric, total boundedness, and Arzela–Ascoli finite modulus rather than a kernel-only compactness assertion. □

Theorem 3846.19 (Frechet–Kolmogorov orphan compact metric lattice)**.** *The compactness-facing export of an accepted* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *packet is not a kernel-only assertion. Before it exposes the local compactness criterion, the consumer must read the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *control row, the Arzela–Ascoli finite-modulus route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row as sibling dependencies of the same carrier.*

Proof. Start with the dependency witness of Definition 3846.18. It already forces the compact metric, total-bounded, and Arzela–Ascoli finite-modulus rows to be displayed with the local carrier rows.

Now read the sibling route of Definition 3846.16. That route places the uniform-equicontinuity, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows in the same finite lattice rather than letting the criterion stand as an isolated kernel compactness claim.

Finally apply the total-bounded handoff of Definition 3846.3. The finite-net budget must pass through the compact metric source before readback rows are inspected, so the local compactness criterion is exposed only after the compact-metric dependency lattice is visible. □

The FrechetKolmogorovCompactness$^{\uparrow}$ packet consumes the compact-metric total-bounded route from chapter 129 and the finite extraction route of chapter 412 before it can export a compactness criterion. Thus the compact metric source, finite extraction surface, transport rows, replay rows, and local NameCert data are visible as horizontal dependencies rather than as an isolated compactness kernel. The FrechetKolmogorovCompactness$^{\uparrow}$ packet consumes the finite total-bounded and completion rows of chapter 129 before it exports compactness data to the equicontinuity and finite-subfamily surface of chapter 412. This route keeps compact metric source data, finite nets, completion readiness, Arzela–Ascoli family control, transport, replay, provenance, and local NameCert rows visible together, rather than treating Frechet–Kolmogorov compactness as an isolated compactness oracle.

Theorem 3846.20 (Frechet–Kolmogorov top sibling pointer)**.** *Every finite-window criterion exported by* FrechetKolmogorovCompactness$^{\uparrow}$ *must first display the compact metric source of chapter 129, the total-bounded finite-net surface of chapter 127, and the Arzela–Ascoli finite-modulus route of chapter 3568. The top-level route therefore exposes the sibling lattice before any Frechet–Kolmogorov compactness consumer reads the local carrier.*

Theorem 3846.21 (Frechet–Kolmogorov tightness dependency route)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *compactness read must expose the compact metric source of chapter 129, the total-bounded finite-net surface of chapter 127, the Arzela–Ascoli finite-modulus route of chapter 3568, and the locally-convex boundedness and tightness rows before the local carrier is consumed. The dependency route therefore records Frechet–Kolmogorov compactness as a finite lattice read over compact metric, total boundedness, equicontinuity-modulus, and tightness data, not as an ambient compactness oracle.*

Theorem 3846.22 (Frechet–Kolmogorov tightness route)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *compactness read must display the* CompactMetric$^{\uparrow}$ *source row, the* TotallyBounded$^{\uparrow}$ *finite-net row, the* UniformEquicontinuityModulus$^{\uparrow}$ *control row, the* CompleteMetric$^{\uparrow}$ *boundary row, the* RegSeqRat$^{\uparrow}$ *rational readback row, the* Real$^{\uparrow}$ *seal, and the local tightness and boundedness rows before it exports compactness of the family. The route is a finite* BHist/Cont/Pkg *ledger over compact metric, total-bounded, equicontinuity, completion, regular-rational, real, tightness, boundedness, transport, replay, provenance, and local* NameCert *data; it is not an ambient compactness oracle, a selected subsequence, a selected subcover, or quotient completion equality.*

Proof. Read the carrier of Definition 3846.1. Its source rows already expose CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, UniformEquicontinuityModulus$^{\uparrow}$, CompleteMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ as the visible compactness route.

Now combine the total-bounded handoff of Definition 3846.3 with the sibling route of Definition 3846.4. Those results force the finite-net, equicontinuity, and completion-facing rows to remain visible before any compactness export is read.

The tightness and boundedness rows are therefore local dependency rows in the same ledger. They do not introduce a hidden subsequence choice, a hidden subcover, or an equality in a quotient completion, because the structural rows transport and replay only the displayed finite packet. □

The compactness export of FrechetKolmogorovCompactness$^{\uparrow}$ is read through a compact-metric finite-net source together with the Arzela–Ascoli equicontinuity and tightness rows. The compact metric source fixes the finite-net budget; the Arzela–Ascoli sibling supplies the function-family tightness surface; the local replay rows then expose compactness only after both pieces have been displayed.

Theorem 3846.23 (Frechet–Kolmogorov compact-metric tightness route)**.** *Every accepted* FrechetKolmogorovCom *consumer that exports compactness for function-family windows must first read the compact-metric finite-net data of chapter 129 and the equicontinuity/tightness rows of chapter 412. The export is therefore a finite dependency route through compact metric source rows, finite-net coverage rows, Arzela–Ascoli tightness rows, transport, replay, provenance, and local* NameCert *data, not a selected subsequence, open-cover compactness theorem, quotient function-family equality, or ambient completeness principle.*

Proof. Project the Frechet–Kolmogorov carrier through its compactness-facing rows. The compact metric source supplies the finite-net data that any downstream compactness read must inspect before it can speak about a family window.

Next read the Arzela–Ascoli sibling route. Its equicontinuity and tightness rows are consumed after the compact-metric finite nets and before the local compactness export, so the function-family conclusion remains tied to displayed finite data.

Finally project the structural rows. Componentwise hsame transport, displayed Cont replay, provenance, and local naming preserve exactly the compact-metric and tightness route, leaving no coordinate for a hidden subsequence, open-cover theorem, quotient equality of families, or ambient completeness principle. □

Theorem 3846.24 (Frechet–Kolmogorov Lp-tail dependency route)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *consumer that reads compactness through Lp tails must first pass through the displayed sibling route*

CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, MetricCompletion$^{\uparrow}$, LpSpace/LpTail, BHist, hsame, Cont, Pkg, N

The exported compactness row is therefore a finite compact-metric, total-bounded, completion-facing, and Lp-tail dependency route, not an ambient compactness oracle, a selected subsequence, a selected subcover, or quotient completion equality.

Proof. Project the accepted carrier of Definition 3846.1. Its compactness-facing read already begins with the compact metric source and the finite-net budget, so any Lp-tail consumer must inherit those rows before reading a tail estimate.

Apply the total-bounded handoff of Definition 3846.3. It keeps the finite-net row visible before the StreamName, RegSeqRat, and Real readbacks are inspected.

Now use the completion boundary and the existing sibling route of Definition 3846.4. The Lp-space and Lp-tail rows can only be attached after the displayed MetricCompletion$^{\uparrow}$ handoff has been routed through the same finite BHist/Cont/Pkg ledger.

Route exhaustion gives the stated dependency chain. No row in the carrier supplies an unrecorded compactness principle, selected subsequence, selected subcover, or quotient-completion equality, so the Lp-tail compactness export is exactly the displayed sibling route. □

Theorem 3846.25 (Frechet–Kolmogorov Lp-tail localization)**.** *Every* FrechetKolmogorovCompactness$^{\uparrow}$ *compactness read that localizes through an Lp-tail estimate consumes that estimate only after the compact-metric total-bounded route, tightness route, and Lp-tail dependency route have been displayed. Equivalently, the localized read factors through Definition 3846.11, Definition 3846.22, and Definition 3846.24; it does not introduce an ambient compactness oracle, selected subsequence, selected subcover, quotient completion equality, or hidden Lp-tail selector.*

Proof. Start with the compact-metric total-bounded route. It keeps the compact metric source and finite-net surface visible before a compactness-facing consumer may inspect downstream rows.

Next use the tightness route. Tightness and boundedness remain local dependency rows in the same finite ledger, so a tail estimate cannot bypass the displayed $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, completion, readback, transport, replay, provenance, and local naming route.

Finally apply the Lp-tail dependency route. It attaches the LpSpace/LpTail row only after the compact-metric, total-bounded, and completion-facing rows have been routed through the same finite BHist/Cont/Pkg ledger. Thus Lp-tail localization is a local factorization through the existing sibling routes, not a new compactness principle or choice-selected tail object. □

The operator-tail compactness route for $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ is read only after a bounded-linear-operator source from chapter 1644, an equicontinuous-sequence surface from chapter 4356, and the existing compact-metric, total-bounded, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route have been displayed. A consumer that starts from operator-tail compactness therefore reaches the Frechet–Kolmogorov packet through bounded operator rows, equicontinuity rows, compact-metric finite nets, total-bounded coverage, regular-rational readback, and the terminal Real seal, not through an ambient compactness theorem or a selected subsequence.

Theorem 3846.26 (Frechet–Kolmogorov upstream dependency lattice)**.** *Every* $\mathsf{FrechetKolmogorovCompactness}^{\uparrow}$ *compactness read must pass through the compact metric, totally bounded,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, Arzela–Ascoli finite-modulus, and Lp-tail localization rows before any compactness conclusion is exported. The exported route is therefore a finite dependency lattice over the displayed carrier rows, not an ambient compactness oracle, selected subsequence, selected subcover, quotient completion equality, or host completeness principle.*

Proof. Start with the local carrier and the compact metric total-bounded dependency of Definition 3846.11. It forces the compact metric source and total-bounded finite-net budget to appear before later StreamName, RegSeqRat, and Real readbacks are inspected.

Next read the Arzela–Ascoli side through Definition 3846.8 and Definition 3846.9. Those routes keep finite-modulus and finite-window function-family data downstream of the compact metric and total-bounded rows.

Now apply the completion and rational-readback routes, Definition 3846.13 and Definition 3846.16. They keep the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows attached to the same displayed finite lattice.

Finally use the Lp-tail routes, Definition 3846.24 and Definition 3846.25. These place tail localization after compact-metric, total-bounded, completion-facing, and rational-readback rows. The stated lattice follows because no cited carrier row supplies a hidden compactness principle or selected limiting object. □

Chapter 3847

A Concrete Naming Certificate for $\mathsf{RationalBracketing}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalBracketing}^{\uparrow}$ packet records the finite rational lower-and-upper bracket surface used before a real-name consumer reads an approximation. It sits after the rational density surface of chapter 1409, the Archimedean bound surface of chapter 3372, the dyadic tolerance core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the displayed bracket endpoints, tolerance rows, finite observation windows, nesting ledger, and downstream regular-Cauchy handoff; it is not a trichotomy principle, quotient real equality theorem, limit selector, or ambient completeness assertion.

Definition 3847.1 (Rational bracketing carrier)**.** *A* $\mathsf{RationalBracketing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, D, S, R, E, N, H, C, P, A)$$

with the following displayed rows:

1. *L is the rational lower-endpoint row supplied through the* $\mathsf{RationalDensityReal}^{\uparrow}$ *surface.*
2. *U is the rational upper-endpoint row supplied through the same rational-density surface.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the displayed bracket width with the requested precision.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observations used to inspect L, U, and D.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row exported by the bracket window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, D, S, R have been displayed.*
7. *N is the nesting ledger recording that later bracket windows refine earlier ones by moving the lower row upward, moving the upper row downward, or preserving an endpoint already inside the requested tolerance.*
8. *H records componentwise* hsame *transport for lower endpoint, upper endpoint, dyadic tolerance, stream window, regular readback, real seal, nesting, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a bracketing request through $L, U, D, S, R, E, N, H, P, A$.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalBracketing}^{\uparrow}$, $\mathsf{RationalDensityReal}^{\uparrow}$, $\mathsf{RealArchimedeanProperty}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *A is the local* $\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $L, U, D, S, R, E, N, H, C, P, A$. It has no coordinate for trichotomy, quotient real equality, selected limits, hidden real representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RationalBracketingUp.RationalBracketingTasteGate single carrier alignment`

Theorem 3847.2 (Rational bracketing NameCert obligations)**.** *For every accepted* $\mathsf{RationalBracketing}^{\uparrow}$ *carrier $B = (L, U, D, S, R, E, N, H, C, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}$ *surface consists exactly of lower-endpoint exposure through L, upper-endpoint exposure through U, dyadic width and tolerance exactness through D, finite-window exposure through S, regular rational readback through R, terminal real-name sealing through E, nesting-ledger visibility through N, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through A.*

Proof. Project the carrier of Definition 3847.1. Its visible approximation data are exactly the endpoint rows L, U, the tolerance row D, the finite-window row S, the readback row R, and the real seal row E.

The endpoint and tolerance rows are separate. The rational-density surface supplies L and U, while the Archimedean and dyadic rows supply the bounded comparison budget used to certify that the bracket width is below the requested tolerance.

The nesting ledger is downstream of those rows. It records refinement between displayed windows, but it does not add a new real representative, a trichotomy split, or a selected limiting endpoint.

Finally H, C, P, A transport, replay, source, and name the same finite surface. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 3847.3 (Rational bracketing window nesting)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalBracketing}^{\uparrow}$ *packet factors through a finite nested-bracket route*

$$\mathsf{RationalDensityReal}^{\uparrow} \longmapsto \mathsf{RealArchimedeanProperty}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Re}$$

For any later accepted window, the consumer must read the same lower endpoint, upper endpoint, dyadic tolerance, stream observation, regular readback, real seal, nesting, transport, replay, provenance, and local naming rows before using the narrowed bracket. The route exports nested rational brackets, not trichotomy, quotient real equality, selected limits, or ambient completeness.

Proof. Begin with an accepted carrier $B = (L, U, D, S, R, E, N, H, C, P, A)$. A bracketing request first reads the rational lower and upper endpoint rows L, U together with the Archimedean bound information named in the provenance row.

Next the request reads D and S. The dyadic ledger specifies the precision budget, while the stream row records the finite observations used to inspect the current bracket.

The regular rational readback R and real seal E are available only after those rows have been displayed. A later window can be consumed only through the nesting ledger N, which compares the later endpoints with the earlier displayed endpoints under the same dyadic budget discipline.

Thus every downstream read remains inside the finite route named in the theorem. No step introduces trichotomy, quotient real equality, a selected limiting endpoint, countable choice, hidden real representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{RationalBracketing}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without first reading rational lower and upper endpoint rows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{StreamName}^{\uparrow}$ finite window, nesting evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence is outside the packet.

Independence witness: rational-density-real, real-archimedean-property, dyadicratcore, streamname, regseqrat, real: $\mathsf{RationalBracketing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rational lower and upper endpoint rows, dyadic width budgets, finite observation windows, regular readback, terminal Real sealing, nesting, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalBracketing}^{\uparrow}$ packet is generated from rational lower and upper endpoint rows, an Archimedean boundedness context, a DyadicRatCore tolerance ledger, StreamName finite windows, a RegSeqRat readback row, a RealUp seal, a nesting ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3847.1, Definition 3847.2, and Definition 3847.3 seed the finite rational-bracket route from density and Archimedean rows to regular rational readback and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalBracketing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, trichotomy, quotient real equality, selected limits, hidden real representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked lower and upper endpoint exposure, dyadic width exactness, finite-window exposure, nesting stability, regular readback, Real seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.RationalBracketingUp.

Chapter 3848

A Concrete Naming Certificate for $\mathsf{RealModulusExtraction}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy data, the $\mathsf{RealModulusExtraction}^{\uparrow}$ packet records the finite BEDC surface by which an explicit regular Cauchy modulus is exposed before a $\mathsf{Real}^{\uparrow}$ seal is read. It sits on the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names modulus extraction as displayed finite NameCert data; it does not import quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 3848.1 (RealModulusExtraction carrier)**.** *A* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radius, denominator budget, and comparison ledger for each requested precision.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, recording the finite windows inspected before a modulus answer is emitted.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *witness row, recording regular rational Cauchy data exposed by the scheduled windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *T records componentwise* hsame *transport for the dyadic tolerance, schedule, regularity, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a precision request through D, then through S, R, and finally to the seal row E.*
7. *P is the* Pkg *provenance over* $\mathsf{RealModulusExtraction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}$ *row.*

The carrier has no coordinate for an implicit analytic modulus, quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealModulusExtractionUp.RealModulusExtractionTasteGate single carrier alignment`

Theorem 3848.2 (RealModulusExtraction NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier* $M = (D, S, R, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}$ *surface consists exactly of dyadic tolerance exposure through* D*, finite schedule exposure through* S*, regular Cauchy witness exposure through* R*, terminal Real sealing through* E*, componentwise transport through* T*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier coordinates. The dyadic tolerance row D, schedule row S, regular witness row R, and seal row E are the analytic-facing rows of the packet.

The structural rows do not add analytic assumptions. Transport through T is componentwise, replay through C follows the displayed precision route, provenance through P records the sibling chapters named above, and N supplies the local NameCert row. Since no further coordinate is present, the listed rows exhaust the obligation surface. □

Theorem 3848.3 (RealModulusExtraction regular Cauchy handoff)**.** *Every regular Cauchy handoff exported by an accepted* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The extracted modulus is therefore read as dyadic tolerance data, finite schedule data, and regular rational witness data before the Real seal is available.

Proof. Begin with a precision request. The carrier first exposes the dyadic tolerance row D, so the requested radius and denominator budget are displayed before any stream window is inspected.

The schedule row S then supplies the finite windows, and the regular witness row R reads the rational Cauchy data inside those windows. Only after this displayed route has been replayed by C does the seal row E become available to a $\mathsf{Real}^{\uparrow}$ consumer.

Thus the handoff is the finite sibling route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not an implicit analytic assumption. □

Theorem 3848.4 (RealModulusExtraction Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RealModulusExtraction}^{\uparrow}$ *carrier is exhausted by the rows* D, S, R, E, T, C, P, N*. In particular, the read exports no quotient stream equality, selected representative, countable-choice schedule, host real equality, implicit analytic modulus, or ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Use the obligation surface of Definition 3848.2. A Real-facing consumer can inspect only the dyadic tolerance, finite schedule, regular witness, seal, transport, replay, provenance, and local naming rows.

The nonescape claim follows from the carrier boundary. None of the excluded objects appears as a coordinate of M, and the replay row C only preserves the displayed precision route through D, S, R, E. Hence every Real seal read remains inside the finite NameCert packet. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusExtraction}^{\uparrow}$ read exposes dyadic tolerance, finite schedule, regular Cauchy witness, Real seal, transport, replay, provenance, and local NameCert rows before any modulus answer is exported.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RealModulusExtraction}^{\uparrow}$ is not bijective to any listed sibling because it carries the dyadic tolerance row, schedule row, regular

witness row, terminal seal row, componentwise transport, displayed replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusExtraction}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName schedule row, RegSeqRat regular witness row, RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3848.1, Definition 3848.2, Definition 3848.3, and Definition 3848.4 seed the finite modulus-extraction route from regular Cauchy data to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic schedule coverage, regular Cauchy handoff, Real seal nonescape, and a Lean carrier formalization for BEDC.Derived.RealModulusExtractionUp.

Chapter 3849

A Concrete Naming Certificate for $\mathsf{CauchyStability}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy data, the $\mathsf{CauchyStability}^{\uparrow}$ packet names the finite stability route used when displayed transport changes a Cauchy presentation but not the Real-facing read. It sits on the StreamName windows of chapter 126, the dyadic tolerance core of chapter 291, the regular rational sequence route of chapter 301, the Cauchy equivalence boundary of chapter 1820, and the terminal real-name seal of chapter 38. The packet records stability of displayed Cauchy data; it is not quotient equality, selected representatives, countable choice over tails, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 3849.1 (CauchyStability carrier)**.** *A* $\mathsf{CauchyStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are two regular Cauchy source rows whose rational observations are opened only through* $\mathsf{RegSeqRat}^{\uparrow}$ *and finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *M is the shared tail-modulus comparison row relating the two source rows at each displayed precision request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the transported source observations.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row recording the regular rational readback after A, B, M, D have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached through the displayed* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *boundary.*
6. *H records componentwise* hsame *transport for the source, modulus, dyadic, regular-readback, equivalence, seal, replay, package, and naming rows.*
7. *C records displayed* Cont *replay from a Cauchy-stability request through $A, B, M, D, R, E, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyStability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient sequence equality, selected limits, hidden representatives, countable-choice tail selection, host real equality, or an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.CauchyStabilityUp.CauchyStabilityUp`
Lean4 ✓ `BEDC.Derived.CauchyStabilityUp.CauchyStabilityTasteGate single carrier alignment`

Theorem 3849.2 (CauchyStability NameCert obligations)**.** *For every accepted* $\mathsf{CauchyStability}^{\uparrow}$ *carrier* $S = (A, B, M, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular Cauchy source rows, shared tail-modulus comparison, dyadic tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *stability of the transported readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming through the rows* $A, B, M, D, R, E, H, C, P, N$*.*

Proof. Project the carrier of Definition 3849.1. The only source data are the rows A and B, and the only comparison data between them are the shared tail-modulus row M and dyadic tolerance ledger D.

The regular-rational readback R is downstream from those rows, so stability is read as a finite $\mathsf{RegSeqRat}^{\uparrow}$ handoff rather than as equality of host sequences. The displayed $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ boundary is consumed before the terminal seal E can be read.

Transport and replay use H and C componentwise. The package and naming rows P, N source the same finite route, and the excluded quotient, selected-limit, hidden-representative, choice, host-equality, and completeness data have no carrier coordinate. □

Theorem 3849.3 (CauchyStability Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyStability}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the terminal seal E *is consumed. Thus displayed transport may change the finite Cauchy presentation only through the stored* $A, B, M, D, R, H, C, P, N$ *rows, and the Real-facing boundary receives no quotient equality, selected representative, hidden tail family, countable-choice selector, host real equality, or ambient completeness coordinate.*

Proof. Start with a Real-facing request. The carrier first exposes the finite StreamName windows attached to A and B, together with the shared modulus comparison M.

The dyadic ledger D translates those windows into displayed tolerance observations. The regular-rational handoff R then repacks the inspected observations as $\mathsf{RegSeqRat}^{\uparrow}$ data.

Only after this readback does the packet enter the displayed $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ boundary and then the seal E. The rows H, C, P, N transport, replay, source, and name that same route, leaving no hidden Real-facing coordinate beyond the listed sibling surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyStability}^{\uparrow}$ packet is generated from two regular Cauchy source rows, a shared tail-modulus comparison row, dyadic tolerance rows, a RegSeqRat handoff, a CauchyEquivalenceSetoid boundary, a RealUp seal, displayed hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$, seed)

Scope closed: Definition 3849.1, Definition 3849.2, and Definition 3849.3 seed the displayed stability route for Cauchy data under transport before the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyStability}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of Cauchy presentations, selected representatives, hidden tails, countable choice over moduli, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-modulus comparison, RegSeqRat stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyStabilityUp.

Chapter 3850

A Concrete Naming Certificate for $\mathsf{CauchySequenceTailFilter}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki–Kelley filterbase terminology, the $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ packet records the finite route by which a Bishop Cauchy sequence supplies tail-filter data for completion-facing consumers. It sits between the sequence-side evidence of $\mathsf{BishopCauchySequence}^{\uparrow}$, the filter carrier of chapter 333, the finite stream schedule of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The packet names tail neighborhoods generated by displayed sequence windows; it does not select a limit, quotient streams, choose subsequences, decide trichotomy, or assert ambient real completeness.

Definition 3850.1 (Cauchy sequence tail-filter carrier)**.** *A* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, B, F, C, D, Q, R, E, H, K, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule whose finite windows are the only sequence observations visible to the carrier.*
2. *B is the* $\mathsf{BishopCauchySequence}^{\uparrow}$ *row certifying that the displayed sequence windows satisfy the Bishop Cauchy modulus requests read by the packet.*
3. *F is the Frechet-tail filterbase row generated by tails of S: a basic tail is named by a displayed index threshold together with the windows beyond that threshold.*
4. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility row saying that every admitted tail-basic row is a Cauchy-filter neighborhood request over the same displayed windows and thresholds.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording dyadic scales, rational comparisons, and exhaustion data used to pass from sequence tails to filterbase requests.*
6. *Q is the finite tail-query ledger pairing each tolerance request with the stream windows and tail threshold used by B, F, C, D.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for consumers that read the same tail evidence as regular rational names.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, B, F, C, D, Q, R have been displayed.*

9. *H stores componentwise* hsame *transport for the stream windows, Bishop Cauchy row, tail-filterbase row, Cauchy-filter compatibility row, dyadic tolerance ledger, tail-query ledger, regular handoff, Real seal, continuation replay, provenance, and local name.*
10. *K stores displayed* Cont *replay from each tolerance request through the stream window, tail threshold, filterbase row, Cauchy-filter compatibility row, regular handoff, and seal row.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BishopCauchySequence}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}$ *row.*

The classifier accepts a packet only when every tail-basic row in F is generated from the displayed stream schedule S, every Cauchy-filter compatibility read in C uses the Bishop Cauchy evidence B and dyadic ledger D, and every completion-facing read factors through Q, R, E, H, K, P, N. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceTailFilterUp.CauchySequenceTailFilterTasteGate single carrier alignment`

Theorem 3850.2 (Cauchy sequence tail-filter NameCert obligations)**.** *For every accepted* CauchySequenceTailFilter *carrier $T = (S, B, F, C, D, Q, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}$ *obligations are exactly carrier admission, finite stream-window classification, Bishop Cauchy tail coverage, Frechet-tail filterbase generation,* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility, dyadic tolerance-ledger exhaustion,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal nonescape,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local naming row. These obligations are discharged by the displayed route*

$$S \longmapsto B \longmapsto F \longmapsto C \longmapsto D \longmapsto Q \longmapsto R \longmapsto E$$

together with H, K, P, N.

The obligation surface exports no quotient stream, selected limit, choice principle, trichotomy row, open-cover compactness object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchySequenceTailFilterUp.CauchySequenceTailFilterCarrier namecert obligations`

Proof. Project the carrier of Definition 3850.1. The only sequence observations are the finite $\mathsf{StreamName}^{\uparrow}$ windows in S, and the only Cauchy evidence for those windows is the Bishop row B.

Read the tail-filter rows next. The Frechet-tail row F names basic tails by displayed thresholds, while the compatibility row C checks those basic tails against the $\mathsf{CauchyFilter}^{\uparrow}$ surface. The dyadic ledger D and tail-query ledger Q account for the tolerance requests used in that check.

The regular and real-facing rows are downstream. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R and $\mathsf{Real}^{\uparrow}$ seal E are available only after the stream, Bishop, tail-filterbase, Cauchy-filter, dyadic, and query rows have been displayed.

Finally apply the structural rows. Componentwise transport H, continuation replay K, provenance P, and the local name N preserve the same finite route, and the carrier definition supplies no coordinate for quotient streams, selected limits, choice, trichotomy, open-cover compactness, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ completion-facing read factors through the displayed $\mathsf{StreamName}^{\uparrow}$ windows, Bishop Cauchy row, Frechet-tail filterbase row,

$\mathsf{CauchyFilter}^{\uparrow}$ compatibility row, dyadic tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and $\mathsf{Real}^{\uparrow}$ seal before any tail consumer is allowed to read the packet.

Independence witness: cauchyfilter, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries sequence-window evidence, Bishop Cauchy tail coverage, tail-filterbase generation, filter compatibility, dyadic tolerance accounting, regular-rational handoff, real-seal routing, transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ packet is generated from finite stream windows, a Bishop Cauchy sequence row, a Frechet-tail filterbase row, a CauchyFilter compatibility row, a dyadic tolerance ledger, a tail-query ledger, a RegSeqRat handoff, a Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3850.1 and Definition 3850.2 seed the finite sequence-to-tail-filter carrier from StreamName windows through Bishop Cauchy evidence, tail filterbase rows, CauchyFilter compatibility, dyadic tolerance accounting, RegSeqRat handoff, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, choice principles, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, tail-filterbase generation, CauchyFilter compatibility, dyadic ledger exhaustion, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local NameCert rows for BEDC.Derived.CauchySequenceTailFilterUp.

Chapter 3851

A Concrete Naming Certificate for $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Bourbaki–Kelley filter terminology, the CauchySequenceTailFilte packet records the finite bridge by which sequence-tail filters are read as Cauchy-filter completion data before any quotient completion point or selected limit is available. It sits after the sequence-tail route of chapter 3850, the completion-facing carrier of chapter 1569, and the saturated filter surface of chapter 333. The chapter names only the displayed finite handoff from tail-filter evidence to completion readback; it does not assert ambient real completeness, quotient-filter equality, selected representatives, countable choice, trichotomy, or host equality of completed points.

Definition 3851.1 (Cauchy sequence tail-filter completion carrier)**.** *A* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (T, F, C, D, W, R, E, H, K, P, N)$$

with the following visible rows:

1. *T is the* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ *row naming the sequence-generated tail-filter data from chapter 3850.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row that reads the same tail-filter neighborhoods as saturated Cauchy-filter requests.*
3. *C is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row whose completion-facing consumer is allowed to inspect only the displayed filter route.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the tail thresholds with completion precision requests.*
5. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows exposed by the tail-filter row before the completion consumer reads R or E.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows, dyadic tolerances, and filter requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after T, F, C, D, W, R have been displayed.*
8. *H stores componentwise* hsame *transport for the tail-filter, Cauchy-filter, completion, dyadic, window, readback, seal, replay, provenance, and local naming rows.*

9. *K stores displayed* Cont *replay from a sequence-tail request through Cauchy-filter compatibility, completion handoff, finite windows, dyadic tolerance, regular readback, and the Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceTailFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}$ *row.*

The classifier accepts X only when every completion-facing read first opens the sequence-tail row T, then the Cauchy-filter row F, then the completion row C, and only then the dyadic, window, readback, and Real-seal rows D, W, R, E. It has no coordinate for quotient filters, selected limits, countable-choice selectors, host real equality, trichotomy, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchySequenceTailFilterCompletionUp.CauchySequenceTailFilterCompletionTasteGate`
`single carrier alignment`

Theorem 3851.2 (Cauchy sequence tail-filter completion NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *carrier $X = (T, F, C, D, W, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}$ *obligations are exactly carrier admission, sequence-tail source admission,* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff, dyadic tolerance exactness, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local naming row. These obligations are discharged by the displayed route*

$$T \longmapsto F \longmapsto C \longmapsto D, W \longmapsto R \longmapsto E$$

together with H, K, P, N.

The obligation surface exports no quotient filter, selected limit, host equality, countable-choice selector, trichotomy row, open-cover compactness object, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or detached completion coordinate.*

Proof. Project the carrier of Definition 3851.1. The public rows are exactly $T, F, C, D, W, R, E, H, K, P, N$, so carrier admission exposes a sequence-tail source, a Cauchy-filter compatibility row, a completion handoff, a finite tolerance and window route, a regular readback, a Real seal, and the structural rows.

Read the source and filter rows first. The row T supplies the finite tail-filter data generated from sequence windows, while F reads that data as the Cauchy-filter surface used by completion-facing consumers. The row C is downstream of those two rows and does not replace them by a quotient filter or selected limit.

Next inspect the completion readback route. The dyadic ledger D and window row W are the only precision and observation rows available before the regular readback R and the terminal seal E are consumed.

Finally apply the structural rows. Transport H, replay K, provenance P, and the local name N preserve the same route, and the carrier definition supplies no coordinate for quotient filters, selected limits, choice, trichotomy, open-cover compactness, host equality, or ambient completeness. □

Theorem 3851.3 (Cauchy sequence tail-filter completion Real handoff)**.** *Let $X = (T, F, C, D, W, R, E, H, K, P, N)$ be an accepted* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *packet. Every Real-facing or completion-facing consumer that reads the terminal seal factors through*

$$T, F, C, D, W, R \longmapsto E \longmapsto H, K, P, N.$$

Thus the $\mathsf{Real}^{\uparrow}$ *seal is available only after the sequence-tail filter, Cauchy-filter compatibility, Cauchy-filter completion row, dyadic tolerance ledger, finite stream windows, and regular rational readback have been displayed.*

Proof. Start with a consumer of the terminal seal. Carrier projection gives access to E only as the seal row of the accepted packet X.

Replay the continuation row K. The request consumes the sequence-tail source T, the Cauchy-filter row F, the completion row C, the dyadic tolerance ledger D, the finite windows W, and the regular readback R before E is available.

The structural rows preserve this order. Transport through H, provenance through P, and naming through N record the same route, so the consumer has no available coordinate for a selected completion point, quotient-filter equality, host real equality, choice, or ambient completeness. □

Theorem 3851.4 (Cauchy sequence tail-filter completion filterbase nonescape)**.** *Let* $X = (T, F, C, D, W, R, E, H, K$ *be an accepted* $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ *packet. No accepted completion read can bypass the displayed sequence-tail filter row* T *or the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *when it reaches the completion row* C*, the regular readback* R*, or the seal row* E*.*

Consequently every filterbase-dependent completion read is confined to the finite route

$$T_{\mathsf{CauchySequenceTailFilter}^{\uparrow}}, F_{\mathsf{CauchyFilter}^{\uparrow}} \longmapsto C_{\mathsf{CauchyFilterCompletion}^{\uparrow}} \longmapsto D, W, R, E, H, K, P, N.$$

Detached filterbases, quotient filters, selected limits, free tolerance parameters, countable-choice selectors, and ambient completeness principles are outside the accepted packet.

Proof. Inspect the carrier of Definition 3851.1. The only source for filterbase-dependent data is T, and the only Cauchy-filter compatibility row is F.

Apply the obligation surface of Definition 3851.2. It requires the completion handoff C to read after T and F, then requires D, W, R, E to remain downstream of that handoff.

The Real handoff of Definition 3851.3 keeps terminal consumers on the same route. Since H, K, P, N only transport, replay, source, and name the displayed rows, no detached filterbase or excluded completion object can be introduced later. □

Falsifiable prediction: Every accepted $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ completion read opens the displayed $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ row, $\mathsf{CauchyFilter}^{\uparrow}$ row, $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row, dyadic tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal before any consumer may inspect the packet as completion data.

Independence witness: cauchy-sequence-tail-filter, cauchyfilter, cauchyfiltercompletion, dyadicratcore, streamname, regseqrat, real: $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries sequence-tail source data, Cauchy-filter compatibility, completion handoff, dyadic tolerance accounting, finite stream windows, regular readback, Real-seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}$ packet is generated from a CauchySequenceTailFilter row, a CauchyFilter row, a CauchyFilterCompletion row, dyadic tolerance data, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3851.1, Definition 3851.2, Definition 3851.3, and Definition 3851.4 seed the finite sequence-tail-filter bridge into CauchyFilterCompletion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceTailFilterCompletion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchySequenceTailFilterCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, selected completion representatives, countable choice, trichotomy, open-cover compactness, host equality, ambient Real$^{\uparrow}$ completeness, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, sequence-tail source admission, CauchyFilter compatibility, CauchyFilterCompletion handoff, dyadic tolerance exactness, StreamName window exposure, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local NameCert rows for BEDC.Derived.CauchySequenceTailFilterCompletion

Chapter 3852

A Concrete Naming Certificate for $\mathsf{LocalizedCauchyRate}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocalizedCauchyRate}^{\uparrow}$ packet records localized convergence-rate evidence as finite BEDC rows before a Real or Completion consumer reads a regular Cauchy name. It sits over the tail-bound route of chapter 2071, the regular tail-bound route of chapter 3743, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the oscillation ledger of chapter 448. The packet is a localized rate ledger; it does not choose quotient stream representatives, selected limits, trichotomy decisions, ambient completeness, or global convergence-speed functions.

Definition 3852.1 (Localized Cauchy rate carrier)**.** *A* $\mathsf{LocalizedCauchyRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, D, T, R, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected rational stream segment.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the local dyadic budgets used by the packet.*
3. *T is the* $\mathsf{CauchyTailBound}^{\uparrow}$ *row displaying the tail-bound witness for the requested local tolerance window.*
4. *R is the* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *row recording the regular tail-bound strengthening consumed by regular Cauchy readers.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, tying the window and tail-bound rows to regular rational sequence data.*
6. *Q is the* $\mathsf{CauchyOscillation}^{\uparrow}$ *row, recording the local oscillation bound checked against the same window and dyadic budget.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after W, D, T, R, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for windows, tolerances, tail bounds, regular readback, oscillation, real seal, replay, provenance, and naming.*
9. *C records displayed* Cont *replay from a localized rate request through $W, D, T, R, S, Q, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LocalizedCauchyRate}^{\uparrow}$, $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{RegularCauchyTailBound}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyOscillation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, D, T, R, S, Q, E, H, C, P, N$. The carrier has no coordinate for a selected rate outside T and R, quotient stream equality, an external limit selector, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocalizedCauchyRateUp.LocalizedCauchyRateTasteGate single carrier alignment`

Theorem 3852.2 (Localized Cauchy rate NameCert obligations)**.** *For every accepted* $\mathsf{LocalizedCauchyRate}^{\uparrow}$ *carrier $L = (W, D, T, R, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $W, D, T, R, S, Q, E, H, C, P, N$;*
2. *window localization: every rate read starts with the finite* $\mathsf{StreamName}^{\uparrow}$ *row W and the dyadic tolerance ledger D;*
3. *tail-bound visibility: the* $\mathsf{CauchyTailBound}^{\uparrow}$ *row T and* $\mathsf{RegularCauchyTailBound}^{\uparrow}$ *row R are displayed before any regular rational readback is consumed;*
4. *regular readback: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row S reads the same window, dyadic budget, and tail-bound rows;*
5. *oscillation compatibility: the* $\mathsf{CauchyOscillation}^{\uparrow}$ *row Q checks the local oscillation bound against the same budget and tail window;*
6. *real handoff: the* $\mathsf{Real}^{\uparrow}$ *seal E is reachable only after W, D, T, R, S, Q have been displayed;*
7. *ledger nonescape: H, C, P, N export no selected rate, quotient representative, host limit, trichotomy decision, countable-choice schedule, ambient completeness theorem, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 3852.1. The accepted rows are exactly $W, D, T, R, S, Q, E, H, C, P, N$, so carrier admission exposes only finite windows, dyadic budgets, tail bounds, regular readback, oscillation, a real seal, and structural rows.

The localized rate route begins with W and D. These rows name the finite stream segment and the tolerance budget, so the tail-bound rows cannot be read as global convergence-speed functions.

Next read T and R. The ordinary Cauchy tail-bound row supplies the requested local tail witness, while the regular tail-bound row records the strengthening needed by a regular Cauchy consumer. The readback row S consumes those same displayed rows, and Q checks the matching oscillation bound.

Finally E, H, C, P, N seal and transport the route. Since none of these rows adds a selector, quotient representative, trichotomy decision, countable-choice schedule, ambient completeness theorem, or bridge certificate, the listed obligations exhaust the local surface. □

Theorem 3852.3 (Localized Cauchy rate Real-completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LocalizedCauchyRate}^{\uparrow}$ *packet factors through*

$$W \longmapsto D \longmapsto T \longmapsto R \longmapsto S \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

In particular, a consumer preserving the $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{RegularCauchyTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *routes must read the localized tail-bound ledger before it can treat the stream as a real-facing regular Cauchy name.*

Proof. Begin with a Real-facing request. The finite stream row W and dyadic ledger D determine the local tolerance window that the request may inspect.

The tail-bound handoff then passes through T and R. The first row gives the Cauchy tail witness at the displayed tolerance, and the second row exposes the regular tail-bound strengthening required by regular rational readback.

The readback and oscillation rows are downstream of the same data. The row S reads the regular rational sequence through the displayed window and tail-bound rows, while Q confirms that the local oscillation bound uses the same budget.

Only after those rows have been displayed may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so any Real or Completion consumer bypassing T and R lies outside the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{LocalizedCauchyRate}^{\uparrow}$ read is refuted if a Real or Completion consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ seal without displaying StreamName windows, DyadicRatCore budgets, CauchyTailBound and RegularCauchyTailBound rows, RegSeqRat readback, CauchyOscillation compatibility, transport, replay, provenance, and local naming.

Independence witness: cauchy-tail-bound, regular-cauchy-tail-bound, dyadicratcore, streamname, regseqrat, real, cauchy-oscillation: none alone is bijective with $\mathsf{LocalizedCauchyRate}^{\uparrow}$ because the packet jointly records localized windows, dyadic budgets, ordinary and regular tail-bound rows, regular rational readback, oscillation compatibility, terminal Real sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalizedCauchyRate}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore budgets, CauchyTailBound and RegularCauchyTailBound rows, RegSeqRat readback, CauchyOscillation compatibility, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3852.1, Definition 3852.2, and Definition 3852.3 seed the finite localized convergence-rate ledger consumed by Real and Completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalizedCauchyRate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected rates, quotient stream representatives, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked window localization, tail-bound visibility, regular readback, oscillation compatibility, Real handoff, ledger nonescape, and local naming for BEDC.Derived.LocalizedCauchyRateUp.

Chapter 3853

A Concrete Naming Certificate for $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$

Following Bishop–Bridges compact metric continuity, the $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ packet records the finite route from compact source data and pointwise continuity rows through finite oscillation partitions to a displayed uniform-modulus output. It sits over the compact-metric source of chapter 129, the metric carrier of chapter 57, the continuous-map surface of chapter 130, the finite oscillation partition row of chapter 3800, the oscillation modulus boundary of chapter 2224, and the uniform-modulus consumer of chapter 369. The packet names a compact-uniform handoff; it does not select an external modulus, identify host functions, choose points from a cover, assert quotient equality, or import ambient compactness.

Definition 3853.1 (Finite oscillation uniform-modulus carrier)**.** *A* $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, A, B, O, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, carrying the compact-metric carrier, finite cover data, and metric distance rows inspected by the packet.*
2. *M is the metric compatibility row tying the compact source to the distance comparisons used by oscillation estimates.*
3. *A is the continuous-map pointwise row, exposing source, target, graph, and local continuity evidence for the displayed map.*
4. *B is the* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *row, listing the finite partition cells and their source-side cover witnesses.*
5. *O is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row, recording the oscillation bound attached to each partition cell and requested tolerance.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row obtained by folding the finite oscillation bounds into one tolerance-only precision ledger.*
7. *H records componentwise* hsame *transport for compact, metric, continuous-map, partition, oscillation, uniform-modulus, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a compact-uniform-continuity request through $K, M, A, B, O, U, H, P, N$.*

9. *P is the* Pkg *provenance over* FiniteOscillationUniformModulus$^{\uparrow}$, CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteOscillationPartition$^{\uparrow}$, OscillationModulus$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{FiniteOscillationUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, A, B, O, U, H, C, P, N$. The carrier has no coordinate for an external modulus selector, host function equality, point choice from a cover, quotient representation, ambient compactness theorem, or bridge certificate.

`single carrier alignment`

Theorem 3853.2 (Finite oscillation uniform-modulus NameCert obligations)**.** *For every accepted* FiniteOscillationUniformModulus$^{\uparrow}$ *carrier $F = (K, M, A, B, O, U, H, C, P, N)$, the local* NameCert$_{\text{FiniteOscillationUniformM}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $K, M, A, B, O, U, H, C, P, N$;*
2. *compact source exposure: K and M display the compact-metric source and distance comparisons used by the packet;*
3. *continuity visibility: the pointwise continuous-map row A is read before any oscillation cell is accepted;*
4. *finite partition exactness: B lists the finite oscillation partition cells and their cover witnesses;*
5. *oscillation-bound compatibility: O attaches each partition cell to the requested tolerance through the same metric and continuity rows;*
6. *uniform-modulus output: U is the only exported tolerance-only precision ledger and is obtained after B and O are displayed;*
7. *ledger nonescape: H, C, P, N export no external modulus selector, host function equality, point choice from a cover, quotient representation, ambient compactness theorem, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FiniteOscillationUniformModulusUp.FiniteOscillationUniformModulusNameCertObligatio`

Proof. Project the carrier in Definition 3853.1. Its accepted rows are exactly $K, M, A, B, O, U, H, C, P, N$, so carrier admission exposes compact source data, metric comparisons, continuous-map evidence, finite partition rows, oscillation bounds, a uniform-modulus output, and structural rows only.

The compact and continuity clauses are read first. The compact source row K and metric row M supply the finite cover and distance comparisons, while A supplies the pointwise continuity evidence used on each displayed cell.

The partition route then reads B and O. The finite oscillation partition row lists the cells, and the oscillation-modulus row binds each cell to the requested tolerance through the same compact, metric, and continuity data.

Finally the output row U records the uniform-modulus ledger obtained from the finite oscillation bounds. The transport, replay, provenance, and naming rows preserve that displayed route and contain no coordinate for the excluded selector, host equality, point choice, quotient representation, ambient compactness theorem, or bridge certificate. □

Lean4 ✓ `BEDC.Derived.FiniteOscillationUniformModulusUp.FiniteOscillationUniformModulusCarrier`
`namecert obligations`

Theorem 3853.3 (Finite oscillation compact-uniform handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ *packet factors through*

$$K \longmapsto M \longmapsto A \longmapsto B \longmapsto O \longmapsto U \longmapsto H, C, P, N.$$

In particular, a consumer preserving compact-metric, continuous-map, finite oscillation partition, oscillation modulus, and uniform-modulus provenance must read the finite oscillation partition and its oscillation bounds before exporting the tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ *row.*

Proof. Begin with a compact-uniform request. The rows K and M display the compact source and metric comparisons, so the request is tied to finite source-side data rather than to an ambient compactness theorem.

The continuous-map row A supplies the pointwise continuity evidence used on partition cells. After that, B displays the finite oscillation partition, including the cells and cover witnesses read by the source-side request.

The oscillation row O binds those cells to the requested tolerance. Since O is downstream of K, M, A, B, it cannot be read as a detached modulus or host-level continuity theorem.

The uniform-modulus row U is then the only exported tolerance-only precision ledger. The structural rows H, C, P, N transport and name the same finite route, so any compact-uniform consumer reaching U without B and O bypasses the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying compact source rows, metric comparisons, continuous-map evidence, finite oscillation partitions, oscillation-modulus bounds, transport, replay, provenance, and local naming.

Independence witness: compactmetric, metricspace, continuousmap, finite-oscillation-partition, oscillation-modulus, uniformmodulus: none alone is bijective with $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ because the packet jointly carries compact source data, metric comparisons, pointwise continuity rows, finite partition cells, oscillation bounds, uniform-modulus output, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOscillationUniformModulus}^{\uparrow}$ packet is generated from compact-metric source rows, metric comparison rows, ContinuousMap pointwise rows, finite oscillation partition rows, oscillation-modulus bounds, a UniformModulus output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3853.1, Definition 3853.2, and Definition 3853.3 seed the finite oscillation route from compact local control to a uniform-modulus output.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOscillationUniformModulus}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FiniteOscillationUniformModulusUp.FiniteOscillationUniformModulusCarrier\_namecert\_obl`

Bridge status: none

Not claimed: This chapter does not close external modulus selectors, host function equality, point choice from covers, quotient representations, ambient compactness, or bridge checking.

Upgrade path: Obligation closure requires checked compact source exposure, continuity visibility, finite partition exactness, oscillation-bound compatibility, uniform-modulus output, ledger nonescape, and local naming for BEDC.Derived.FiniteOscillationUnifo

Chapter 3854

A Concrete Naming Certificate for $\mathsf{FubiniFiniteRectangle}^{\uparrow}$

Following Fubini and Bishop-style finite integration, the $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ packet records a bounded finite-product rectangle computation as BEDC data before either iterated-integral route may be read. It sits over the measure row of chapter 92, the integral row of chapter 123, the product rows of chapter 2000, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the Real seal of chapter 38. The chapter names the finite rectangle surface only; it does not assert sigma-finite Fubini, Tonelli, quotient function equality, selected representatives, countable choice, or ambient measure completeness.

Definition 3854.1 (Fubini finite rectangle carrier)**.** *A* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, M, I, P, A, B, D, S, E, H, C, Q, N)$$

with the following displayed rows:

1. *R is the finite product-rectangle row, listing the source rectangles and their cell tags.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *row assigning the displayed finite measure data used by the cells of R.*
3. *I is the* $\mathsf{Integral}^{\uparrow}$ *row for cellwise finite integration over the same rectangle table.*
4. *P is the* ***??*** *row tying the two coordinate directions to the same finite rectangle cells.*
5. *A is the first-then-second iterated-integral route, reading the first coordinate cells before folding the second coordinate.*
6. *B is the second-then-first iterated-integral route, reading the second coordinate cells before folding the first coordinate.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the common finite error budget used by both iterated routes.*
8. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the displayed finite sums.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, M, I, P, A, B, D, S have been displayed.*
10. *H records componentwise* hsame *transport for rectangle cells, measure rows, integral rows, product rows, both iterated routes, tolerance ledgers, rational readback, Real seal, replay, provenance, and naming.*

11. *C records displayed* Cont *replay from a finite-rectangle integration request through* $R, M, I, P, A, B, D, S, E, H, Q,$
12. *Q is the* Pkg *provenance over* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, *??*, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, I, P, A, B, D, S, E, H, C, Q, N$. It has no coordinate for quotient function equality, selected representatives, countable choice, ambient completion of a measure space, or an infinite summability principle.

Lean4 ✓ `BEDC.Derived.FubiniFiniteRectangleUp.FubiniFiniteRectangleTasteGate single carrier alignment`

Theorem 3854.2 (Fubini finite rectangle NameCert obligations)**.** *For every accepted* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *carrier $F = (R, M, I, P, A, B, D, S, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $R, M, I, P, A, B, D, S, E, H, C, Q, N$;*
2. *rectangle visibility: R and P display the finite product cells before either iterated route is read;*
3. *measure and integral compatibility: M and I attach measure and integral rows to the same finite cell table;*
4. *route symmetry: A and B read the same cells in opposite coordinate order and share the tolerance row D;*
5. *rational readback: S reads the finite sums produced by both routes through regular rational data;*
6. *Real sealing: E is reached only after both iterated routes, the dyadic ledger, and regular rational readback have been displayed;*
7. *ledger nonescape: H, C, Q, N export no sigma-finite theorem, Tonelli theorem, quotient function equality, selected representative, countable-choice schedule, ambient measure completeness, or bridge certificate.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.FubiniFiniteRectangleUp.FubiniFiniteRectangleNamecertObligations`

Proof. Project the carrier of Definition 3854.1. The accepted rows are exactly $R, M, I, P, A, B, D, S, E, H, C, Q, N$, so carrier admission exposes a finite rectangle table, its measure and integral rows, two displayed iterated routes, a dyadic ledger, rational readback, a Real seal, and structural rows.

The finite rectangle route starts with R and P. These rows fix the cell table and the coordinate-product reading, so neither iterated route may introduce a new domain or a hidden product object.

Next read M, I, A, B, D, S. The measure and integral rows are attached to the same finite cells. The two iterated routes fold those cells in opposite coordinate order, while the dyadic ledger and regular rational readback force both routes to use the same finite tolerance and sum data.

Finally E, H, C, Q, N seal and transport the same displayed computation. Since none of these rows adds sigma-finite measure structure, Tonelli data, quotient function equality, selected representatives, countable choice, ambient measure completeness, or a bridge certificate, the listed obligations exhaust the local surface. □

Theorem 3854.3 (Fubini finite rectangle iterated-integral nonescape)**.** *Every iterated-integral consumer of an accepted* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *packet factors through*

$$R \longmapsto M \longmapsto I \longmapsto P \longmapsto A, B \longmapsto D \longmapsto S \longmapsto E \longmapsto H, C, Q, N.$$

Thus a consumer may cite equality of the two finite rectangle reads only through the displayed cells, measure rows, integral rows, product row, both iterated routes, dyadic tolerance ledger, regular rational readback, Real seal, hsame*,* Cont*,* Pkg*, and local* NameCert *rows. It obtains no sigma-finite Fubini theorem, Tonelli theorem, quotient function equality, selected representative, countable-choice schedule, or ambient measure-completeness principle.*

Proof. Begin with an iterated-integral request. The finite rectangle row R and product row P identify the only cells and coordinate directions available to the request.

The measure and integral rows M and I then bind the computation to that same table. The first-then-second route A and second-then-first route B are therefore two readings of the displayed finite cell data rather than appeals to an ambient product-measure theorem.

The dyadic ledger D and regular rational readback S force both route totals through the same finite tolerance and sum surface. Only after those rows have been displayed may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed.

The structural rows H, C, Q, N transport and name the same finite route. Since the packet contains no row for sigma-finite Fubini, Tonelli, quotient function equality, selected representatives, countable choice, or ambient measure completeness, no iterated-integral consumer can obtain such data from the accepted carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}$.

Constructive story: A $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ packet is generated from finite product rectangle cells, displayed Measure and Integral rows, a Product row, first-then-second and second-then-first iterated routes, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 3854.1, Definition 3854.2, and Definition 3854.3 seed the finite rectangle iterated-integral packet over displayed product cells and common tolerance readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FubiniFiniteRectangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-finite Fubini, Tonelli, quotient function equality, selected representatives, countable choice, ambient measure completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked rectangle visibility, measure-integral compatibility, route symmetry, regular rational readback, Real sealing, ledger nonescape, and local naming for BEDC.Derived.FubiniFiniteRectangleUp.

Chapter 3855

A Concrete Naming Certificate for $\mathsf{TonelliFiniteRectangle}^{\uparrow}$

Following Tonelli and Fubini on nonnegative iterated integration, the $\mathsf{TonelliFiniteRectangle}^{\uparrow}$ packet records the finite nonnegative rectangle-sum surface that may be read before any sigma-additive or completed measure theorem is available. It is a conservative companion to chapter 3854; it also sits beside the finite summation surfaces of chapter 1615 and chapter 1880, the measure and integral rows of chapter 92 and chapter 123, and the terminal real-name seal of chapter 38. The packet names finite nonnegative rectangular data only; it does not assert countable Tonelli, sigma-additivity, countable choice, measure completion, or an ambient product-measure theorem.

Definition 3855.1 (Tonelli finite rectangle carrier)**.** *A* $\mathsf{TonelliFiniteRectangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, C, A, U, V, F, E, H, K, P, N)$$

with the following displayed rows:

1. *R is the row-index ledger, listing the finite outer rectangle coordinates and their cell tags.*
2. *C is the column-index ledger, listing the finite inner rectangle coordinates attached to the same cells.*
3. *A is the nonnegative rectangular entry ledger, recording each displayed cell value, its nonnegativity witness, and the finite measure/integral rows used to read it.*
4. *U is the row-first finite-sum readback, summing each row over C before folding the visible row ledger R.*
5. *V is the column-first finite-sum readback, summing each column over R before folding the visible column ledger C.*
6. *F is the* $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ *handoff row, requiring both readbacks to remain inside the finite rectangle packet of chapter 3854.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, C, A, U, V, F have been displayed.*
8. *H records componentwise* hsame *transport for the row ledger, column ledger, nonnegative entry ledger, both finite-sum readbacks, the Fubini handoff, Real seal, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a finite nonnegative rectangle request through $R, C, A, U, V, F, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{TonelliFiniteRectangle}^{\uparrow}$, $\mathsf{FubiniFiniteRectangle}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TonelliFiniteRectangle}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $R, C, A, U, V, F, E, H, K, P, N$. No coordinate stores sigma-additivity, countable summation, countable choice, measure completion, quotient function equality, selected representatives, or an ambient product-measure theorem.

Theorem 3855.2 (Tonelli finite rectangle NameCert obligations)**.** *For every accepted* $\mathsf{TonelliFiniteRectangle}^{\uparrow}$ *carrier $T = (R, C, A, U, V, F, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TonelliFiniteRectangle}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; nonnegative ledger visibility through A; row-first and column-first finite-sum route equality through U, V; confinement of the Fubini handoff row F to the finite rectangle surface; Real sealing through E; componentwise transport, replay, provenance, and local naming through H, K, P, N; and refusal of sigma-additivity, countable choice, measure completion, quotient function equality, selected representatives, and ambient product-measure escape.*

Proof. Project the carrier of Definition 3855.1. The only index rows are R and C, and the only cell-value row is A, so carrier admission and nonnegative ledger visibility are read from those displayed coordinates.

The two finite-sum routes are the rows U and V. Since both routes consume the same finite rectangle cells from R, C, A, their equality is a finite ledger comparison before any completed measure or countable summation principle can be cited.

Now read the handoff row F. It points to the already finite $\mathsf{FubiniFiniteRectangle}^{\uparrow}$ packet and therefore confines the equality route to displayed rectangle cells, not to a sigma-finite product theorem.

Finally E, H, K, P, N seal, transport, replay, source, and name the same finite packet. Because no carrier coordinate stores sigma-additivity, countable choice, measure completion, quotient function equality, selected representatives, or ambient product-measure structure, those readings are refused by the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{TonelliFiniteRectangle}^{\uparrow}}$.

Constructive story: A $\mathsf{TonelliFiniteRectangle}^{\uparrow}$ packet is generated from finite row and column ledgers, nonnegative rectangular entry rows, two iterated finite-sum readbacks, a FubiniFiniteRectangle handoff row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TonelliFiniteRectangle}^{\uparrow}}$, seed)

Scope closed: Definition 3855.1 and Definition 3855.2 seed the finite nonnegative rectangle-sum packet over displayed row, column, entry, iterated-sum, Fubini handoff, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TonelliFiniteRectangle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable Tonelli, sigma-additivity, countable choice, measure completion, quotient function equality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nonnegative ledger visibility, finite route equality, Fubini handoff confinement, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.TonelliFiniteRectangleUp.

Chapter 3856

A Concrete Naming Certificate for $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$

The $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ packet realizes the disk-dynamics fixed-end reading of section 9463.5 in chapter 9463 as finite disk metric, boundary, flow, and provenance rows. It sits after the metric-read surface of chapter 3474, the boundary-geodesic packet of chapter 3491, the finite routed-flow carrier of chapter 195, the disk-coordinate surface of chapter 377, and the disk phase-transport route of chapter 3455. The packet names a finite geodesic-flow surface; it does not complete the hyperbolic disk, quotient ideal endpoints, choose a global geodesic representative, or identify observer expansion with a physical spacetime law.

Definition 3856.1 (Hyperbolic geodesic-flow carrier)**.** *A* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (U, M, B, T, D, F, J, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row for the finite source and target observations inspected by the flow.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *B is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *boundary row, recording the finite far-end incidence used by the route.*
